Preface

Welcome to the world of the Liferay DXP development platform! This book was written for anyone who wants to create applications built on Liferay DXP. It contains everything you need to know about Liferay's development tools and projects. You'll learn all you need to know about plugins, OSGi, the Liferay Workspace, Service Builder, and more. Use this book as a handbook for everything you need to do to get your application running on Liferay DXP, and then keep it by your side as you update and add features to help your users work more effectively.

Conventions

The information contained herein has been organized in a way that makes it easy to locate information. The book has two parts. The first part, *Developer Tutorials*, shows you how to work step-by-step with Liferay's technology. The second part, *Developer Reference*, shows exhaustively the options and APIs you need.

Sections are broken up into multiple levels of headings, and these are designed to make it easy to find information.

Source code and configuration file directives are presented monospaced, as below.

```
Source code appears in a non-proportional font.
```

Italics represent links or buttons to be clicked on in a user interface.

`Monospaced type` denotes Java classes, code, or properties within the text.

Bold describes field labels and portlets.

Page headers denote the chapters and the section within the chapter.

Publisher Notes

It is our hope that this book is valuable to you, and that it becomes an indispensable resource as you work with Liferay DXP. If you need assistance beyond what is covered in this book, Liferay offers training[1], consulting[2], and support[3] services to fill any need that you might have.

[1]https://learn.liferay.com
[2]https://www.liferay.com/consulting
[3]https://help.liferay.com

For up-to-date documentation on the latest versions of Liferay, please see the documentation pages on Liferay Learn.[4]

As always, we welcome feedback. If there is any way you think we could make this book better, please feel free to mention it on our forums or in the feedback on Liferay Learn. You can also use any of the email addresses on our Contact Us page.[5] We are here to serve you, our users and customers, and to help make your experience using Liferay DXP the best it can be.

Part I

Developer Tutorials

Chapter 1

Introduction to Liferay Development

How many times have you had to start over from scratch? Probably almost as many times as you've started a new project, because each time you have to write not only the code to build the project, but also the underlying code that supports the project. It's never a good feeling to have to write the same kind of code over and over again. But each new project that you do after a while can feel like that: you're writing a new set of database tables, a new API, a new set of CSS classes and HTML, a new set of JavaScript functions.

Wouldn't it be great if there were a platform that provided a baseline set of features that gave you a head start on all that repetitive code? Something that lets you get right to the features of your app or site, rather than making you start over every time with the basic building blocks? There is such a thing, and it's called Liferay DXP.

Figure 1.1: With Liferay DXP, you never have to start from scratch.

1.1 Leveraging a Suite of Products, Frameworks and Libraries

Liferay DXP offers developers a complete platform for building web apps, mobile apps, and web services quickly, using features and frameworks designed for rapid development, good performance, and ease of use. The base platform is already there, and it's built as a robust container for applications that you can put together in far less time than you would from scratch.

It also ships with a default set of common applications you can make use of right away: web experience management, collaboration applications such as forums and wikis, documents and media, blogs, and more. All of these applications are designed to be customized, as is the system itself. You can also extend them to include your own functionality, and this is no hack: because of Liferay's extensible design, customization is by design.

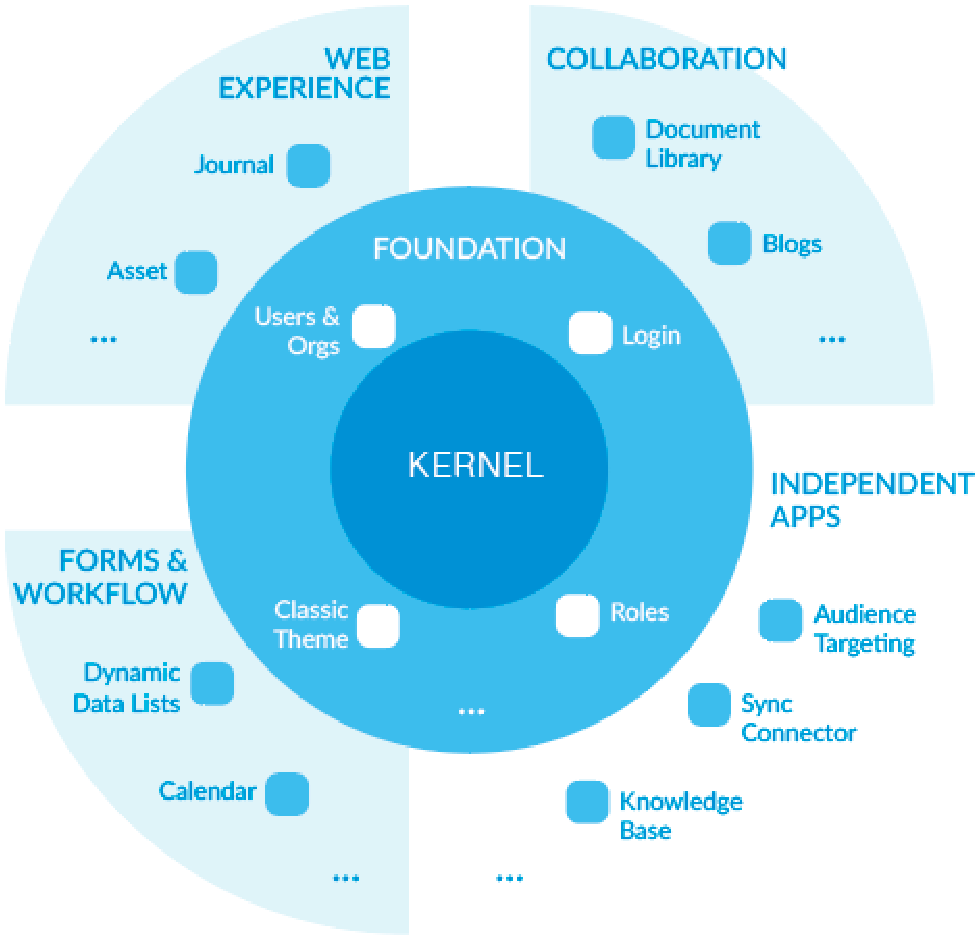

Figure 1.2: Liferay DXP ships with suites of applications to get you started building your site quickly.

In short, Liferay was written by developers for developers, to help you get your work done faster and more easily, to take the drudgery out of web and mobile app development, so that writing code becomes enjoyable again.

1.2 Build Websites, Intranets, Collaborative Environments, Mobile Apps, and More

One of the most often cited best characteristics of Liferay is how versatile it is. It can be used to build websites of all sorts, from very large websites with hundreds of thousands of articles, to smaller, highly dynamic and interactive sites. This includes public sites, internal sites like intranets, or mixed environments like collaboration platforms.

Developers often choose Liferay for one of these cases and quickly find that Liferay is a great fit for completely different projects.

1.3 Creating Your Own Applications and Extending the Existing Ones

Liferay DXP is based on the Java platform and can be extended by adding new applications, customizing existing applications, modifying its behavior, or creating new themes. You can do this with any programming language supported by the JVM, such as Java itself, Scala, jRuby, Jython, Groovy, and others. Liferay DXP is lightweight, can be deployed to a variety of Java EE containers and app servers, and it supports a variety of databases. Because of its ability to be customized, you can add support for more app servers or databases without modifying its source code: just develop and deploy a module with the features you need.

Speaking of code and deploying, here are some of the most common ways of expanding or customizing Liferay DXP's features:

1. Developing a new full-blown web application. The most common way to develop web applications for Liferay DXP is with portlets, because they integrate well with other existing applications. You are not, however, limited to portlets if you don't need to integrate your apps with others.
2. Customizing an existing web application or feature. Liferay DXP is designed to be extended. Many extension points can be leveraged to modify existing behavior, and most of these can be developed through a single Java class with some annotations (more details later).
3. Creating a new web service for an external system, a mobile app, an IoT device, or anything else.
4. Developing a mobile app that leverages Liferay as its back-end, which you can write in a fraction of the normal time thanks to Liferay Screens and Liferay Mobile SDK.
5. Developing a custom theme that adapts the look and feel of the platform to the visual needs of your project.

The Liferay platform can be used as a headless platform to develop web or mobile apps with any technology of your choice (Angular, React, Backbone, Cocoa, Android's Material Design components, Apache Cordova, etc). It can also be used as a web integration layer, leveraging technologies such as portlets to allow several applications to coexist on the same web page.

1.4 Fundamentals

What are the fundamentals that every Liferay developer should know?

Figure 1.3: Liferay DXP can be used by developers in many ways.

1. It's Open Source and puts a strong emphasis on following standards, instead of reinventing the wheel.
2. It's based on JavaEE and heavily leverages OSGi and several other popular technologies for the Java Platform.
3. It is based on a modular architecture and facilitates following a modular development paradigm for your own projects.
4. You can build your own web applications, portlets, or mobile apps on top of it.
5. It provides mature development tools, while staying agnostic so each developer can use his or her preferred tools.
6. It's all about reusing, providing reusable frameworks and libraries and allowing you to create your own.

Interested? More details below.

Open Source and based on Standards

Liferay DXP is both open source and built in the open, following a collaborative development model. That means that you can follow new development as it's happening, make comments on it, and contribute! Here are some tools that you can use to do all this:

1. Our ticketing system. All the changes made to the product, including all bug fixes, improvements, and new features start with a ticket created in JIRA. We have several projects there, but the main one for tracking the work of Liferay DXP or for reporting bugs you have found (with as many details as you can and steps to reproduce, of course) is LPS

2. GitHub: The home of our source code. You can use it to see the code changes as they happen and also to send pull requests for improvements. There are also many repos, but the main one is liferay-portal

3. Forums: It's where our community gets together to share ideas, discuss, and collaborate. Go ahead and ask your questions and help others ask theirs.

4. Blogs: Read the latest news, advice, and best practices from key core developers and our most active community members.

5. Participate: Learn how to get started participating. You will find options for all levels of expertise and time available.

In addition to being Open Source, Liferay is also heavily based on standards. This is great news for your project, since it significantly reduces the lock-in on Liferay. That also encourages us to improve constantly.

Here are some key standards supported by Liferay DXP:

- Portlets 1.0 (JSR-168) and Portlets 2.0 (JSR-286): Liferay DXP can run any portlets that follow these two versions of the specification. Liferay is also heavily involved in the upcoming Portlets 3.0 specification.

- JSF (JSR-127, JSR-314, JSR-344): The Java standard for building component based web applications. Liferay is an active contributor to the standard and lead of the JSF-Portlet Bridge specification.

- EcmaScript 2015: The latest incarnation of the JavaScript standard. Liferay's tooling provides the ability to use it in all modern browsers thanks to the integration of Babel JS.

- Content Management Interoperability Services (CMIS): Liferay's Documents and Media can behave as an interface for any external Documents Repository that supports this widely adopted standard.

- Java Content Repository (JSR-170): Files stored in the internal repository of Liferay's Documents and Media can be configured to be stored in a JSR-170 compatible repository if desired.

- WebDAV: Any Documents & Media folder can be mounted anywhere WebDAV is supported, such as Windows explorer or WebDAV-specific clients.

- SAML and OAuth 1.1: These are the most widely adopted security protocols for SSO and application sign in, supported through specific Apps that can be installed from Liferay's Marketplace.

- JAX-RS and JAX-WS: Incorporated since Liferay 7 as the preferred tooling to create web services.

- WSRP 1 and 2: Allows execution of portlets running in a remote container.

- OSGi r6: Liferay supports a wide range of the OSGi family of standards through its own implementations and also integrates the high quality implementations of the Apache Felix and Eclipse Equinox projects (which we also collaborate). Here are some of the most relevant supported standards:

  - OSGi runtime: Allowing any OSGi module to run in Liferay DXP
  - Declarative Services: Supports a dynamic component model for Liferay development.
  - Configuration Admin: Lets you create highly configurable applications that can be reconfigured on the fly. Liferay provides an auto-generated UI to change the configuration of any component that leverages this standard.

Technologies

Like any open source application, Liferay is built on the shoulders of giants. When we choose the technology on which to build our platform, it must have the following characteristics:

- It must balance being modern and being mature enough for demanding and critical enterprise environments.
- It should be widely adopted and have a mature community.
- It should be as easy as possible to contribute back, since we love to contribute to the open source projects we use.
- It should be possible to use only the piece of the project we need if we don't need the whole thing. That way, it's easier to replace that piece in the future if we find something that works better.

The goal, of course, is to give our developers and users the most up to date, easy-to-use, and stable platform to build your services on.

At its base, Liferay is a JavaEE application that also includes an OSGi container. This offers the best of both worlds: access to the world's most robust and fully featured enterprise platform, along with the benefits of the world's most fully featured and stable modular container. Now developers can develop and deploy enterprise-ready, scalable web and mobile-based applications in a dynamic, component-based environment.

With JavaEE and OSGi at the bottom of the stack, we build the rest of our core on well known or widely used products:

- Spring for transactions (and Dependency Injection in the core)
- Hibernate for database access (along with direct JDBC access for optimized queries)
- Elasticsearch for indexing and searching
- Ehcache for caching.

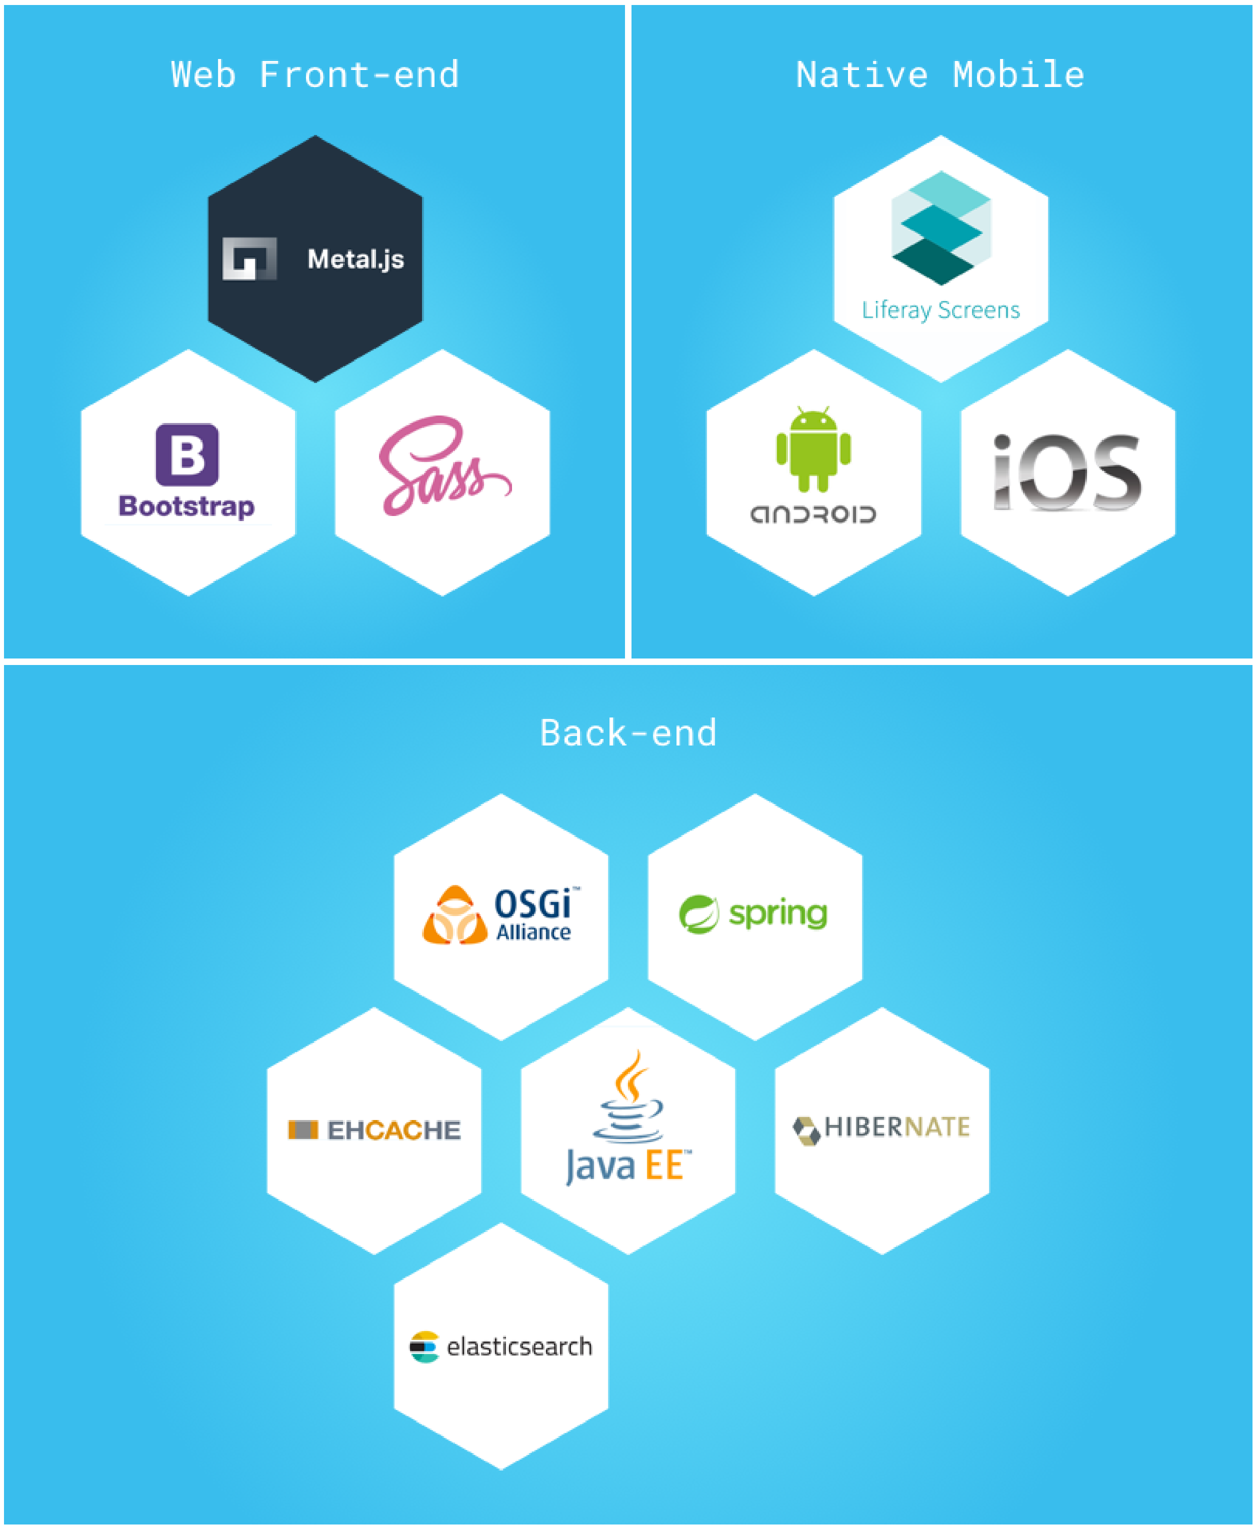

Figure 1.4: Liferay is based on popular, well known, and well supported technologies.

In the application layer, developers have access to many of the libraries they're familiar with and have been using for years:

- Xalan
- Xerces
- Apache Commons
- Tika
- dom4j

If you're approaching Liferay DXP with the intention of customizing it, you can know that most if not all of the tools you're familiar with are there. If you're writing applications on Liferay's platform, the sky's the limit: you can use any web framework you like, and you can write both servlet and portlet-based applications. If you're looking for a recommendation, though, we're happy to point you to either our MVCPortlet or our JSF-based LiferayFaces frameworks.

On the front-end, Liferay has kept pace with the most recent progressions in that space. If you've used Liferay in the past, you can of course continue to use Liferay's venerable Alloy UI, but you are also free to use the front-end technologies you love the most:

- Bootstrap
- SaSS
- EcmaScript 2015 (using Babel.js)

You can also use any JavaScript library, including

- Metal.js (developed by Liferay)
- jQuery (included)
- Lodash (included)
- Angular 1 or 2
- React
- Your library of choice

Liferay DXP follows a design language created by our designers at Liferay called Lexicon Experience Language, which has been implemented for use of the web as Lexicon.

Lexicon is automatically made available to application developers through a set of CSS classes and markup, although it's even easier to use our tag library.

For templating, JavaEE's JSP is there as expected as well as FreeMarker, but the modularity of the platform allows you to use Google's Soy (aka Closure Templates) or whatever else you like.

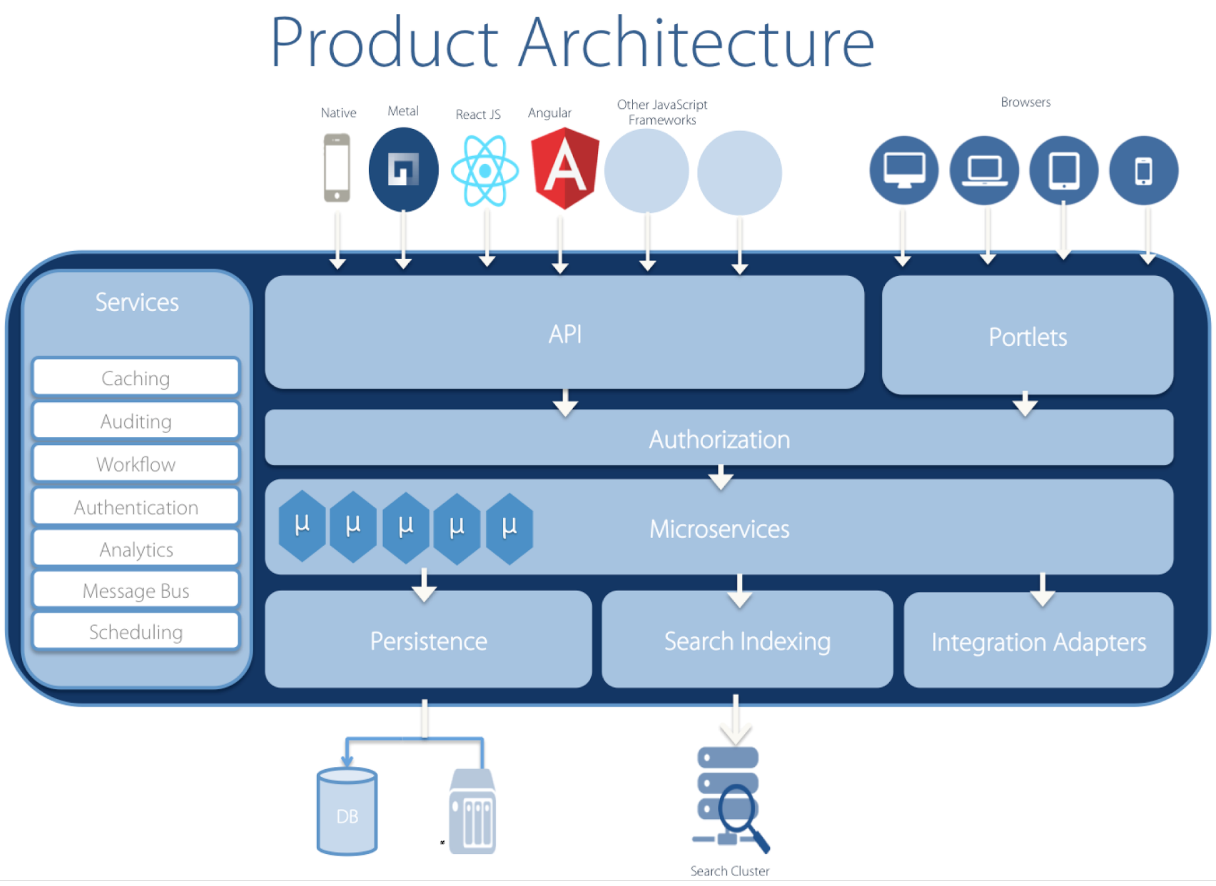
Liferay has also chosen build tools that give you freedom to use any development environment. Gradle along with bnd powers the product's build, but project layouts are dynamic, which means you can use anything from Maven to Ant/Ivy to build applications for Liferay.

In short, Liferay has done a lot to make sure its users and developers have access to the most widely used, robust tools possible–as well as the freedom to use the tools they like the most. Know that Liferay has your back and will do everything we can to provide you with the most flexible technology platform possible, so that you have the freedom to go and build great things on it–things we never could have expected or imagined.

Architecture

Liferay's design goals have from the beginning been to give you all the tools to create exactly the web presence you have in mind. To achieve this, the product must do these things:

- Provide a usable default configuration and interface
- Ship with best-of-breed apps that can be used to build sites quickly
- Make the UI customizable at any level of detail from small tweaks to a complete replacement
- Make the apps customizable at any level of detail
- Provide a robust development platform upon which new best-of-breed apps can be built and shared



These goals are now achieved to the furthest extent ever in Liferay's history, and it's all because of our new modular architecture.

Imagine an environment where every piece of functionality is an independent module. The modules declare three important things:

- The functionality they implement or define
- Their dependency on other modules
- Their priority relative to their functionality

Using this information, the container can start all the modules that fulfill their definitions, implementations, dependencies, and priorities.

Anything a developer wants to do is implemented as one or more modules. If it's a new application, that application can depend on existing modules and define a dependency on them. This enables you to use functionality that's already there without rewriting it yourself for your app. If it's a customization, in many cases it's just a simple matter of defining your customization with a higher priority than the existing functionality.

This is the power of a modular architecture.

Modules

All new applications, extensions, and customizations built on Liferay are built in a modular way. A module is the single unit of distribution and deployment in a modular architecture.

In the spirit of following existing standards, Liferay has leveraged a set of very powerful standards known as OSGi. OSGi defines, among other things, how modules can depend on each other and communicate. It also defines the packaging format for modules: OSGi bundles. An OSGi module is just a typical JAR file, familiar to Java developers as a ZIP file containing compiled code, templates, resources, and some meta information.

Services

One aspect of modern software architecture is the notion of services. These are independently running pieces of code that provide specific functionality when called. They operate just like services in the real world do. For example, you might call a service to come mow your lawn. You know how to call the service and to give it what it needs (money) in order to receive the service (a mown lawn). Software-based services work the same way.

Liferay's services are standard services as defined by the OSGi Alliance. Writing anything, whether it be an application, an interface to a database, or even a "service" as you define it, is easy to implement as an OSGi service, because they're both incredibly powerful and easy to develop. If you understand Java interfaces and how they are implemented–which is introductory Java material–you already understand more than 90% of what you need to know. First, you define the interface, or contract for the service: what it returns, and what it needs to return what it returns. Next, you define an implementation class that implements the contract.

In the services model, a class requests the service that provides the functionality it needs. This functionality is provided (often injected) with the right implementation automatically. It's similar to Spring or EJBs with one important addition: implementations can be changed at runtime, without restarting the system. This is achieved because when a service is deployed, it becomes part of a service registry maintained by Liferay's OSGi container. The container dynamically manages the lifecycle of the service and can start and stop services when appropriate.

The real power of services shines when they are extended. You can replace existing implementations or in advanced use cases have several implementations of a service. The developer can then choose to invoke all implementations or just the one with the highest priority (specified with what is called the service ranking). This means that if Liferay has a service that does something, you can customize or override that service by implementing its interface yourself and then deploying it with a higher ranking than the original service. The container then instantiates your implementation when the service is called by existing code. This simple, clean method is how most customizations are made to Liferay 7.

Components

In OSGi, possibly the best and certainly the easiest way to create services is through Declarative Services. In Declarative Services (aka DS), you create Components. A Component is a Java class (marked with an `@Component` annotation) that provides an implementation of a Service (as described above) and whose instantiation is handled automatically by DS. This is similar to what you might be used to if you have used Spring Beans or EJBs. DS also provides dependency injection using annotations (`@Reference`). This is convenient because the "wiring" of components is done by the container but can be changed while the server is running (unlike Spring).

Modules may contain as many service declarations and as many components as desired (or zero, of course).

In software engineering terms, a component is the smallest building block of a larger application, and that application is itself made up of many small components. This makes it easier to develop an application because you only have to deal with small, well-defined, bite-sized chunks of code at a time.

Real Life Benefits of Modular Development

The next question then becomes, so what? Why is this a big deal? Why should I have components, and what do I need them for?

It helps to examine two common development scenarios: a customization task and a full-blown application. Picture this: you have a system that generates a report in PDF format from data in a database. The data is captured from a web application running in Liferay. You come in to work in the morning and something's happened (it doesn't matter what it is; it could be corrupt data, the company has been bought, or a national emergency). You need to change that report as fast as possible, either to insert a new title page, add a warning to the existing title page, or whatever.

In the monolithic model you'd have to modify the application to change the report and then you'd have to redeploy the complete application. If this was a temporary change, to restore the application to its original state you'd again have to modify the application and redeploy it.

With a modular and component-based application, you'd fix a simple, small component–probably one Java class–that provides the functionality you need. You'd then deploy its module to the server. If you need to roll back that change in the future, you'd just do the same thing in reverse. In each case, you're only changing and redeploying the small piece of functionality that needs to change, not the whole application. At no time would you ever have to redeploy the whole application or take the server down.

For a full-blown application, the benefits are even greater. Modular development helps developers be more efficient in three important ways:

- An application made up of components can be written in parallel by multiple developers working on different components.
- An existing application can be extended by writing new components to implement features in different ways.
- Components can be enabled and disabled, allowing administrators to choose which features to enable in production.

For example, Liferay's Documents and Media library is a file repository that supports many back-ends. Each back-end is a component that can be maintained by different developers. They can be added and removed on the fly while the server is running.

Similarly, the services provided by the application are independent of the front-end technology. In fact, there can be multiple front-ends, from the web-based front-end Liferay provides out of the box, to a new front-end you might develop for either the web or mobile.

As you can see, many components running inside Liferay's OSGi container form something of an ecosystem of complementary services. Much of Liferay's functionality is in components, and when you deploy your code, it sits in the same ecosystem as Liferay's, with the same extension points. You can write components to provide new services or to override existing services with your own implementation, and the container manages it all. Liferay is an exciting platform that empowers developers to be more productive.

1.5 Liferay as a Development Platform

If you've been reading everything up to this point, you've heard all about Liferay DXP's architecture, modularity, and technologies. What's left is to tell you what it's like to use Liferay's platform as a basis for your site by customizing it or by developing applications on it. The platform is designed to make this easy and pleasant, and to integrate with the tools developers use every day.

But you're likely not interested in a bunch of prolegomena about it. Read on to learn the details.

Web Applications and Portlets

Liferay as a development platform has always provided flexibility for both administrators and developers by making it easy to have more than one application on a single page. Applications written this way are called *portlets*, and are a mainstay of Liferay's platform. You can use Liferay's MVC Portlet framework or common frameworks such as Spring MVC or JSF to write portlets. If you plan to have a web-based interface to your application, and want its administrator to have a lot of flexibility configuring it, portlets provide a very powerful model. In this model you can create several portlets instead of a larger application and let the administrator choose how to combine them with other pre-existing portlets into a larger interface.

That's not to say you don't have other choices. Since Liferay decouples its business logic from its UI (which is provided in separate modules), you have freedom to implement the UI in any other technology.

Because of this, you can use Liferay as a headless platform, because it's easy to create web services based on Service Builder, JAX-RS, and JAX-WS. Then you can build standalone web applications using any front-end technology or mobile technology you like.

Extensibility

As you might imagine, the system described above contains all the tools necessary to make a well designed system that allows developers not only to create applications based on modules, but also to extend the existing functionality of the system. Liferay can benefit from this now because the platform on which it rests is designed for both application development and customization.

Components make developing extensions and customizations convenient. If you compare this model to other products that aren't designed for customization, you'll see just how convenient it can be.

To customize an existing service, the only thing you need to do is deploy a component that extends the existing implementation. If you want to remove your implementation and revert back to the default behavior, you simply un-deploy your component.

Compare that with the traditional way of customizing software by downloading its source and maintaining a set of patches against it. Each time the software is updated, you have to re-download the source, re-apply your patches, and recompile the software.

With Liferay, your custom code is kept in your own modules, which the container takes care of applying based on metadata you supply.

Developer Tools

As you learned above, Liferay's OSGi container gives you these benefits:

- The container can start and stop components.
- A component implements an OSGi service.
- A component may use or consume OSGi services.
- The framework manages the binding of the services a component consumes (just like Spring or EJBs, but dynamically).

If all of this sounds great to you (as it does to us), there's only one thing left: how do you get started developing components? We believe in providing an easy path for new developers while at the same time preserving flexibility for experienced developers with strong tooling preferences. To achieve that, Liferay provides some great tools, and if you're an experienced developer, these also integrate into what you likely already use. If you use any of the standard build tools like Gradle or Maven, any text editor or common Java IDEs like Eclipse, intelliJ, or NetBeans, or any testing framework like Spock or JUnit, you can use them with Liferay to develop components.

Liferay's tools add some important enhancements:

- Blade CLI speeds you up by creating Gradle-based Liferay projects from templates.
- Liferay Workspace is an opinionated SDK based on Gradle that uses Blade CLI to integrate your projects and your runtime into one convenient, distributable and sharable place.
- Liferay IDE is an Eclipse-based development environment that integrates all the convenience of Blade CLI and Liferay Workspace into a best-of-breed graphical environment with all the bells and whistles you'd expect.
- Liferay Developer Studio provides all that Liferay IDE provides, plus additional tools that enterprise developers need.
- Liferay Service Builder helps you create your back-end faster by generating all your database tables, local services, and web services from a single XML file.

You can choose to use or ignore Liferay's tools. The point is you have the freedom to do that, because Liferay provides an open development framework that's designed to meet you where you are. We hate proprietary lock-in as much as you do, so our tools are designed to complement the tools you're using already instead of replacing them.

Beyond build tools and IDEs are the frameworks you'll use to build applications. Liferay's development frameworks include a lot of functionality–comments, social relationships, user management, and lots more–to speed up development of your applications. They help you build applications out of well-tested, modern, scalable, skinnable building blocks. You wind up not only with a great, functional application, but also with one that took less time to develop, looks the way you want it to, and performs well. This doesn't mean you're limited only to what Liferay provides; again, you can use third-party frameworks if that's what you like to use.

To develop portlets, Liferay provides a convenient and easy-to-use framework called MVCPortlet to make writing portlets easy, but developers are free to use any other framework, such as Spring MVC, to create portlets. MVCPortlet uses components to handle requests, benefiting from all the characteristics described above (lifecycle, extensibility, ease of composition, etc.). If you don't have a strong opinion on which framework to use, we recommend that you try it out.

Liferay also includes a utility called Service Builder that makes it easy to create back-end database tables, an object-relational map in Java for accessing them, and a place to put your business logic. It can also generate JSON or SOAP web services, giving developers a full stack for storing and retrieving data using web or mobile clients. But that doesn't prevent you from using Java Persistence (JPA) and generating JAX-WS web services.

In addition to the tooling, Liferay also provides many reusable frameworks.

Frameworks and APIs

Liferay's development platform provides a great framework for application development and also offers APIs. Lots of them. Applications can be created by leveraging Liferay's many frameworks that encapsulate features that are commonly needed by today's applications. For example, a commenting system allows developers to attach comments to any asset that they define, whether they be assets they develop or assets that ship with the system. Assets are shared by the system and are used to represent many common elements, such as Users, Organizations, Sites, User Groups, blog entries, and even folders and files.

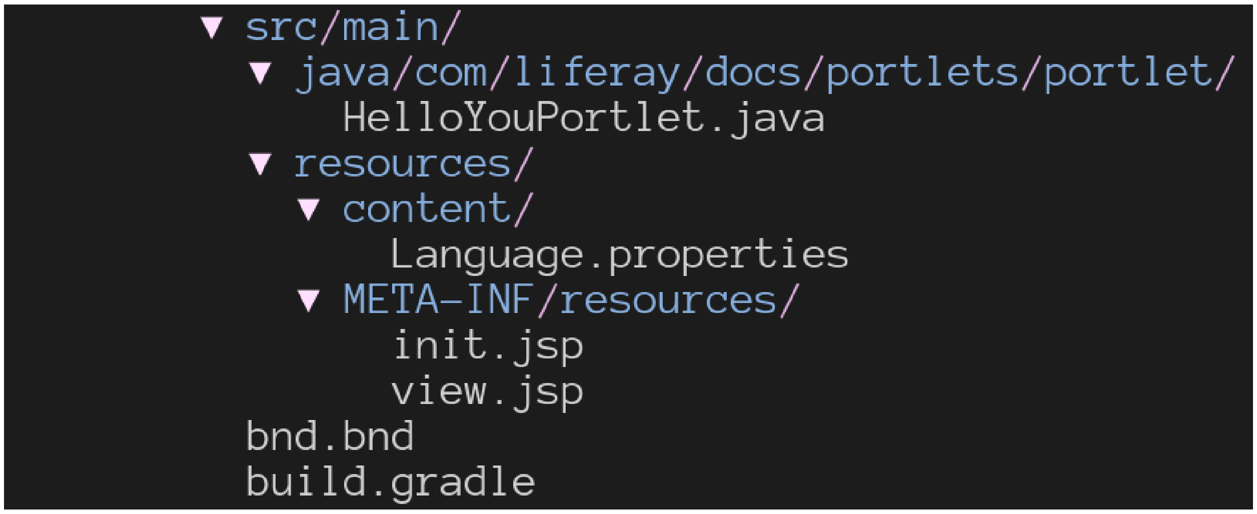
Liferay also includes many frameworks for operating on assets. A workflow system makes it easy to create applications that require an approval process for users to follow. The recycle bin stores deleted assets for a specified period of time, making it easy for users to restore data without the intervention of an administrator. A file storage API with multiple available back-ends makes storing and sharing files trivial. Search is built into the system as well, and it is designed for developers to integrate it with their applications. Many of the frameworks you might need when developing complex applications are already there; you just need to take advantage of them: a Social Networking API, user-generated forms with data lists, a message bus, an audit system, and much more.

Example Liferay Projects

Enough theory. It's time for practice. A good way to get the flavor of developing on Liferay's platform across is to show you some projects. First, you'll see a portlet developed with MVCPortlet, showcasing the use of components as well. Once you've seen that, the next best thing is to see an extension. Both of these examples serve to show you how easy it is to build functionality following a modular paradigm.

It would be nice to show you the standard Hello World project, Liferay style, but that would be too easy: the default template that Blade or Liferay IDE creates already does that by default. Instead, you'll see the Hello *You* portlet. This does the same thing as Hello World, except it adds the first name of the user to the message. If your name therefore is John, it'll return Hello, John.

Here's what the project layout looks like:



```
▼ src/main/
  ▼ java/com/liferay/docs/portlets/portlet/
      HelloYouPortlet.java
  ▼ resources/
    ▼ content/
        Language.properties
    ▼ META-INF/resources/
        init.jsp
        view.jsp
bnd.bnd
build.gradle
```

Figure 1.5: The Hello You portlet has a simple project structure.

No new files were created after this project was generated by Liferay's Blade CLI tool, so this is as simple as it gets. You have your portlet class, which is in the .java file. You also have two different kinds of resources: language properties and JSP files. Finally, the `bnd.bnd` file describes the application's metadata for the OSGi container, and the `build.gradle` file builds the project.

Any web developer that's familiar with Java can understand the JSPs, but some explanation is in order because of the style. Liferay's coding style defines a single `init.jsp` that contains all the imports and tag library initializations necessary for the front-end. This way, any JSP can simply include `init.jsp`, and all of its imports are satisfied. The `init.jsp` for this project was not modified from the generated project, and it looks like this:

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>

<%@ taglib uri="http://java.sun.com/portlet\_2\_0" prefix="portlet" %>

<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>

<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>

<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>

<%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

<liferay-theme:defineObjects />

<portlet:defineObjects />
```

As you can see, all it does is declare the tag libraries you probably want to use, and then it calls a couple of tags that makes objects from the portlet framework available. Since there's nothing really interesting here, you'll want to look at `view.jsp` next:

```
<%@ include file="/init.jsp" %>

<jsp:useBean id="userName" type="java.lang.String" scope="request" />

<p>

    <b>Hello, <%=userName %>!</b>

</p>
```

Now we've got something. The portlet class (the Controller, in MVC terms) has made a `userName` string available in the request, and this JSP retrieves it and uses it to say hello to the user. The real functionality, therefore is in the portlet class:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.instanceable=true",
        "javax.portlet.display-name=hello-you Portlet",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=power-user,user"
    },
    service = Portlet.class
)
public class HelloYouPortlet extends MVCPortlet {

    @Override
    public void render(RenderRequest renderRequest,
                RenderResponse renderResponse)
            throws IOException, PortletException
    {
        ThemeDisplay themeDisplay = (ThemeDisplay)
                renderRequest.getAttribute(WebKeys.THEME\_DISPLAY);

        User user = themeDisplay.getUser();

        renderRequest.setAttribute("userName",
                user.getFirstName());

        super.render(renderRequest, renderResponse);
    }

}
```

Now we're talking; here's the real stuff. At the top is the `@Component` annotation, which tells the OSGi container how it should treat this module. By specifying `immediate=true`, you're saying that when this module is deployed and all of its dependencies are satisfied, it should be started immediately instead of being lazy-loaded. Next are several properties specific to portlets: the category in which it should appear in Liferay's UI, its display name, its default view, and more. Finally, the service–which is just a Java Interface–that it implements is defined, which is the portlet class.

Next, you have the class itself, which extends Liferay's `MVCPortlet` class (that extends `GenericPortlet`, that implements `Portlet`). The only method overridden is the `render()` method, and Liferay's API is used to get the user's first name and put it in a request attribute called `userName`.

So you can see how this works: the portlet runs and retrieves the user's first name, puts that in the request, and then by the use of the template path and view template properties specified in the `@Component` annotation, forwards processing to `view.jsp`, where the user's first name is retrieved and displayed.

The only other item of interest is the `bnd.bnd` file:

```
Bundle-SymbolicName: com.liferay.docs.hello.you
Bundle-Version: 1.0.0
```

This declares the name of the module (sometimes also called a bundle). It's a good practice to namespace it properly to avoid name conflicts in the container. The version is also declared, which allows the container to manage dependencies down to the version level of a module. This is called Semantic Versioning, and is a discussion by itself.

That's all there is to this portlet. Next, you'll see an extension, which in many cases is even simpler than a portlet.

Liferay's UI is divided up into several areas. There's the control menu and the product menu, which contains the add menu and the simulation menu. If you want to extend the UI, you can do that by deploying a module that adds what you want. In this example, you'll add a link to the product menu, which is the menu that by default sits in the top right of the browser:

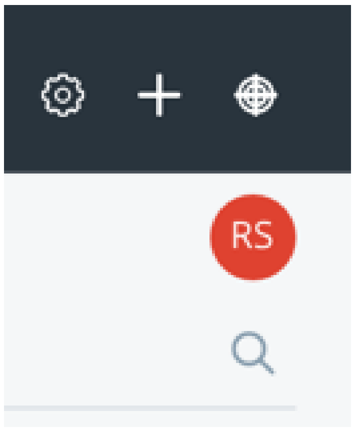


Figure 1.6: The product menu appears beneath the user's profile link.

To this, you'll add a link to this website:

As with the portlet project, this project's layout contains only a few items that are easy to understand.

As before, you have a build script, a `bnd.bnd` file that declares the module's name and version, and this time, only a Java class and a language properties file.

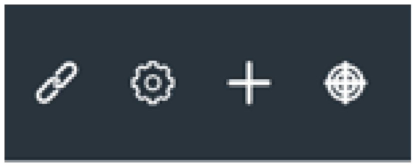

Figure 1.7: You can add links to the product menu by deploying a component.

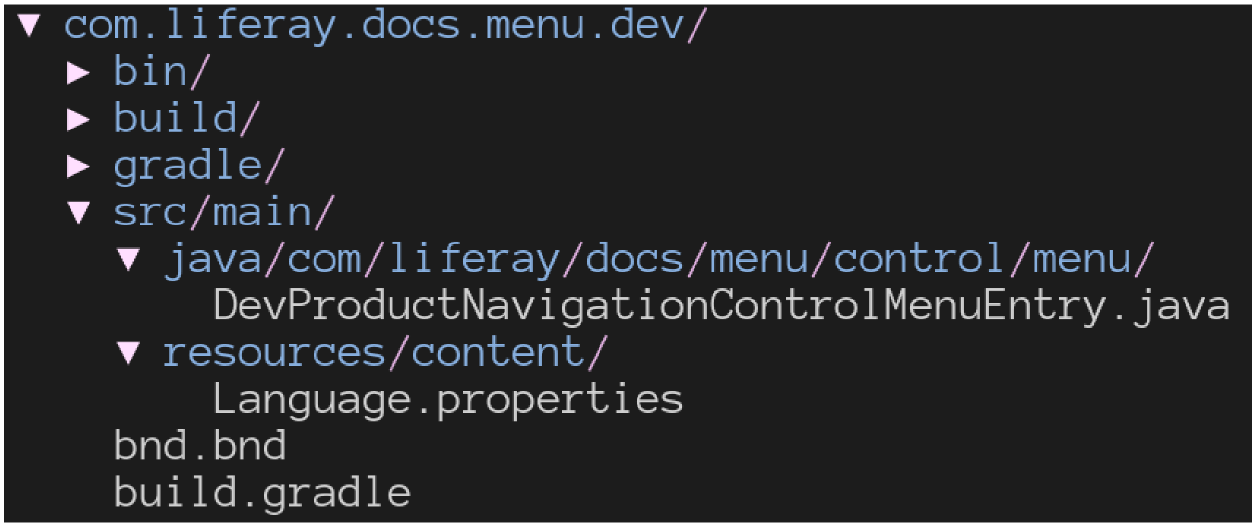


```
▼ com.liferay.docs.menu.dev/
  ▶ bin/
  ▶ build/
  ▶ gradle/
  ▼ src/main/
    ▼ java/com/liferay/docs/menu/control/menu/
        DevProductNavigationControlMenuEntry.java
    ▼ resources/content/
        Language.properties
    bnd.bnd
    build.gradle
```

Figure 1.8: The product menu project is simpler than the portlet was.

The Java class defines only four methods:

```
@Component(
    immediate = true,
    property = {
        "product.navigation.control.menu.category.key=" +
                ProductNavigationControlMenuCategoryKeys.USER,
        "product.navigation.control.menu.entry.order:Integer=1"
    },
    service = ProductNavigationControlMenuEntry.class
)
public class DevProductNavigationControlMenuEntry
    extends BaseProductNavigationControlMenuEntry
    implements ProductNavigationControlMenuEntry {

    @Override
    public String getIcon(HttpServletRequest request) {

        return "link";
    }

    @Override
    public String getLabel(Locale locale) {

        ResourceBundle resourceBundle = ResourceBundleUtil.getBundle(
            "content.Language", locale, getClass());

        return LanguageUtil.get(resourceBundle, "custom-message");
    }

    @Override
    public String getURL(HttpServletRequest request) {

        return "https://portal.liferay.dev";

    }

    @Override
    public boolean isShow(HttpServletRequest request) throws
        PortalException {

        return true;
    }

}
```

As before, this project was generated using a template from Blade CLI. The source code is part of the template; the only thing you'll need to do is provide the link.

The first method gets the Font Awesome icon you want to use in the menu. The next gets the "label," the text that appears when a user hovers the mouse over the link. This text is the value of the only property in the `Language.properties` file:

```
custom-message=Liferay Developer Network
```

The next method returns the URL that's the destination for this link, and the final method returns a boolean for showing or hiding the link.

When you deploy this module, the link is added to the menu when the module starts. You don't have to mess around looking in Liferay's JSP or JavaScript files to customize the menu: it's an extension point, and it is designed to be customized.

This is the modular paradigm for development. It helps you keep a clean separation of your code, whether it be applications or extensions, from the code that ships by default, and it gives you the power to customize the system dynamically, while it's running, to avoid downtime. It is a different way of doing things, but we believe it's a better way. When you start working with modules and see the benefits you can gain, we think you'll agree.

Now you're ready to explore some more about Liferay. We're not planning to leave you here, as though this were a dead site. Please feel free to use the suggestions link at the bottom of every article you'll encounter if you think something could be improved about that article. If you have feedback about the site itself, the feedback button is always floating at the bottom right. There are living, breathing people behind all the content on this site, and we stand ready to assist you on your Liferay journey.

Chapter 2

Introduction to Front-End Development

When approaching the development of your application's front-end, Liferay DXP offers a wide range of approaches, frameworks, utilities, and mechanisms to make your life easier.

2.1 JavaScript

If you've used Liferay in the past, you can of course continue to use Liferay's venerable Alloy UI, but you are also free to use the front-end technologies you love the most:

- ECMAScript 2015
- Metal.js (developed by Liferay)
- AlloyUI (developed by Liferay)
- jQuery (included)
- Lodash (included)

2.2 Lexicon

Liferay DXP follows a design language created by our designers at Liferay called Lexicon Experience Language, which has been implemented for use of the web as Lexicon.

Lexicon is automatically made available to application developers through a set of CSS classes and markup, although it's even easier to use our tag library.

2.3 Templates

For templating, Java EE's JSP is there as expected as well as FreeMarker, but the platform's modularity enables using Google's Soy (aka Closure Templates) or whatever else you like.

2.4 Themes

A Liferay Theme is the overall look and feel for a site. Themes are a combination of CSS, JavaScript, HTML, and FreeMarker templates. Although the default themes are nice, you may wish to create your own look and feel for your site.

In Liferay DXP, Liferay provides an easy-to-use tool called the Liferay Theme Generator that helps automate the theme development process.

Themes created with the Liferay Theme Generator give you access to theme gulp tasks that offer basic functions, such as `build` and `deploy`, along with more complex interactions, such as auto deploying when a change is made and setting the base theme.

2.5 Front-End Extensions

Liferay DXP's modularity has many benefits for the front-end developer, in the form of development customizations and extension points. These extensions assure the stability, conformity, and future evolution of your applications.

Below are some of the available front-end extensions:

- Theme Contributors
- Context Contributors
- Portlet Decorators
- Editor Config Contributors

CHAPTER 3

JAVASCRIPT IN LIFERAY DXP

Liferay DXP's front-end is extendable, flexible, and future ready.

Like previous versions, many components are written using AlloyUI. AlloyUI is based on YUI, and is no longer under active development. Because of this, we have included jQuery and also have developed a new framework called MetalJS.

3.1 MetalJS

Metal.js is a JavaScript library for building UI components in a solid and flexible way. Metal is built from the ground up with performance in mind and is flexible enough to be built as global objects, AMD modules, or jQuery plugins. Metal is cutting edge JavaScript, using ECMAScript 6 (ES6)/ ECMAScript 2015 (ES2015), which provides you with clean code that's easy-to-read.

For more information see the Metal.js docs.

3.2 ES2015

ECMAScript 6 (ES6)/ ECMAScript 2015 (ES2015) is enabled by default in your plugins, so you can write your own modules using the latest improvements to the language.

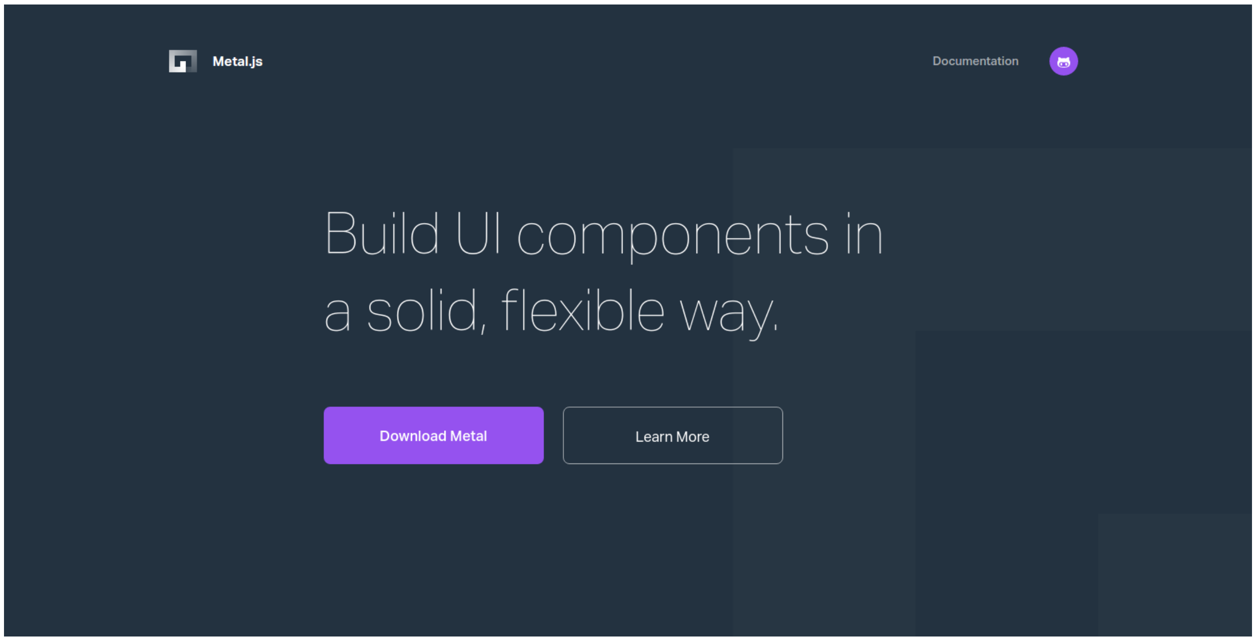
You can learn more about how to leverage ES6 in your modules in the Preparing Your JavaScript Files for ES2015 and Using ES2015 Modules in your Portlet tutorials.

3.3 AlloyUI

AlloyUI is an open source front-end framework built on top of Yahoo! User Interface Library (YUI). It leverages all of YUI's modules and adds even more cutting edge components and features to help you build terrific UIs. AlloyUI provides the following key benefits:

- Create modern UI components that provide a consistent look & feel across Liferay DXP.
- Server-agnostic, so you can use it with any technology.

As of 7.0, AlloyUI has been officially sunsetted. This means that we are no longer developing new features for it, but it is still included in the product and actively maintained.



Build UI components in a solid, flexible way.

Figure 3.1: Metal.js is a new framework for building UI components.

Simply Powerful

Robust UI tools at your fingertips.

AlloyUI is a framework built on top of YUI3 (JavaScript) that uses Bootstrap (HTML/CSS) to provide a simple API for building high scalable applications.

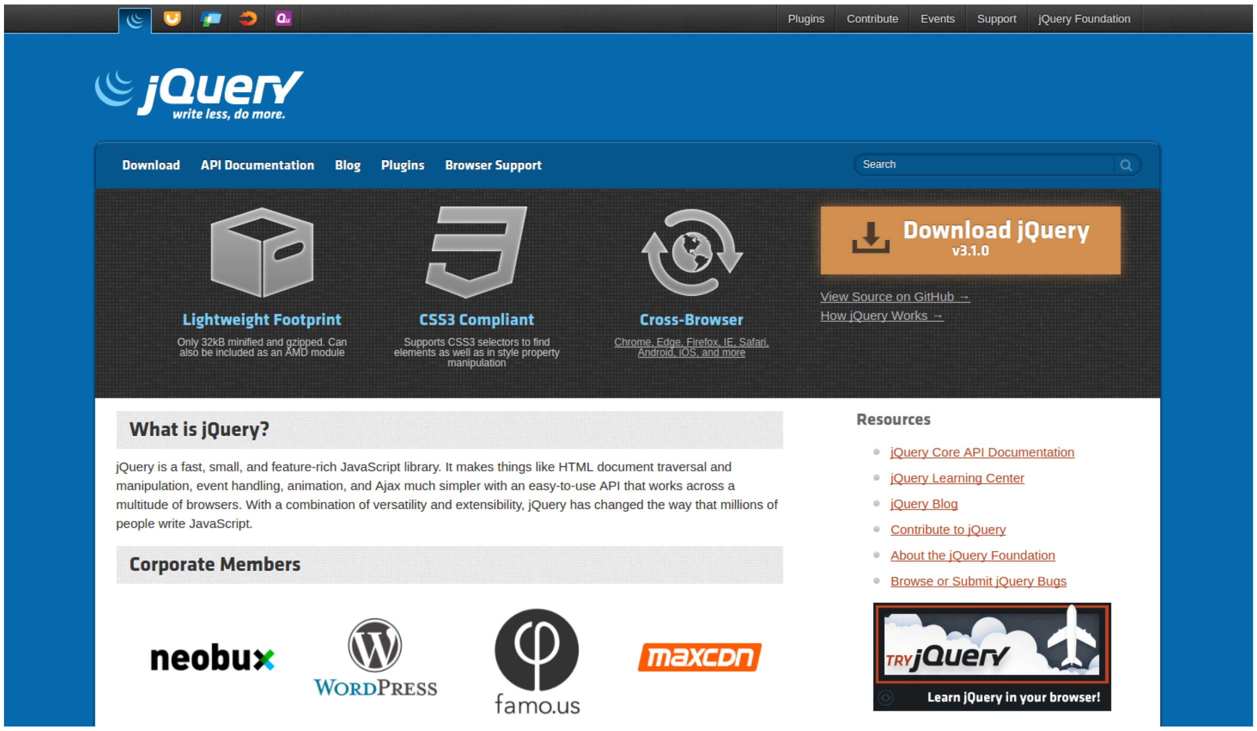
"When AlloyUI arrived on the scene, it added a new dimension to YUI contributorship. Professional, robust, and beautifully designed, the Alloy project and its engineers created a world of new options for YUI implementers, and it helped the YUI project turn the corner to become a contributor-driven, community-owned open source project."
— Eric Miraglia, Product Manager, Google Inc. & Former YUI Manager

Figure 3.2: AlloyUI is sunsetted as of 7.0.

3.4 jQuery

jQuery is a cross-platform JavaScript library designed to simplify the client-side scripting of HTML. It is the most popular JavaScript library in use today. The syntax is designed to make it easier to navigate a document, select DOM elements, create animations, handle events, and develop Ajax applications.

While jQuery is great for small websites, once you start creating highly scalable applications like Java portals, you'll need a more robust solution. That being the case, we strongly recommend you to use one of our other provided solutions mentioned above.



Lightweight Footprint
Only 32kB minified and gzipped. Can also be included as an AMD module

CSS3 Compliant
Supports CSS3 selectors to find elements as well as in style property manipulation

Cross-Browser
Chrome, Edge, Firefox, IE, Safari, Android, iOS, and more

What is jQuery?

jQuery is a fast, small, and feature-rich JavaScript library. It makes things like HTML document traversal and manipulation, event handling, animation, and Ajax much simpler with an easy-to-use API that works across a multitude of browsers. With a combination of versatility and extensibility, jQuery has changed the way that millions of people write JavaScript.

Figure 3.3: jQuery is a fast, small, and feature-rich JavaScript library.

Chapter 4

Metal.js

Metal.js is a lightweight, easy-to-use JavaScript framework that lets you create UI Components with ease, thanks to its integration with templating languages.

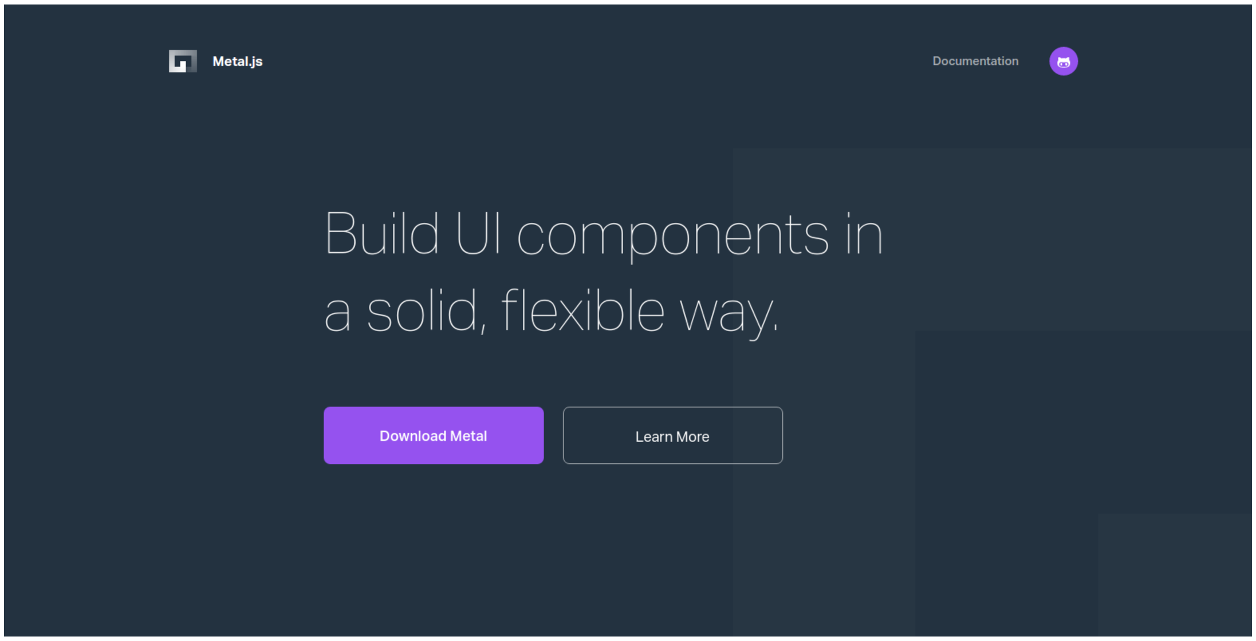

Figure 4.1: You can create UI's easily, thanks to Metal.js.

Metal.js is built with you in mind, offering flexibility with how your rendering logic is handled. You can use template languages to write your rendering logic or keep your rendering logic and business logic within the same file if you prefer.

By default, Metal.js offers integration points with Google closure templates and Facebook JSX templates. The rendering layer is completely customizable though, so you can add more rendering options if needed.

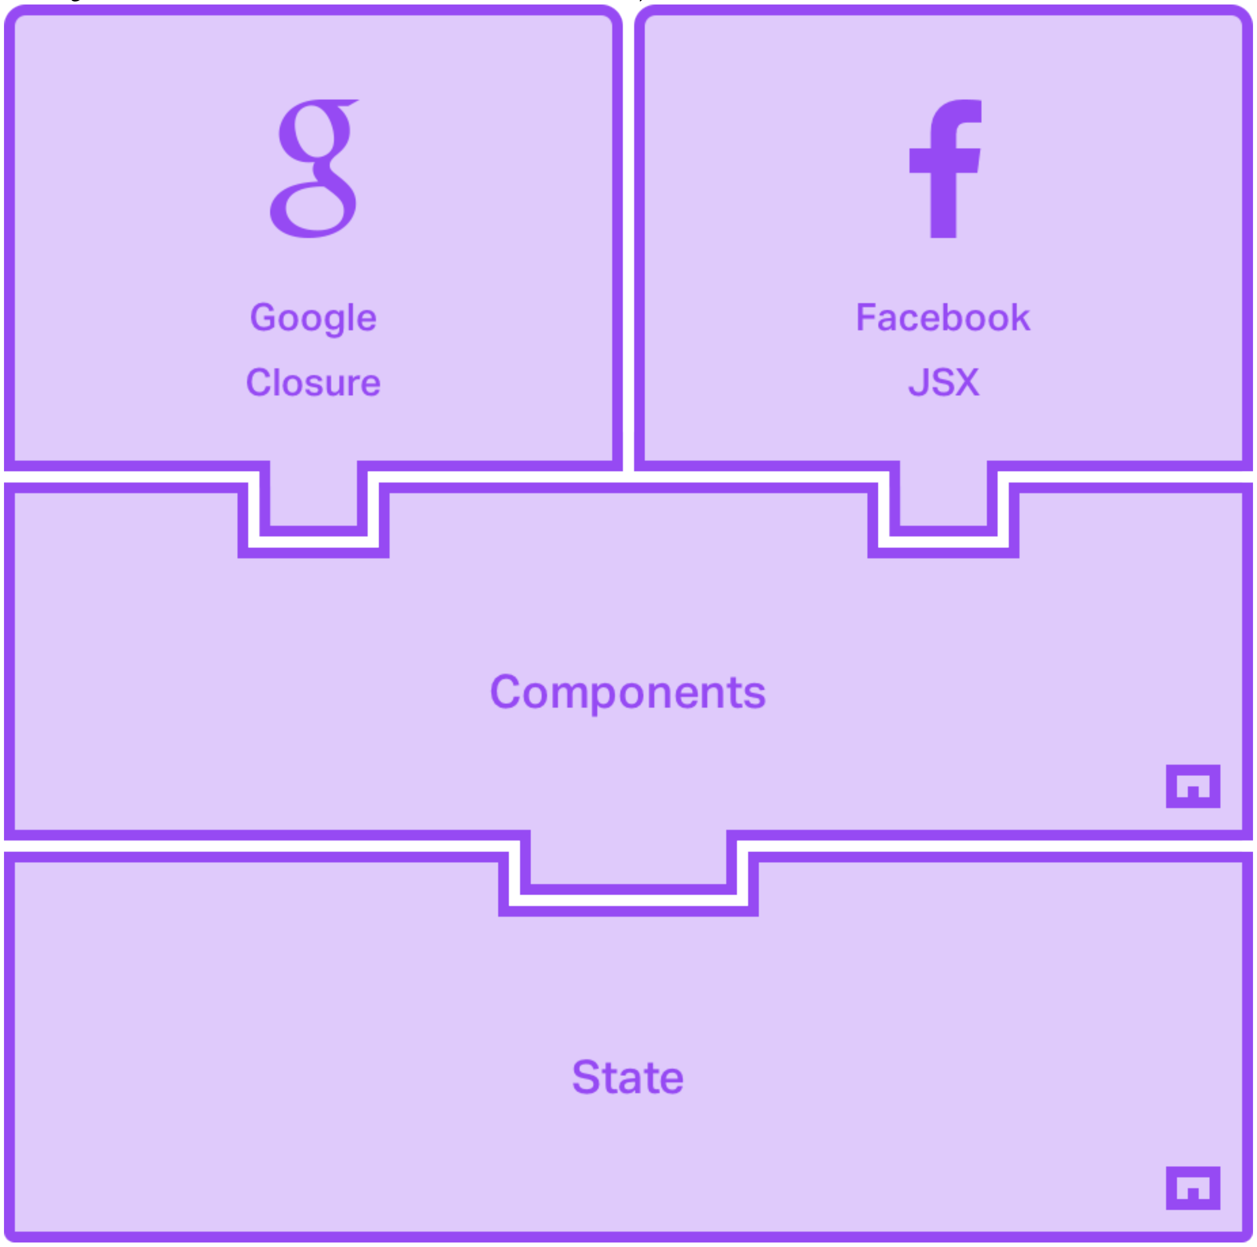
Below is an example of a closure(Soy) template written for Metal.js:

```
{template .render}
// ...
```

```
<button onClick="{$close}" type="button" class="close">
// ...
{/template}
```

Metal.js has two main classes: `State`, and `Component` which extends from `State`. The `Component` class adds additional rendering features for your Component. If your Component doesn't require rendering, you can just use `State`.

The figure below illustrates the architecture for Metal.js:



Metal.js takes full advantage of the ECMAScript 6 (AKA ECMAScript 2015) language, so you can use the latest features that the language has to offer. Below is a list of some of the great features that you get with ES6:

- Class syntax like other OO languages. Classes support prototype-based inheritance, super calls, instance and static methods and constructors.

- Arrow method syntax. `var odds = numbers.map(v => v + 1);`
- Language-level support for modules for Component definition. Codifies patterns from popular JavaScript module loaders like AMD (as shown below):

```
export function sum(x, y) {
  return x + y;
}
export var pi = 3.141593;
```

These are just a few of the ES6 features available that you can use in your Metal.js components.

JavaScript Module Loaders

Chapter 5

Starting Module Development

Developing modules for Liferay DXP requires:

- **Creating a folder structure**: A good folder structure facilitates evolving and maintaining code, especially in collaboration. Popular tools use pre-defined folder structures familiar to developers.
- **Writing code and configuration files**: A manifest, Java classes, and resources. Modules stubbed out with them let developers focus on implementing logic.
- **Compilation**: Acquiring dependencies and building the module. Common build tools that manage dependencies include Gradle, Maven, and Ant/Ivy.
- **Deployment**: Interacting with the runtime environment to install, monitor, and modify modules.

There are several good build tools for developing modules on Liferay DXP. This tutorial demonstrates starting a new module using Liferay Workspace. It's Liferay's opinionated build environment based on Gradle and BndTools that simplifies module development and automates much of it.

Note: Liferay supports developers using their build tool of choice. In addition to providing Liferay Workspace for those who don't already have a preferred build environment, Liferay provides good support for Maven and Gradle. The following tutorials and samples demonstrate developing in these environments.

- Maven tutorials and samples
- Gradle in Liferay @ide@ and samples

Note: Themes and Layout Templates are not built as modules. To learn how to create them, see the Themes and Layout Templates tutorials.

Here are the steps for starting module development:

1. Set up a Liferay Workspace
2. Create a module

3. Build and deploy the module

On completing this tutorial you'll have created a module and deployed it to a local Liferay DXP bundle.

5.1 Setting up a Liferay Workspace

Creating and configuring a Liferay Workspace (Workspace) is straightforward using a tool called Blade CLI (Blade). Blade is a command line tool that creates Workspaces and performs common tasks.

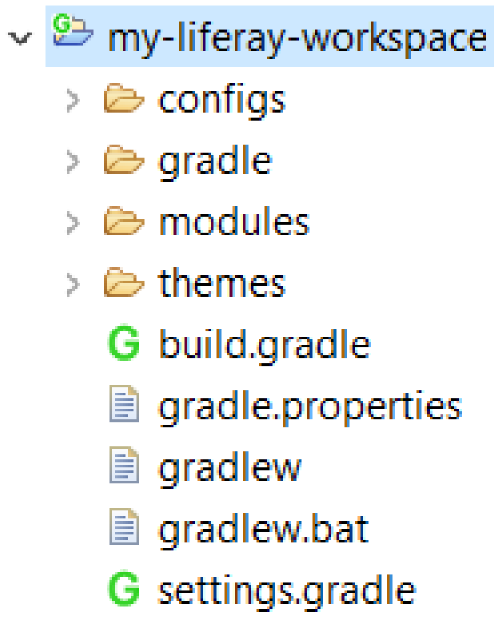
Follow the steps in this tutorial to install Blade if you don't already have it.

The `blade` executable is now in the system path.

You can create a Workspace in the current directory by executing this command:

```
blade init <workspaceName>
```

You've created a Workspace! Its directory structure looks like the one shown in the figure below.



```
my-liferay-workspace
    configs
    gradle
    modules
    themes
    build.gradle
    gradle.properties
    gradlew
    gradlew.bat
    settings.gradle
```

Figure 5.1: Liferay Workspace aggregates projects so they can leverage the Gradle build environment.

Workspace can be configured to use a Liferay DXP installation bundle anywhere on the local file system. The `liferay.workspace.home.dir` property in `gradle.properties` sets the default bundle location to a folder `<workspace>/bundles` (not yet created). For convenience it's suggested to install a Liferay DXP bundle there. If you install it to a different location, uncomment the `liferay.workspace.home.dir` property and set it to that location.

Note: User interfaces in Liferay @ide@ lets developers create and import Liferay Workspace projects. To create a project, follow the tutorial Creating a Liferay Workspace Project with Liferay @ide@. To import a project, use the wizard from *File* → *Import* → *Liferay* → *Liferay Workspace Project*.

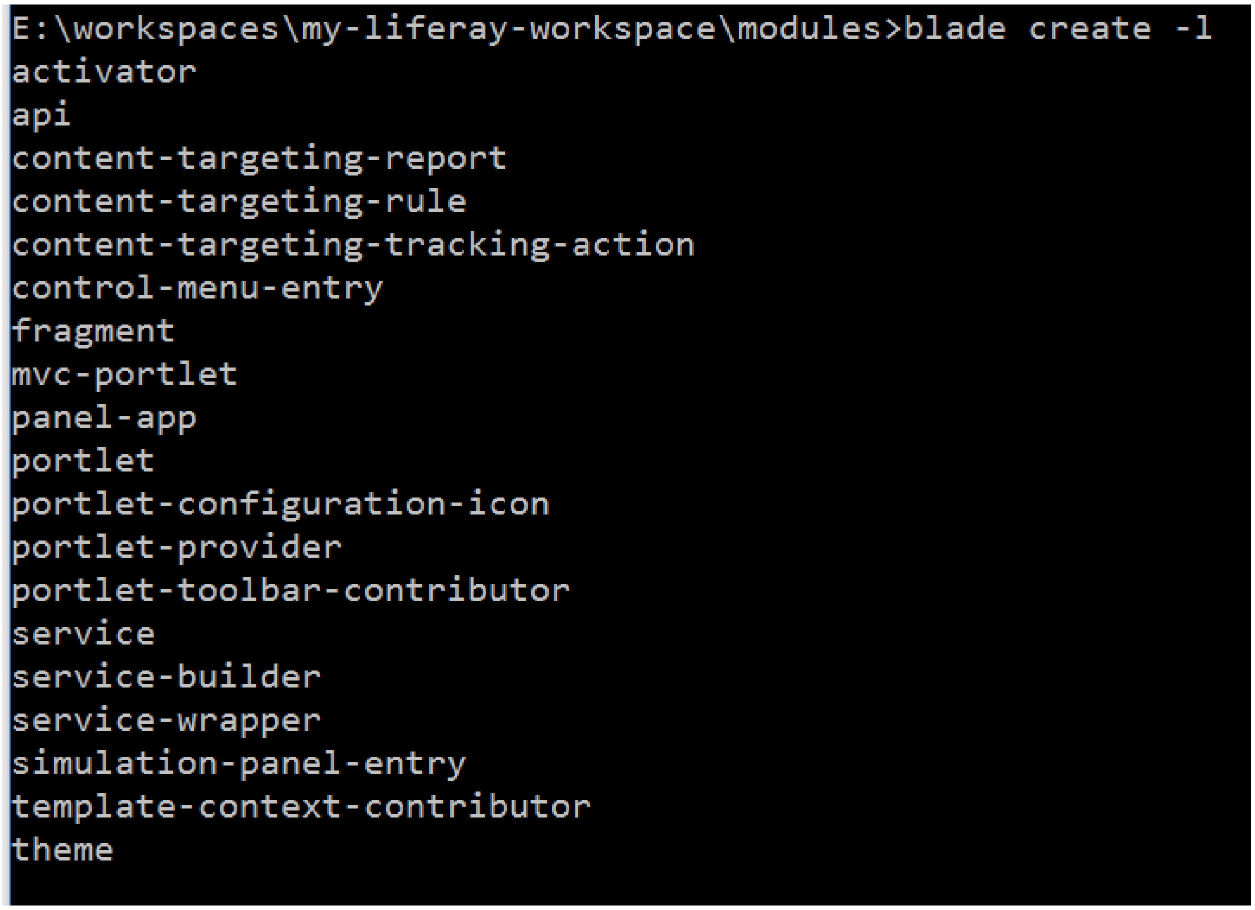
The Workspace is ready for creating modules.

5.2 Creating a Module

Blade provides module *templates* and module *samples*. The templates stub out files for different types of modules. The samples can be generated in a Workspace and demonstrate many module types. Developers can use templates and samples to develop modules.

Using Module Templates

The Blade command `blade create -l` lists the module templates.



```
E:\workspaces\my-liferay-workspace\modules>blade create -l
activator
api
content-targeting-report
content-targeting-rule
content-targeting-tracking-action
control-menu-entry
fragment
mvc-portlet
panel-app
portlet
portlet-configuration-icon
portlet-provider
portlet-toolbar-contributor
service
service-builder
service-wrapper
simulation-panel-entry
template-context-contributor
theme
```

Figure 5.2: Blade's `create` command generates a module based on a template. Executing `create -l` lists the template names.

Note: Liferay @ide@'s module wizard lets developers select a template for their module project. For details, see the tutorial Creating a Module with Liferay @ide@.

Here's the command syntax for creating a module:

```
blade create [options] moduleName
```

Module templates and their options are described here.

Here's an example of creating a Liferay MVC Portlet module:

```
blade create -t mvc-portlet -p com.liferay.docs.mymodule -c MyMvcPortlet my-module
```

Module projects are created in the `modules` folder by default.
Here's the module project anatomy:

- `src/main/java/` → Java package root
- `src/main/resources/content/` (optional) → Language resource bundle root
- `src/main/resources/META-INF/resources/` (optional) → Root for UI templates, such as JSPs
- `bnd.bnd` → Specifies essential OSGi module manifest headers
- `build.gradle` → Configures dependencies and more using Gradle

The figure below shows an MVC portlet module project.

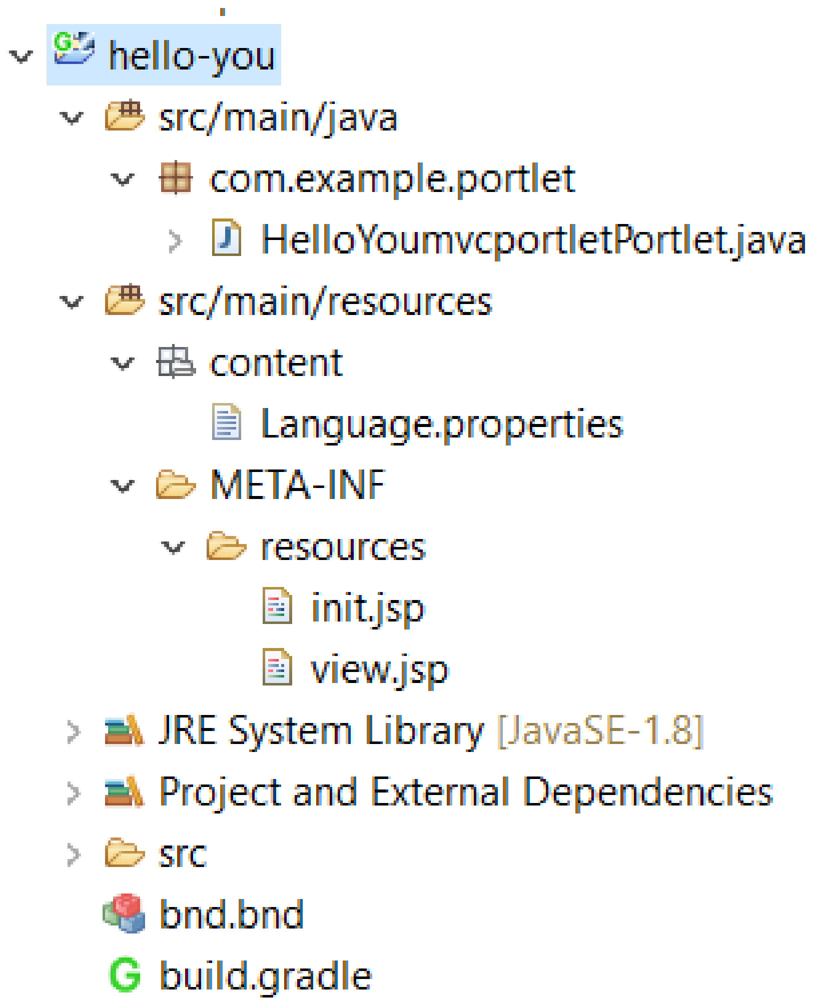


Figure 5.3: Liferay modules use the standard Maven directory structure.

Sample modules are another helpful development resource.

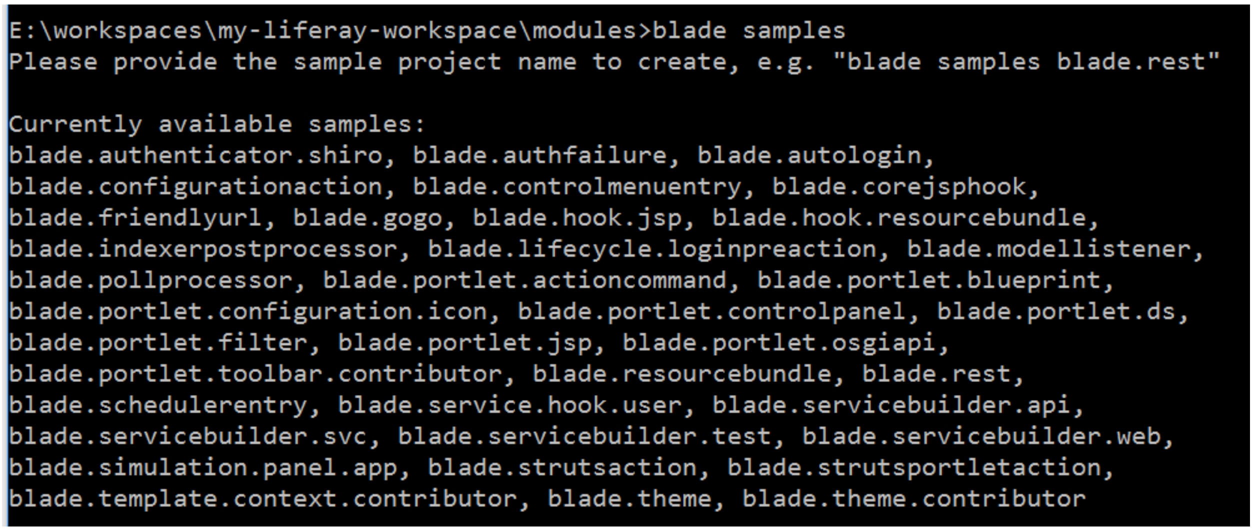
Using Module Samples

An alternative to creating a module from a template is to generate a *sample* module. Developers can examine or modify sample modules as desired.

This command lists the sample names:

```
blade samples
```

The figure below shows the listing.



```
E:\workspaces\my-liferay-workspace\modules>blade samples
Please provide the sample project name to create, e.g. "blade samples blade.rest"

Currently available samples:
blade.authenticator.shiro, blade.authfailure, blade.autologin,
blade.configurationaction, blade.controlmenuentry, blade.corejsphook,
blade.friendlyurl, blade.gogo, blade.hook.jsp, blade.hook.resourcebundle,
blade.indexerpostprocessor, blade.lifecycle.loginpreaction, blade.modellistener,
blade.pollprocessor, blade.portlet.actioncommand, blade.portlet.blueprint,
blade.portlet.configuration.icon, blade.portlet.controlpanel, blade.portlet.ds,
blade.portlet.filter, blade.portlet.jsp, blade.portlet.osgiapi,
blade.portlet.toolbar.contributor, blade.resourcebundle, blade.rest,
blade.schedulerentry, blade.service.hook.user, blade.servicebuilder.api,
blade.servicebuilder.svc, blade.servicebuilder.test, blade.servicebuilder.web,
blade.simulation.panel.app, blade.strutsaction, blade.strutsportletaction,
blade.template.context.contributor, blade.theme, blade.theme.contributor
```

Figure 5.4: The `blade samples` command lists the names of sample modules developers can create, examine, and modify to meet their needs.

Here's the Blade samples command syntax:

```
blade samples <sampleName>
```

It creates the sample project in a subfolder of the current folder.

Building a module and deploying it to Liferay DXP is easy.

5.3 Building and Deploying a Module

Liferay Workspace provides Gradle tasks for building and deploying modules. Blade's `blade gw` command solves a common need in Gradle projects: invoking the Gradle wrapper from any project directory. You can use `blade gw` just as you would invoke `gradlew`, without having to specify the wrapper path.

Note: For an even simpler Gradle wrapper command, install *gw*.
`(sudo) jpm install gw@1.0.1`
Usage: `gw <task>`

In a module folder, execute this command to list the Gradle tasks available:

```
blade gw tasks
```

Workspace uses BndTools to generate the module's OSGi `MANIFEST.MF` file and package it in the module JAR. To compile the module and generate the module JAR, execute the `jar` Gradle task:

```
blade gw jar
```

The generated JAR is in the module project's `build/libs` folder and ready for deployment to Liferay DXP.

Start your Liferay DXP server, if you haven't already started it.

Tip: To open a new terminal window and the Workspace's Liferay DXP server (bundled with Tomcat or JBoss/Wildfly), execute this command:

`blade server start -b`

Blade can deploy modules to any local Liferay DXP server. It communicates with Liferay DXP's OSGi framework using Felix Gogo shell and deploys modules directly to the OSGi container using Felix File Install commands. The command uses the default port 11311.

To deploy the module, execute this command:

```
blade deploy
```

Also Blade lets developers deploy all modules in the current folder tree. To deploy all modules in a Workspace's modules folder, for example, execute `blade deploy` in the `<workspace>/modules` folder.

If you're using Liferay @ide@, you can deploy modules by dragging them from the Package Explorer onto the Liferay DXP server. @ide@ provides access to Liferay Workspace Gradle tasks too.

Note: When deploying a module to Liferay DXP using Blade CLI, the module is directly installed into Liferay DXP's OSGi container. This means that the module is stored differently in Liferay DXP than if it were copied into the `LIFERAY_HOME/deploy` folder. See the Deploying Modules with Blade CLI tutorial for more information.

Once you've deployed a portlet module, it's available in the Liferay DXP UI under the application category and name you specified via the portlet component's `com.liferay.portlet.display-category` and `javax.portlet.display-name` properties in the `@Component` annotation.

5.4 Redeploying Module Changes Automatically

Blade lets developers set a *watch* on changes to a module project's output files. If they're modified, Blade redeploys the module automatically. To set a watch on a module at deployment, execute this command in the module project:

```
blade deploy -w
```

Here's output from deploying (and watching) a module named *com.liferay.docs.mymodule*:

```
E:\workspaces\my-liferay-workspace\modules\my-module-project>blade deploy -w

:modules:my-module-project:compileJava UP-TO-DATE
:modules:my-module-project:buildCSS UP-TO-DATE
:modules:my-module-project:processResources UP-TO-DATE
:modules:my-module-project:transpileJS SKIPPED
:modules:my-module-project:configJSModules SKIPPED
:modules:my-module-project:classes UP-TO-DATE
:modules:my-module-project:jar UP-TO-DATE
```

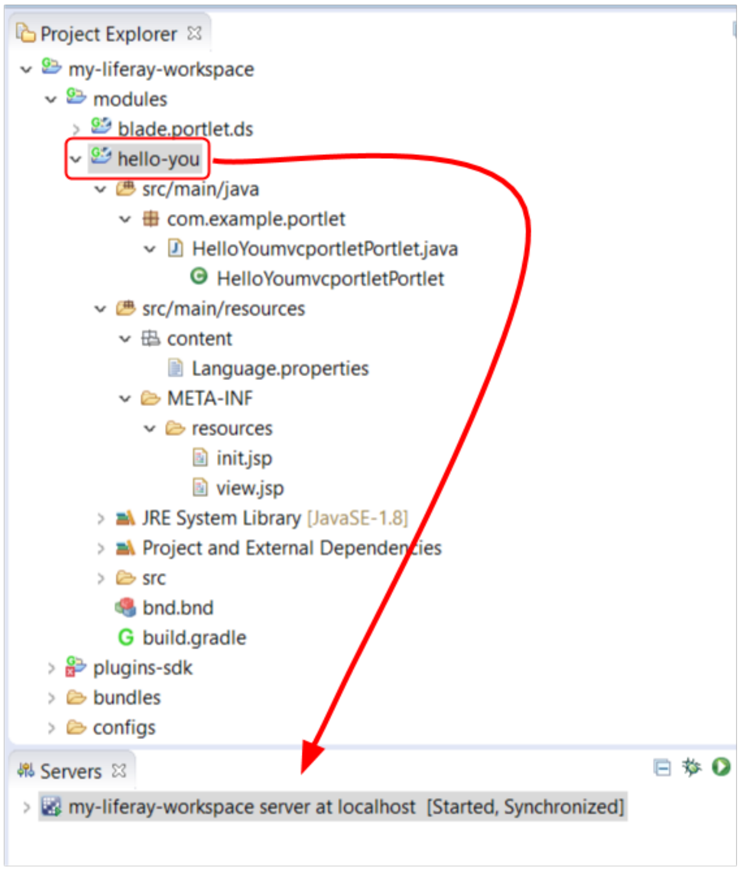


Figure 5.5: Liferay @ide@ lets developers deploy modules using drag-and-drop.

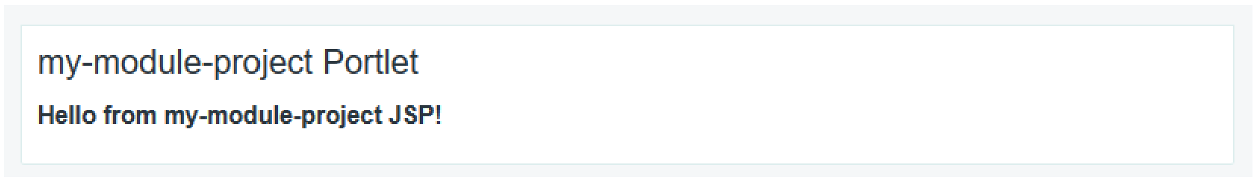

my-module-project Portlet

Hello from my-module-project JSP!

Figure 5.6: Here's a bare-bones portlet based on one of Liferay's module templates.

```
:modules:my-module-project:assemble UP-TO-DATE
:modules:my-module-project:build

BUILD SUCCESSFUL

Total time: 2.962 secs
install file:/E:/workspaces/my-liferay-workspace/modules/my-module-project/build/libs/com.liferay.docs.mymodule-1.0.0.jar
Bundle ID: 505
start 505

Scanning E:\workspaces\my-liferay-workspace\modules\my-module-project

...

Waiting for changes to input files of tasks... (ctrl-d then enter to exit)
```

Output from the `blade deploy -w` command indicates that the module is installed and started, reports the module's OSGi bundle ID, and stands ready to redeploy the module if its output files change.

Congratulations on a great start to developing your module!

OSGi Basics for Liferay Development

Portlets

Chapter 6

Configuring Dependencies

Using external artifacts in your project requires configuring their dependencies. To do this, look up the artifact's attributes and plug them into dependency entries for your build system (either Gradle, Maven, or Ant/Ivy). Your build system downloads the dependency artifacts your project needs to compile successfully.

Before specifying an artifact as a dependency, you must first find its attributes. Artifacts have these attributes:

- *Group ID*: Authoring organization
- *Artifact ID*: Name/identifier
- *Version*: Release number

This tutorial shows you how to make sure your projects have the right dependencies:

- Find Core artifacts
- Find Liferay app and independent artifacts
- Configure dependencies

6.1 Finding Core Artifacts

Each Liferay artifact is a JAR file whose `META-INF/MANIFEST.MF` file contains the artifact's OSGi metadata. The manifest also specifies the artifact's attributes. For example, these two OSGi headers specify the artifact ID and version:

```
Bundle-SymbolicName:  [artifact ID]
Bundle-Version: [version]
```

Important: Artifacts in Liferay DXP fix packs override Liferay DXP installation artifacts. Subfolders of a fix pack ZIP file's `binaries` folder hold the artifacts. If an installed fix pack provides an artifact you depend on, specify the version of that fix pack artifact in your dependency.

This table lists the group ID, artifact ID, version, and origin for each core Liferay DXP artifact:

Core Liferay DXP Artifacts:

File	Group ID	Artifact ID	Version	Origin
`portal-kernel.jar`	`com.liferay.portal`	`com.liferay.portal.kernel`	(see JAR's `MANIFEST.MF`)	fix pack ZIP, Liferay DXP installation, or Liferay DXP dependencies ZIP
`portal-impl.jar`	`com.liferay.portal`	`com.liferay.portal.impl`	(see JAR's `MANIFEST.MF`)	fix pack ZIP or Liferay DXP `.war`
`portal-test.jar`	`com.liferay.portal`	`com.liferay.portal.test`	(see JAR's `MANIFEST.MF`)	fix pack ZIP or Liferay DXP `.war`

`com.liferay.*` JAR files	`com.liferay`	(see JAR's `MANIFEST.MF`)	(see JAR's `MANIFEST.MF`)	fix pack ZIP, Liferay DXP installation, Liferay DXP dependencies ZIP, or the OSGi ZIP

Next, you'll learn how to find artifacts for Liferay DXP apps and independent modules.

6.2 Finding Liferay App and Independent Artifacts

Independent modules and modules that make up Liferay DXP's apps aren't part of the Liferay DXP core. You must still, however, find their artifact attributes if you want to declare dependencies on them. The resources below provide the artifact details for Liferay DXP's apps and independent modules:

Resource	Artifact Type
App Manager	Deployed modules
Reference Docs	Liferay DXP modules (per release)
Maven Central	All artifact types: Liferay DXP and third party, module and non-module

Important: `com.liferay` is the group ID for all Liferay DXP's apps and independent modules.

The App Manager is the best source for information on deployed modules. You'll learn about it next.

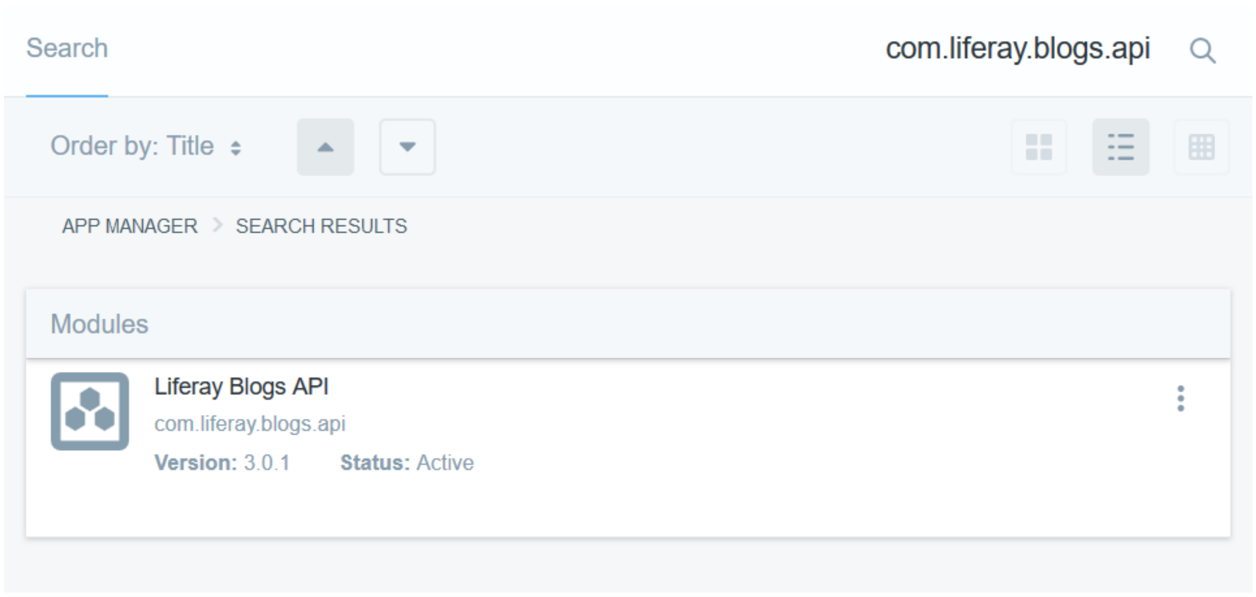
App Manager

The App Manager knows what's deployed on your Liferay DXP server. You can use it to find whatever modules you're looking for.

Follow these steps to get a deployed module's information:

1. In Liferay DXP, navigate to *Control Panel* → *Apps* → *App Manager*.

2. Search for the module by its display name, symbolic name, or related keywords. You can also browse for the module in its app. Whether browsing or searching, the App Manager shows the module's artifact ID and version number.



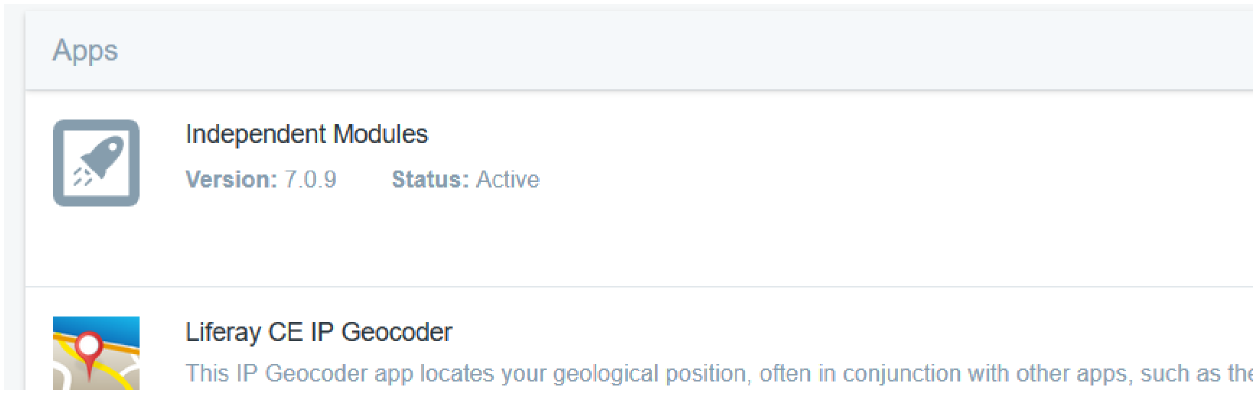
Liferay Blogs API
com.liferay.blogs.api
Version: 3.0.1 **Status:** Active

Figure 6.1: You can inspect deployed module artifact IDs and version numbers.

If you don't know a deployed module's group, use the Felix Gogo Shell to find it:

1. Open a Gogo Shell session by entering the following into a command prompt:

```
telnet localhost 11311
```



Apps

Independent Modules

Version: 7.0.9 Status: Active

Liferay CE IP Geocoder

This IP Geocoder app locates your geological position, often in conjunction with other apps, such as the

Figure 6.2: The App Manager aggregates Liferay and independent modules.

This results in a `g!`: the Felix Gogo Shell command prompt.

2. Search for the module by its display name (e.g., `Liferay Bookmarks API`) or a keyword. In the results, note the module's number. You can use it in the next step. For example, these results show the Liferay Bookmarks API module's number is 52:

```
g! lb | grep "Liferay Bookmarks API"

   52|Active     |   10|Liferay Bookmarks API (2.0.1)
```

3. To list the module's manifest headers, pass the module number to the `headers` command. In the results, note the `Bundle-Vendor` value: you'll match it with an artifact group in a later step:

```
g! headers 52

Liferay Bookmarks API (52)
--------------------------
Manifest-Version = 1.0
Bnd-LastModified = 1464725366614
Bundle-ManifestVersion = 2
Bundle-Name = Liferay Bookmarks API
Bundle-SymbolicName = com.liferay.bookmarks.api
Bundle-Vendor = Liferay, Inc.
Bundle-Version = 2.0.1
...
```

4. Disconnect from the Gogo Shell session:

```
g! disconnect
```

5. On Maven Central or MVNRepository, search for the module by its artifact ID.

6. Determine the group ID by matching the `Bundle-Vendor` value from step 3 with a group listed that provides the artifact.

Next, you'll learn how to use Liferay DXP's reference documentation to find a Liferay DXP app module's attributes.

Reference Docs

Liferay DXP's app Javadoc lists each app module's artifact ID, version number, and display name. This is the best place to look up Liferay DXP app modules that aren't yet deployed to your Liferay DXP instance.

Note: To find artifact information on a Core Liferay DXP artifact, refer to the previous section Finding Core artifacts.

Follow these steps to find a Liferay DXP app module's attributes in the Javadoc:

1. Navigate to Javadoc for an app module class. If you don't have a link to the class's Javadoc, find it by browsing @app-ref@.
2. Copy the class's package name.
3. Navigate to the *Overview* page.
4. On the *Overview* page, search for the package name you copied in step 2.

The heading above the package name shows the module's artifact ID, version number, and display name. Remember, the group ID for all app modules is `com.liferay`.

Liferay Blogs Demo Data Creator API - com.liferay:com.liferay.blogs.demo.data.creator.api:1.0.2

Figure 6.3: Liferay DXP app Javadoc overviews list each app module's display name, followed by its group ID, artifact ID, and version number in a colon-separated string. It's a Gradle artifact syntax.

Note: Module version numbers aren't currently included in any tag library reference docs.

Next, you'll learn how to look up artifacts on MVNRepository and Maven Central.

Maven Central

Most artifacts, regardless of type or origin, are on MVNRepository and Maven Central. These sites can help you find artifacts based on class packages. It's common to include an artifact's ID in the start of an artifact's package names. For example, if you depend on the class `org.osgi.service.component.annotations.Component`, search for the package name `org.osgi.service.component.annotations` on one of the Maven sites.

Note: Make sure to follow the instructions listed earlier to determine the version of Liferay artifacts you need.

Now that you have your artifact's attribute values, you're ready to configure a dependency on it.

6.3 Configuring Dependencies

Specifying dependencies to build systems is straightforward. Edit your project's build file, specifying a dependency entry that includes the group ID, artifact ID, and version number.

Note: To configure third-party libraries in a module, see the tutorial Adding Third Party Libraries to a Module.

Note that different build systems use different artifact attribute names, as shown below:
Artifact Terminology

Framework	Group ID	Artifact ID	Version
Gradle	`group`	`name`	`version`
Maven	`groupId`	`artifactId`	`version`
Ivy	`org`	`name`	`rev`

The following examples demonstrate configuring a dependency on Liferay's Journal API module for Gradle, Maven, and Ivy.

Gradle

Here's the dependency configured in a `build.gradle` file:

```
dependencies {
    compileOnly group: "com.liferay", name: "com.liferay.journal.api", version: "1.0.1"
    ...
}
```

Maven

Here's the dependency configured in a `pom.xml` file:

```
<dependency>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.journal.api</artifactId>
    <version>1.0.1</version>
</dependency>
```

Ivy

Here's the dependency configured in an `ivy.xml` file:

```
<dependency name="com.liferay.journal.api" org="com.liferay" rev="1.0.1" />
```

Important: Liferay DXP exports many third-party packages. If you're developing a WAR, deploy it to check if the packages you're using are in the OSGi runtime container already. If they are already in there, specify their corresponding artifacts as being "provided". Here's how to specify a provided dependency:

Maven: `<scope>provided</scope>`

Gradle: `providedCompile`

Don't deploy a provided package's JAR again or embed the JAR in your project. Exporting the same package from different JARs leads to "split package" issues, whose side affects differ from case to case. If the package is in a third-party library (not an OSGi module), refer to [Resolving Third

---

Party Library Dependencies](/docs/7-0/tutorials/-/knowledge_base/t/adding-third-party-libraries-to-a-module).

If you're developing a WAR that requires a different version of a third-party package that Liferay DXP or another module exports, specify that package in your `Import-Package:` list. If the package provider is an OSGi module, publish its exported packages by deploying that module. Otherwise, follow the instructions for adding a third-party library (not an OSGi module).

Nice! Now you know how to find artifacts and configure them as dependencies. Now that's a skill you can depend on!

Chapter 7

Finding Extension Points

Liferay DXP provides many features that help users accomplish their tasks. Sometimes, however, you may find it necessary to customize a built-in feature. It's easy to **find** an area you want to customize, but it may seem like a daunting task to figure out **how** to customize it. Liferay DXP was developed for easy customization, meaning there are many extension points you can use to add your own flavor.

There's a process you can follow that makes finding an extension point a breeze.

1. Locate the bundle (module) that provides the functionality you want to change.
2. Find the components available in the module.
3. Discover the extension points for the chosen component.

In this tutorial, you'll learn how to find an extension point. You'll step through a simple example that locates an extension point for importing LDAP users. This will require the use of Liferay DXP's Application Manager and Felix Gogo Shell.

7.1 Locate the Related Module and Component

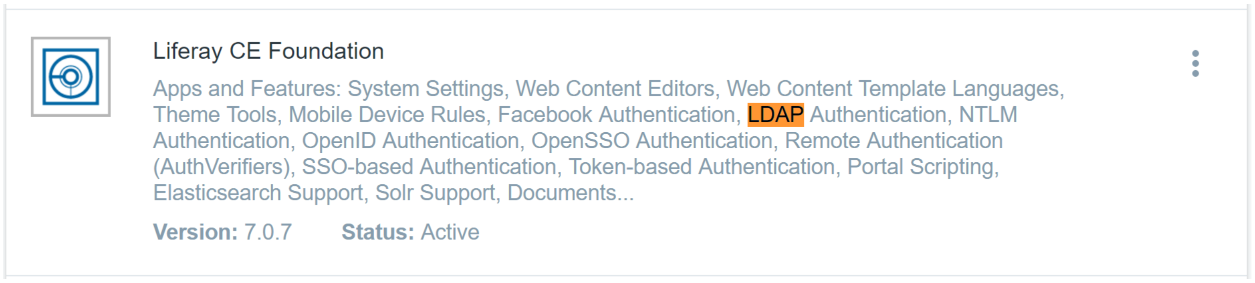
You must first think of words that describe the application behavior you want to change. With the right keywords, you can easily track down the desired module and its component. Consider the example for importing LDAP users. Some candidate keywords for finding the component are *import*, *user*, and *LDAP*.

The easiest way to discover the module responsible for a particular feature in Liferay DXP is to use the Application Manager. The Application Manager lists app suites and their included modules/components in an easy-to-use interface. It even lists third party apps! You'll use your keywords to target the applicable component.

1. Open the App Manager by navigating to *Control Panel → Apps → App Manager*. The top level lists app suites, independent apps, and independent modules.

2. Navigate the app suites, apps, and modules, or use Search to find components that might provide your desired extension point. Remember to check for your keywords in element names and descriptions. The keyword *LDAP* resides under the Liferay Foundation app suite; select it.

3. Select the *LDAP* application from the app listing.



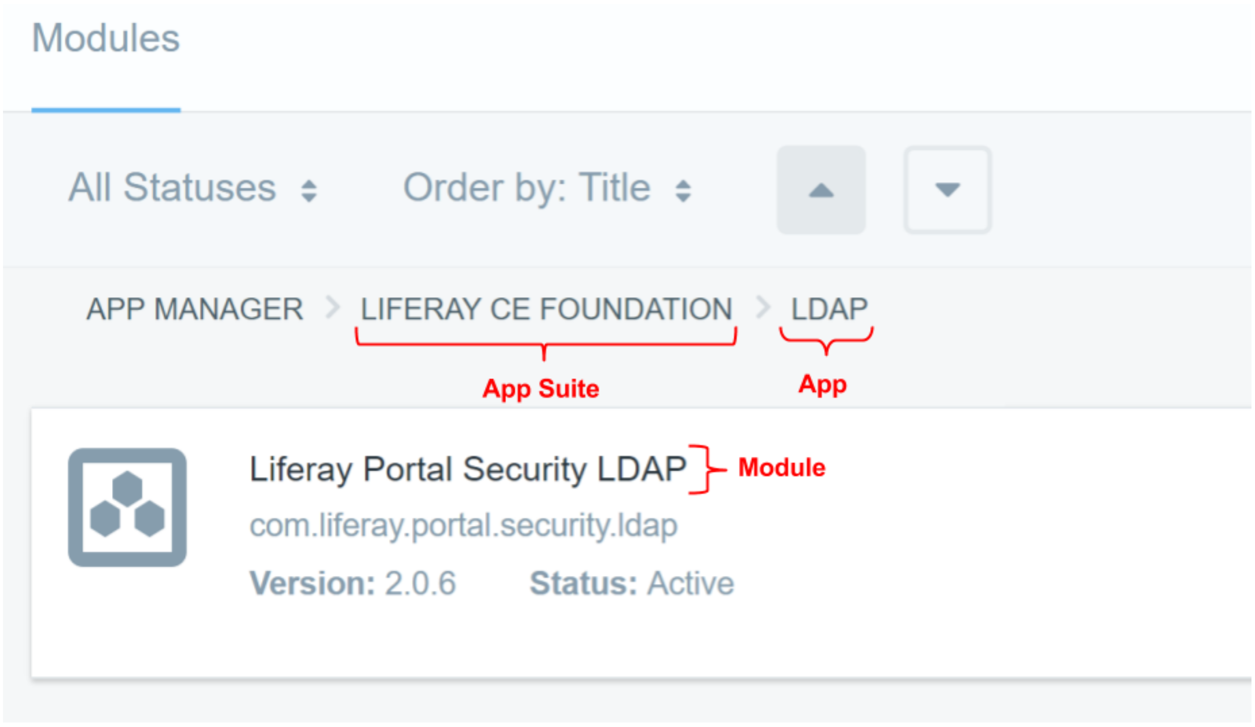
Liferay CE Foundation

Apps and Features: System Settings, Web Content Editors, Web Content Template Languages, Theme Tools, Mobile Device Rules, Facebook Authentication, LDAP Authentication, NTLM Authentication, OpenID Authentication, OpenSSO Authentication, Remote Authentication (AuthVerifiers), SSO-based Authentication, Token-based Authentication, Portal Scripting, Elasticsearch Support, Solr Support, Documents...

Version: 7.0.7 **Status:** Active

Figure 7.1: The Liferay Foundation app suite contains the LDAP Authentication application.

4. The LDAP application only has one module, but typically, applications have more than one module to inspect. Select the *Liferay Portal Security LDAP* module.



Liferay Portal Security LDAP

com.liferay.portal.security.ldap

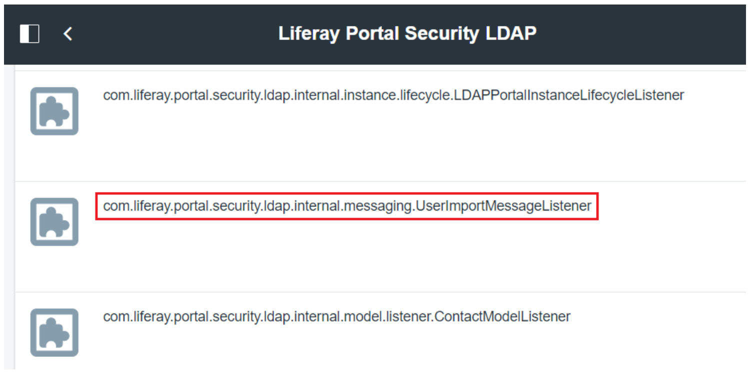
Version: 2.0.6 **Status:** Active

Figure 7.2: The App Manager lists the module, package name, version, and status.

5. Search through the components, applying your keywords as a guide. Copy the component name you think best fits the functionality you want to customize; you'll inspect it later using the Gogo shell.

```
**Note:** When using the Gogo shell later, understand that it can take
several tries to find the component for which you're looking; naming
conventions should allow you to find your desired extension point in a
manageable time frame.
```

Next, you'll begin using the Gogo shell to inspect the component for extension points.



Liferay Portal Security LDAP

com.liferay.portal.security.ldap.internal.instance.lifecycle.LDAPPortalInstanceLifecycleListener

com.liferay.portal.security.ldap.internal.messaging.UserImportMessageListener

com.liferay.portal.security.ldap.internal.model.listener.ContactModelListener

Figure 7.3: The component name can be found using the App Manager.

7.2 Finding Extension Points in a Component

Once you have the component that relates to the functionality you want to extend, you can use the Gogo shell's Service Component Runtime (SCR) commands to inspect it. You can execute SCR commands using Liferay Blade CLI or in Gogo shell via telnet. This tutorial assumes you're using the Gogo shell via telnet.

Execute the following command:

```
scr:info [COMPONENT_NAME]
```

For the LDAP example component you copied previously, the command would look like this:

```
scr:info com.liferay.portal.security.ldap.internal.messaging.UserImportMessageListener
```

The output includes a lot of information. For this exercise, you're interested in the services the component references. These are extension points. For example, here's the reference for the service that imports LDAP users:

```
...
Reference: LdapUserImporter
Interface Name: com.liferay.portal.security.ldap.exportimport.LDAPUserImporter
Cardinality: 1..1
Policy: static
Policy option: reluctant
Reference Scope: bundle
...
```

The `LDAPUserImporter` is the extension point needed to customize the process of importing users with LDAP! If none of the references satisfy what you're looking for, search other components from the App Manager.

If you plan on overriding the referenced service, you'll need to understand the reference's policy and policy option. If the policy is `static` and the policy option is `reluctant`, binding a new higher ranking service in place of a bound service requires reactivating the component or changing the target. For information on the other policies and policy options, visit the OSGi specification, in particular, sections 112.3.5 and 112.3.6. If you want to learn how to override a component's service reference, visit the following tutorial.

Important Not all Extension points in Liferay DXP are available as referenced services. Referenced services are common extension points when using Declarative Services (DS), but there are extension points not exposed this way. If your project does not use the DS component framework, you'd need to look for the API that describes its service consumption from the OSGi registry. Here's a brief list of other potential extension points in Liferay DXP:

- Instances of `org.osgi.util.tracker.ServiceTracker<S, T>`
- Uses of Liferay's `Registry.getServiceTracker`
- Uses of Liferay's `ServiceTrackerMap` or `ServiceTrackerCollection`
- Any other component framework or whiteboard implementation (e.g., HTTP, JAX-RS) that supports tracking services; Blueprint, Apache Dependency Manager, etc. could also introduce extension points.

There you have it! You successfully formulated keywords that described the functionality you wanted to customize, used those keywords in the App Manager to target the applicable module component, and used the Gogo shell to inspect the component for extension points.

Chapter 8

From Liferay Portal 6 to 7

Becoming familiar with a platform as large and fully featured as Liferay is a big task. You learn the ins and outs of what it can do, the tips and best practices of the experts, and you work your way through the APIs. As you do this, you become more and more familiar with how things work, become more proficient with the platform as you multiply successes on it, and start to think in terms of how you'd solve problems most effectively using the tools the platform gives you. Eventually, if you use it long enough, it can seem like an old friend that's ready to stand by you and help you succeed in your projects.

7.0 was designed as an enhancement that builds off of what you already know. Its Upgrade Planner and this tutorial series–or Learning Path–help get your existing plugins running on 7.0 right away. The tool automates much of the process. After you upgrade your plugins, you can build and deploy them as you always have.

7.0 has exciting improvements for developers too. This Learning Path shows you how to leverage them. Since you already know previous versions of Liferay Portal, you're several steps ahead of everybody else.

This Learning Path describes the benefits of 7.0 for developers compared to previous versions, the architectural improvements, the benefits that modularity brings, and how to develop modules and how they differ from traditional plugins. You'll see all the options for leveraging new developer features, learn the pros and cons of each, and examine steps for optimizing your existing plugins for 7.0.

In the end, we believe you'll both want to adopt 7.0, and you'll see how you can thrive using it.

Note: If you want to learn about 7.0's architectural improvements, OSGi and modularity, and tooling improvements, read on. If you're more interested in upgrading your plugins first, skip to Planning Plugin Upgrades and Optimizations.

You'll start by seeing the familiar, good things that remain the same and then examine what's changed the most since Liferay Portal 6.

Chapter 9

What Hasn't Changed and What Has

7.0 is a new major version of the Liferay platform and as such it includes many improvements over previous versions. Having said that, most of the characteristics from Liferay Portal 6 that you have learned to love are preserved, having been changed only slightly or not at all. Any experienced Liferay developer will be able to reuse most of his/her existing knowledge to developing for 7.0.

What has not changed? Even though there are many improvements in 7.0, there are also many great familiar aspects from previous versions that have been preserved. Here are some of the most relevant ones:

1. The Portal Core and each Liferay app continue to use the three layer architecture: presentation, services, and persistence. The presentation layer is now always provided as an independent module, facilitating replacing it with a different presentation, if desired.

2. Support remains for previously supported standards such as Portlets (JSR-168, JSR-286), CMIS, WebDAV, LDAP, JCP (JSR-170), etc.

3. Most Liferay APIs have remained functionally similar to those of 6.2, even if many of their classes have moved to new packages, as part of the modularization effort.

4. Liferay @ide@ is still the preferred tool to develop for Liferay, even though you are still free to use tools that best fit your needs.

5. Service Builder and other developer tools and libraries continue to work as they have in 6.2.

6. Traditional plugins for portlets and hooks still work (once they're adapted to 7.0's API) through a compatibility layer.

7. The Plugins SDK can also still be used and transition to the new Liferay Workspace, if desired, is easy.

Here are some key changes of interest to existing Liferay developers:

1. Extraction of many features as modules: So far you have been used to working with Liferay as a large web application, of which all of it had to be deployed or none of it. In 7.0, many out of the box portlets, features, and associated APIs have been extracted as OSGi modules. You can choose which ones to deploy and use.

2. Adoption of modern OSGi standards: OSGi is a set of standards for building modular systems. It's very powerful. Although it was previously difficult to learn and use, its modernized standards, such as Declarative Services, have made learning and using it much easier.

3. Core Public APIs are provided through portal-kernel (previously known as portal-service); all other public APIs are provided by their own modules.

4. You can reuse modules and libraries, and manage the dependencies among them.

5. Registration of classes implementing extension points is now simpler and more consistent; it's based on the standard `@Component` annotation instead of declarations in `portal.properties` or `portlet.xml`. Note, previous registration mechanisms have been preserved where possible. See the Breaking Changes article to examine where extensions and configurations that have not kept backwards compatibility.

6. Third party extensions and applications are now first-class citizens. Traditional plugins had some limitations that developments done in the core (or done as Ext Plugins) did not have. Modules don't have these limitations and are much more powerful than plugins ever were.

7. Complete integration of Liferay specific tools (such as Service Builder) within Maven and Gradle. Additionally we've adopted some new tools such as Bnd.

Since the modularization of the Liferay web application is the change most relevant to you as a developer, let's dig deeper into that change and how it affects Liferay's architecture.

9.1 Embracing a Modular Architecture

The largest improvement in Liferay's architecture is the adoption of a modular development paradigm. Within each Liferay module (or group of modules that form an app), as well as within what remains as Liferay's core, the existing great characteristics of previous versions of Liferay prevail.

Tiered Architecture

Liferay Portal 6's architecture diagrams often focused on the tiers for the frontend, services layer (for the business logic), and persistence layer (mostly auto-generated by Service Builder). These layers still exist and have been embraced throughout the modularization effort.

The most significant change (and improvement) over this architecture is that the portal is no longer a single large Java EE Web Application. Liferay has been broken down into many modules to benefit from the Modular Development Paradigm. Those benefits are described in the next section. The modules are often grouped into apps (such as Wiki or Message Boards) and the main apps are grouped into suites (such as Web Experience, Collaboration, and Forms & Workflow).

Modular Architecture

The figure below represents 7.0's architecture from a structural perspective.

Liferay Core

As its name implies, it's 7.0's central and most important part. The Liferay Core is a Java EE application in charge of bootstrapping the system and receiving and delegating all requests. It also contains Liferay's OSGi Engine on top of which all applications run.

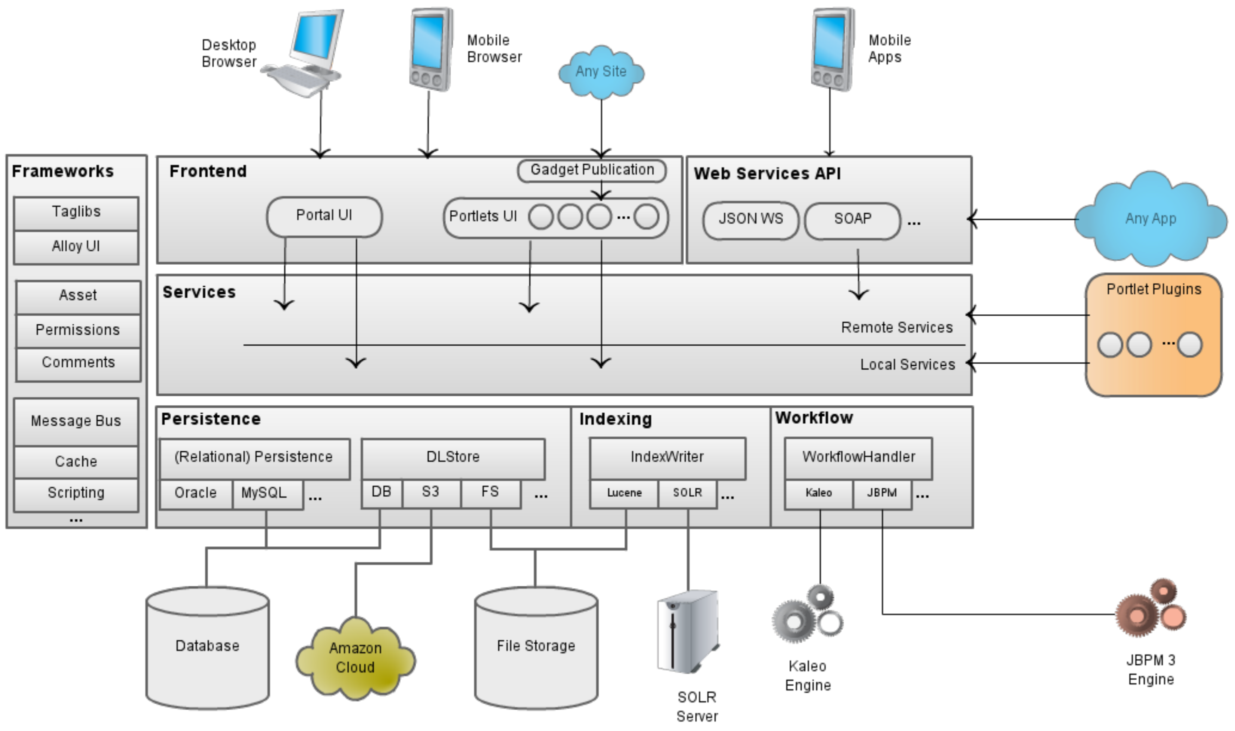


Figure 9.1: Liferay Portal 6's architecture, shown in this figure, is still generally valid in 7.0.

Foundation

The Foundation suite sits on top of the core, providing administrative interfaces and familiar development building blocks. It includes modules for user and role administration, LDAP integration, authentication, licensing, upgrades, clustering, DAO, and front-end mainstays for themes, CSS, taglibs, and JavaScript. The Foundation suite's modules depend on Liferay Core, as do all the App Suites and non-core modules.

Most of the apps, frameworks, and APIs you've come to know and love have been aggregated in App Suites. The suites are available in Liferay bundles and are also available on the Marketplace. Here are the different App Suites:

Liferay Web Experience

Contains apps such as Web Content and Site management, Web Content Display, Asset Publisher, and Breadcrumbs and features and frameworks such as Application Display Templates, Tags, and Recycle Bin.

Liferay Collaboration

Comprises Liferay's social apps and collaboration apps, such as Message Boards, Wiki, and Blogs. It also contains Liferay's Documents & Media Library.

Liferay Forms and Workflow

Provides apps such as Forms (New!), Dynamic Data Lists, Kaleo Workflow, and Calendar. It also contains the Dynamic Data Mapping framework used by Web Content and Documents & Media to provide custom form and templating capabilities.

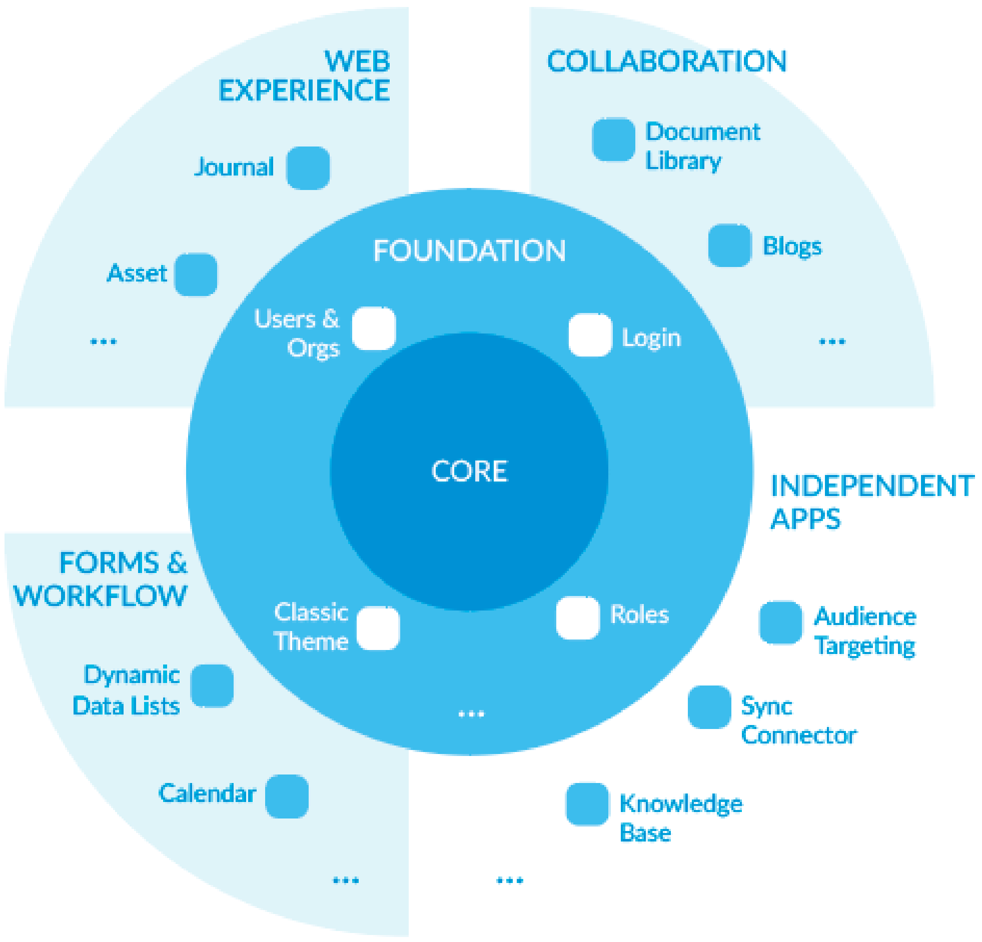

Figure 9.2: 7.0 is composed of the Liferay Core, independent application modules, and App Suites, each with their own set of application and framework modules.

Independent Apps

Last but not least, Liferay's independent apps and modules also play a part. They provide unique functionality and stand on their own; it would be unnatural to add any one of them to a particular suite. Apps such as Liferay Sync, the Marketplace Client, Knowledge Base, and many more apps available on the Marketplace are independent Liferay apps.

The beauty of the 7.0 ecosystem is that it is made up of simple easy-to-use modules that depend on and communicate with each other. And you as a third-party developer can create and deploy your own modules into the mix.

You can continue developing traditional WAR-style apps for 7.0 too. Liferay DXP's Portlet Compatibility Layer converts each plugin WAR to a Web Application Bundle (WAB), which is a module.

Let's consider the structure of a 7.0 modular app.

The Structure of a Modular App

As mentioned, each app can be formed by one or more modules. This section explains the most common way to structure an app.

The best practice for structuring an app is in several modules. In particular the following modules are the often the best way of structuring an app:

- **Service**: Contains the service (business logic) and persistence implementations.
- **API**: Contains the public API of the application. By being separate from the service it's simpler and faster to deploy new versions of the implementation without affecting any module using the API. It also allows changing the versioning of the implementation independent from the versioning of the API.
- **Web**: Contains the presentation tier, very often the portlets provided by this app.
- **Test**: Contains the tests. These are not included in the app for production.
- **Specific purpose modules**: Other modules are also often created for specific purposes or to provide alternative implementations of some of the app's features. For example the Wiki app has one module for each of the supported Wiki Engines.

All the modules in an app usually sit in directories next to each other in the source to facilitate referencing them.

For deployment to production Liferay provides the LPKG packaging format that allows bundling a set of modules into a single file and add additional metadata about it. This format can also be used to upload apps to Liferay's Marketplace.

Now you have a basic understanding of the architectural changes introduced in 7.0 and have become acquainted with the new structure used in Liferay's apps. You have learned some key concepts that are new for Liferay Portal 6 developers and have been assured about developer features you've used in previous Liferay releases that have been carried into 7.0.

Next, you'll explore how these new concepts and the new modular architecture benefit you as a developer.

Chapter 10

Benefits of 7.0 for Liferay Portal 6 Developers

More than in any other Liferay release, 7.0 centers on you, the developer. Liferay's platform has been rebuilt, making it easier to build on and maintain, and providing more new developer features than any previous Liferay release.

Here are some key benefits of this release for developers:

1. **Simpler and Leaner**
2. **Modular Development Paradigm**
3. **Enhanced Reusability**
4. **More extensible, easier to maintain**
5. **Optimized for your tooling of choice**
6. **Powerful Configurability**

Let's consider how they make development easier for you.

10.1 Simpler and Leaner

Liferay has always been simple and lean, compared to the proprietary alternatives; this version widens the gap even more.

7.0 is simpler than its predecessors, thanks to a streamlined and modular architecture. In addition, many Liferay specific ways of creating extensions and applications have evolved to follow official or de-facto standards. As a result, developers can now more easily reuse their existing knowledge and use what they learn developing for Liferay outside of it.

7.0 is also leaner. Its modularized core allows developers and system administrators to remove parts they don't need or don't want; this facilitates deployment, reduces startup times and memory footprints, and results in more efficiencies and performance improvements.

10.2 Modular Development Paradigm

If you have been using Liferay, you've already experienced some of the benefits of modular development, thanks to plugins. 7.0 takes these benefits to a whole new level.

In addition to building plugins as you have previously, you can take advantage of a complete module development and runtime system based on OSGi standards. 7.0 facilitates creating applications of all types by composing and reusing modules.

And don't worry, modules are easy to understand. A module is distributed as a JAR file and can be as small as one Java class or as large as any application you can think of. An application for Liferay can comprise one single module or as many modules as you want. The cool thing is that modules can cooperate, allowing you to build applications by combining smaller pieces that are easier to develop, deploy, maintain, and reuse.

10.3 Enhanced Reusability

If you have worked on large developments on top of Liferay you have probably experienced situations in which you wanted to share a subset of classes from from one plugin with another.

Java EE does not provide any standard way to achieve this, but Liferay provided certain capabilities to achieve it with a mechanism known as CLP that used class loader *magic* to allow plugins to invoke services in other plugins created with Service Builder. This mechanism, however, is still a bit limited (Java EE's class loader doesn't allow for much more) and doesn't give you the freedom to specify any or all classes from one module to use from within another module.

7.0 enables greater reusability, both in code and runtime memory, several folds. For any desired reusable functionality you just create a module (remember, it's just a JAR file with some metadata) with the classes you want and deploy it. Other modules need only declare that they use the classes in that module (by specifying their packages) and 7.0 automatically wires them together. All invocations are regular Java calls! Try it out; it's beautiful. :)

This mechanism eliminates the dreaded "JAR/classpath hell" issue. No longer do you have to jockey JAR files in classpaths; nor do you have to implement intricate class loaders. The runtime environment uses separate class spaces per module; it even accommodates using multiple versions of libraries in the same application (as long as they can coexist).

10.4 More Extensible, Easier to Maintain

Whenever we ask Liferay developers what is their favorite characteristic of Liferay, "Great extensibility" is one of the top three most popular responses. You can customize almost every detail and add your own functionality on top.

Is 7.0 more extensible? You bet! Many more extension points have been added. But not only that, all new extension points and many existing ones which have been upgraded, use a new extension mechanism based on OSGi's service model. Here are some of the mechanism's benefits:

1. **Simpler**: An implementation of an extension point is now always a Java class that implements an interface and has one annotation (@Component). That's it; it couldn't be any easier.

2. **Easier to maintain**: Extension points are now more strictly defined through a Java interface that uses Semantic Versioning rules. This means that your extensions can work without changes, even across several Liferay versions, as long as the specific extension API is backwards compatible.

3. **Dynamic**: Extensions can be loaded and removed at any time during development or in production.

But that is not all. Your own developments can now also leverage this model and become extensible. You can create simple extension points by just creating an interface and annotating a setter method with an annotation (@Reference). Implementing extensibility has never been easier.

10.5 Optimized for Your Tooling of Choice

7.0 empowers you to use the tools you like.

If you don't have strong preferences and are open to our suggestions, we offer Liferay Workspace. It provides an opinionated directory structure and build system based on Gradle and Bnd. Liferay Workspace can be used standalone through the command line or with Liferay @ide@, which runs on Eclipse.

And if you want to continue using the Plugins SDK, we've got you covered. The Plugins SDK is available to facilitate your transition to 7.0. In fact, a Plugins SDK structure can reside in a Liferay Workspace alongside new developments that use the new build environment; you can switch between traditional projects and new projects at your own pace.

Finally, we have also developed a lightweight tool called Blade CLI, which facilitates starting new projects from templates – it's especially useful for Gradle which doesn't have Maven's concept of archetypes. Blade CLI also offers commands to start/stop the server and deploy and administer modules.

10.6 Powerful Configurability

Creating configurable code is a breeze with 7.0. And applications that use Liferay's new Configuration API allow administrators to change the configuration on the fly, through an auto-generated user interface called System Settings.

Now you understand how 7.0 enriches your experience as a developer and makes developing apps and customizations fun.

Next, we'll take a look at OSGi and modularity to discuss key concepts and demonstrate how easy and gratifying it is to build modules.

Chapter 11

OSGi and Modularity for Liferay Portal 6 Developers

To create a powerful, reliable platform for developing modular applications, Liferay sought best-of-breed standards-based frameworks and technologies. It was imperative not only to meet demands for enterprise digital experiences but also to offer developers, both experienced with Liferay and new to Liferay, a clear and elegant way to create apps.

Here were some of the key goals:

- Allow breaking down a large system into smaller pieces of code, whose boundaries and relationships could be clearly defined.
- Explicitly differentiate public APIs from private APIs.
- Facilitate extensibility of existing code.
- Modernize the development environment, leveraging more state-of-the-art tools to provide a great developer experience.

It wasn't long before Liferay discovered that OSGi and its supporting tools/technologies fit the bill!

In this tutorial, you'll learn how 7.0 uses OSGi to meet these objectives. And equally important, you'll find out how easy and fun modular development can be.

Here are the topics you'll dig into:

1. Modules as an Improvement over Traditional Plugins: Development and customization of applications for Liferay has been done traditionally in WAR-style plugins (Portlet, Hook, Ext, and Web). In 7.0, traditional Liferay plugins can be replaced with (or can be automatically converted to) modules. You'll see the similarities and differences of plugins and modules, and you'll learn the benefits of using modules.
2. Leveraging Dependencies: In 7.0, you can both declare dependencies among modules and combine modules to create applications. Since leveraging dependencies provides huge benefits, it's important to devote a large section for it.

3. OSGi Services and Dependency Injection: OSGi provides a powerful concept called OSGi Services (also known as microservices). OSGi's Declarative Services standard provides a clean way to inject dependencies in a dynamic environment. This is similar to Spring DI, except the changes happen while the system is running. It also offers an elegant extensibility model that 7.0 leverages extensively.

4. Dynamic Deployment: Module deployment is managed by 7.0 (not the application server). This section demonstrates how to use dynamic deployment for better control and efficiency.

After investigating these topics, you'll get hands-on experience creating and deploying an OSGi module. Let's start with learning how modules are better than traditional plugins.

11.1 Modules as an Improvement over Traditional Plugins

In 7.0, you can develop applications using OSGi modules or using traditional Liferay plugins (WAR-style portlets, hooks, EXT, and web applications). Liferay's Plugin Compatibility Layer (explained later) makes it possible to deploy traditional plugins to the OSGi runtime framework. To benefit from all 7.0 and OSGi offer, however, you should use OSGi modules.

Modules offer these benefits:

- **Better Encapsulation** - The only classes a module exposes publicly are those it exports explicitly. This lets you define internal public classes transparent to external clients.

- **Dependencies by Package** - Dependencies are specified by Java package, not by JAR file. In traditional plugins, you had to add *all* of a JAR file's classes to the classpath to use *any* of its classes. With OSGi, you need only import packages containing the classes you need. Only the classes in those packages are added to the module's classpath.

- **Lightweight** - A module can be as small as you want it to be. In contrast to a traditional plugin, which may require several descriptor files, a module requires only a single descriptor file–a standard JAR manifest. Also, traditional plugins are typically larger than modules and deployed on app server startup, which can slow down that process considerably. Modules deploy more quickly and require minimal overhead cost.

- **Easy Reuse** - Modules lend themselves well to developing small, highly cohesive chunks of code. They can be combined to create applications that are easier to test and maintain. Modules can be distributed publicly (e.g., on Maven Central) or privately. And since modules are versioned, you can specify precisely the modules you want to use.

- **In-Context Descriptors** - Where plugins use descriptor files (e.g., `web.xml`, `portlet.xml`, etc.) to describe classes, module classes use OSGi annotations to describe themselves. For example, a module portlet class can use OSGi Service annotation properties to specify its name, display name, resource bundle, public render parameters, and much more. Instead of specifying that information in descriptor files separate from the code, you specify them in context in the code.

These are just a few ways modules outshine traditional plugins. Note, however, that developers experienced with Liferay plugins have the best of both worlds. 7.0 supports traditional plugins *and* modules. Existing Liferay developers can find comfort in the simplicity of modules and their similarities with plugins.

Here are some fundamental characteristics modules share with plugins:

- Developers use them to create applications (portlets for Liferay)

- They're zipped up packages of classes and resources

- They're packaged as a standard Java JARs

Now that you've compared and contrasted modules with plugins, it's time to tour the module anatomy.

Module Structure: A JAR File with a Manifest

A module's structure is extremely simple. It has one mandatory file: `META-INF/MANIFEST.MF`. You add code and resources to the module and organize them as desired.

Here's the essential structure of a module JAR file:

```
- [Module's files]
_ META-INF
    _ MANIFEST.MF
```

The `MANIFEST.MF` file describes the module to the system. The manifest's OSGi headers identify the module and its relationship to other modules.

Here are some of the most commonly used headers:

- `Bundle-Name`: User friendly name of the module.

- `Bundle-SymbolicName`: Globally unique identifier for the module. Java package conventions (e.g., `com.liferay.journal.api`) are commonly used.

- `Bundle-Version`: Version of the module.

- `Export-Package`: Packages from this module to make accessible to other modules.

- `Import-Package`: Packages this module requires that other modules provide.

Other headers can be used to specify more characteristics, such as how the module was built, development tools used, etc.

For example, here are some headers from the Liferay Journal Web module manifest:

```
Manifest-Version: 1.0
Bundle-ManifestVersion: 2
Bundle-Name: Liferay Journal Web
Bundle-SymbolicName: com.liferay.journal.web
Bundle-Vendor: Liferay, Inc.
Bundle-Version: 1.1.2
Export-Package:\
    com.liferay.journal.web.asset,\
    com.liferay.dynamic.data.mapping.util,\
    com.liferay.journal.model,
    com.liferay.journal.service,com.liferay.journal.util, [..]
Import-Package:\
    aQute.bnd.annotation.metatype,\
    com.liferay.announcements.kernel.model,
    com.liferay.application.list,\
    com.liferay.asset.kernel,\
    com.liferay.asset.kernel.exception, [..]
```

Note: to remove unnecessary "noise" from this example, some headers have been abbreviated ([..]) and some have been removed.

You can organize and build a module's Java code and resources however you like. You're free to use any directory structure conventions, such as those used in Maven or by your development team. And you can use any build tool, such as Gradle or Maven, to manage dependencies.

Liferay Workspace is an environment for managing module projects (and theme projects). A default Workspace provides Gradle build scripts and a Workspace created from the Liferay Project Templates Workspace archetype provides Maven build scripts for developing on Liferay. Workspace can be used from the command line or from within Liferay @ide@. Note also that Liferay @ide@ provides plugins for Gradle, Maven, and BndTools. Tooling details are covered later in this series.

Now that you're familiar with the module structure and manifest, it's time to explore how to build modules.

Building Modules with Bnd

The most common way to build modules is with a little tool called Bnd. It's an engine that, among other things, simplifies generating manifest metadata. Instead of manually creating a `MANIFEST.MF` file, developers use Bnd to generate it. Bnd can be used on its own or along with other build tools, such as Gradle or Maven. Liferay Workspace uses Bnd together with Gradle or Maven.

One of Bnd's best features is that it automatically transverses a module's code to identify external classes the module uses and adds them to the manifest's list of packages to import. Bnd also provides several OSGi-specific operations that simplify module development.

Bnd generates the manifest based on a file called `bnd.bnd` in the project root. This file's header list is similar to (but shorter than) that of the `MANIFEST.MF`. Compare the Liferay Journal Web module's `bnd.bnd` file content (simplified a bit) below to its `MANIFEST.MF` file content that was listed earlier:

```
Bundle-Name: Liferay Journal Web
Bundle-SymbolicName: com.liferay.journal.web
Bundle-Version: 1.1.2
Export-Package:\
    com.liferay.journal.web.asset,\
    com.liferay.journal.web.dynamic.data.mapping.util,\
    com.liferay.journal.web.social,\
    com.liferay.journal.web.util
```

The main difference is that the `bnd.bnd` file doesn't specify an `Import-Package` header. It's unnecessary because Bnd generates it in the `MANIFEST.MF` file automatically. It's metadata made easy!

Bnd plugins are available to use with Gradle and Maven. And since Liferay Workspace includes Bnd, developers can use Bnd from the command line and from Liferay @ide@.

Now that you're familiar with Bnd and the `Export-Package` and `Import-Package` manifest headers, let's explore how to use them to leverage dependencies.

11.2 Leveraging Dependencies

Using an OSGi manifest, a module declares the Java packages it consumes and shares. The manifest's `Import-Package` and `Export-Package` settings expose this information. As you determine whether to use a particular module, you know up-front what it offers and what it depends on. As an improvement over Java EE, OSGi takes away dependency guesswork.

This part of the tutorial explains:

- **How dependencies work**

- **How to develop modular apps using dependencies**

Let's start by learning how dependencies operate in 7.0.

How Dependencies Work

Since all of 7.0 leverages dependencies, it also demonstrates how to use them. As mentioned previously, all of what was in Liferay Portal 6 and its apps has been refactored into OSGi modules. The `portal-service` API (the main API in Liferay Portal 6) has been replaced by the `portal-kernel` module (7.0's kernel API) and many small, highly-cohesive modules that provide frameworks, utilities, apps, and more.

Not only do Liferay DXP modules depend on third-party modules but they also depend on each other. You can likewise leverage dependencies in your projects. Whether you're developing new OSGi modules or continuing to develop traditional apps, you need only set dependencies on modules whose packages you need.

Each module's manifest lists the packages the module depends on. Using a build environment such as Gradle, Maven, or Ant/Ivy, you can set dependencies on each package's module. At build time, the dependency framework verifies the entire dependency chain, downloading all newly specified modules. The same thing happens at runtime: the OSGi runtime knows exactly which modules depend on which other modules (failing fast if any dependency is unmet). Dependency management is explicit and enforced automatically upfront.

Versioning is independent for each Liferay module and its exported packages. You can use a specific package version by depending on the version of the module that exports it. And you're free to use a mix of Liferay modules in the versions you want (but remember, "With great power comes great responsibility," so unless you really know what you're doing, use the same version of each module you depend on).

For all its modules, Liferay DXP uses Semantic Versioning. It's a standard that enables API authors to communicate programmatic compatibility of a package or module automatically as it relates to dependent consumers and API implementations. If a package is programmatically (i.e., semantically) incompatible with a project, Bnd (used in Liferay Workspace) fails that project's build immediately. Developers not using Bnd can check package versions manually in each dependency module's manifest.

Semantic Versioning also gives module developers flexibility to specify a version range of packages and modules to depend on. In other words, if several versions of a package work for an app, the developer can configure the app to use any of them. What's more, Bnd automatically determines the semantically compatible range of each package a module depends on and records the range to the module's manifest.

On testing your project, you might find a new version of a dependency package has bugs or behaves differently than you'd like. No problem. You can adjust the package version range to include versions up to, but not including, the one you don't want.

Next you want to consider when to modularize existing apps and when to combine modules to create apps.

Dependencies Facilitate Modular Development

7.0's support of dependencies and semantic versioning facilitates modular development. The dependency frameworks enable you to use modules and link them together. You can use these modules throughout your organization and distribute them to others. 7.0's integration with dependency management frees you to modularize existing apps and develop apps that combine modules. It's a powerful and fun way to develop apps on Liferay DXP.

Here are some general steps to consider when modularizing an existing app:

1. **Start by putting the entire app in a single module**: This is a minimal first step that acquaints you with 7.0's module framework. You'll gain confidence as you build, deploy, and test your app in an environment of your choice, such as a Liferay Workspace, Gradle, or Maven project.

2. **Split the front-end from the back-end**: Modularizing front-end portlets and servlets and back-end implementations (e.g., Service Builder or OSGi component) is a logical next step. This enables each code area to evolve separately and allows for varying implementations.

3. **Extract non-essential features to modules**: You may have functionality or API extensions that need not be tied to an app's core codebase. They can be refactored as independent modules that implement APIs you provide. Examples might be connectors to third-party systems or support for various data export/import formats.

The principles listed above also apply to developing new modular-based apps. As you design an app, consider possible implementation variations with respect to its features, front-end, and back-end. Encapsulate the variations using APIs. Then develop the APIs and implementations as separate modules. You can wire them together using dependencies.

Liferay's Blogs application exemplifies modularization in the manner we've described:

API:

- `blogs-api` - Encapsulates the core implementation

Back-end:

- `blogs-service` - Implements `blogs-api`

Front-end:

- `blogs-web` - Provides the app's UI

Non-essential features and extensions:

- `blogs-editor-configuration` - Extends the `portal-kernel` module for extending editors
- `blogs-recent-bloggers-web` - Provides the Recent Bloggers app
- `blogs-item-selector-api` - Encapsulates the item-selector implementation
- `blogs-item-selector-web` - Renders the Blogs app's item-selector
- `blogs-layout-prototype` - Creates a Page Template showcasing blog entries

The Blogs app, like many modular apps, separates concerns into modules. In this way, front-end developers concentrate on front-end code, back-end developers concentrate on that code, and so on. These logical boundaries free developers to design, implement, and test the modules independently.

As you develop app-centered modules, you can consider bundling them with your app (e.g., as part of a Liferay Marketplace app). Including them as part of the app is convenient for the consumer. By bundling a module with an app, however, you're committing to the app's release schedule. In other words, you can't directly deploy a new version of a module for the app–you must release it as part of the app's next release.

So far, you've learned how dependencies and Semantic Versioning work. You've considered guidelines for modularizing existing apps and creating new modular apps. Now, to add to the momentum around OSGi and modularity, you'll explore OSGi Services and dependency injection using OSGi Declarative Services.

11.3 OSGi Services and Dependency Injection with Declarative Services

In 7.0, the OSGi framework registers objects as *services*. Each service offers functionality and can leverage functionality other services provide. The OSGi Services model supports a collaborative environment for objects.

Declarative Services (DS) provides a service component model on top of OSGi Services. DS service components are marked with the `@Component` annotation and implement or extend a service class. Service component can refer to and use each other's services. The Service Component Runtime (SCR) registers component services and handles binding them to other components that reference them.

Here's how the "magic" happens:

1. **Service registration:** On installing a module that contains a service component, the SCR creates a component configuration that associates the component with its specified service type and stores it in a service registry.

2. **Service reference handling:** On installing a module whose service component references another service type, the SCR searches the registry for a component configuration that matches the service type and on finding a match binds an instance of that service to the referring component.

It's publish, find, and bind at its best!

How does a developer use DS to register and bind services? Does it involve creating XML files? No, it's much easier than that. The developer uses two annotations: `@Component` and `@Reference`.

- `@Component`: Add this annotation to a class definition to make the class a component–a service provider.

- `@Reference`: Add this annotation to a field to inject it with a service that matches the field's type.

The `@Component` annotation makes the class an OSGi component. Setting a `service` property to a particular service type in the annotation, allows other components to reference the service component by the specified service type.

For example, the following class is a service component of type `SomeApi.class`.

```
@Component(
    service = SomeApi.class
)
public class Service1 implements SomeApi {

   ...
}
```

On deploying this class's module, the SCR creates a component configuration that associates the class with the service type `SomeApi`.

Specifying a service reference is easy too. Applying the `@Reference` annotation to a field marks it to be injected with a service matching the field's type.

```
@Reference
SomeApi _someApi;
```

On deploying this class's module, the SCR finds a component configuration of the class type `SomeApi` and binds the service to this referencing component class.

At build time, Bnd creates a *component description* file for each module's components automatically. The file specifies the component's services, dependencies, and activation characteristics. On module deployment, the OSGi framework reads the component description to create the component and manage its dependency on other components.

The SCR stands ready to pair service components with each other. For each referencing component, the SCR binds an instance of the targeted service to it.

As an improvement over dependency injection with Spring, OSGi Declarative Services supports dynamic dependency injection. Developers can create and publish service components for other classes to use. Developers can update the components and even publish alternative component implementations for a service. This kind of dynamism is a powerful part of 7.0.

11.4 Dynamic Deployment

In OSGi, all components, Java classes, resources, and descriptors are deployed via modules. The `MANIFEST.MF` file describes the module's physical characteristics, such as the packages it exports and imports. The module's component description files specify its functional characteristics (i.e., the services its components offer and consume). Also modules and their components have their own lifecycles and administrative APIs. Declarative Services and shell tools give you fine-grained control over module and component deployment.

Since a module's contents depend on its activation, consider the activation steps:

1. *Installation*: Copying the module JAR into Liferay DXP's `deploy` folder installs the module to the OSGi framework, marking the module `INSTALLED`.

2. *Resolution*: Once all the module's requirements are met (e.g., all packages it imports are available), the framework publishes the module's exported packages and marks it `RESOLVED`.

3. *Activation*: Modules are activated *eagerly* by default. That is, they're started in the framework and marked `ACTIVE` on resolution. An active module's components are enabled. If a module specifies a `lazy` activation policy, as shown in the manifest header below, it's activated only after another module requests one of its classes.

   ```
   Bundle-ActivationPolicy: lazy
   ```

The figure below illustrates the module lifecycle.

The Apache Felix Gogo Shell lets developers manage the module lifecycle. They can install/uninstall modules and start/stop them. Developers can update a module and notify dependent modules to use the update. Liferay's tools, including Liferay @ide@, Liferay Workspace, and Blade CLI offer similar shell commands that use the OSGi Admin API.

On activating a module, its components are enabled. But only *activated* components can be used. Component activation requires all its referenced services be satisfied. That is, all services it references must be registered. The highest ranked service that matches a reference is bound to the component. When the container finds and binds all the services the component references, it registers the component. It's now ready for activation.

Components can use *delayed* (default) or *immediate* activation policies. To specify immediate activation, the developer adds the attribute `immediate=true` to the `@Component` annotation.

```
@Component(
    immediate = true,
    ...)
```

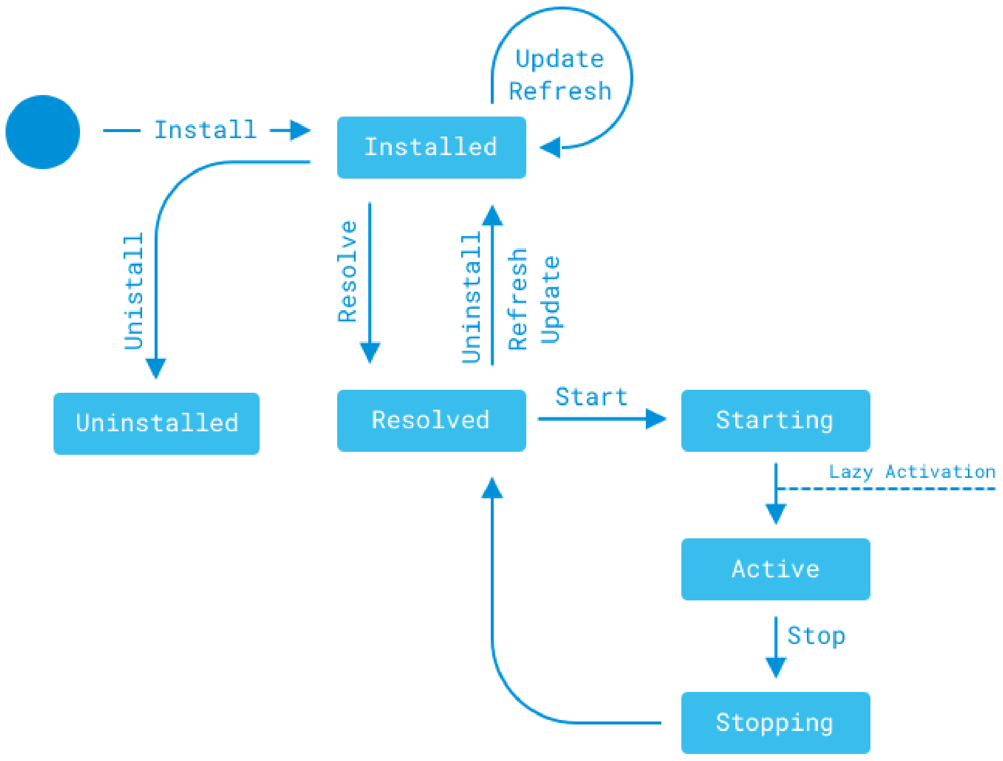

Figure 11.1: This state diagram illustrates the module lifecycle.

Unless immediate activation is specified, the component's activation is delayed. That is, the component's object is created and its classes are loaded once the component is requested. In this way delayed activation can improve startup times and conserve resources.

Gogo Shell's Service Component Runtime commands let you manage components:

- `scr:list [bundleID]`: Lists the module's (bundle's) components.
- `scr:info [componentID|fullClassName]`: Describes the component, including its status and the services it provides.
- `scr:enable [componentID|fullClassName]`: Enables the component.
- `scr:disable [componentID|fullClassName]`: Disables the component. It's disabled on the server (or current server node in a cluster) until the server is restarted.

Service references are static and reluctant by default. That is, an injected service remains bound to the referencing component until the service is disabled. Alternatively, developers can specify *greedy* service policies for references. Every time a higher ranked matching service is registered, the framework unbinds the lower ranked service from the component and binds the new service in its place automatically. Here's a `@Reference` annotation that uses a greedy policy:

```
@Reference(policyOption = ReferencePolicyOption.GREEDY)
```

Declarative Services annotations let you specify component activation and service policies. Gogo Shell commands let you control modules and components. Next, you'll create and deploy a module and component to Liferay DXP.

11.5 Example: Building an OSGi Module

The previous sections explained some of the most important concepts for Liferay Portal 6 developers to understand about OSGi and modularity. Now it's time to put this knowledge to practice by creating and deploying a module.

The module includes a Java class that implements an OSGi service using Declarative Services. The project uses Gradle and Bnd, and can be built and deployed from within a Liferay Workspace.

Here's the module project's anatomy:

- `bnd.bnd`
- `build.gradle`
- `src/main/java/com/liferay/docs/service/MyService.java`

On building the module JAR, Bnd generates the module manifest automatically.

Here's the Java class:

```
package com.liferay.docs.service;

import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;

@Component(
    immediate = true,
    service = MyService.class
)
public class MyService {

    @Activate
    void activate() throws Exception {

        System.out.println("Activating " + this.getDescription());
    }

    public String getDescription() {

        return this.getClass().getSimpleName();
    }

}
```

It contains these methods:

- `getDescription` - returns the class's name
- `activate` - prints the console message *Activating MyService*. The `@Activate` annotation signals the OSGi runtime environment to invoke this method on component activation.

The `@Component` annotation defines the class as an OSGi service component. The following properties specify its details:

- `service=MyService.class` - designates the component to be a service component for registering under the type `MyService`. In this example, the class implements a service of itself. Note, service components typically implement services for interface classes.

- `immediate=true` - signals the Service Component Runtime to activate the component immediately after the component's dependencies are resolved.

The `bnd.bnd` file is next:

```
Bundle-SymbolicName: my.service.project
Bundle-Version: 1.0.0
```

The `Bundle-SymbolicName` is the arbitrary name for the module. The module's version value `1.0.0` is appropriate.

Bnd generates the module's OSGi manifest to the file `META-INF/MANIFEST.MF` in the module's JAR. In this project, the JAR is created in the `build/libs` folder.

The last file to examine is the Gradle build file `build.gradle`:

```
dependencies {
    compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

Since the `MyService` class uses the `@Component` annotation, the project depends on the OSGi service component annotations module. The build script is so simple because Liferay Workspace module projects leverage the Workspace's Gradle build infrastructure.

Although this module project was created in a Liferay Workspace, it can easily be modified to use in other build environments. To keep the focus on what's most important, it was created in a Liferay Workspace.

Place the project files in a folder under the `modules` folder (e.g., `[Liferay_Workspace]/modules/my.service.project`).

To build the module JAR and deploy it to Liferay DXP, execute the `deploy` Gradle task:

```
../../gradlew deploy
```

Note: If Blade is installed (recommended), Gradle can be executed by entering `blade gw` followed by a task name (e.g., `blade gw deploy`). For details on Blade commands, see Blade CLI.

On deploying the module, the following message is printed to the server console:

`Activating MyService`

Congratulations! You've successfully built and deployed an OSGi module to Liferay DXP.

11.6 Learning More about OSGi

There is much more to learn about developing apps using OSGi. Several resources are listed below and many more abound. To make the best of your time, however, avoid OSGi service articles that explain techniques that are older and more complicated than Declarative Services.

Developers new to OSGi should check out these resources:

- Introduction to Liferay Development: For using OSGi to develop on Liferay DXP.

- OSGi enRoute is a site the OSGi Alliance provides to the OSGi community. Its Tutorials provide hands-on experience with OSGi modules and Declarative Services.

- OSGi Alliance's Developer section explains OSGi's architecture and modularity.

Developers ready to dive deep into OSGi should read the OSGi specifications. They're well-written and provide comprehensive details on all that OSGi offers. *The OSGi Alliance OSGi Compendium: Release 6* specifies the following services that 7.0 leverages extensively.

- *Declarative Services Specification*
- *Configuration Admin Service Specification*: For modifying deployed bundles. Since Configuration Admin services are already integrated with Declarative Services, however, Liferay developers need not use the low-level API.
- *Metatype Service Specification*: For describing attribute types as metadata.

Chapter 12

Improved Developer Tooling: Liferay Workspace, Maven Plugins and More

Creating applications is fun when you have the right tools. Here are some key ingredients:

- Rich templates for stubbing out projects
- Extensible build environments that offer state-of-the-art plugins
- Deployment and runtime management tools
- Application upgrade automation

Liferay Workspace (Workspace) boils over with all these things! It's a Gradle-based development environment that integrates with Liferay @ide@ and can be used in conjunction with other IDEs, such as a "vanilla" Eclipse, IntelliJ, and NetBeans. You can extend Workspace's Gradle environment with community-developed (or home-grown) plugins for testing, code coverage analysis, and more.

Workspace comes with Blade CLI: a command line tool for creating and deploying modules, managing the runtime environment, and more. It provides all kinds of module templates, to create modules for developing in any Gradle environment.

Liferay's tools also streamline the application upgrade process. Liferay @ide@'s Upgrade Planner adapts traditional plugins to 7.0 APIs. Liferay's Liferay Theme Generator migrates themes and layout templates to the new NodeJS-based environment and adapts them to 7.0.

Liferay DXP offers you more with Maven too. The archetype Liferay Project Templates Workspace lets you develop in Liferay Workspace using Maven. 7.0's' lean artifacts and new project archetypes and Maven plugins make Liferay DXP development with Maven easier than ever.

Here are the tooling improvement topics:

- Moving from the Plugins SDK to Liferay Workspace
- Developing modules with Liferay Workspace
- What's new in Liferay DXP for Maven Users
- Using other build systems and IDEs

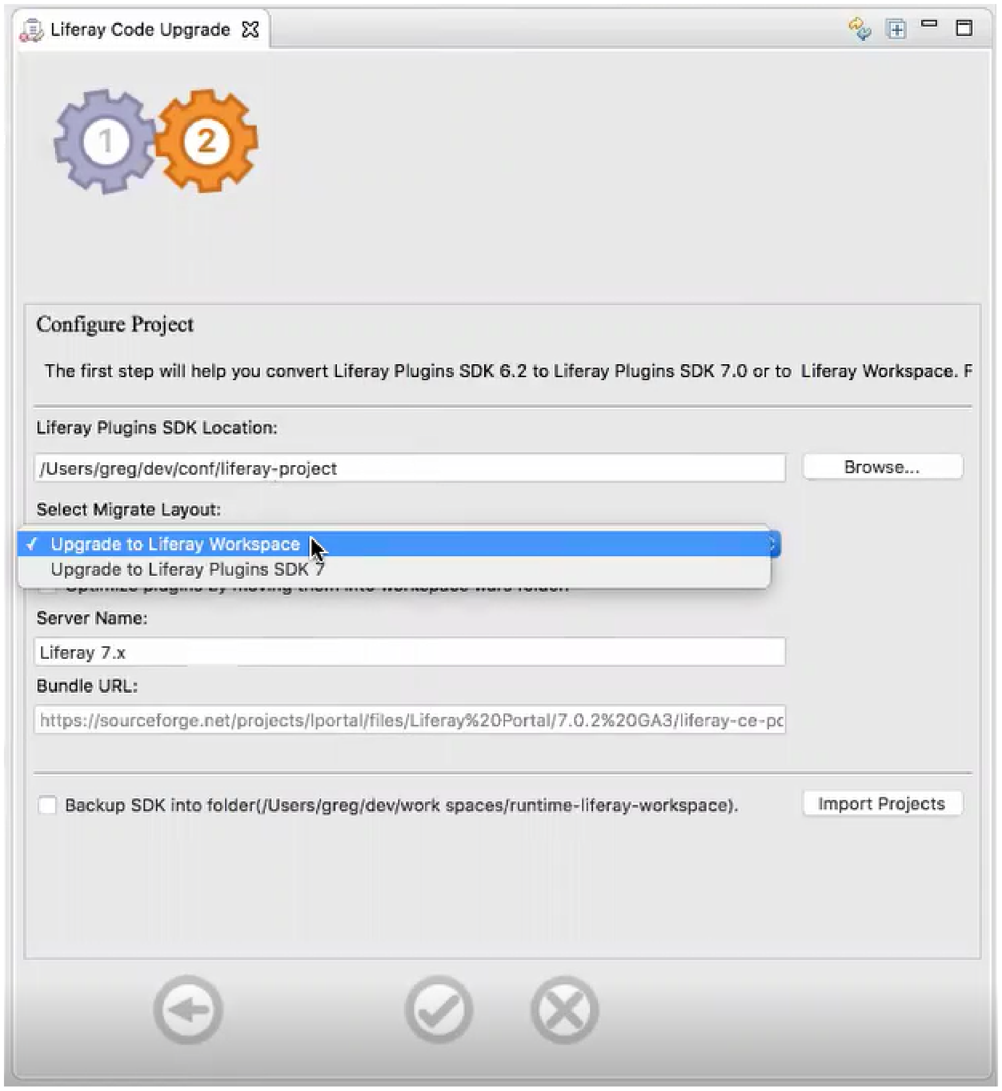
12.1 From the Plugins SDK to Liferay Workspace

The Liferay Plugins SDK is deprecated as of 7.0. You can continue developing on it, but should plan to eventually move to a new environment. Liferay Workspace succeeds the Plugins SDK as Liferay's opinionated development environment. You should use it if you're not using an alternative build system like Gradle or Maven.

Here are Workspace's key features:

- Module and component templates
- Sample projects
- Portal server configurations
- Folder structure flexibility
- Commands to migrate plugins, install Liferay DXP bundles, and start/stop Portal instances

The plugin upgrade tutorials later in this series show how Liferay 7.0 automatically adapts existing plugins to @product-ver@. There's also a tutorial that demonstrates how you can optionally migrate traditional plugins to Workspace.



Configure Project

The first step will help you convert Liferay Plugins SDK 6.2 to Liferay Plugins SDK 7.0 or to Liferay Workspace. F

Liferay Plugins SDK Location:
/Users/greg/dev/conf/liferay-project

Select Migrate Layout:
✓ Upgrade to Liferay Workspace
Upgrade to Liferay Plugins SDK 7

Server Name:
Liferay 7.x

Bundle URL:
https://sourceforge.net/projects/lportal/files/Liferay%20Portal/7.0.2%20GA3/liferay-ce-pc

Backup SDK into folder(/Users/greg/dev/work spaces/runtime-liferay-workspace).

Figure 12.1: Liferay @ide@'s Upgrade Planner automates many aspects of the plugin upgrade process.

Here's an example Workspace folder structure:

Here's the Workspace anatomy:

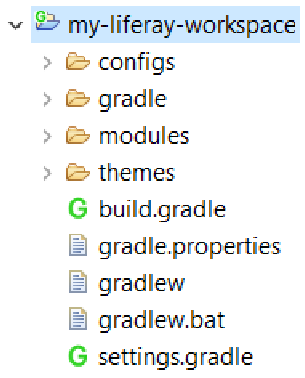


Figure 12.2: Liferay Workspace aggregates projects to use the same server configurations and Gradle build environment.

- `bundles/` (generated) → default folder for Liferay DXP bundles
- `configs/` → holds Portal server configurations
- `gradle/` → holds the Gradle wrapper files
- `modules/` → holds module projects
- `plugins-sdk/` (generated) → holds plugins from previous releases
- `themes/` → holds NodeJS-based theme projects
- `wars/` (generated) → holds traditional web application projects
- `build.gradle` → common Gradle build file
- `gradle.properties` → specifies the Portal server configuration and project locations
- `gradlew / gradlew.bat` → executes the Gradle command wrapper
- `pom.xml` (only in Workspaces generated by Maven) → common Maven build file
- `settings.gradle` → applies plugins to the Workspace and configures its dependencies

Workspace module, theme, and war projects use the same Portal server configurations. Developers can create configurations for module development, user acceptance testing, production, and more.

Each subfolder under `configs` holds a Portal server configuration defined by its `portal-ext.properties` file. Gradle property `liferay.workspace.environment` in Workspace's `gradle.properties` file specifies the configuration to use.

Other Gradle properties let you set root locations for the Liferay DXP bundle, modules, themes, and a Plugins SDK.

Workspace Folder Structure Properties

Property	Description
`liferay.workspace.environment`	Name of a `configs` subfolder holding the Portal server configuration to use
`liferay.workspace.home.dir`	Liferay DXP bundle root folder
`liferay.workspace.modules.dir`	Module projects root folder
`liferay.workspace.plugins.sdk.dir`	Plugins SDK root folder
`liferay.workspace.themes.dir`	Theme projects root folder

Workspace has Gradle tasks equivalent to the Plugins SDK Ant targets.

Plugins SDK to Workspace Task Map

Plugins SDK Ant Target	Workspace Gradle Task	Task Description
`build-css`	`buildCSS`	Builds CSS files
`build-lang`	`buildLang`	Translates language keys using Language Builder
`build-service`	`buildService`	Runs Service Builder
`clean`	`clean`	Deletes all build outputs
`compile`	`classes`	Compiles classes
`deploy`	`deploy` (or `blade deploy`)	Installs the current module to Liferay DXP's module framework
`jar`	`jar`	Compiles the project and packages it as a JAR file
`war`	`assemble`	Assembles project output

Other Workspace Gradle tasks provide additional functionality.

Workspace Gradle Task	Task Description
`buildSoy`	Compiles Closure Templates in JavaScript functions
`components`	Lists the project's components
`dependencies`	Lists the project's declared dependencies
`initBundle`	Downloads and installs a Liferay DXP bundle
`model`	Lists the project's configuration model
`transpileJS`	Transpiles the project's JavaScript files

Next, learn how Workspace facilitates module development.

12.2 Developing Modules with Liferay Workspace

Workspace is a great Liferay module development environment because of these features:

- Templates that bootstrap module creation
- Gradle and Maven build systems for managing dependencies and assembling modules
- Module deployment and runtime management capabilities

Blade CLI (Blade), which is a part of Workspace, has over twenty templates for Gradle-based module projects–and more are being added. The templates stub out classes and resource files for you to fill in with business logic and key information.

Here are some of the template's names:

- Activator
- API

- Content Targeting Report
- Content Targeting Rule
- Content Targeting Tracking Action
- Control Menu Entry
- MVC Portlet
- Panel App
- Portlet
- Portlet Configuration Icon
- Portlet Provider
- Portlet Toolbar Contributor
- Service
- Service Builder
- Service Wrapper
- Simulation Panel Entry
- Template Context Contributor

Blade creates modules based on these templates.

For example, the following Blade command creates a Liferay MVC Portlet module called `my-module`:

```
blade create -t mvc-portlet -p com.liferay.docs.mymodule -c MyMvcPortlet my-module
```

Liferay @ide@'s module project wizard creates Workspace modules from the templates too.

Liferay @ide@'s component wizard facilitates creating component classes for portlets, service wrappers, Struts actions, and more.

Building and deploying modules in a Workspace is a snap using Liferay @ide@ and Blade. Workspace uses BndTools to generate each module's OSGi headers in a `META-INF/MANIFEST.MF` file. Workspace deploy modules to the OSGi container using Felix File Install commands.

Liferay @ide@ lets you deploy modules by dragging them onto your Portal server.

In a terminal, you can deploy modules using Blade's `deploy` command. For example, the following command deploys the current module and "watches" for module changes to redeploy automatically.

```
blade deploy -w
```

To learn more about Workspace and using it in Liferay @ide@, see these tutorials:

- Workspace
- Blade CLI
- Liferay @ide@

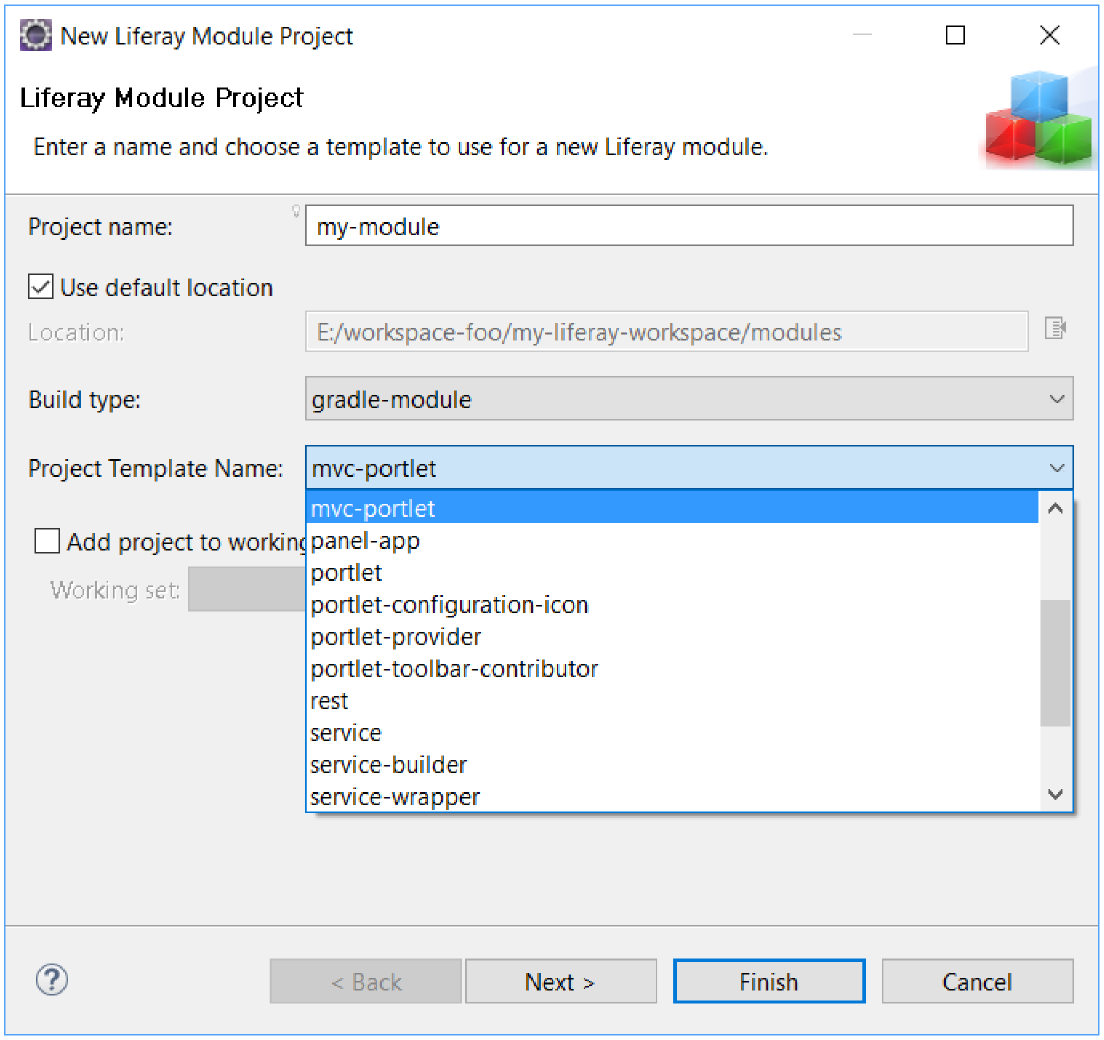
And make sure to check out the tutorial Starting Module Development.

Next, you'll learn new features for developing on Liferay DXP using Maven.

12.3 What's New in 7.0 for Maven Users

7.0 fully supports Maven development and offers several new and improved features:

- Liferay Workspace for Maven
- New archetypes
- New Maven plugins



New Liferay Module Project

Liferay Module Project

Enter a name and choose a template to use for a new Liferay module.

Project name: my-module

[✓] Use default location

Location: E:/workspace-foo/my-liferay-workspace/modules

Build type: gradle-module

Project Template Name: mvc-portlet

mvc-portlet
panel-app
portlet
portlet-configuration-icon
portlet-provider
portlet-toolbar-contributor
rest
service
service-builder
service-wrapper

[ ] Add project to working set

Working set:

Figure 12.3: Liferay @ide@ lets developers select templates to stub out modules.

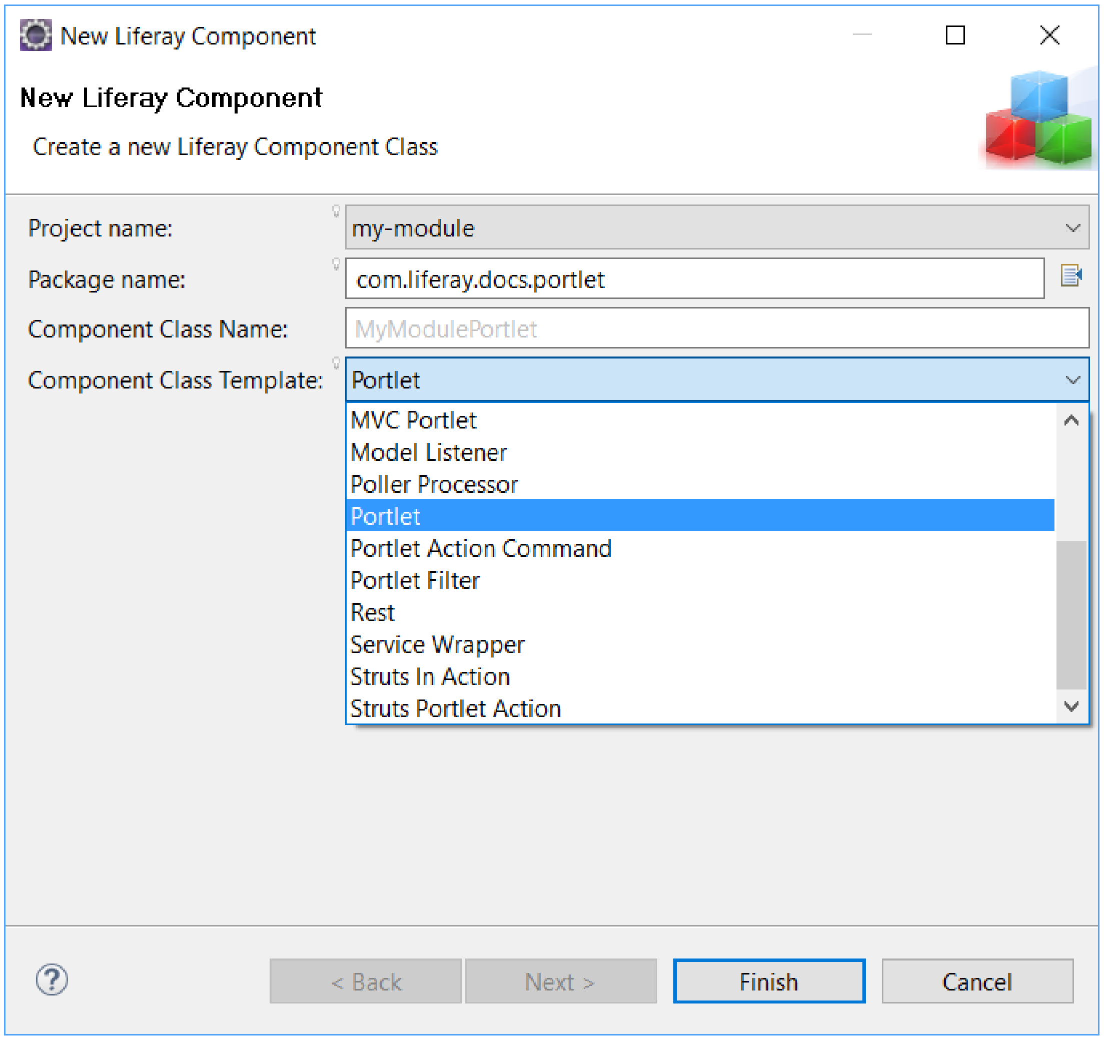
- More granular dependency management

The new archetype Liferay Project Templates Workspace generates a Liferay Workspace that includes a POM file for developing in Workspace using Maven. You can develop modules and themes in the Workspace subfolders.

7.0 provides many new Maven archetypes for various Liferay module projects. There are over twenty-five Maven archetypes for 7.0, and more are in development. Here are some popular ones:

- Portlets
- Themes
- Configuration Icons
- Menu Buttons
- Service Builder

Liferay's Maven archetypes cover many different Liferay frameworks and service types. These make Maven a first-class tool for creating Liferay modules and themes. Visit the Generating New Projects Using Archetypes tutorial to learn more about Liferay's Maven archetypes and how to use them.



New Liferay Component

New Liferay Component

Create a new Liferay Component Class

Project name: my-module

Package name: com.liferay.docs.portlet

Component Class Name: MyModulePortlet

Component Class Template: Portlet

- MVC Portlet
- Model Listener
- Poller Processor
- Portlet
- Portlet Action Command
- Portlet Filter
- Rest
- Service Wrapper
- Struts In Action
- Struts Portlet Action

Figure 12.4: Liferay @ide@'s component wizard facilitates creating component classes.

Liferay also provides several new and updated Maven plugins that simplify the build process. The following plugins build style sheets, services, and themes respectively:

- CSS Builder
- Service Builder
- Theme Builder

7.0's modularity provides a more granular dependency management experience. You no longer need to depend on `portal-impl` or `portal-service` (now `portal-kernel`) for everything. For example, to use Liferay's Wiki framework, you need only depend on the Wiki module. You set dependencies on concise modules that provide the functionality you want without inheriting extra baggage.

Liferay's new Workspace environment, Maven archetypes, Maven plugins, and streamlined modules make developing on Liferay DXP easier than ever. To learn more, see the Maven tutorials.

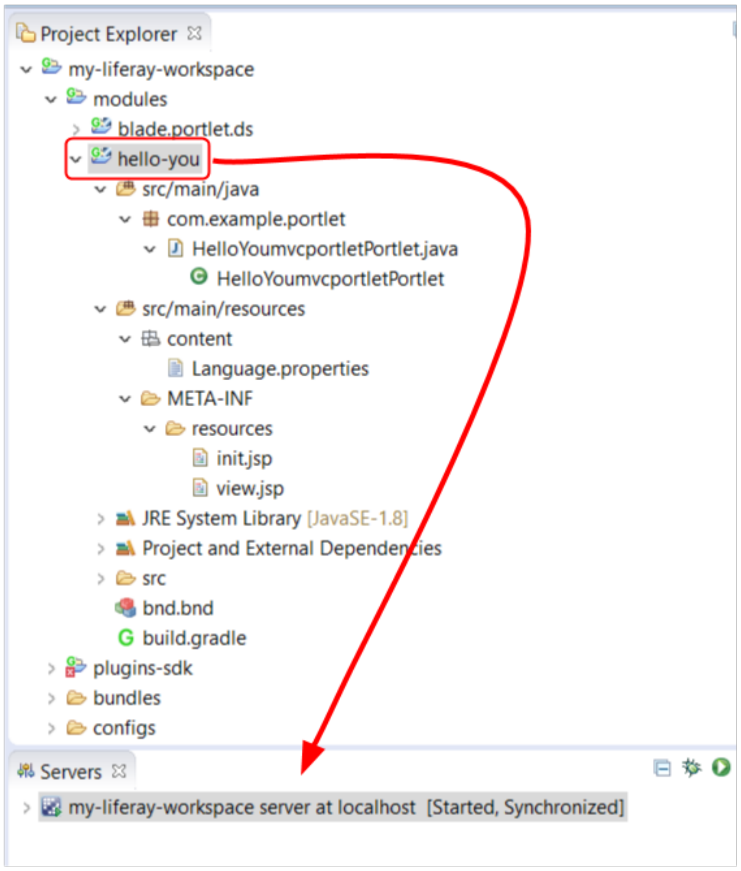


Figure 12.5: Liferay @ide@ lets you deploy modules using drag-and-drop.

12.4 Using Other Build Systems and IDEs

Liferay DXP is tool agnostic–you can use whatever tools you like to develop on it. You can use any IDE and even use Gradle, Bnd, or BndTools if you don't want to use Workspace. The drawback is you lose the Liferay-specific project templates that you get with Blade and Workspace.

Blade lets you create modules to develop anywhere, not only in Liferay Workspace.

Here are some new Gradle features Liferay provides that are independent of Workspace:

- Liferay's Gradle plugins
- Buildship plugins in Liferay @ide@
- Liferay @ide@'s new Gradle views for developing modules and working with Gradle tasks

Liferay has worked hard to make Liferay DXP IDE-agnostic. There are Liferay module developers who use IntelliJ and some enjoy using NetBeans.

Finally, you can copy and modify Liferay sample projects to serve as templates in place of the Blade templates. They're available for these build systems:

- Maven

- Gradle
- Liferay's Gradle environment based on the `com.liferay.plugin` plugin

Liferay's approach to tooling has vastly improved for 7.0. Our tools help you upgrade to 7.0, continue developing traditional plugins the way you have been, and migrate to optimal development environments. Liferay Workspace and the improved Maven support facilitate module development. And developing on Liferay DXP using other tools is easier than ever. Your tool options are wide open.

Chapter 13

Planning Plugin Upgrades and Optimizations

If you've explored 7.0's features and possibly created new portlet modules themes with Liferay's new tooling and techniques, you may be wondering how you'd upgrade existing plugins. The great thing is that Liferay has automated much of the upgrade process. In addition, you can continue developing plugins in traditional ways and adopt new development tooling and techniques when you're ready.

This tutorial guides you through phases of *upgrading* plugins and optionally *optimizing* them.

Upgrade: A process for deploying an existing plugin on 7.0 with minimal changes.

Optimization: An optional but recommended process for modifying a plugin or migrating it to a new environment to improve the plugin or facilitate developing it.

Importantly, you should *upgrade* a plugin before applying any optimizations to it.

The good news is that upgrading plugins to 7.0 is straightforward. For Plugins SDK and Maven projects, Liferay @ide@'s Upgrade Planner automates much of the process. In addition, the upgrade tutorials demonstrate any remaining upgrade steps.

You can deploy plugins to 7.0 as you have for previous releases (e.g., `ant clean deploy`). Since everything in 7.0 runs as OSGi modules, however, you might wonder how traditional WAR-style plugins can run on it. The answer: Liferay's Plugin Compatibility Layer.

The Plugin Compatibility Layer converts standard WARs to Web Application Bundles (WABs). WABs are full-fledged OSGi modules. The Plugin Compatibility Layer's WAB Generator supports deploying traditional plugins and web applications that contain Servlets, JSPs, and other Java web technologies without making any OSGi specific changes to them.

Note, you can still use an application server's mechanisms to deploy regular web applications along with Liferay DXP, without using the Plugin Compatibility Layer.

After upgrading your plugins you can consider optimizations such as these:

- Migrating plugins to Gradle or Maven to leverage their development commands and rich Liferay plugin templates.
- Migrating themes to the Liferay Theme Generator to add Themelets (new) and to leverage Node.js, Yeoman, and Gulp.
- Converting plugins to modules to leverage Declarative Services, extendability, and more modularity benefits.
- Using the Lexicon, to apply a clean consistent application user experience.

See the optimization tutorials for more options and details.

You *can* continue using the Plugins SDK to develop plugins. But the Plugins SDK is deprecated as of 7.0. In light of the deprecation, you should consider migrating plugins from the Plugins SDK to one of the new environments:

- Liferay Workspace is a Gradle environment that supports developing modules and traditional plugins. Blade's `migrateWar command` moves Plugins SDK portlets to Liferay Workspace (Workspace) in a snap.
- Liferay's Maven plugins and archetypes support developing modules and traditional plugins. There's also a Liferay Workspace archetype for generating a Workspace that uses Maven.

Liferay @ide@ supports developing in Workspaces using Gradle or Maven.

In short, there's plenty of time to move plugins out of the Plugins SDK, but you should at least plan for migrating to a new environment that works best for you.

Speaking of planning, properly planned upgrades and optimizations reduce the time and effort they take. To help guide you through the upgrade and optimization tutorials, you get these things:

- Upgrade and optimization phase descriptions
- Upgrade and optimization paths

13.1 Upgrade and Optimization Phases

Follow these upgrade and optimization phases:

1. Read the applicable upgrade tutorials for your plugin. Examine the upgrade and optimization paths.
2. Upgrade the plugin, making only the minimal changes necessary for it to work on 7.0.
3. (Optional) Identify and apply only the most beneficial optimizations for your plugin.
4. (Optional) Apply additional optimizations as desired.

13.2 Upgrade and Optimization Paths

The following tables provide upgrade and optimization paths for 6.2 plugins and features.

Plugin Upgrade and Optimization Paths

Plugin	Upgrade path	Optimizations (optional)
Ext	Customization with Ext Plugins	None
Hook - Language files	- Upgrading Core Language Key Hooks- Upgrading Portlet Language Key Hooks	Same
Hook - Override a Liferay DXP Core JSP	Upgrading Core JSP Hooks	Same
Hook - Override an app's JSP	Upgrading App JSP Hooks	Same

Plugin	Upgrade path	Optimizations (optional)
Hook - Event Actions (Portal/Session/Servlet Service/Shutdown/Startup)	Upgrading Portal Property and Event Action Hooks	None
Hook - Model Listeners	Upgrading Model Listener Hooks	Same
Hook - Portal Properties	Upgrading Portal Property and Event Action Hooks	Same
Hook - Properties	- If the property is now a System Setting, edit it there and/or use a `.config` file- If the property is in the liferay-hook.xml's DTD, then adapt code to API and resolve dependencies	None
Hook - Service Wrappers	Upgrading Service Wrappers	None
Hook - Servlet Filter	Upgrading Servlet Filter Hooks	None
Hook - Struts actions	- StrutsAction → StrutsActionWrapper - processAction → MVCActionCommand - render → MVCRender-Command - serveResource → MVCResourceCom-mand	Same
Layout Template	1. Adapt code to API2. Resolve dependencies3. Update Layout Template	- Migrate to Liferay Theme Generator (Node.js/Gulp/Yeoman)
Portlet - GenericPortlet	Upgrading a GenericPortlet	- Migrate to Workspace/Gradle- Apply Lexicon- Convert to OSGi modules
Portlet - Liferay MVC	Upgrading a Liferay MVC Portlet	- Migrate to Workspace/Gradle- Apply Lexicon- Convert to OSGi modules
Portlet - JSF	Upgrading a Liferay JSF Portlet	None
Portlet - Servlet/JSP	Upgrading a Servlet-based Portlet	None
Portlet - Spring MVC	Upgrading a Spring MVC Portlet	None

Plugin	Upgrade path	Optimizations (optional)
Portlet - Struts 1	Upgrading a Struts Portlet	None
Theme	1. Adapt code to API2. Resolve dependencies3. Upgrade Theme	- Migrate to Liferay Theme Generator (Node.js/Gulp/Yeoman)- Use Themelets
Web plugin	1. Adapt code to API2. Resolve dependencies	Convert to OSGi module, e.g., `portlet-x-web`

Feature Upgrade and Optimization Paths

Feature	Upgrade path	Optimizations (optional)
JNDI data source	Use Liferay DXP's classloader to access the app server's JNDI API	None
Resources Importer	Update the Resources Importer	None
Services - Invoke a service from Liferay DXP Core or another portlet or module	Implement a Service Tracker	Invoke Liferay services from a module
Services - Module dependency	Copy `x-service.jar` to `WEB-INF/lib`	- Migrate to Gradle/Maven and add dependency on the OSGi service
Services - Service Builder	Upgrading Portlets that use Service Builder	Convert to OSGi modules, e.g., `x-api` and `x-service`
Services - Web services	1. Adapt code to API2. Resolve dependencies	Use a Service Builder service with JAX-RS with a REST service in front
Template - FreeMarker	- Adapt code to API- Adapt Theme templates	None
Template - Velocity (deprecated)	Adapt code to API	Convert to FreeMarker

Now you have a game plan and a cheat sheet for upgrading and optimizing plugins with confidence.

13.3 Upgrading Plugins to 7.0

Upgrading to 7.0 involves migrating your installation and code (your custom apps) to the new version. You'll learn how to upgrade your code in this section.

The first upgrade process step is to adapt your existing plugin's code to 7.0's APIs. The great news is that Liferay's Upgrade Planner makes this easier than ever. It identifies Liferay API changes affecting your code, explains the API changes, and offers resolution steps. And the tool offers auto-correction where it can.

You might be tempted to optimize your existing plugins right away to benefit from the new things Liferay DXP offers, but you shouldn't. It's much better to upgrade your plugins according to these tutorials. In this way, you'll get your plugins running in Liferay as fast as possible, and at the same time you'll have prepared the plugins for the optimizations you can implement later.

These tutorials assume you're using the Liferay Upgrade Planner. To follow along with this section, install the planner and step through the upgrade instructions.

For convenience, this tutorial section also references documentation and outlined steps to aid those opting to upgrade their code manually.

Here are the code upgrade steps:

1. Upgrade Your Development Environment

   Legacy project environments should be upgraded to the latest version of Liferay Workspace to ensure you leverage all available features.

   1. Set Up Liferay Workspace
      A Liferay Workspace is a generated environment that is built to hold and manage your Liferay projects. Create/import a workspace to get started.
      1. Create New Liferay Workspace
         If you don't have an existing 7.x Liferay Workspace, you must create one. Skip to the next step if you have an existing workspace.
      2. Import Existing Liferay Workspace
         Import an existing Liferay Workspace. If you don't have one, revisit the previous step.
   2. Configure Liferay Workspace Settings
      Set the Liferay DXP version in workspace's configuration you intend to upgrade to.
      1. Configure Bundle URL
         Configure your bundle URL that the Liferay DXP bundle is downloaded from.
      2. Configure Target Platform Version
         Configure your Target Platform version, which provides the specific artifacts associated with a Liferay DXP release.
      3. Initialize Server Bundle
         Download the Liferay DXP bundle you're upgrading to.

2. Migrate Plugins SDK Projects

   Copy your Plugins SDK projects into workspace and convert them to Gradle/Maven projects.

   1. Import Existing Plugins SDK Projects
      Import your existing Plugins SDK projects.
   2. Migrate Existing Plugins to Workspace
      Migrate your existing plugins to workspace. This involves moving the plugin to workspace and converting it to the workspace's build environment.

3. Upgrade Build Dependencies

   Optimize your workspace's build environment for the most efficient code upgrade experience.

   1. Update Repository URL
      Update your repository URL to Liferay's frequently updated CDN repository.

    2. Update Workspace Plugin Version
       Update your Workspace plugin version to leverage the latest features of Liferay Workspace.
    3. Remove Dependency Versions
       Remove the project's dependency versions since it's leveraging target platform.

4. Fix Upgrade Problems

   Fix common upgrade problems dealing with your project's dependencies and breaking changes.

    1. Auto-Correct Upgrade Problems
       Auto-correct straightforward upgrade problems.
    2. Find Upgrade Problems
       Find upgrade problems. These are problems that cannot be auto-corrected; you can update them manually according to the breaking changes documentation.
    3. Resolve Upgrade Problems
       Mark upgrade problems as resolved after addressing them.
    4. Remove Problem Markers
       After fixing your upgrade problems, remove the problem markers.
    5. Resolving a Plugin's Dependencies
    6. Resolving Breaking Changes

5. Upgrade Customization Plugins

   Upgrade your customization plugins so they're deployable to 7.0.

    1. Upgrade Customization Modules
    2. Upgrade Core JSP Hooks
    3. Upgrade Portlet JSP Hooks
    4. Upgrade Service Wrapper Hooks
    5. Upgrade Core Language Key Hooks
    6. Upgrade Portlet Language Key Hooks
    7. Upgrade Model Listener Hooks
    8. Upgrade Event Action Hooks
    9. Upgrade Servlet Filter Hooks
    10. Upgrade Portal Properties Hooks
    11. Upgrade Struts Action Hooks

6. Upgrade Themes

   Upgrade your themes so they're deployable to 7.0.

    1. Upgrading Your Theme from Liferay Portal 6.1 to 7.0
    2. Upgrading Your Theme from Liferay Portal 6.2 to 7.0

7. Upgrade Layout Templates

   Upgrade your layout templates so they're deployable to 7.0.

8. Upgrade Frameworks & Features

   1. Upgrade JNDI Data Source Usage
      Use Liferay DXP's class loader to access the app server's JNDI API.
   2. Upgrade Service Builder Service Invocation
      For Service Builder logic remaining in a WAR, you must implement a service tracker to call services. For logic divided into OSGi modules, you can leverage Declarative Services.
   3. Upgrade Service Builder
      Adapt your app to account for Service Builder-specific changes.
   4. Migrate Off of Velocity Templates
      Velocity template usage is deprecated for 7.0. You should convert your template to FreeMarker.

9. Upgrade Portlets

   Upgrade your portlets so they're deployable to 7.0.

   1. Upgrade Generic Portlets
   2. Upgrade Liferay MVC Portlets
   3. Upgrade JSF Portlets
   4. Upgrade Servlet-based Portlets
   5. Upgrading Spring MVC Portlets
   6. Upgrade Struts Portlets

10. Upgrade Web Plugins

    Upgrade web plugins previously stored in the `webs` folder of your legacy Plugins SDK.

11. Upgrade Ext Plugins

    Attempt to leverage an extension point instead of upgrading your Ext plugin. If an Ext plugin is necessary, you must review all changes between the previous Liferay Portal instance you were using and 7.0, and then manually modify your Ext plugin to merge your changes with Liferay DXP's.

Once you've finished the code upgrade steps, your custom apps will be compatible with 7.0!

13.4 Upgrading Your Development Environment

A Liferay Workspace is a generated environment that is built to hold and manage your Liferay projects. It is intended to aid in the management of Liferay projects by providing various build scripts and configured properties.

Liferay Workspace is the recommended environment for your code migration; therefore, it will be the assumed development environment in this section.

Continue on to set up a workspace.

Setting Up Liferay Workspace

You must set up your workspace development environment before you begin upgrading your custom apps. If you don't have an existing workspace, follow the step for creating one. If you have an existing workspace, follow the step on importing it into the Upgrade Planner.

Creating New Liferay Workspace

Initiating this step in the Upgrade Planner loads the Liferay Workspace Project wizard.

1. Give your new workspace a name.
2. Choose the build type (Gradle or Maven) you prefer for your workspace environment and future Liferay projects.
3. Click Finish.

You now have a new Liferay Workspace available in the Upgrade Planner!

For more information on creating a Liferay Workspace outside the planner, see the Creating a Liferay Workspace section.

Importing Existing Liferay Workspace

If you already have an existing 7.x Liferay Workspace, you should import it into the planner. Once you initiate this step, you're given a File Explorer/Manager to select your existing workspace. After selecting it, the workspace is imported into the Project Explorer.

For more information importing a workspace into your IDE, see this article.

Configuring Liferay Workspace Settings

You must configure your workspace with the Liferay DXP version you intend to upgrade to. You should verify the workspace's

- Bundle URL
- Target Platform Version

The bundle URL version and target platform version must match.

Visit these steps to begin.

Configuring Bundle URL

The bundle URL points to the Liferay DXP version you want workspace to download. When initiating this step, your workspace's Bundle URL property is updated to the latest release of 7.0.

For more information on configuring a workspace's bundle URL, see the Adding a Liferay Bundle to Liferay Workspace article.

Configuring Target Platform Version

The target platform is the Liferay DXP version you intend to develop for in your workspace. This is used to specify dependencies associated with a specific release. You set the target platform, define your dependencies, and workspace automatically assigns the dependency versions based on the set Liferay DXP version. When initiating this step, your workspace's Target Platform property is updated to the latest release of 7.0.

For more information on this, see the Managing the Target Platform article.

Initializing Server Bundle

Once your workspace is configured for the Liferay DXP version you're upgrading to, you can initialize the server bundle. This involves downloading the bundle and extracting it into its folder (e.g., `bundles`). If you have an existing workspace already equipped with an older Liferay bundle, this deletes the old bundle and initializes the new one.

If you're upgrading your code manually and working in Dev Studio, you can do this by right-clicking the workspace project and selecting *Liferay → Initialize Server Bundle*. See the Installing a Server in IntelliJ article if you use IntelliJ instead. Visit the Managing Your Liferay Server with Blade CLI article for information on how to do this via the command line.

13.5 Migrating Plugins SDK Projects to Liferay Workspace

The Plugins SDK was deprecated for Liferay DXP 7.0. Therefore, to upgrade your custom apps to 7.0, it's recommended to migrate them to a new environment. Liferay Workspace is the recommended environment for your code migration and will be the assumed choice in this section.

There are two steps you must follow to migrate your custom code to workspace:

1. Import the Plugins SDK project into the Upgrade Planner.
2. Convert the Plugins SDK project to a supported workspace build type.

You'll step through importing a Plugins SDK project first.

Importing Existing Plugins SDK Projects

Initiating this step in the Upgrade Planner imports your Plugins SDK projects into the Upgrade Planner. These projects originate from the Plugins SDK you set when the Upgrade Planner process was started.

If you're manually upgrading your code, you can skip this step.

You're now ready to migrate your Plugins SDK projects to your new workspace!

Migrating Existing Plugins to Workspace

Liferay Workspace can be generated as a Gradle or Maven environment, but it does not support the Plugins SDK's Ant build. Because of this, you must convert your projects to one of the supported build tools:

- Gradle
- Maven

When initiating this step for a Gradle-based workspace, your Ant-based Plugins SDK project is copied to the applicable workspace folder based on its project type (e.g., `wars`) and is converted to a Gradle project. There is also a Blade CLI command that completes this via the command line. Visit the Converting Plugins SDK Projects with Blade CLI article for more information.

If you're migrating your Ant project to a Maven workspace, you must manually copy the project to the applicable folder based on the project type (e.g., `wars`). The majority of Plugins SDK projects belong in the workspace's `wars` folder. You can consult the Workspace Anatomy section for a full overview of a workspace's folder structure and choose where your custom app should reside. Once you've made the decision, copy your custom app to the applicable workspace folder.

Then you must convert your project from Ant to Maven. You'll have to complete this conversion manually.

Once you're finished, you should have your project(s) residing in the applicable workspace folders as Gradle/Maven projects.

13.6 Upgrading Build Dependencies

Now that your projects are readily available in a workspace, you must ensure your project build dependencies are upgraded. Your workspace streamlines the build dependency upgrade process by only requiring three modifications:

- Update the repository URL (Gradle only)
- Update the workspace plugin version
- Remove your project's build dependency versions (Gradle only)

If you're upgrading a recently created workspace, only a subset of these tasks may be required.
You'll start by updating the repository URL.

Updating the Repository URL

Initiating this step in the Upgrade Planner updates the repository URL used to download artifacts for your workspace.

If you're using a Gradle-based workspace, the repository URL is updated to point to the latest Liferay CDN repository. This is set in your workspace's `settings.gradle` file within the `buildscript` block like this:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Once the repository URL is set to the proper CDN repository, your build dependencies will be downloaded from Liferay's own managed repo.

For Maven-based workspaces, Maven Central is the default repository, so no action is required.

Updating the Workspace Plugin Version

For the best upgrade experience, you should ensure you're leveraging the latest Liferay Workspace version so all the latest features are available to you. Initiate this step to upgrade the appropriate plugin.

See the Updating Liferay Workspace article to do this for Gradle-based workspaces manually. For Maven-based workspaces, make sure you set the latest Bundle Support plugin version in your root `pom.xml` file.

Removing Your Project's Build Dependency Versions

Note: This step only applies to Gradle-based workspaces since the target platform feature is only available for Gradle projects at this time.

Since your workspace is leveraging the target platform feature, there is no need to set your plugin's dependency versions in its `build.gradle` file. This is because the target platform version you set already defines the artifact versions your project uses. Therefore, if dependency versions are present in any of your projects' `build.gradle` files, you must remove them.

Initiate this step to remove your dependency versions from your project's `build.gradle` file

As an example of what a `build.gradle`'s `dependencies` block should look like, see the below snippet:

```
dependencies {
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel"
    compileOnly group: "com.liferay.portal", name: "com.liferay.util.taglib"
    compileOnly group: "javax.portlet", name: "portlet-api"
    compileOnly group: "javax.servlet", name: "javax.servlet-api"
    compileOnly group: "jstl", name: "jstl"
    compileOnly group: "org.osgi", name: "osgi.cmpn"
}
```

If you have not set the target platform feature in your workspace, see the Managing the Target Platform article for more information.

Great! You've successfully upgraded your build dependencies! You likely have compile errors in your project; this is because your dependencies may have changed. You'll learn how to update that and more next.

13.7 Fixing Upgrade Problems

Now that your development environment build configuration is settled, you can start upgrading your project(s). The two most common upgrade problems are

- Broken project dependencies
- Breaking changes

Visit these upgrade problem tutorials for tips on how to fix them.

This tutorial is heavily focused on the Liferay Upgrade Planner. If you're upgrading your code manually, continue to the listed tutorials above to fix your code upgrade problems.

You'll begin auto-correcting upgrade problems first.

Auto-Correcting Upgrade Problems

Initiate this step to auto-correct straightforward updates like

- package imports
- JSP tag names
- Liferay descriptor versions
- XML descriptor content
- etc.

If you choose to preview the auto-correct upgrade problems first, you can view them in the Project Explorer under the *Liferay Upgrade Problems* dropdown. If you click one of the upgrade problems listed with the preview, you're offered documentation in the *Liferay Upgrade Plan Info* window on the proposed change.

Once you've performed this step, the result list is removed.

Finding Upgrade Problems

Initiating this step finds the upgrade problems that were not eligible for auto-correction. The problems are listed under the *Liferay Upgrade Problems* dropdown. If you click one of the upgrade problems listed with the preview, you're offered documentation in the *Liferay Upgrade Plan Info* window on the proposed change.

These upgrade problems are available in the breaking changes for the version upgrade you're performing.

The next step is resolving the reported upgrade problems.

Resolving Upgrade Problems

Now that the upgrade problems have been located, you must resolve them. As you select each upgrade problem, the documentation for how to adapt your code is displayed in the *Liferay Upgrade Plan Info* window.

For each upgrade problem node, you're also given the version the upgrade problem applies to (e.g., when upgrading to Liferay DXP 7.2 from Liferay Portal 6.2, you could have upgrade problems from the 7.0, 7.1, or 7.2 upgrade). As you step through the reported problems, mark them as resolved/skipped using the context menu. You can right-click on the problem in the Project Explorer and choose from four options:

- Mark done
- Mark undone
- Ignore
- Ignore all problems of this type

Leave this step marked as *Incomplete* until you have resolved all upgrade problems accordingly.

Removing Problem Markers

After resolving all the reported upgrade problems, you must remove all previously found markers because, in most cases, the line number and other accompanying marker information are out of date and must be removed before continuing. Initiate this step to remove all the problem markers.

Great! You've fixed all the upgrade problems that could be automatically detected by the Upgrade Planner. Next, you'll take a deeper look at resolving project dependency errors.

13.8 Resolving a Plugin's Dependencies

Now that you've imported your plugin project to Liferay @ide@, you probably see compile errors for some of the Liferay classes it uses. These classes are listed as undefined classes or unresolved symbols because they've been moved, renamed, or removed. As a part of modularization in Liferay DXP, many of these classes reside in new modules.

You must resolve all of these Liferay classes for your plugin. Some of the class changes are quick and easy to fix. Changes involving the new modules require more effort to resolve, but doing so is still straightforward.

Liferay class changes and required adaptations are described here:

1. **Class moved to a package that's in the classpath**: This change is common and easy to fix. Since the module is already on your classpath, you need only update the class import. You can do this by using the Liferay Code Upgrade Tool or by organizing imports in @ide@. The Upgrade Planner reports each moved class for you to address one by one. Organizing imports in @ide@ automatically resolves multiple classes at once.

   It's typically faster to resolve moved classes using the mentioned Eclipse feature. Since Liferay @ide@ is based on Eclipse, you can generate imports of classes in your classpath with the *Organize Imports* keyboard sequence *Ctrl-Shift-o*. Comment out or remove any imports marked as errors, then press *Ctrl-Shift-o*. If there's only one match for the import, @ide@ automatically generates its import statement. Otherwise, a wizard appears that lets you select the correct import.

2. **Class moved to a module that's *not* in the classpath**: You must resolve the new module as a dependency for your project. This requires identifying the module and specifying your project's dependency on it.

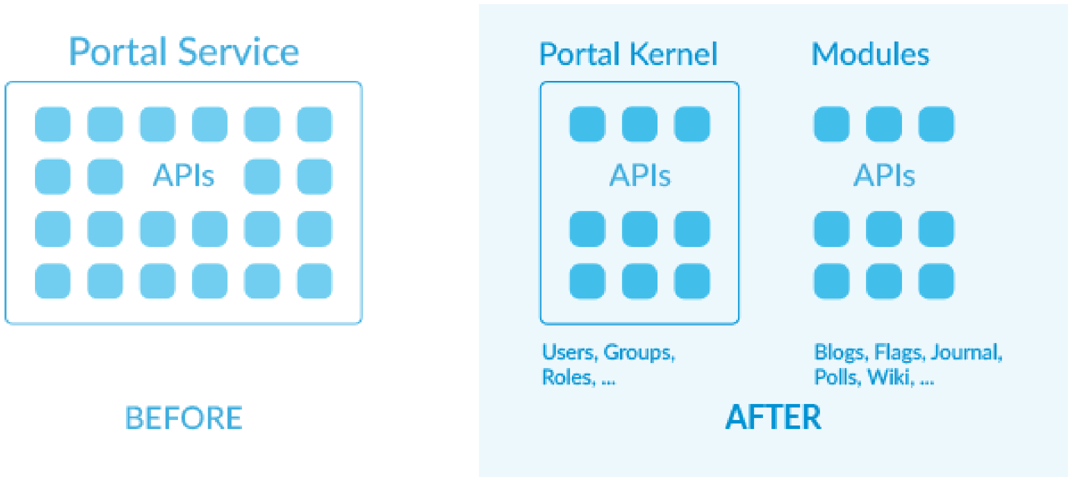
3. **Class replaced or removed**: The class has been replaced by another class or removed from the product. The Upgrade Planner (discussed later) explains what happened to the class, how to handle the change, and why the change was made.

Resolving a class that's moved within your classpath is straightforward. Consider resolving such classes first. The remainder of this tutorial explains how to resolve the last two cases and starts with configuring your plugin project to declare the modules it needs.

Identifying Module Dependencies

Before 7.0, all the platform APIs were in `portal-service.jar`. Many of these APIs are now in independent modules. Modularization has resulted in many benefits, as described in the article Benefits of 7.0 for Liferay Portal 6 Developers. One such advantage is that these API modules can evolve separately from the platform kernel. They also simplify future upgrades. For example, instead of having to check all of Liferay's APIs, each module's Semantic Versioning indicates whether the module contains any backwards-incompatible changes. You need only adapt your code to such modules (if any).

As part of the modularization, `portal-service.jar` has been renamed appropriately to `portal-kernel.jar`, as it continues to hold the portal kernel's APIs.



Portal Service
APIs
BEFORE
Portal Kernel
APIs
Users, Groups, Roles, ...
Modules
APIs
Blogs, Flags, Journal, Polls, Wiki, ...
AFTER

Figure 13.1: Liferay refactored the portal-service JAR for 7.0. Application APIs now exist in their own modules, and the portal-service JAR is now *portal-kernel*.

Each app module consists of a set of classes that are highly cohesive and have a specific purpose, such as providing the app's API, implementation, or UI. The app modules are therefore much easier to understand. Next, you'll track down the modules that now hold the classes referenced by your plugin.

The reference article Classes Moved from `portal-service.jar` contains a table that maps each class moved from `portal-service.jar` to its new module. The table includes each class's new package and symbolic name (artifact ID). You'll use this information to configure your plugin's dependencies on these modules.

Your plugin might reference classes that are in Liferay utility modules such as `util-java`, `util-bridges`, `util-taglib`, or `util-slf4j`.

The following table shows each Liferay utility module's symbolic name.

Liferay Utility	Symbolic Name (Artifact ID)
util-bridges	`com.liferay.util.bridges`
util-java	`com.liferay.util.java`
util-slf4j	`com.liferay.util.slf4j`
util-taglib	`com.liferay.util.taglib`

You can use Liferay DXP's App Manager, Felix Gogo Shell, or module JAR file manifests to find versions of modules deployed on your Liferay DXP instance.

Note: Previous versions of the Plugins SDK made `portal-service.jar` available to projects. The 7.0 Plugins SDK similarly makes `portal-kernel.jar` available. If you're using a Liferay DXP bundle (Liferay DXP pre-installed on an app server), the Liferay utility modules are already on your classpath. If you manually installed Liferay DXP on your app server, the Liferay utility modules might not be on your classpath. If a utility module you need is not on your classpath, note its symbolic name (artifact ID) and version.

Resolving Dependencies

Now that you have the module artifact IDs and versions, you can make the modules available to your plugin project. The modules your plugin uses must be available to it at compile time and run time. Here are two options for resolving module dependencies in your traditional plugin project:

Option 1: Use a dependency management tool

Option 2: Manage dependencies manually

The next sections explain and demonstrate these options.

Using a Dependency Management Tool

Dependency management tools such as Ant/Ivy, Maven, and Gradle facilitate acquiring Java artifacts that provide packages your plugins need. They can download artifacts from public repositories or from internal repositories you configure as a proxies. From internal repositories you can audit dependencies.

The following links provide proxy details:

- Ant/Ivy - See documentation on proxy configuration, the `Setproxy` task, and resolvers
- Maven
- Liferay Workspace (Gradle)
- Setting proxies in Liferay @ide@

The Liferay Plugins SDK provides an Ant/Ivy infrastructure. You declare your dependencies in an `ivy.xml` file in your plugin project's root folder. The Plugins SDK's Ant tasks leverage the `ivy.xml` file and the Plugins SDK's Ivy scripts to download the specified modules and their dependencies and make them available to your plugin.

Note: You can use Gradle or Maven in place of Ivy for dependency management, but this isn't in this tutorial's scope. Liferay's Maven and Liferay Workspace tutorials demonstrate using these tools.

Additionally, Liferay Workspace provides a command for migrating Ant/Ivy projects to Gradle-based Liferay Workspace projects. See the tutorial Migrating Traditional Plugins to Workspace Web Applications.

Here's an example dependency element for the Liferay Journal API module, version 2.0.1:

```
<dependency name="com.liferay.journal.api" org="com.liferay" rev="2.0.1" />
```

Each dependency includes the module's name (`name`), organization (`org`), and revision number (`rev`). The Configuring Dependencies tutorial explains how to determine the module's organization (`org`).

At compile time, Ivy downloads the dependency JAR files to a cache folder so you can compile against them.

At deployment, Liferay DXP's WAB Generator creates an OSGi Web Application Bundle (WAB) for the plugin. The WAB generator detects the Java packages your plugin uses and declares dependencies on them. Your plugin can use the packages once a registered OSGi service provides them.

If your project doesn't already have an `ivy.xml` file, you can get one by creating a new plugin project in Liferay @ide@ and copying the `ivy.xml` file it generates.

Here's an example of an `ivy.xml` file from the Liferay Portal 6.2 Knowledge Base portlet:

```
<?xml version="1.0"?>

<ivy-module
    version="2.0"
    xmlns:m2="http://ant.apache.org/ivy/maven"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://ant.apache.org/ivy/schemas/ivy.xsd"
>
    <info module="knowledge-base-portlet" organisation="com.liferay">
        <extends extendType="configurations,description,info" location="${sdk.dir}/ivy.xml" module="com.liferay.sdk" organisation="com.liferay" revision="la
    </info>

    <dependencies defaultconf="default">
        <dependency org="com.liferay" name="com.liferay.markdown.converter" rev="1.0.2" />
    </dependencies>
</ivy-module>
```

The Plugins SDK works with project Ivy files to store artifacts and make them accessible to your plugin projects.

If you don't want to use Ivy or some other dependency management framework, you can store dependency JARs within your plugin project manually. You'll learn about this next.

Managing Dependencies Manually

Plugins rely on their dependencies' availability at compile time and run time. To compile your plugin, you must make sure the dependencies are available in the plugin's `WEB-INF/lib` folder. To run your plugin, the container must be able to find them: either 1) the dependency Java packages must already be active in Liferay DXP's OSGi framework or 2) the dependency JARs must be included in the WAB generated for the plugin. Your plugin can use both the JARs it currently has and the packages Liferay DXP exports.

Using Packages Liferay DXP Exports The Plugins SDK for Liferay Portal 6 provided a way to compile against JARs it had. You'd specify these JARs in the `portal-dependency-jars` property in your `liferay-plugin-package.properties` file. On seeing a plugin's `portal-dependency-jars` list, the Liferay Plugins SDK copied the JARs into the plugin's `WEB-INF/lib`. The Plugins SDK refrained from adding the JARs to the plugin WAR.

This kept the WARs small for deploying faster. It was especially useful for deploying WARs remotely or to cluster nodes.

In 7.0, the `portal-dependency-jars` property is deprecated and behaves differently from previous versions. Because importing and exporting Java packages has replaced wholesale use of JARs, modules and WABs can import packages without concerning themselves with JARs. Liferay DXP exports many third party packages for plugins can use.

If you're still using the `portal-dependency-jars` property, you may run into one of the scenarios below. Follow the instructions below the scenario to fix the issue.

1. **I've specified a JAR, but in 7.0 none of the classes are available to my plugin.**

   Some JARs that Liferay Portal 6.2 used were removed in 7.0. If you specify them in your `portal-dependency-jars`, Liferay DXP can't provide them. If you still need them, remove them from the `portal-dependency-jars` property and add the JARs you need to your plugin's `WEB-INF/lib` folder.

2. **I've specified JARs, and 7.0 also exports all the JAR's packages my plugin imports**

   Keep the JAR in your `portal-dependency-jars` list. The Plugins SDK copies the JAR to your plugin's `WEB-INF/lib` folder at compile time but refrains from adding the JAR to the plugin WAB. The WAB generated for the plugin imports the packages from a registered provider at run time.

3. **7.0 provides the JAR but doesn't export a package my plugin imports**

   Keep the JAR in your `portal-dependency-jars` property. The Plugins SDK copies the JAR to your plugin's `WEB-INF/lib` folder at compile time and adds the JAR to the plugin WAB at deployment.

Understanding Excluded JARs Portal property `module.framework.web.generator.excluded.paths` declares JARs that are stripped from all Liferay DXP generated WABs. These JARs are excluded from WABs because Liferay DXP provides them already. All JARs listed for this property are excluded from the WABs, even if the plugins listed the JAR in their `portal-dependency-jars` property.

If your plugin requires different versions of the packages Liferay DXP exports, you must include them in JARs named differently from the ones `module.framework.web.generator.excluded.paths` excludes.

For example, Liferay DXP's `system.packages.extra.bnd` file exports Spring Framework version 4.1.9 packages:

```
Export-Package:\
    ...
    org.springframework.*;version='4.1.9',\
    ...
```

Liferay DXP uses the `module.framework.web.generator.excluded.paths` portal property to exclude their JARs.

```
module.framework.web.generator.excluded.paths=\
    ...
    WEB-INF/lib/spring-aop.jar,\
    WEB-INF/lib/spring-aspects.jar,\
    WEB-INF/lib/spring-beans.jar,\
    WEB-INF/lib/spring-context.jar,\
    WEB-INF/lib/spring-context-support.jar,\
    WEB-INF/lib/spring-core.jar,\
    WEB-INF/lib/spring-expression.jar,\
    WEB-INF/lib/spring-jdbc.jar,\
    WEB-INF/lib/spring-jms.jar,\
    WEB-INF/lib/spring-orm.jar,\
    WEB-INF/lib/spring-oxm.jar,\
    WEB-INF/lib/spring-tx.jar,\
    WEB-INF/lib/spring-web.jar,\
    WEB-INF/lib/spring-webmvc.jar,\
    WEB-INF/lib/spring-webmvc-portlet.jar,\
    ...
```

To use a different Spring Framework version in your WAB, you must name the corresponding Spring Framework JARs differently from the glob-patterned JARs `module.framework.web.generator.excluded.paths` lists.

For example, to use Spring Framework version 3.0.7's Spring AOP JAR, include it in your plugin's `WEB-INF/lib` but name it something other than `spring-aop.jar`. Adding the version to the JAR name (i.e., `spring-aop-3.0.7.RELEASE.jar`) differentiates it from the excluded JAR and prevents it from being stripped from the WAB.

Using Packages Liferay DXP Doesn't Export You must download and install to your plugin's `WEB-INF/lib` folder JARs that provide packages Liferay DXP doesn't export that your plugin requires.

Follow these steps to do this:

1. Go to Maven Central at https://search.maven.org/.
2. Search for the module by its artifact ID and group ID.
3. Navigate the search results to find the version of the module you want.
4. Click the *jar* link to download the module's JAR file.
5. Add the JAR to your project's `WEB-INF/lib` folder.

< 1 > displaying 1 to 1 of 1

GroupId	ArtifactId	Latest Version	Updated	Download
com.liferay	com.liferay.journal.api	2.2.2 all (8)	04-Jan-2017	pom jar javadoc.jar sources.jar

Figure 13.2: After searching Maven Central, download an artifact's JAR file by clicking the *jar* link.

As you manage module JARs, make sure **not** to deploy any OSGi framework JARs or Liferay module JARs (e.g., `com.liferay.journal.api.jar`). If you deploy these, they'll conflict with the JARs already installed in the OSGi framework. Identical JARs in two different classloaders can cause class cast exceptions. The easiest way to exclude such JARs from your plugin's deployment is to list them in a `deploy-excludes` property in your plugin's `liferay-plugin-package.properties`. You must otherwise remove the JARs manually from the plugin WAR file. To exclude JARs in your plugin's `liferay-plugin-package.properties` file, add an entry like the one below, replacing the square-bracketed items with the names of JAR files to exclude:

```
deploy-excludes=\
    **/WEB-INF/lib/[module-artifact.jar],\
    **/WEB-INF/lib/[another-module-artifact.jar]
```

For example, here's an example property that excludes the OSGi framework JAR `osgi.core.jar` and the Liferay app module JAR `com.liferay.journal.api.jar`:

```
deploy-excludes=\
    **/WEB-INF/lib/com.liferay.portal.journal.api.jar,\
    **/WEB-INF/lib/org.osgi.core.jar
```

How do you know what modules are already installed in Liferay DXP? If your Liferay DXP instance has a particular Liferay app suite installed, then don't deploy module JARs you know are in that app suite. For example, if the Web Experience Management App Suite is already installed (which is the case for a Liferay DXP bundle), then don't deploy Web Content module JARs such as `com.liferay.journal.api.jar`. Searching for a module in Liferay DXP's App Manager is a sure-fire way to verify existing module installations.

Using Liferay DXP's Tag Library Definitions

Before adding Tag Library Definition (TLD) files to your plugin, check Liferay DXP for them. The Liferay DXP web application folder `WEB-INF/TLD` has over twenty TLDs, including Struts TLDs.

You can use Liferay DXP's TLDs in a traditional plugin by adding them to the `portal-dependency-tlds` property in the plugin's `liferay-plugin-package.properties` file.

Way to go! You've fixed class imports and resolved dependencies on all the modules and tag libraries your plugin uses.

13.9 Resolving Breaking Changes

Liferay goes to great lengths to maintain backwards compatibility. Sometimes, breaking changes are necessary to improve Liferay DXP. There may be cases where breaking changes affect your code upgrade process and must be resolved. A breaking change can include

- Functionality that is removed or replaced
- API incompatibilities: Changes to public Java or JavaScript APIs
- Changes to context variables available to templates
- Changes in CSS classes available to Liferay themes and portlets
- Configuration changes: Changes in configuration files, like `portal.properties`, `system.properties`, etc.
- Execution requirements: Java version, J2EE Version, browser versions, etc.

- Deprecations or end of support: For example, warning that a certain feature or API will be dropped in an upcoming version.
- Recommendations: For example, recommending using a newly introduced API that replaces an old API, in spite of the old API being kept in Liferay Portal for backwards compatibility.

Liferay provides a list of breaking changes for every major release to ensure you can easily adapt your code during the upgrade process.

- 7.0 Breaking Changes
- Liferay DXP 7.1 Breaking Changes
- Liferay DXP 7.2 Breaking Changes

The easiest way to resolve breaking changes is by using the Liferay Upgrade Planner. It automatically finds all documented breaking changes and can automatically resolve some of them on its own.

If you're resolving breaking changes manually, make sure to investigate each breaking change document if you're upgrading code across multiple versions. For example, if you're upgrading from Liferay Portal 6.2 to 7.0, you must resolve all the breaking changes listed in the three documents listed above.

Now that you've resolved your breaking changes, you'll learn how to upgrade service builder services next.

CHAPTER 14

UPGRADING HOOK PLUGINS

Liferay DXP has more extension points than ever, and connecting existing hook plugins to them takes very few steps. In most cases, after you upgrade your hook using the Liferay Upgrade Planner, it's ready to run on Liferay DXP. The following tutorials show you how to upgrade each type of hook plugin.

- Override/Extension Modules
- Core JSP Hooks
- App JSP Hooks
- Service Wrapper Hooks
- Core Language Key Hooks
- Portlet Language Key Hooks
- Model Listener Hooks
- Servlet Filter Hooks
- Portal Property and Event Action Hooks
- Struts Action Hooks

Continue on to get started!

14.1 Upgrading Customization Modules

Customization modules include any module extension or override used to customize another module. For examples of these types of modules, visit the `extensions` and `overrides` sample projects.

Getting a customization module running on 7.0 takes two steps:

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy your module.

Note: A fragment was a common customization module in past versions of Liferay DXP. Fragments are no longer recommended; you should upgrade a fragment to a dynamic include or portlet filter. For more information on recommended ways of customizing JSPs in 7.0, see the Customizing JSPs section.

Great! Your customization module is upgraded for 7.0!

14.2 Upgrading Core JSP Hooks

Getting a core JSP hook running on 7.0 takes two steps:

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy your hook plugin.

Liferay DXP's Plugin Compatibility Layer converts the plugin WAR to a Web Application Bundle (WAB) and installs it to Liferay's OSGi Runtime.

It's just that easy!

14.3 Upgrading App JSP Hooks

JSPs in OSGi modules are customized using module fragments. The module fragment attaches to the host module to alter the JSPs. To the OSGi runtime, the fragment is part of the host module. Section 3.14 of the OSGi Alliance's core specification document explains module fragments in detail. This tutorial shows you how to upgrade your app JSP hooks to 7.0.

Liferay @ide@'s Upgrade Planner's *Fixing Upgrade Problems* step generates module fragments from app JSP hook plugins. The tool creates module fragments in the same folder as your Plugins SDK root if your hook is in a Plugins SDK or in the `[liferay_workspace]/modules` folder if your hook is in a Liferay Workspace.

Module fragments follow this name convention: `[plugin_name]-[app]-fragment`. For example, if the plugin's name is `app-jsp-hook` and it modifies a JSP in the Blogs app, the Upgrade Planner generates a module fragment named `app-jsp-hook-blogs-fragment`.

Here are the steps for upgrading app JSP hook plugins:

1. Declare the Fragment Host
2. Update the JSP

Declare the Fragment Host

The module fragment's `bnd.bnd` file must specify an OSGi header `Fragment-Host` set to the host module name and version.

If the host module belongs to one of Liferay DXP's app suites, the Code Upgrade Tool generates a `bnd.bnd` file that specifies an appropriate `Fragment-Host` header automatically.

For example, here's a `Fragment-Host` that attaches a module fragment to the Blogs Web module.

```
Fragment-Host: com.liferay.blogs.web;bundle-version="1.1.9"
```

Updating the JSP is straightforward too.

Update the JSP

The Upgrade Planner creates a module fragment that contains an upgraded version of your custom app JSP.

The following table shows the old and new JSP paths.

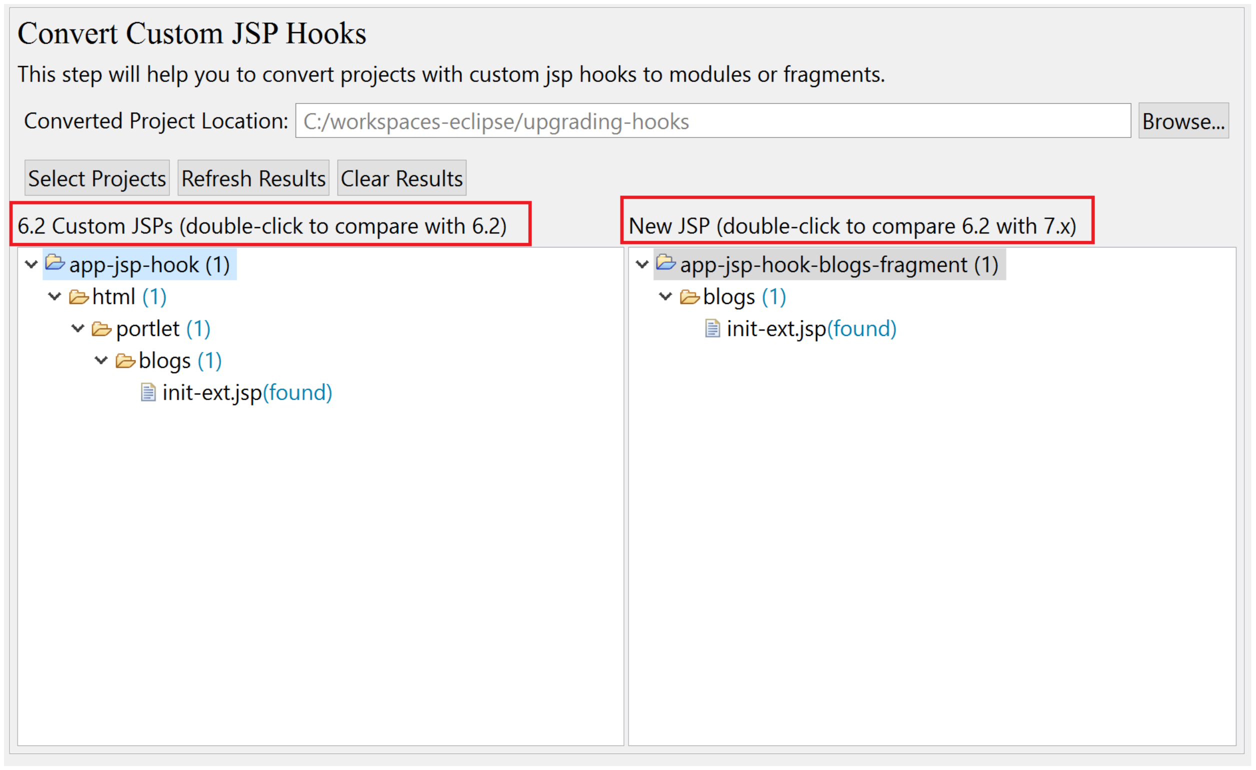
Liferay Portal version	JSP File Path
6.2	`docroot/META-INF/custom_jsps/html/portlet/[jsp_file_path]`
7.0	`src/main/resources/META-INF/resources/[jsp_file_path]`

For example, the Upgrade Planner generates a customized version of the Blogs app's `init-ext.jsp` file here:

```
src/main/resources/META-INF/resources/blogs/init-ext.jsp
```

The tool's *Fixing Upgrade Problems* step lets you compare custom JSPs with originals:

- Compare your custom 6.2 JSP with the original 6.2 JSP.
- Compare your custom 7.0 JSP with your custom 6.2 JSP.



Convert Custom JSP Hooks

This step will help you to convert projects with custom jsp hooks to modules or fragments.

Converted Project Location: C:/workspaces-eclipse/upgrading-hooks

Figure 14.1: The Upgrade Planner lets you compare custom JSPs with originals.

Make any additional needed changes in your 7.0 custom JSP. Then deploy your module fragment. This stops the host module momentarily, attaches the fragment to the host, and then restarts the host module. The console output reflects this process.

Here's output from deploying a module fragment that attaches to the Blogs web module.

```
19:23:11,740 INFO  [Refresh Thread: Equinox Container: 00ce6547-2355-0017-1884-846599e789c4][BundleStartStopLogger:38] STOPPED com.liferay.blogs.web_1.1.9 [
19:23:12,910 INFO  [Refresh Thread: Equinox Container: 00ce6547-2355-0017-1884-846599e789c4][BundleStartStopLogger:35] STARTED com.liferay.blogs.web_1.1.9 [
```

Your custom JSP is live.

14.4 Upgrading Service Wrappers

Upgrading traditional service wrapper hook plugins to 7.0 is quick and easy.

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy the plugin.

Liferay DXP's Plugin Compatibility Layer converts the plugin WAR to a Web Application Bundle (WAB) and installs it to Liferay's OSGi Runtime.

14.5 Upgrading Core Language Key Hooks

Here are the steps for upgrading a core language key hook to 7.0.

1. Create a new module based on the Blade sample `resource-bundle` in Gradle or Maven.

   Here are the main parts of the module folder structure:

   - `src/main/java/[resource bundle path]` → Custom resource bundle class goes here
   - `src/main/resources/content`
     - `Language.properties`
     - `Language_xx.properties`
     - ...

2. Copy all your plugin's language properties files into the module folder `src/main/resources/content/`.

3. Create a resource bundle loader.

4. Deploy your module.

Your core language key customizations are deployed to 7.0.

Related Topics

Upgrading the Liferay Maven Build

14.6 Upgrading Portlet Language Key Hooks

You can upgrade your portlet language key hooks to 7.0 by following these steps:

1. Create a new module based on the Blade sample `resource-bundle` (Gradle or Maven project).

   Here are the module folder structure's main files:

   - `src/main/java/[resource bundle path]` → `ResourceBundleLoader` extension goes here
   - `src/main/resources/content`
     - `Language.properties`
     - `Language_xx.properties`
     - ...

2. Copy your language properties files into module folder `src/main/resources/content/`.

3. In your `bnd.bnd` file, specify OSGi manifest headers that target the portlet module's resource bundle, but prioritize yours.

4. Deploy your module.

Your portlet language key customizations are deployed in your new module on 7.0.

Related Topics

14.7 Upgrading Model Listener Hooks

Developers have been creating model listeners for several Liferay Portal versions. Upgrading Model Listener Hooks from previous portal versions has never been easier.

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy the plugin.

Liferay DXP's Plugin Compatibility Layer converts the plugin WAR to a Web Application Bundle (WAB) and installs it to Liferay's OSGi Runtime.

Your model listener hook is "all ears" and ready to act.

Related Topics

Creating Model Listeners
Resolving a Plugin's Dependencies
Upgrading the Liferay Maven Build

14.8 Upgrading Servlet Filter Hooks

If you have Servlet Filter Hooks ready to be upgraded, this tutorial's for you. The process is quite simple:

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy the plugin.

Liferay DXP's Plugin Compatibility Layer converts the plugin WAR to a Web Application Bundle (WAB) and installs it to Liferay's OSGi Runtime.

Your Servlet Filter is running on 7.0!

Upgrading the Liferay Maven Build

14.9 Upgrading Portal Property and Event Action Hooks

All portal properties in Liferay Portal 6.2 that are also used in 7.0 can be overridden. Portal property and portal event action hooks that use these properties can be upgraded to 7.0 by following these steps:

1. Adapt your code to 7.0's API using the Liferay Upgrade Planner. When you ran the planner's *Fix Upgrade Problems* step, many of the existing issues were autocorrected or flagged. For any remaining errors, consult the Resolving a Plugin's Dependencies article.

2. Deploy your hook plugin.

Liferay DXP's Plugin Compatibility Layer converts the plugin WAR to a Web Application Bundle (WAB) and installs it to Liferay's OSGi Runtime.

Your custom property values and actions are live.

Upgrading the Liferay Maven Build

14.10 Converting StrutsActionWrappers to MVCCommands

Since Liferay Portal 6.1, developers could customize the Portal and Portlet Struts Actions using a Hook and `StrutsActionWrappers`. For example, the `liferay-hook.xml` file for a hook that overrode the login portlet's login action had this entry:

```
<struts-action>
    <struts-action-path>/login/login</struts-action-path>
    <struts-action-impl>
    com.liferay.sample.hook.action.ExampleStrutsPortletAction
    </struts-action-impl>
</struts-action>
```

The `liferay-hook.xml` contains the struts mapping and the new class that overrides the default login action.

The wrapper could extend either `BaseStrutsAction` or `BaseStrutsPortletAction`, depending on whether the struts action was a portal or portlet action respectively.

Starting in 7.0, this mechanism no longer applies for most of the portal portlets because they are no longer using Struts Actions, but instead use `MVCCommands`.

This tutorial demonstrates how to convert your existing `StrutsActionWrappers` to `MVCCommands`.

Converting Your old wrapper to MVCCommands

Converting `StrutsActionWrappers` to `MVCCommands` is easier than you may think.

As a review, legacy `StrutsActionWrappers` needed to implement all the methods, such as `processAction`, `render`, and `serveResource`, even if only one method was being customized. Each of these methods can now be customized independently, using different classes, making the logic simpler and easier to maintain. Depending on the method you customized in your `StrutsActionWrapper`, you need to use the matching MVCCommand shown below:

- processAction → MVCActionCommand
- render → MVCRenderCommand
- serveResource → MVCResourceCommand

Look at the ExampleStrutsPortletAction class for a `StrutsActionWrapper` example. Depending on the actions overridden, the user must use different `MVCCommands`. In this example, the action and render were overridden, so in order to migrate to the new pattern, you would need to create two classes: `MVCActionCommand` and `MVCRenderCommand`.

Next you'll need to determine the associated mapping that is used by the `MVCCommand`.

Mapping Your MVCCommand URLs

For most cases, the `MVCCommand` mapping is the same mapping defined in the legacy struts action.

Using the beginning login example once again, the `struts-action-path` mapping, `/login/login`, remains the same for the `MVCCommand` mapping in 7.0, but some of the mappings may have changed. It's best to check Liferay's source code to determine the correct mapping.

Depending on the URL it is a different parameter:

- `RenderURLs` contain a parameter named `mvcRenderCommandName`. For example:

```
<portlet:renderURL var="editEntryURL">
    <portlet:param name="mvcRenderCommandName" value="/hello/edit_entry"
    />
    <portlet:param name="entryId" value="<%= String.valueOf(
    entry.getEntryId()) %>" />
</portlet:renderURL>
```

- `ActionURLs` are contained in the attribute `name` of the tag library or with the parameter `ActionRequest.ACTION_NAME`. For example:

```
<portlet:actionURL name="/blogs/edit_entry" var="editEntryURL" />
```

- `ResourceURLs` are contained as the attribute `id`. For example:

```
<portlet:resourceURL id="/login/captcha" var="captchaURL" />
```

Once you have this information, you can override the `MVCCommand` by following the instructions found in these sections of the Overriding MVC Commands tutorial:

- Overriding MVCActionCommands
- Overriding MVCResourceCommands
- Overriding MVCRenderCommands

Now you know how to convert your `StrutsActionWrappers` to `MVCCommands`!

Chapter 15

Upgrading Themes

If you've developed themes in Liferay Portal 6.1 or Liferay Portal 6.2, as part of your upgrade you'll want to use them in 7.0. The upgrade process requires several modifications. To help automate this process you'll use the Liferay Theme Generator.

The following tutorials show you how to upgrade your Liferay Portal 6.1 and Liferay Portal 6.2 themes to 7.0.

15.1 Upgrading Your Theme from Liferay Portal 6.1 to 7.0

This tutorial guides you through the process of upgrading your 6.1 theme to run on 7.0.

For a more in depth tutorial that covers upgrading 6.2 themes, please see the Upgrading Themes tutorial.

Setting Up Your Theme With Liferay Theme Generator

You'll use Liferay Theme Generator to get the upgrade process started. Liferay Theme Generator supplies your theme with the necessary tools to deploy and make quick modifications.

In this tutorial, you'll use Liferay Theme Generator's Import feature to help set up the upgrade process.

Preparing Your Theme

Before you import your theme, you need to make some modifications to your theme to ensure Liferay Theme Generator sets up the correct version and template language.

Make sure these settings are present in your theme:

1. Open your `liferay-look-and-feel.xml` file and make sure the template language (`vm`, `ftl`, `jsp`) is defined:

```
<look-and-feel>
    ...
    <theme id="my-theme-name" name="My Theme Name">
        <template-extension>vm</template-extension>
        ...
```

2. Also in `liferay-look-and-feel.xml`, set the theme version to 6.2+:

```
<look-and-feel>
    <compatibility>
        <version>6.2+</version>
    </compatibility>
    ...
```

3. Finally, open your `liferay-plugin-package.properties` file and update the Liferay Portal version to 6.2+, as well:

   ```
   liferay-versions=6.2+
   ```

Note: Liferay Theme Generator's importer only recognizes 6.2 themes. Therefore, 6.1 themes must be versioned as 6.2+ to be recognized by the importer.

The importer only supports importing 6.2 themes generated with the Plugins SDK. If your theme was not generated with the Plugins SDK, such as those created with Maven, you must modify your theme to match the Plugins SDK structure before importing.

Now that your theme is prepped, you can start the import process next.

Importing Your Theme

Follow these steps to import your theme:

1. Install Liferay Theme Generator and its required dependencies, as explained in the Liferay Theme Generator tutorial.

2. Navigate to the folder where you want your theme imported:

   ```
   $ cd /where/i/want/my-theme/imported
   ```

3. Import your theme by running this command:

   ```
   $ yo liferay-theme:import
   ```

4. Follow the prompts to complete your theme import.

Your theme has been imported into a folder named after your original theme. For example, a theme named `my-awesome-theme-for-61` would be imported into a folder called `my-awesome-theme-for-61-theme`.

Next, you can learn how to update your theme for 7.0.

Updating Your Theme For 7.0

Now that you've successfully imported your theme, you have the tools necessary to develop your theme for 7.0. These tools are provided by the Liferay Theme Tasks, part of the Liferay JS Theme Toolkit.

The first of these tools you'll use is the Upgrade task. This task does a few things:

- Backs up your files so you can revert them later if needed.

- Modifies and renames some files for compatibility.

- Creates a `css.diff` file under `/_backup`, so you can easily see what's been changed.
- Updates NPM dependencies.
- Creates a "compatibility" file for Compass mixins, which may have been used in your 6.1 theme.

Important: Before you run the Update task, read the section below titled An Important Note About Core Stylesheets for advice on renaming (effectively overriding) "core" stylesheets.

Upgrade your theme, by running these commands:

```
$ cd my-awesome-theme-for-62-theme
```

```
$ gulp upgrade
```

If the Upgrade task didn't update your files like you expected, you can easily revert them back using the Upgrade Revert task:

```
$ gulp upgrade:revert
```

The Upgrade task automates some of the steps for you, but some manual changes are still required. These are covered next.

Additional Manual Changes To Your Theme

When the Upgrade task finishes, the console may output additional manual changes you may need to make to your theme.

Note: Because Liferay Portal 7.0 uses Bootstrap 3, the default box model has been changed to box-sizing: border-box. If you were using width or height and padding together on an element, you may need to make changes, or those elements may have unexpected sizes.

There are likely changes that you still need to make, which these tools and this guide can't realistically cover. Therefore, it's recommended that you make changes gradually, rather than all at once. This allows you to more easily identify any issues your theme may have.

Please refer to the Appendix below for ways on how to update your theme manually.

Follow the instructions in the next section to build and deploy your theme.

Building And Deploying Your Theme

Follow these steps to build and deploy your theme:

1. To check that everything is running smoothly, run this command:

   ```
   $ gulp build
   ```

2. If all goes well, you can now deploy your theme by running this command:

   ```
   $ gulp deploy
   ```

If you're using Velocity as your template language, you'll notice this message on your server console when deploying your theme:

Support of Velocity is deprecated. Update your theme to use FreeMarker for forward compatibility.

It's recommended that you migrate to using Freemarker for your theme templates. For more details, please see the Upgrading Theme Templates section in the Appendix.

Additional tasks and info can be found in the Liferay Gulp Tasks reference guide.

Congratulations! You've now completed a major step in upgrading your theme.

Appendix: Making Manual Compatibility Adjustments To Your Theme

This appendix covers the changes you need to make to your theme if you manually update your files, or if you need to make additional changes after using the Liferay JS Theme Toolkit's Upgrade task.

Upgrading Theme Metadata

Your theme contains metadata about its capabilities and requirements. This metadata needs to be updated to ensure your theme is available for use in Liferay DXP.

Liferay Portal Version Your theme must target the proper Liferay DXP version: in your case, 7.0.0+. You must update the theme version in two places:

1. In the file `liferay-plugin-package.properties`, add the following property to ensure Liferay DXP deploys your theme:

   ```
   liferay-versions=7.0.0+
   ```

2. Add the following version information to your `liferay-look-and-feel.xml` to ensure Liferay DXP makes your theme available for use:

   ```
   <look-and-feel>
       <compatibility>
           <version>7.0.0+</version>
       </compatibility>
       ...
   ```

Template Extension If you're not using the default Theme Template language, Freemarker (.ftl), you must add a `template-extension` tag to your `liferay-look-and-feel.xml` file:

```
<look-and-feel>
    ...
    <theme id="my-theme-name" name="My Theme Name">
        <template-extension>vm</template-extension>
        ...
```

Required Deployment Contexts If you have any Required Deployment Contexts listed in your `liferay-plugin-package.properties` file, these will likely need to be removed.

- `resources-importer-web`: Portal Compatibility Hook is for previous versions of Liferay Portal.
- `portal-compat-hook`: Because this tutorial is focused on upgrading a theme rather than importing content and assets, it does not cover the Resources Importer. You can learn more about the Resources Importer in the Importing Resources with a Theme tutorial.

Upgrading Stylesheets

An Important Note About "Core" Stylesheets If you've made customizations to "core" Liferay DXP stylesheets, it's recommended that you not use these customizations right away. Liferay DXP's UI has changed significantly since version 6.1, and any customizations you may have are either not likely to work, or will cause problems in the UI.

These "core" files would be:

- `application.css`
- `aui.css`
- `base.css`
- `dockbar.css`
- `extras.css`
- `layout.css`
- `main.css`
- `navigation.css`
- `portal.css`
- `portlet.css`
- `taglib.css`

Important: Rename these files to something like `my_application.css`, `my_aui.css`, etc. If you don't rename these files, you may get an error when building your theme. This is because Sass is importing ambiguous names like application, aui, etc.

It's recommended that you get your theme working in 7.0 first, and then audit the styles in these "core" CSS files to see if they're still necessary and don't cause any issues.

Renaming CSS Files 7.0 now uses the `.scss` extension for Sass stylesheets.

1. Under `my-imported-theme/src/css`, rename your `custom.css` file to `_custom.scss`.
2. If you have any additional CSS files that need to take advantage of Sass and Bourbon, you must rename those as well.

   For example, `my-feature.css` becomes `_my-feature.scss`, and `fonts.css` becomes `_fonts.scss`.

Imported Stylesheet References If you've imported any renamed stylesheets into another, you'll want to update those references.

For example `_my-fonts.scss` needs to be updated from:

```
@import url(my-fonts.css);
```

to:

```
@import "my-fonts";
```

Sass Framework Import Beginning with version 7.0, Liferay Portal now uses Bourbon for mixins, rather than Compass. Bourbon is being imported in a core stylesheet, _imports.scss, so you shouldn't need to import it yourself.

Also, files with the `.scss` extension are processed by Sass automatically. But you must still import or link to these to use them.

Remove `@import "compass"` from all your Sass files, and don't worry about importing Bourbon.

Mixins When Liferay Portal switched from using Compass to Bourbon, some mixins changed syntax, became unsupported, or became unnecessary in modern browsers. These mixins should be updated or removed.

For example:

```
.my-component {

    @include border-radius(8px);

    @include opaque;

    @include scale(0.9);

}

input[type="text"] {

    @include input-placeholder {

        color: #bfbfbf;

    }

}
```

becomes:

```
.my-component {

    border-radius: 8px;

    opacity: 1;

    @include transform(scale(0.9));

input[type="text"] {

    @include placeholder {

        color: #bfbfbf;

    }

}
```

Please refer to Compass and Bourbon documentation for more details.

Bootstrap 3 If you've used Bootstrap 2.3.2 in your theme, a migration guide is available.

Remove `.aui` Class Used In Descendant Selectors The class `.aui` is no longer in use. Selectors that contain `.aui` as a parent qualifier must be modified, or those selectors will not match the expected elements.

For example:

```
.aui{

    my-component {

        // ...

    }

}

.aui my-other-component {

    // ...

}
```

becomes:

```
html {

    my-component {

        // ...

    }

}

html my-other-component {

    // ...

}
```

or maybe:

```
my-component {

    // ...

}

my-other-component {

    // ...
}
```

Upgrading JavaScript

In August 2014 Yahoo stopped all new development of YUI, which AlloyUI was built on. Because of this announcement, Liferay has decided to sunset AlloyUI and deprecate it as of Liferay Portal 7.

Although AlloyUI is deprecated, it's still available by default, and existing AlloyUI 3 based code continues to work.

To further research changes to an AlloyUI module, you can find a `HISTORY.md` file under each component's directory.

Moving forward, it's recommended to migrate your AlloyUI/YUI code to either Metal.js or the framework of your choice. Below, you'll find some libraries used in Liferay DXP. Feel free to use them as well.

jQuery jQuery is a fast, small, and feature-rich JavaScript library. It makes things like HTML document traversal and manipulation, event handling, animation, and Ajax much simpler. It's also popular among front-end developers, making it ideal for getting started quickly.

For more in depth coverage, see jQuery's documentation.

Lodash Lodash is a modern JavaScript utility library delivering modularity, performance & extras. It's used in Liferay DXP to fill the void left by YUI's utility modules.

For more in depth coverage, see Lodash's documentation.

Metal.js Written by Liferay to specifically to meet the needs of Liferay DXP, Metal.js is a JavaScript library for building UI components in a solid, flexible way.

For more in depth coverage, see Metal.js's documentation

Upgrading Theme Templates

In prior versions of Liferay Portal, Velocity templates (`.vm` files) were the default template language for writing theme markup. But Velocity had limitations. In 7.0, Freemarker templates (`.ftl` files) are the default template language, and Velocity templates are deprecated.

With that in mind, if your themes are written in `.vm` files, they should still work, but you're missing out on additional theme features. In a future release, support for Velocity templates will be removed.

Migrating to Freemarker Templates For a typical theme, migrating to Freemarker should be simple. The syntaxes of both languages are relatively similar.

Here's a comparison:

Velocity:

```
$theme.include($my_template_include)

#if ($show_site_name)

    <span title="#language_format ("go-to-x", [$site_name])">

        $site_name

    </span>

#end

#parse ("$full_templates_path/navigation.vm")

#breadcrumbs()

$theme.wrapPortlet("portlet.vm", $content_include)

#foreach ($nav_item in $nav_items)

    $nav_item.getName()

#end
```

Freemarker:

```
<@liferay_util["include"] page=my_template_include />

<#if show_site_name>

    <span title="<@liferay.language_format arguments="${site_name}" key="go-to-x" />">
```

```
        ${site_name}

    </span>

</#if>

<#include "${full_templates_path}/navigation.ftl" />

<@liferay.breadcrumbs />

<@liferay_theme["wrap-portlet"] page="portlet.ftl">

    <@liferay_util["include"] page=content_include />

</@>

<#list nav_items as nav_item>

    ${nav_item.getName()}

</#list>
```

Whichever language you decide to use, there are several convenient macros included with Liferay DXP:

- Freemarker macros on LDN
- Freemarker macros source
- Velocity macros source

Noteworthy Breaking Changes

There are many changes since Liferay Portal 6.1 which break in version 7.0. Some of these changes are documented in Liferay DXP's Breaking Changes. Below are some notable ones.

Dockbar Is Now Called Control Menu In `portal_normal.vm`, admin controls are now called using `#control_menu()`.

Liferay Portal 6.1:

```
#if ($is_signed_in)

    #dockbar()

#end
```

7.0:

```
#control_menu()
```

Portlet Configuration Options In `portlet.vm`, portlet menu icons have been condensed into a single call and are now controlled using the `PortletConfigurationIcon` classes.

Liferay Portal 6.1:

```
$theme.iconOptions()

$theme.iconMinimize()

$theme.iconMaximize()

$theme.iconClose()
```

7.0:

```
$theme.portletIconOptions()
```

See Liferay Portal's Breaking Changes for more details:

- Removed the Tags that Start with portlet:icon-
- Portlet Configuration Options May Not Always Be Displayed

Navigation Item Icons In `navigation.vm`, access to icons have been changed, to minimize dependency on taglibs.

Liferay Portal 6.1:

```
nav_item.icon()
```

7.0:

```
$theme.layoutIcon($nav_item.getLayout())
```

See Liferay Portal's Breaking Changes for more details.

Upgrading Layout Templates

The only significant change to Layout Templates has been the addition of Bootstrap's Grid system.

If you're using any custom Layout Templates, you'll want to integrate Bootstrap into them.

A comparison between Layout Templates in Liferay Portal 6.1 and Liferay Portal 7.0 is shown in the example below:

Liferay Portal 6.1:

```
<div class="portlet-layout">

    <div class="portlet-column portlet-column-only" id="column-1">

        $processor.processColumn("column-1", "portlet-column-content portlet-column-content-only")

    </div>

</div>
```

Liferay Portal 7.0:

```
<div class="portlet-layout row">

    <div class="col-md-12 portlet-column portlet-column-only" id="column-1">

        $processor.processColumn("column-1", "portlet-column-content portlet-column-content-only")

    </div>

</div>
```

Importing Resources with a Theme

15.2 Upgrading Your Theme from Liferay Portal 6.2 to 7.0

This tutorial guides you through the process of upgrading your 6.2 theme to run on 7.0. While you're at it, you should leverage theme improvements, including support for Sass, Bootstrap 3, and Lexicon (Liferay's UI design language). This tutorial demonstrates upgrading a Liferay Portal 6.2 theme to 7.0.

Theme upgrades involve these steps:

- Updating project metadata
- Updating CSS
- Updating theme templates
- Updating resources importer configuration and content
- Applying Lexicon design patterns

As an example, this tutorial applies the steps to a Liferay Portal 6.2 theme called the Lunar Resort theme—developed in the Liferay Portal 6.2 Learning Path Developing a Liferay Theme. It's similar to many Liferay Portal 6.2 themes as it extends the `_styled` theme, adding configurable settings and incorporating a responsive design that leverages Font Awesome icons and Bootstrap. The theme ZIP file contains its original source code.

Before upgrading a theme, consider migrating the theme to use the Liferay JS Theme Toolkit, such as those created with the Liferay Theme Generator. 7.0 doesn't require this migration, but the Liferay JS Theme Toolkit's Gulp `upgrade` task automates many upgrade steps. Themes that use the Liferay JS Theme Toolkit can also leverage exclusive new features, such as the Liferay Theme Generator's sub-generators, and Themelets. If you migrate your theme, return here afterward to upgrade it.

No matter the environment in which you're developing your theme, this tutorial explains everything required to upgrade it. The easiest option is to use the Liferay JS Theme Toolkit's Gulp `upgrade` task, so you'll see that first. Then you'll see *all* upgrade steps, in case you want to run them manually.

Running the Upgrade Task for Themes that Use Liferay JS Theme Toolkit

A Liferay Portal 6.2 theme can be upgraded to 7.0, regardless of its project environment (Liferay JS Theme Toolkit, Plugins SDK, Maven, etc.). But a theme that's been migrated to use the Liferay JS Theme Toolkit can leverage the Gulp `upgrade` task. If you're not going to leverage Liferay JS Theme Toolkit, skip to the *Updating Project Metadata* section.

Here's what the Upgrade task does:

- Updates the theme's Liferay version
- Updates the CSS
- Suggests specific code updates

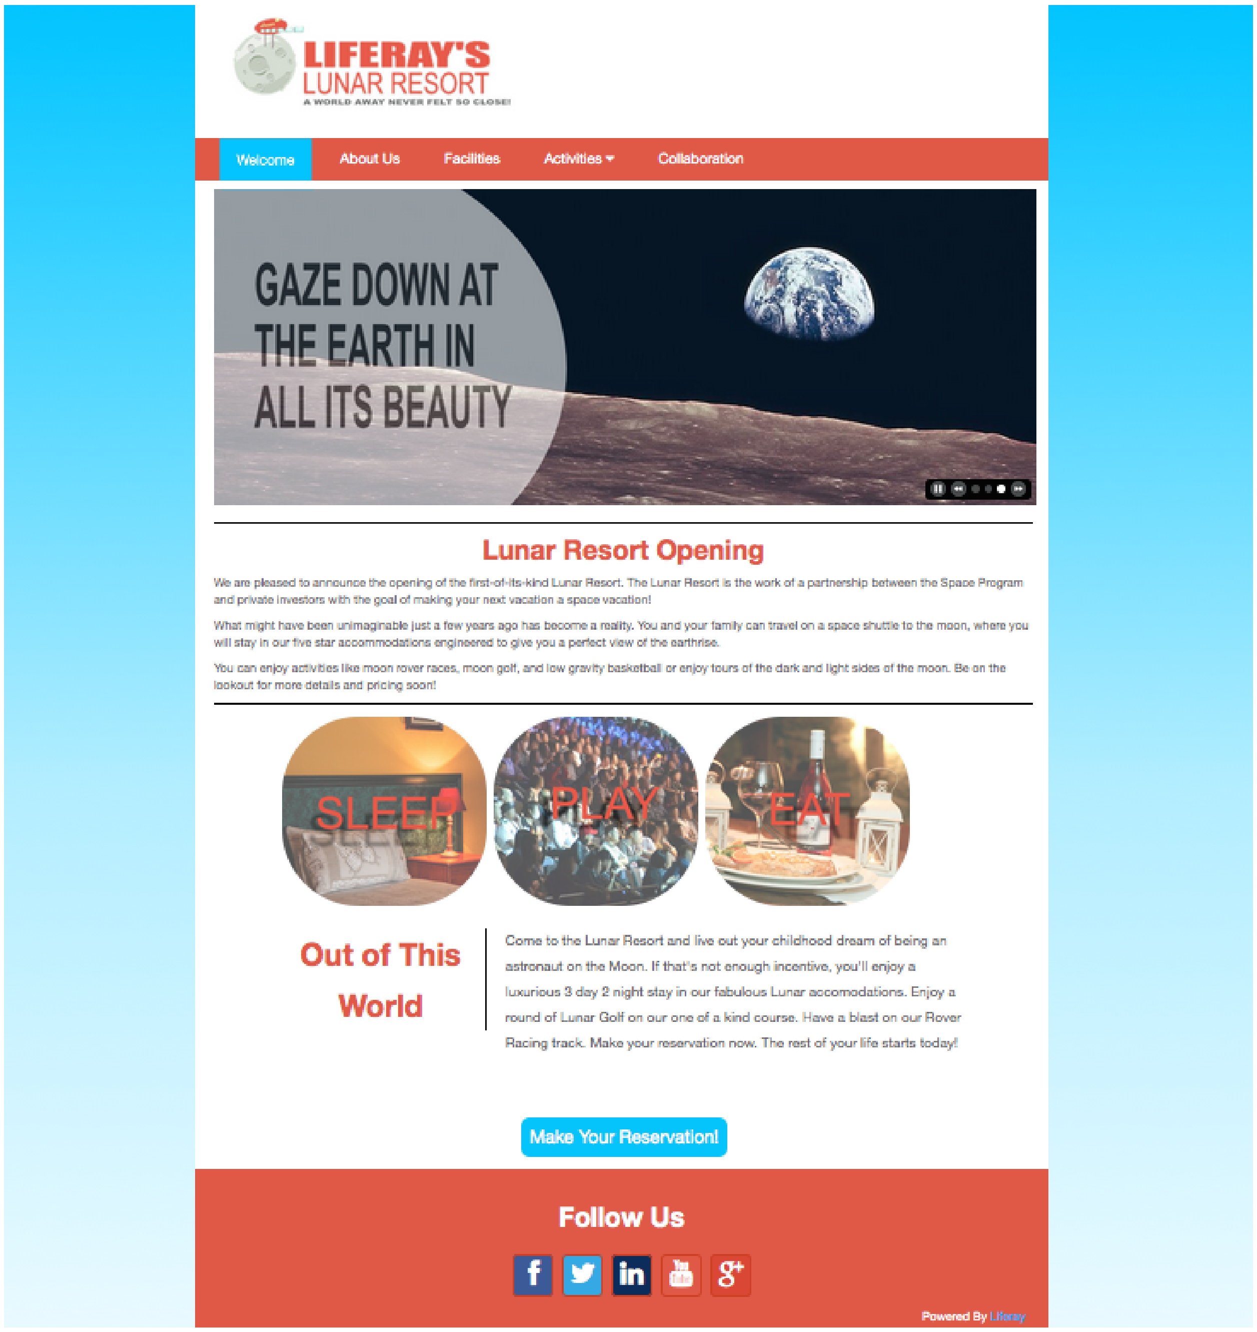
The Upgrade task automatically upgrades CSS code that it can identify. For everything else, it suggests manual upgrades that you can make.

Here are the steps for using the theme `gulp upgrade` task:

1. In your theme's root directory, run this command:

   ```
   gulp upgrade
   ```

   Here's what it does initially:



LIFERAY'S
LUNAR RESORT
A WORLD AWAY NEVER FELT SO CLOSE!
Welcome
About Us
Facilities
Activities
Collaboration
GAZE DOWN AT THE EARTH IN ALL ITS BEAUTY

Lunar Resort Opening

We are pleased to announce the opening of the first-of-its-kind Lunar Resort. The Lunar Resort is the work of a partnership between the Space Program and private investors with the goal of making your next vacation a space vacation!

What might have been unimaginable just a few years ago has become a reality. You and your family can travel on a space shuttle to the moon, where you will stay in our five star accommodations engineered to give you a perfect view of the earthrise.

You can enjoy activities like moon rover races, moon golf, and low gravity basketball or enjoy tours of the dark and light sides of the moon. Be on the lookout for more details and pricing soon!

Out of This World

Come to the Lunar Resort and live out your childhood dream of being an astronaut on the Moon. If that's not enough incentive, you'll enjoy a luxurious 3 day 2 night stay in our fabulous Lunar accomodations. Enjoy a round of Lunar Golf on our one of a kind course. Have a blast on our Rover Racing track. Make your reservation now. The rest of your life starts today!

Figure 15.1: The Lunar Resort example theme upgraded in this tutorial uses a clean, minimal design.

- Copies the existing theme to a folder called `backup`
- Creates core code for generating theme base files
- Updates Liferay version references

```
**Note**: An upgraded theme can be restored to its original state by
executing `gulp upgrade:revert`.
```

```
The task continues upgrading CSS files, prompting you to update CSS file
names.
```

2. For 7.0, Sass files should use the `.scss` extension and file names for Sass partials should start with an underscore (e.g., `_custom.scss`). The `upgrade` task prompts you for each CSS file to rename.

The Upgrade task makes a best effort to upgrade the theme's Bootstrap code from version 2 to 3. For other areas of the code it suspects might need updates, it logs suggestions (covered later). The task also reports changes that may affect theme templates.

A *breaking change* is a code modification between versions of Liferay DXP that might be incompatible with existing plugins, including themes. Liferay minimized the number of breaking changes, but couldn't avoid some. The Breaking Changes reference document describes them. The theme's `gulp upgrade` command and the Upgrade Planner, in Liferay @ide@ identify and address these changes.

The Gulp `upgrade` task jump-starts the upgrade process, but it doesn't complete it. Manual updates are required.

The rest of this tutorial explains all the theme upgrade steps, regardless of whether the Gulp `upgrade` task performs them. Steps the Upgrade task performs are noted in context. Even if you've already executed the Upgrade task, it's best to learn all the steps and make sure they're applied to your theme.

The next step is to update the theme's metadata.

Updating Project Metadata

If you're developing your theme in an environment other than the Plugins SDK, skip this section.

A theme's Liferay version must be updated to `7.0.0+` for the theme to run on 7.0.

If you're using the Plugins SDK, open the `liferay-plugin-package.properties` file and change the `liferay-versions` property value to `7.0.0+`:

```
liferay-versions=7.0.0+
```

If you're using the Liferay JS Theme Toolkit, open the `liferay-look-and-feel.xml` file and specify `liferay-look-and-feel_7_0_0.dtd` as the DTD and `7.0.0+` as the compatibility version:

```
<?xml version="1.0"?>
<!DOCTYPE look-and-feel PUBLIC "-//Liferay//DTD Look and Feel 7.0.0//EN"
"http://www.liferay.com/dtd/liferay-look-and-feel_7_0_0.dtd">

<look-and-feel>
        <compatibility>
                <version>7.0.0+</version>
        </compatibility>

        ...

</look-and-feel>
```

3. If your theme uses the Liferay JS Theme Toolkit and has a `package.json` file, update the file's Liferay version references to `7.0`.

Your theme's Liferay version references are updated for 7.0. Next, you'll update the CSS.

Updating CSS Code

7.0's UI improvements required these CSS-related changes:

- Adding new CSS files
- Removing unneeded CSS files
- Class variable changes (required by Bootstrap 3)
- Modifications to CSS responsiveness tokens

The theme upgrade process involves conforming to these changes.

In this section, you'll update your theme's CSS to leverage the styling improvements. Start with updating CSS file names for Sass.

Updating CSS File Names for Sass

Although Sass was available in Liferay Portal 6.2, only Sass partial files followed the Sass naming convention (using file suffix `.scss`). In 7.0 themes, all Sass files must end in scss.

Note: The Gulp `upgrade` task renames Sass files automatically.

For each CSS file you've modified in your theme, except `main.scss` and `aui.scss`, change its suffix from `.css` to `.scss`.

Then prepend an underscore (_) to all Sass partial file names.

For example, rename `custom.css` to `_custom.scss`.

Here are the Lunar Resort theme's renamed CSS files:

- `css/`
  - `_aui_variables.scss`
  - `_custom.scss`

Refer to the Theme Reference Guide for a complete list of expected theme CSS files.

Next, the CSS rules must be updated to use Bootstrap 3 syntax.

Updating CSS Rules

7.0 uses Bootstrap 3's CSS rule syntax. The new syntax lets developers leverage Bootstrap 3 features and improvements.

If your theme does not use the Liferay JS Theme Toolkit, you can refer to the Migrating from 2.x to 3.0 guide for updating CSS rules to Bootstrap 3.

If your theme uses the Liferay JS Theme Toolkit, the Gulp `upgrade` task reports automatic CSS updates and suggested manual updates. For example, here is part of the task log for the Lunar Resort theme:

```
----------------------------------------------------------------
 Bootstrap Upgrade (2 to 3)
----------------------------------------------------------------

File: src/css/_aui_variables.scss
    Line 5: "$white" has been removed
    Line 11: "$baseBorderRadius" has changed to "$border-radius-base"
    Line 15: "$btnBackground" has changed to "$btn-default-bg"
    Line 16: "$btnBackgroundHighlight" has been removed
    Line 17: "$btnBorder" has changed to "$btn-default-border"
    Line 18: "$btnDangerBackground" has changed to "$btn-danger-bg"
    Line 19: "$btnDangerBackgroundHighlight" has been removed
    Line 21: "$btnInfoBackgroundHighlight" has been removed
    Line 21: "$btnInfoBackground" has changed to "$btn-info-bg"
    Line 22: "$btnPrimaryBackground" has changed to "$btn-primary-bg"
    Line 23: "$btnPrimaryBackgroundHighlight" has been removed
    Line 24: "$btnSuccessBackground" has changed to "$btn-success-bg"
    Line 25: "$btnSuccessBackgroundHighlight" has been removed
    Line 26: "$btnWarningBackground" has changed to "$btn-warning-bg"
    Line 27: "$btnWarningBackgroundHighlight" has been removed
    Line 29: "$dropdownLinkBackgroundActive" has changed to
    "$dropdown-link-active-bg"
    Line 30: "$dropdownLinkBackgroundHover" has changed to
    "$dropdown-link-hover-bg"
    Line 31: "$dropdownLinkColorActive" has changed to
    "$dropdown-link-active-color"
    Line 31: "$white" has been removed
    Line 34: "$navbarBackgroundHighlight" has been removed
    Line 35: "$navbarBorder" has changed to "$navbar-default-border"
    Line 36: "$navbarBackground" has changed to "$navbar-default-bg"
    Line 36: "$navbarLinkBackgroundActive" has changed to
    "$navbar-default-link-active-bg"
    Line 38: "$linkColorHover" has changed to "$link-hover-color"
    Line 38: "$navbarLinkColorHover" has changed to
    "$navbar-default-link-hover-color"
    Line 39: "$navbarLinkColor" has changed to
    "$navbar-default-link-color"
    Line 39: "$navbarText" has changed to "$navbar-default-color"
    Line 41: "$errorBackground" has changed to "$error-bg"
    Line 45: "$infoBackground" has changed to "$info-bg"
    Line 47: "$successBackground" has changed to "$success-bg"
    Line 50: "$warningBackground" has changed to "$warning-bg"
File: src/css/custom.css
    Line 201: Padding no longer affects width or height, you may need to
    change your rule (lines 201-227)
    Line 207: Padding no longer affects width or height, you may need to
    change your rule (lines 207-226)
    Line 212: You would change height from "62px" to "82px"
    Line 305: Padding no longer affects width or height, you may need to
    change your rule (lines 305-314)
    Line 308: You would change height from "39px" to "46px"
    Line 403: "nav-collapse" has changed to "navbar-collapse"
    Line 409: Padding no longer affects width or height, you may need to
    change your rule (lines 409-418)
    Line 490: "btn-navbar" has changed to "navbar-btn"
    Line 490: "btn" has changed to "btn btn-default"
    Line 586: "nav-collapse" has changed to "navbar-collapse"
```

For each update performed and suggested, the task reports a file name and line number range.

Since Bootstrap 3 adopts the `box-sizing: border-box` property for all elements and pseudo-elements (e.g., `:before` and `:after`), padding no longer affects dimensions. Bootstrap's documentation describes the box sizing changes. Consider the padding updates the `upgrade` task reports for CSS rules.

Note: For individual elements, you can overwrite the `box-sizing: border-box` rule with `box-sizing: content-box`.

In all CSS rules that use padding, make sure to update the width and height.

For example, examine the `height` value change in this CSS rule from the Lunar Resort theme's `_custom.scss` file.

Old way:

```
#reserveBtn {
    background-color: #00C4FB;
    border-radius: 10px;
    color: #FFF;
    font-size: 1.5em;
    height: 62px;
    margin: 30px;
    padding: 10px 0;
    ...
}
```

New way:

```
#reserveBtn {
    background-color: #00C4FB;
    border-radius: 10px;
    color: #FFF;
    font-size: 1.5em;
    height: 82px;
    margin: 30px;
    padding: 10px 0;
    ...
}
```

After updating your theme's CSS rules, you should update its CSS responsiveness.

Updating the Responsiveness

In 7.0, Bootstrap 3 explicit media queries replace Bootstrap 2 `respond-to` mixins for CSS responsiveness. Follow these steps to update CSS responsiveness:

1. Open your `_custom.scss` file.

2. Replace all `respond-to` mixins with corresponding media queries shown below:

   Media Query Replacements

Liferay Portal 6.2 Mixin	&nbsp;7.0 Media Query
`@include respond-to(phone)`	`@include media-query(null, $screen-xs-max)`
`@include respond-to(tablet)`	`@include media-query(sm, $screen-sm-max)`
`@include respond-to(phone, tablet)`	`@include media-query(null, $breakpoint_tablet - 1)`
`@include respond-to(desktop, tablet)`	`@include sm`
`@include respond-to(desktop)`	`@include media-query($breakpoint_tablet, null)`

For example, here is a responsiveness update to the Lunar Resort's `_custom.scss` file:

Old:

```
@include respond-to(phone, tablet) {
    html #wrapper #banner #navigation {
    ...
    }
    ...
}
```

New:

```
@include media-query(null, $breakpoint_tablet - 1) {
    html #wrapper #banner #navigation {
    ...
    }
    ...
}
```

The new media query `@include media-query(null, $breakpoint_tablet - 1)` replaces the old mixin `@include respond-to(phone, tablet)`.

The Liferay JS Theme Toolkit's Gulp `upgrade` task generates a file `_deprecated_mixins.scss`. The file provides deprecated compass mixins that your migrated theme might be using. Consider upgrading your use of these mixins. Keep the `_deprecated_mixins.scss` file if you're using any of its mixins, but delete all unused mixins. If you're not using any of the mixins, delete the `_deprecated_mixins.scss` file.

You've updated the theme's responsiveness. Next, you'll update its Font Awesome settings.

Updating Font Awesome Icons

Liferay DXP uses Font Awesome icons extensively. For example, the Lunar Resort theme's design incorporates Font Awesome icons in its social media links.

Figure 15.2: Font Awesome icons facilitate creating social media links.

The icons are easy to use in themes too.

In Liferay Portal 6.2, the CSS file `aui.css` defined the Font Awesome icon paths. In 7.0, the Sass file `_aui_variables.scss` defines them.

Note: In 7.0, the `aui.css` file holds the `lexicon-base` style import. The Theme Reference Guide describes all the Liferay DXP theme files.

The top of the `_aui_variables.scss` file must start with the Font Awesome Icons imports. If you modified the `_aui_variables.scss` file in your Liferay Portal 6.2 theme, add these Font Awesome imports to the top of it:

```
// Icon paths
$FontAwesomePath: "aui/lexicon/fonts/alloy-font-awesome/font";
$font-awesome-path: "aui/lexicon/fonts/alloy-font-awesome/font";
$icon-font-path: "aui/lexicon/fonts/";
```

Next, you'll update the theme templates.

Updating Theme Templates

7.0 theme templates are essentially the same as Liferay Portal 6.2 theme templates. Here are the main changes:

- Velocity templates are now deprecated in favor of FreeMarker templates.
- The Dockbar has been replaced and reorganized into a set of three distinct menus.

Key reasons for using FreeMarker templates and deprecating Velocity templates are these:

- FreeMarker is developed and maintained regularly, while Velocity is no longer actively being developed.
- FreeMarker is faster and supports more sophisticated macros.
- FreeMarker supports using taglibs directly rather than requiring a method to represent them. You can pass body content to them, parameters, etc.

The menus that replace the Dockbar supports a more flexible and responsive design for creating better user experiences.

You should start by addressing the Velocity templates. Since Velocity templates have been deprecated, **you should convert your Velocity theme templates to FreeMarker**.

If you're using the Liferay JS Theme Toolkit, the `gulp upgrade` command reports the required theme template changes in the log.

For example, here is the command's output for the Lunar Resort theme:

```
----------------------------------------------------------------
Liferay Upgrade (6.2 to 7)
----------------------------------------------------------------

File: portal_normal.ftl
    Warning: <@liferay.dockbar /> is deprecated, replace with
    <@liferay.control_menu /> for new admin controls.
    Warning: not all admin controls will be visible without
    <@liferay.control_menu />
    Warning: ${theme} variable is no longer available in FreeMarker
    templates, see https://goo.gl/9fXzYt for more information.
```

For all the theme's templates, it suggests replacement code for deprecated code.

Next, you'll learn how to update various theme templates to 7.0. If you didn't modify any theme templates, you can skip these sections.

Updating Portal Normal FTL

The first one to update is the `portal_normal.ftl` theme template. If you didn't customize `portal_normal.ftl`, you can skip this section.

In FreeMarker templates, the new syntax for including taglibs lets you use them directly rather than accessing them via the `theme` variable. The change is described in the Breaking Changes reference document. All modified `portal_normal.ftl` theme templates must be updated to use the new syntax.

1. Open your modified `portal_normal.ftl` file and replace the following 6.2 directives with the corresponding 7.0 directives:

   FreeMarker Theme Variable Replacements

6.2	7.0
`${theme.include(top_head_include)}`	`<@liferay_util["include"] page=top_head_include />`
`${theme.include(body_top_include)}`	`<@liferay_util["include"] page=body_top_include />`
`${theme.include(content_include)}`	`<@liferay_util["include"] page=content_include />`
`${theme.wrapPortlet("portlet.ftl", content_include)}`	`<@liferay_theme["wrap-portlet"] page="portlet.ftl"> <@liferay_util["include"] page=content_include /> </@>`
`${theme.include(body_bottom_include)}`	`<@liferay_util["include"] page=body_bottom_include />`
`${theme.include(bottom_include)}`	`<@liferay_util["include"] page=bottom_include />`
`${theme.getSetting("my-theme-setting")}`	`${theme_settings["my-theme-setting"]}`
`${theme.runtime("56", "articleId=" + my_article_id)}`	`<@liferay_portlet["runtime"] portletName="com_liferay_journal_content_web_portlet_JournalContentPortlet" queryString="articleId=" + my_article_id />`

2. Replace the following link type.

   Old:

   `<a href="#main-content" id="skip-to-content"><@liferay.language key="skip-to-content" /></a>`

   New:

   `<@liferay_ui["quick-access"] contentId="#main-content" />`.

   The `liferay-ui:quick-access` tag provides a keyboard shortcut to the page's main content.

3. Replace all Dockbar references with Control Menu references.

   Old:

```
<#if is_signed_in>
	<@liferay.dockbar />
</#if>
```

   New:

```
<@liferay.control_menu />
```

   The Dockbar was an all-in-one component that contained the page administration menus and the user/portal administration menus. This UI has since been split and reorganized into three menus:

- *The Product Menu*: Manage site and page navigation, content, settings and pages for the current site, and navigate to user account settings, etc.
- *The Control Menu*: Configure and add content to the page and view the page in a simulation window.
- *The User Personal Bar*: Display notifications and the user's avatar and name.

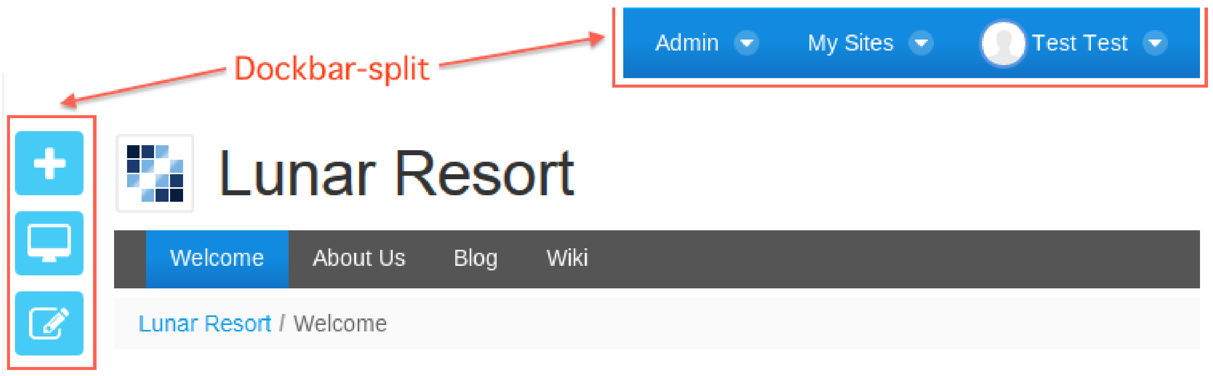


Figure 15.3: The Dockbar was removed in 7.0 and must be replaced with the new Control Menu.

The new design enhances the user experience by providing clear and purposeful menus.

4. If you used the split Dockbar in your Liferay Portal 6.2 theme, remove `dockbar-split` from the `body` element's `class` value.

   For example, remove `dockbar-split` from `<body class="... dockbar-split">`. .

5. Remove the page title code shown below:

```
<h2 class="page-title">
    <span>${the_title}</span>
</h2>
```

   Rather than include the page title on every page, it was decided that this decision should be left up to developers. With the introduction of modularization in themes, this feature can easily be implemented however you like.

6. To ensure navigation is only rendered when there are pages, wrap the `<#include "${full_templates_path}/navigation.f` `/>` include with an `if` statement as demonstrated below:

```
<#if has_navigation && is_setup_complete>
    <#include "${full_templates_path}/navigation.ftl" />
</#if>
```

7. Finally, replace content `div` elements (e.g., `<div id="content">...<div>`) with HTML 5 `section` elements.

   The `div` element works but the `section` element is more accurate and provides better accessibility for screen readers.

   For example, here's a new content `section` element:

```
<section id="content">
    <h1 class="hide-accessible">${the_title}</h1>
    ...
</section>
```

To support accessibility, consider adding an `h1` element like the one above.

Note: The Liferay JS Theme Toolkit's `gulp upgrade` command reports suggested theme template changes.

If you modified the navigation template for your theme, follow the steps in the next section.

Updating Navigation FTL

Follow these steps to update your modified `navigation.ftl` file:

1. Below the `<nav class="${nav_css_class}" id="navigation" role="navigation">` element, add the following hidden heading for accessibility screen readers:

   ```
   <h1 class="hide-accessible">
       <@liferay.language key="navigation" />
   </h1>
   ```

2. To access the layout, add the following variable declaration below the `<#assign nav_item_css_class = "" />` variable declaration:

   ```
   <#assign nav_item_layout = nav_item.getLayout() />
   ```

   This variable grabs the layout for navigation. You can use this variable to retrieve an icon for the navigation menu next.

3. To retrieve an icon for the navigation menu, replace the `${nav_item.icon()}` variable in the `<a aria-labelledby="layout_${nav_item.getLayoutId()}"...</a>` anchor with the following element:

   ```
   <@liferay_theme["layout-icon"] layout=nav_item_layout />
   ```

The navigation template is updated.

That covers most, if not all, of the required theme template changes. If you modified any other FreeMarker theme templates, you can compare them with templates in the `_unstyled` theme. And if your theme uses the Liferay JS Theme Toolkit, refer to the suggested changes that the `gulp upgrade` command reports.

After updating the theme templates, you can update your theme's resources importer code.

Updating the Resources Importer

Liferay's resources importer is now an OSGi module in Liferay's Web Experience application suite. Since the suite is bundled with Liferay DXP, developers no longer need to download the resources importer separately.

API changes and upgrades to Bootstrap 3 affect the following resources importer components:

- Plugin properties
- Web content article files and directory structure
- Sitemap

This section shows you how to update these components.

Note: The example Lunar Resort theme's resources importer web content articles have been modified to avoid known issue LPS-64859. Articles in the Liferay Portal 6.2 theme link to pages in the site's layout. Due to the page and article import order, the links cause a null pointer exception. To avoid this issue with the example theme, the offending links have been removed from its articles.

Start updating the plugin properties for the resources importer.

Updating liferay-plugin-package.properties

If you're upgrading a Plugins SDK theme, follow these instructions to update resources importer properties. Otherwise, skip this section.

Make the following updates to the theme's `liferay-plugin-package.properties` file:

1. Remove the `required-deployment-contexts` property.

   The plugin no longer needs this property as the resources importer is now an OSGi module built-in and deployed with 7.0.

2. Since the group model class's fully-qualified class name has changed, replace the `resources-importer-target-class-name` property's value with the following class name:

   ```
   com.liferay.portal.kernel.model.Group
   ```

Now that the resources importer's properties are configured properly, you can update your theme's web content.

Updating Web Content

All 7.0 web content articles must be written in XML and have a structure and template. Article creation requires a structure and article content rendering requires a template. Follow these steps to update your web content:

1. In the `/resources-importer/journal/articles/` folder, create a subfolder, for example `BASIC_WEB_CONTENT`, to hold the basic HTML articles.

2. Move all basic HTML articles into the folder you just created in step 1.

3. In the `/resources-importer/journal/templates/` and `/resources-importer/journal/structures/` folders, create a subfolder with the same name as the folder you created in step 1.

   For the web content to work properly, the articles, structure, and template folder names must match.

4. In previous Liferay versions, article structures were written in XML. Now they're written in JSON.

   Create a file `[structure-name].json`, for example `BASIC_WEB_CONTENT.json`, in the structure subfolder you created in the previous step.

   For web content articles that use complicated structures and templates, create the structures and templates in Liferay DXP.

5. In the JSON file you just created, add a JSON structure for the web content. For example, you can use a JSON structure like the one below for basic web content articles.

```
{
    "availableLanguageIds": [
        "en_US"
    ],
    "defaultLanguageId": "en_US",
    "fields": [
        {
            "label": {
                "en_US": "Content"
            },
            "predefinedValue": {
                "en_US": ""
            },
            "style": {
                "en_US": ""
            },
            "tip": {
                "en_US": ""
            },
            "dataType": "html",
            "fieldNamespace": "ddm",
            "indexType": "keyword",
            "localizable": true,
            "name": "content",
            "readOnly": false,
            "repeatable": false,
            "required": false,
            "showLabel": true,
            "type": "ddm-text-html"
        }
    ]
}
```

This structure identifies the articles' language and field settings and specifies a name value to identify the content. This example structure's content is named content.

6. In the template subfolder you created in step 3 (e.g., /resources-importer/journal/templates/[template-folder-name]/), create a FreeMarker template file (e.g., [template-folder-name].ftl) and add a method in it to get the article's data.

   For example, this method accesses content from the variable named content and renders it as HTML:

```
${content.getData()}
```

   You've created the basic web content structure and template.

7. Follow this pattern for basic web content articles you convert from HTML to XML:

```
<?xml version="1.0"?>

<root available-locales="en_US" default-locale="en_US">
        <dynamic-element name="content" type="text_area"
        index-type="keyword" index="0">
                <dynamic-content language-id="en_US">
                        <![CDATA[
                        HTML CONTENT GOES HERE
                        ]]>
                </dynamic-content>
        </dynamic-element>
</root>
```

For example, the `2 column description.html` Lunar Resort article's HTML content should be converted to an XML file (e.g., `2 column description.xml`) whose content looks like this:

```
<?xml version="1.0"?>

<root available-locales="en_US" default-locale="en_US">
    <dynamic-element name="content" type="text_area"
    index-type="keyword" index="0">
        <dynamic-content language-id="en_US">
            <![CDATA[
                <div class="container-fluid">
    <div class="span4" id="columnLeft">Out of This World</div>
    <div class="span8" id="columnRight">Come to the Lunar Resort and
    live out your childhood dream of being an astronaut on the Moon. If
    that's not enough incentive, you'll enjoy a luxurious 3 day 2 night
    stay in our fabulous Lunar accommodations. Enjoy a round of Lunar
    Golf on our one of a kind course. Have a blast on our Rover Racing
    track. Make your reservation now. The rest of your life starts
    today!</div>
</div>
]]>
        </dynamic-content>
    </dynamic-element>
</root>
```

8. 7.0's migration from Bootstrap 2 to Bootstrap 3 requires that you replace all `div` element `class` attribute values of Bootstrap 2 format span[`number`] with values that use the Bootstrap 3 format:

```
col-[device-size]-[number]
```

`device-size` can be `xs`, `sm`, `md`, or `lg`. `md` works for most cases. Bootstrap's site at https://getbootstrap.com/docs/3.3/css/#grid explains the Bootstrap 3 grid system

Continuing with the `2 column description.xml` article example, here is its updated content:

```
<?xml version="1.0"?>

<root available-locales="en_US" default-locale="en_US">
    <dynamic-element name="content" type="text_area"
    index-type="keyword" index="0">
        <dynamic-content language-id="en_US">
            <![CDATA[
                <div class="container-fluid">
    <div class="col-md-4" id="columnLeft">Out of This World</div>
    <div class="col-md-8" id="columnRight">Come to the Lunar Resort and
    live out your childhood dream of being an astronaut on the Moon. If
    that's not enough incentive, you'll enjoy a luxurious 3 day 2 night
    stay in our fabulous Lunar accommodations. Enjoy a round of Lunar
    Golf on our one of a kind course. Have a blast on our Rover Racing
    track. Make your reservation now. The rest of your life starts
    today!</div>
</div>
]]>
        </dynamic-content>
    </dynamic-element>
</root>
```

That's all that is needed for most basic web content articles. If you're following along with the Lunar Resort example, the updated XML articles are in the ZIP file's `/resources-importer/journal/articles/Basic Web Content/` folder.

Note: Although Liferay Portal 6.2 used AlloyUI 2.0.x, 7.0 uses AlloyUI 3.0.x. As a result, you may need to update your code that uses AlloyUI. Refer to AlloyUI's examples and API docs for details.

Next, you must update your resources importer's sitemap file.

Updating the Sitemap

In Liferay Portal 6.2, portlet IDs were incremental numbers. In 7.0, they're explicit class names. The new IDs are intuitive and unique. But you must update your `sitemap.json` file with the new portlet IDs.

Some of common portlet IDs are specified in the `sitemap.json` example in the Importing Resources with a Theme tutorial.

You can also retrieve a portlet's ID from the UI:

1. In the portlet's *Options* menu, select *Look and Feel Configuration*.

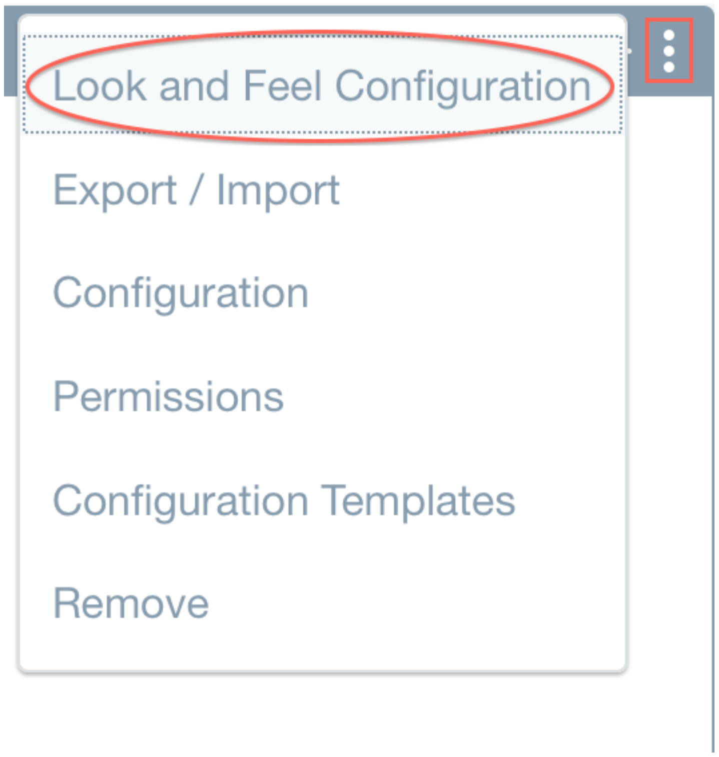

Figure 15.4: You can find the portlet ID in the the *Look and Feel Configuration* menu.

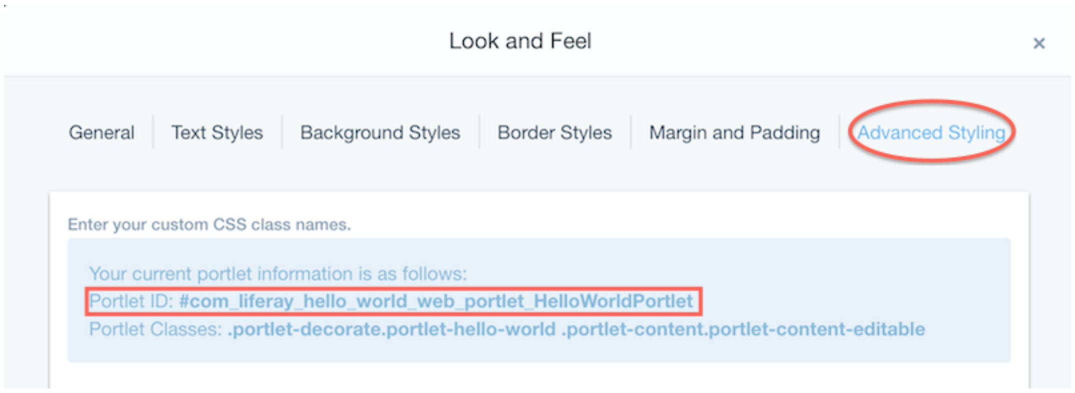
2. Select the *Advanced Styling* tab.

   The `Portlet ID` value is listed in the blue box.

The Portlet ID quick reference lists all the default portlet IDs.

Next, you can learn how to update your theme's UI to follow Lexicon design patterns.



Enter your custom CSS class names.

Your current portlet information is as follows:
Portlet ID: #com_liferay_hello_world_web_portlet_HelloWorldPortlet
Portlet Classes: .portlet-decorate.portlet-hello-world .portlet-content.portlet-content-editable

Figure 15.5: The portlet ID is listed within the blue box in the *Advanced Styling* tab.

Applying Lexicon Design Patterns

7.0 uses Lexicon, a web implementation of Liferay's Lexicon Experience Language. The Lexicon Experience Language provides styling guidelines and best practices for application UIs. While Lexicon's CSS, HTML, and JavaScript components enable developers to build fully-realized UIs quickly and effectively. This section demonstrates how to apply Lexicon to a form.

For example, this is the Liferay Portal 6.2 Lunar Resort's reservation form:

```
<p>
Thanks for choosing to stay at the Liferay Lunar Resort! Please fill out the
form below to book your stay. We know you have a choice in where to stay on
the
Moon... oh wait no you don't. Thanks for picking us anyways. We'll see you
soon on the Moon!
</p>

<form class="form-horizontal">
        <fieldset>
          <legend>Reservation Form</legend>
          <div class="control-group">
              <label class="control-label" for="inputName">Name</label>
              <div class="controls">
                      <input type="text" id="inputName"
                      placeholder="Enter your Name here" required="required">
                  </div>
          </div>
          <div class="control-group">
              <label class="control-label" for="inputEmail">Email</label>
              <div class="controls">
                  <input type="email" id="inputEmail"
                  placeholder="Enter your E-Mail here" required="required">
              </div>
          </div>
          <div class="control-group">
              <div class="controls">
                  <button type="submit" class="btn">Submit</button>
              </div>
          </div>
        </fieldset>
</form>

<p style="padding-bottom:25px;">
Thanks again for booking with Liferay. When you book with Liferay, you
remember your stay. Please take a moment to fill out our guestbook below.
</p>
```

The HTML code above uses Bootstrap 2's markup and CSS classes.

Lexicon extends Bootstrap 3. Here's the Lunar Resort form updated to Lexicon:

```
<?xml version="1.0"?>

<root available-locales="en_US" default-locale="en_US">
        <dynamic-element name="content" type="text_area"
        index-type="keyword" index="0">
                <dynamic-content language-id="en_US">
                        <![CDATA[
                                <p>Thanks for choosing to stay at the
                                Liferay Lunar Resort! Please fill out the
                                form below to book your stay. We know you
                                have a choice in where to stay on the Moon...
                                oh wait no you don't. Thanks for picking us
                                anyways. We'll see you soon on the Moon!</p>
<form role="form-horizontal">
        <fieldset>
          <legend>Reservation Form</legend>
          <div class="form-group">
              <label for="inputName">Name</label>
              <input type="text" id="inputName" class="form-control"
              placeholder="Enter your Name here" required="required">
          </div>
          <div class="form-group">
              <label for="inputEmail">Email</label>
              <input type="email" id="inputEmail" class="form-control"
              placeholder="Enter your E-Mail here" required="required">
          </div>
          <div class="form-group">
                  <button type="submit" class="btn btn-primary">Submit
                  </button>
          </div>
        </fieldset>
</form>

<p style="padding-bottom:25px;">Thanks again for booking with Liferay. When
you book with Liferay, you remember your stay. Please take a moment to fill
out our guestbook below.</p>
                        ]]>
                </dynamic-content>
        </dynamic-element>
</root>
```

The Lexicon updates applied to the form are as follows:

- The `control-group` classes were updated to `form-group` classes.
- The `control-label` classes were removed from the `label` elements.
- The `<div class=""controls>` elements were removed.
- The `form-control` class was added to each input element.
- To emphasize the form's submit button, the `btn-primary` class was added to it.

You can apply similar Lexicon design patterns to your theme's HTML files.

You've updated your theme to 7.0! You can deploy it from your theme project.

Liferay JS Theme Toolkit-based project:

```
gulp deploy
```

Plugins SDK project:

```
ant deploy
```

Now your users can continue enjoying the visual styles you've created in your upgraded themes.

15.3 Upgrading Layout Templates

Layout templates for 7.0 differ slightly from layout templates for Liferay Portal 6. The layout template's rows and columns are affected by Bootstrap's new grid system syntax.

This tutorial demonstrates the following:

- How to upgrade your layout template to 7.0

Upgrading a layout template involves updating its Liferay version and updating the class syntax for its rows and columns.

Follow these steps to upgrade your layout template:

1. Open your `liferay-plugin-package.properties` file and update the `liferay-versions` property to `7.0.0+`:

   ```
   liferay-versions=7.0.0+
   ```

2. Open your layout template's `.tpl` file and replace `row-fluid` with `row`, in each row's class value.

3. Previously, column size was denoted using a class value of format `span[number]`. The new Bootstrap grid system uses the format `col-[device-size]-[number]`.

   The `[device-size]` value must be `xs`, `sm`, `md`, or `lg`. In most cases, an `md` device size works well. You can read more about the Bootstrap grid system on their site at https://getbootstrap.com/docs/3.3/css/#gri d.

   The `[number]` value must be an integer from 1 to 12. A row's width is divisible by twelve; so the combined width of a row's columns must equal 12.

   Inside the `.tpl` file, replace each `span-[number]` class value with `col-[device-size]-[number]`, where `[device-size]` is `xs`, `sm`, `md`, or `lg` and `[number]` is an integeter from 1 to 12.

   Here's an example column that uses the `md` device size and a column that is a third (4/12) of the row's total width:

   ```
   <div class="portlet-column portlet-column-last col-md-4" id="column-3">
   ```

As an example, here's Liferay Portal 6 layout template 1_2_1_columns.tpl upgraded to 7.0:

```
<div class="columns-1-2-1" id="main-content" role="main">
        <div class="portlet-layout row">
                <div class="col-md-12 portlet-column portlet-column-only"
                id="column-1">
                        $processor.processColumn("column-1",
                        "portlet-column-content portlet-column-content-only")
                </div>
        </div>

        <div class="portlet-layout row">
```

```
                <div class="col-md-6 portlet-column portlet-column-first"
                id="column-2">
                        $processor.processColumn("column-2",
                        "portlet-column-content portlet-column-content-first")
                </div>

                <div class="col-md-6 portlet-column portlet-column-last"
                id="column-3">
                        $processor.processColumn("column-3",
                        "portlet-column-content portlet-column-content-last")
                </div>
        </div>

        <div class="portlet-layout row">
                <div class="col-md-12 portlet-column portlet-column-only"
                id="column-4">
                        $processor.processColumn("column-4",
                        "portlet-column-content portlet-column-content-only")
                </div>
        </div>
</div>
```

Your layout template is ready to use in 7.0!

Planning Plugin Upgrades and Optimizations
Benefits of 7.0 for Liferay Portal 6 Developers
Liferay Upgrade Planner

15.4 Upgrading Frameworks and Features

Your upgrade process not only relies on portlet technology, themes, and customization plugins, but also the frameworks your project leverages. The following frameworks and their upgrade processes are discussed in this section:

- JNDI data source usage
- Service Builder service invocation
- Service Builder
- Velocity templates

Continue on to learn more about upgrading these frameworks.

15.5 Upgrading JNDI Data Source Usage

In Liferay DXP's OSGi environment, you must use the portal's class loader to load the application server's JNDI classes. An OSGi bundle's attempt to connect to a JNDI data source without using Liferay DXP's class loader results in a `java.lang.ClassNotFoundException`.

For more information on how to do this, see the Connecting to JNDI Data Sources article.

15.6 Upgrading Service Builder Service Invocation

When upgrading a portlet leveraging Service Builder, you must first decide if you're building your Service Builder logic as a WAR or modularizing it.

Note: Service Builder portlets automatically migrated to Liferay Workspace using the Upgrade Planner or Blade CLI's `convert` command automatically have its Service Builder logic converted to API and implementation modules. This is a best practice for 7.0.

If you prefer keeping your Service Builder logic as a WAR, you must implement a service tracker to call services. See the Service Trackers article for more information.

If you're optimizing your Service Builder logic to invoke Liferay services from a module, see the Invoking Local Services article for more information.

15.7 Upgrading Service Builder

7.0 continues to use Service Builder, so you can focus on your application's business logic instead of its persistence details. It still generates model classes, local and remote services, and persistence.

Upgrading most Service Builder portlets involves these steps:

1. Adapt the code to 7.0's API
2. Resolve dependencies
3. Build the services

Start by adapting the code.

Step 1: Adapt the Code to 7.0's API

Adapt the portlet to 7.0's API using the Upgrade Planner. When running the planner's *Fix Upgrade Problems* step, many of the existing issues are autocorrected. For remaining issues, the planner identifies code affected by the new API and ways to adapt it.

For example, consider an example portlet with the following compilation error:

```
/html/guestbook/view.jsp(58,1) PWC6131: Attribute total invalid for tag search-container-results according to TLD
```

The `view.jsp` file specifies a tag library attribute `total` that doesn't exist in 7.0's `liferay-ui` tag library. Notice the second attribute `total`.

```
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId,
                    guestbookId, searchContainer.getStart(),
                    searchContainer.getEnd())%>"
    total="<%=EntryLocalServiceUtil.getEntriesCount(scopeGroupId,
                    guestbookId)%>" />
```

Remove the `total` attribute assignment to make the tag like this:

```
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId,
                    guestbookId, searchContainer.getStart(),
                    searchContainer.getEnd())%>" />
```

Resolve these error types and others until your code is adapted to the new API.

Step 2: Resolve Dependencies

To adapt your app's dependencies, refer to the Resolving a Plugin's Dependencies tutorial. Once your dependencies are upgraded, rebuild your services!

Step 3: Build the Services

To rebuild your portlet's services, see the Running Service Builder article.

An example change where upgrading legacy Service Builder code can produce differing results is explained below.

A Liferay Portal 6.2 portlet's `service.xml` file specifies exception class names in `exception` elements like this:

```
<service-builder package-path="com.liferay.docs.guestbook">
    ...
    <exceptions>
        <exception>GuestbookName</exception>
        <exception>EntryName</exception>
        <exception>EntryMessage</exception>
        <exception>EntryEmail</exception>
    </exceptions>
</service-builder>
```

In Liferay Portal 6.2, Service Builder generates exception classes to the path attribute `package-path` specifies. In 7.0, Service Builder generates them to `[package-path]/exception`.

Old path:

```
[package-path]
```

New path:

```
[package-path]/exception
```

For example, the example portlet's package path is `com.liferay.docs.guestbook`. Its exception class for `exception` element `GuestbookName` is generated to `docroot/WEB-INF/service/com/liferay/docs/guestbook/exception`. Classes that use the exception must import `com.liferay.docs.guestbook.exception.GuestbookNameException`. If this upgrade is required in your Service Builder project, you must update the references to your portlet's exception classes.

Once your Service Builder portlet is upgraded, deploy it.

Note: Service Builder portlets automatically migrated to Liferay Workspace using the Upgrade Planner or Blade CLI's `convert` command automatically has its Service Builder logic converted to API and implementation modules. This is a best practice for 7.0.

The portlet is now available on Liferay DXP. Congratulations on upgrading a portlet that uses Service Builder!

15.8 Migrating Off of Velocity Templates

Velocity templates were deprecated in Liferay Portal 7.0 and are now removed in favor of FreeMarker templates in 7.0. Below are the key reasons for this move:

- FreeMarker is developed and maintained regularly, while Velocity is no longer actively being developed.
- FreeMarker is faster and supports more sophisticated macros.
- FreeMarker supports using taglibs directly rather than requiring a method to represent them. You can pass body content to them, parameters, etc.

Although Velocity templates still work in 7.0, we highly recommend migrating to FreeMarker templates. For more information on this topic, see the Upgrading Layout Templates section.

Chapter 16

Upgrading Portlet Plugins

All portlet plugin types developed for Liferay Portal 6 can be upgraded and deployed to 7.0.

Upgrading most portlets involves these steps:

1. Adapt the code to 7.0's API
2. Resolve dependencies

Liferay's Upgrade Planner helps you adapt your code to 7.0's API. And resolving a portlet's dependencies is straightforward. In most cases, after you finish the above steps, you can deploy your portlet to Liferay DXP.

The portlet upgrade tutorials show you how to upgrade the following common portlets:

- GenericPortlet
- Servlet-based portlet
- Liferay MVC Portlet
- Portlet that uses Service Builder
- Liferay JSF Portlet
- Struts Portlet
- Spring MVC Portlet

The tutorials provide example portlet source code from before and after upgrading the example portlet. Each tutorial's steps were applied to the example portlet. You can refer to example code as you upgrade your portlet.

Let's get your portlet running on 7.0!

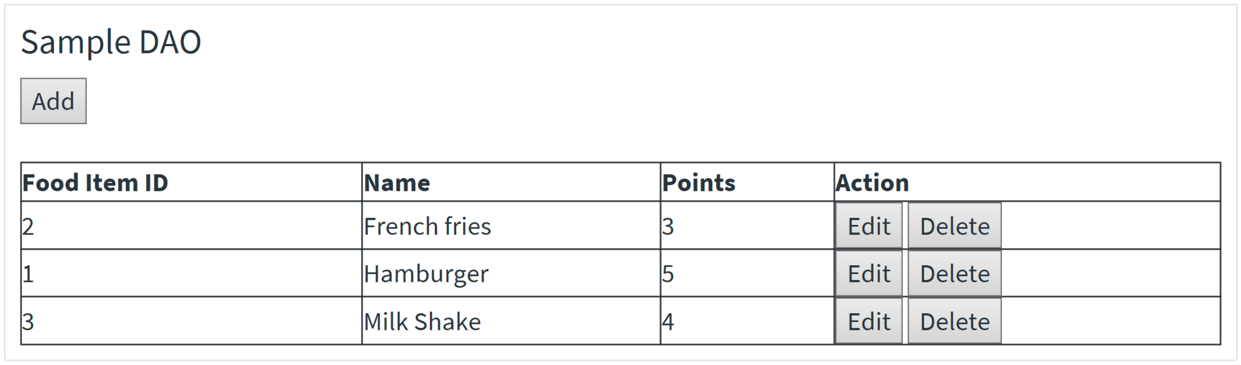
16.1 Upgrading a GenericPortlet

It's common to create portlets that extend `javax.portlet.GenericPortlet`. After all, `GenericPortlet` provides a default `javax.portlet.Portlet` interface implementation. Upgrading a `GenericPortlet` is straightforward and takes only two steps:

1. Adapt the portlet to 7.0's API using the Upgrade Planner.

2. Resolve its dependencies.

This tutorial demonstrates upgrading a Liferay Plugins SDK 6.2 sample portlet called *Sample DAO* (project `sample-dao-portlet`).



Sample DAO

Add

Food Item ID	Name	Points	Action
2	French fries	3	Edit Delete
1	Hamburger	5	Edit Delete
3	Milk Shake	4	Edit Delete

Figure 16.1: The `sample-dao-portlet` lets users manage food items.

The sample portlet lets users view, add, edit, and delete food items from a listing. For reference, you can download the pre-upgraded portlet code and the upgraded code.

The sample portlet has the following characteristics:

- Extends `GenericPortlet`
- View layer implemented by JSPs
- Persists models using the Data Access Object (DAO) design pattern
- Specifies database connection information in a properties file
- Manages dependencies via Ant/Ivy
- Developed in a Liferay Plugins SDK 6.2

The portlet uses a traditional Plugins SDK portlet project folder structure.

Upgrading most `GenericPortlet` portlets involves these steps:

1. Adapt the code to 7.0's API
2. Resolve dependencies

Since the sample portlet's dependencies haven't changed, upgrading it involves only adapting the code to 7.0's API. The Upgrade Planner facilitates updating the code and resolving compilation issues quickly.

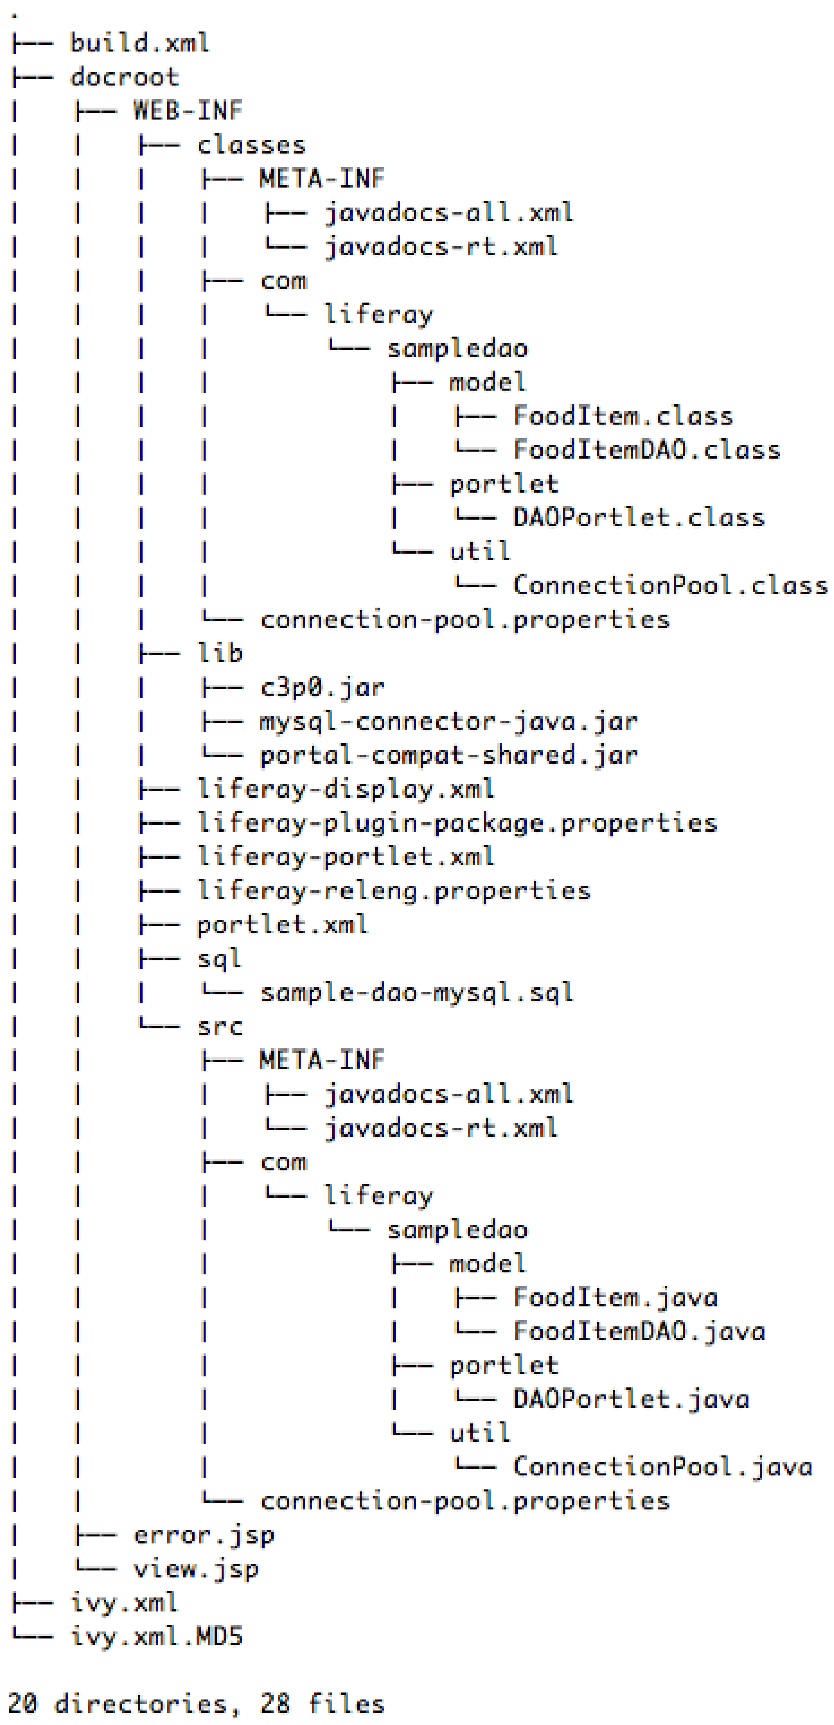
Note: Refer to tutorial Resolving a Plugin's Dependencies if you need to adapt to dependency changes.

You deploy a `GenericPortlet` to 7.0 in the same way you deploy to Portal 6.x. When the plugin WAR file lands in the `[Liferay_Home]/deploy` folder, Liferay DXP's Plugin Compatibility Layer converts the WAR to a Web Application Bundle (WAB) and installs the portlet as a WAB to Liferay DXP's OSGi runtime.

On deploying an upgraded portlet, the server prints messages that indicate the following portlet status:

- WAR processing
- WAB startup
- Availability to users

Deploying the sample portlet produces messages like these:



```

Figure 16.2: The `sample-dao-portlet` project uses a typical Plugins SDK portlet folder structure

```
20:57:02,571 INFO ... [com.liferay.portal.kernel.deploy.auto.AutoDeployScanner][AutoDeployDir:252] Processing sample-dao-portlet-
7.0.0.1.war
...
20:57:12,639 INFO  [fileinstall-C:/portals/liferay-dxp-digital-enterprise-7.0-sp1/osgi/war][BundleStartStopLogger:35] STARTED sample-
dao-portlet_7.0.0.1 [996]
...
20:57:13,480 INFO  [fileinstall-C:/portals/liferay-dxp-digital-enterprise-7.0-sp1/osgi/war][PortletHotDeployListener:313] 1 portlet for sample-
dao-portlet is available for use
```

The portlet is now available on Liferay DXP.

You've learned how to upgrade and deploy a portlet that extends `GenericPortlet`. You adapt the code, resolve dependencies, and deploy the portlet as you always have. It's just that easy!

Migrating Data Upgrade Processes

16.2 Upgrading a Servlet-based Portlet

Servlet-based portlets have little overhead and are easy to upgrade. This tutorial shows you how to upgrade them and refers to code from before and after upgrading a sample servlet-based portlet called *Sample JSON* (project `sample-json-portlet`). The portlet shows a *Click me* link. When users click the link, the Liferay logo appears.

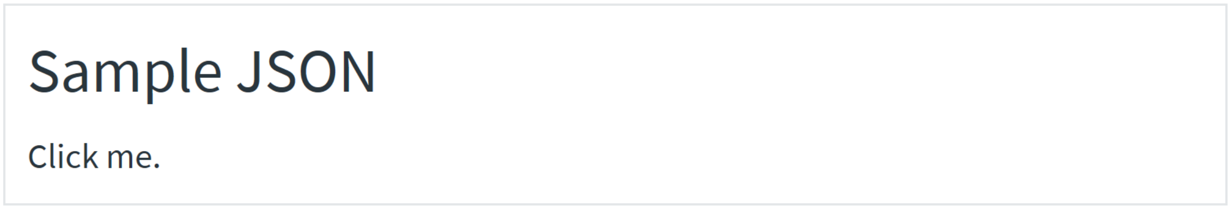

Figure 16.3: The Sample JSON portlet displays text stating *Click me* that you can click to initiate an action.

To get the most from this tutorial, you can download and refer to the original sample portlet source code and the upgraded source code.

Here are the sample portlet's characteristics:

- Processes requests using a servlet that extends `javax.servlet.HttpServlet`
- View layer implemented by JSPs
- Processes data using JSON objects
- Relies on manual dependency management
- Depends on third-party libraries that Liferay Portal 6.2 provides
- Embeds additional dependencies in its `WEB-INF/lib` folder
- Developed in a Liferay Plugins SDK 6.2

Follow these steps to upgrade a servlet-based portlet:

1. Adapt the code to 7.0's API

2. Resolve dependencies

The Upgrade Planner makes adapting a portlet's code straightforward, and it automates much of the process.

The sample portlet relied on Liferay Portal to provide several dependency JAR files. Here's the `portal-dependency-jars` property from the portlet's `liferay-plugin-package.properties` file:

```
portal-dependency-jars=\
    dom4j.jar,\
    jabsorb.jar,\
    json-java.jar
```

Instructions for using packages that Liferay DXP exports are found here. 7.0's core system exports the package this portlet needs from each of the above dependency JARs.

The upgraded sample portlet continues to specify these JARs in the `portal-dependency-jars` property. They're made available to the portlet at compile time. But to avoid packages from compile time conflicting with the core system's exported packages, the Liferay Plugins SDK 7.0 excludes the JARs from the plugin WAR.

Next, deploy your portlet as you always have.

The server prints messages that indicate the following portlet status:

- WAR processing
- WAB startup
- Availability to users

Note: On deploying the sample upgraded portlet, the WAB processor warns that the `portal-dependency-jars` property is deprecated.

```
 21:40:25,347 WARN  [fileinstall-...][WabProcessor:564] The property "portal-dependency-jars" is deprecated. Specified JARs may not be included in the class
```

For running on 7.0, it's fine to specify the`portal-dependency-jars` property per the instructions for using packages that @portal@ exports. After upgrading, consider using a dependency management tool in your project. This helps prepare it for future Liferay DXP versions and facilitates managing dependencies.

The portlet is installed to Liferay DXP's OSGi runtime and is available to users.

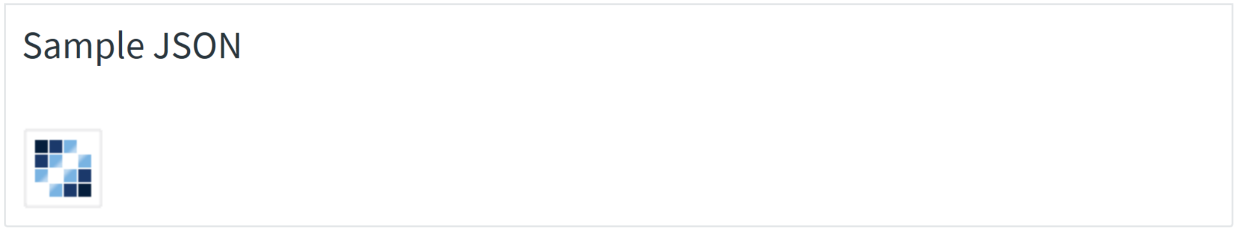

Figure 16.4: Clicking on the sample portlet's *Click me* link shows the Liferay logo.

Congratulations! You've upgraded and deployed your servlet-based portlet to 7.0.

Using the WAB Generator
Migrating Data Upgrade Processes

16.3 Upgrading a Liferay MVC Portlet

Liferay's MVC Portlet framework is used extensively in Liferay's portlets and is a popular choice for Liferay Portal 6.2 portlet developers. The `MVCPortlet` class is a lightweight extension of `javax.portlet.GenericPortlet`. Its `init` method saves you from writing a lot of boilerplate code. MVC portlets can upgraded to 7.0 without a hitch.

Upgrading a Liferay MVC Portlet involves these steps:

1. Adapt the code to 7.0's API

2. Resolve dependencies

Liferay's Upgrade Planner identifies code affected by the new API, explains the API changes and how to adapt to them, and in many cases, provides options for adapting the code automatically.

After upgrading your portlet, deploy it the same way you always do.

The server prints messages that indicate the following portlet status:

- WAR processing
- WAB startup
- Availability to users

You've upgraded and deployed your Liferay MVC Portlet on your 7.0 instance. Have fun showing off your upgraded portlet!

Migrating Data Upgrade Processes

16.4 Upgrading Portlets that use Service Builder

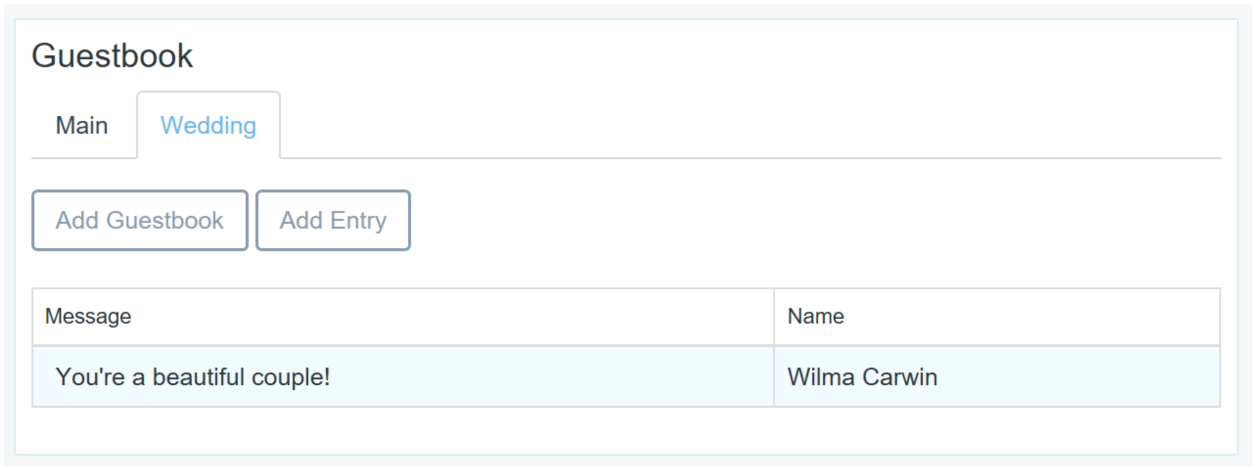
7.0 continues to use Service Builder, so you can focus on your application's business logic instead of its persistence details. It still generates model classes, local and remote services, and persistence.

This tutorial demonstrates upgrading a Liferay Plugins SDK 6.2 portlet called Guestbook portlet (project `guestbook-portlet`). It's from the Writing a Data-Driven Application section of the Liferay Portal 6.2 Learning Path Writing a Liferay MVC Application.

To get the most from this tutorial, you can download and refer to the original portlet source code and the upgraded source code.

The Guestbook portlet has the following characteristics:

- Extends `MVCPortlet`
- Separate Model, View, and Controller layers
- Persistence by Hibernate under Service Builder
- View layer implemented by JSPs



Message	Name
You're a beautiful couple!	Wilma Carwin

Figure 16.5: The Guestbook portlet to model guestbooks and guestbook entries.

- Relies on manual dependency management
- Developed in a Liferay Plugins SDK 6.2

Upgrading most Service Builder Portlets involves these steps:

1. Adapt the code to 7.0's API
2. Resolve dependencies
3. Build the services

Start by adapting the code.

1. Adapt the code to 7.0's API

Use the Upgrade Planner to update the code and resolve compilation issues quickly. Then fix any remaining compilation errors manually.

The Guestbook portlet has the following compilation error:

```
/html/guestbook/view.jsp(58,1) PWC6131: Attribute total invalid for tag search-container-results according to TLD
```

The `view.jsp` file specifies a tag library attribute `total` that doesn't exist in 7.0's `liferay-ui` tag library. Notice the second attribute `total`.

```
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId,
                    guestbookId, searchContainer.getStart(),
                    searchContainer.getEnd())%>"
    total="<%=EntryLocalServiceUtil.getEntriesCount(scopeGroupId,
                    guestbookId)%>" />
```

Remove the total attribute assignment to make the tag like this:

```
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId,
                    guestbookId, searchContainer.getStart(),
                    searchContainer.getEnd())%>" />
```

That's the Guestbook portlet's only compilation error you need to fix manually.

2. Resolve dependencies

Since the Guestbook portlet's dependencies haven't changed, there aren't any dependencies to resolve.
If you need to adapt a portlet's dependencies, refer to tutorial Resolving a Plugin's Dependencies.

3. Build the services

Build the services as you did in Liferay Portal 6.2.
The Guestbook portlet's `service.xml` file specifies exception class names in `exception` elements.

```
<service-builder package-path="com.liferay.docs.guestbook">
    ...
    <exceptions>
        <exception>GuestbookName</exception>
        <exception>EntryName</exception>
        <exception>EntryMessage</exception>
        <exception>EntryEmail</exception>
    </exceptions>
</service-builder>
```

In Liferay Portal 6.2, Service Builder generates exception classes to the path attribute `package-path` specifies. In 7.0, Service Builder generates them to `[package-path]/exception`.
Old path:

```
[package-path]
```

New path:

```
[package-path]/exception
```

For example, the Guestbook portlet's package path is `com.liferay.docs.guestbook`. Its exception class for `exception` element `GuestbookName` is generated to `docroot/WEB-INF/service/com/liferay/docs/guestbook/exception`. Classes that use the exception must import `com.liferay.docs.guestbook.exception.GuestbookNameException`.
Update references to your portlet's exception classes.
Deploy the portlet as you normally would. The server prints messages indicating the following portlet status:

- WAR processing
- WAB startup
- Availability to users

Deploying the Guestbook portlet produces these messages:

```
19:36:27,591 INFO  [RMI TCP Connection(27)-192.168.1.110][BaseAutoDeployListener:42] Copying portlets for C:\portals\liferay-ce-portal-
7.0-ga3-upgrading-portlets\tomcat-8.0.32\temp\20170710193627556LFQNRFGO\guestbook-portlet-7.0.0.1.war
19:36:27,973 INFO  [RMI TCP Connection(27)-192.168.1.110][BaseDeployer:873] Deploying guestbook-portlet-7.0.0.1.war

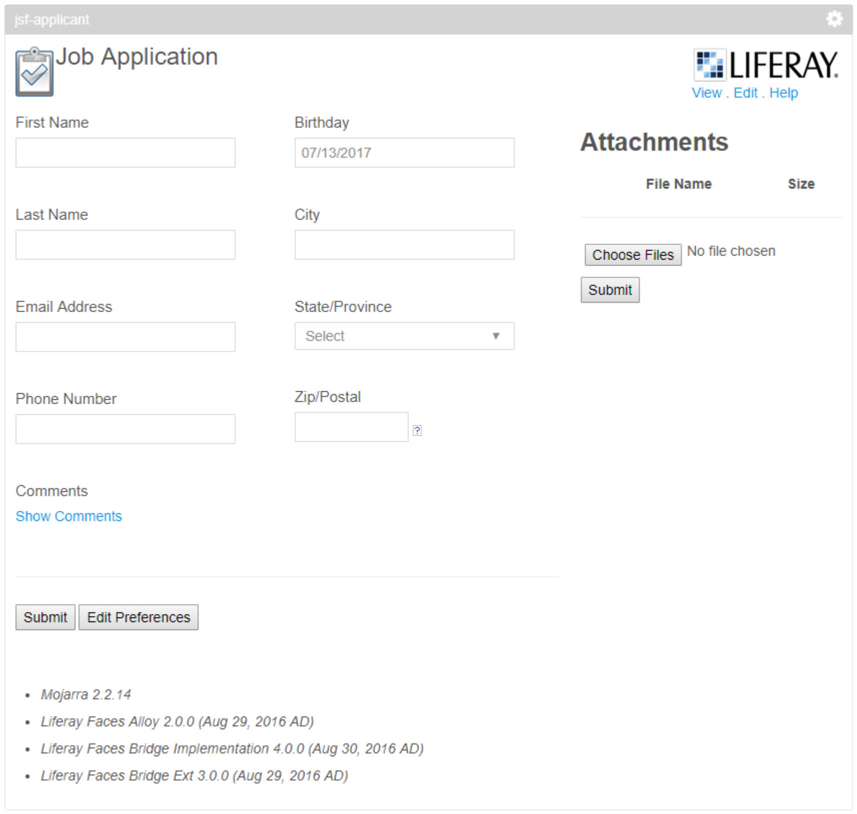
16.5 Upgrading a Liferay JSF Portlet

Liferay JSF portlets are easy to upgrade and require few changes. They interface with the Liferay Faces project, which encapsulates Liferay DXP's Java API and JavaScript code. Because of this, upgrading JSF portlets to 7.0 requires only updating dependencies.

There are two ways to find a JSF portlet's dependencies for 7.0:

- The http://liferayfaces.org/ home page lets you look up the dependencies (Gradle or Maven) by Liferay DXP version, JSF version, and component suites.
- The Liferay Faces Version Scheme article's tables list artifacts by Liferay DXP version, JSF version, portlet version, and AlloyUI and Metal component suite version.

In this tutorial, you'll see how easy it is to upgrade a Liferay Portal 6.2 JSF portlet (JSF 2.2) to 7.0 by upgrading the sample JSF Applicant portlet. This portlet provides a job application users can submit.



- Mojarra 2.2.14
- Liferay Faces Alloy 2.0.0 (Aug 29, 2016 AD)
- Liferay Faces Bridge Implementation 4.0.0 (Aug 30, 2016 AD)
- Liferay Faces Bridge Ext 3.0.0 (Aug 29, 2016 AD)

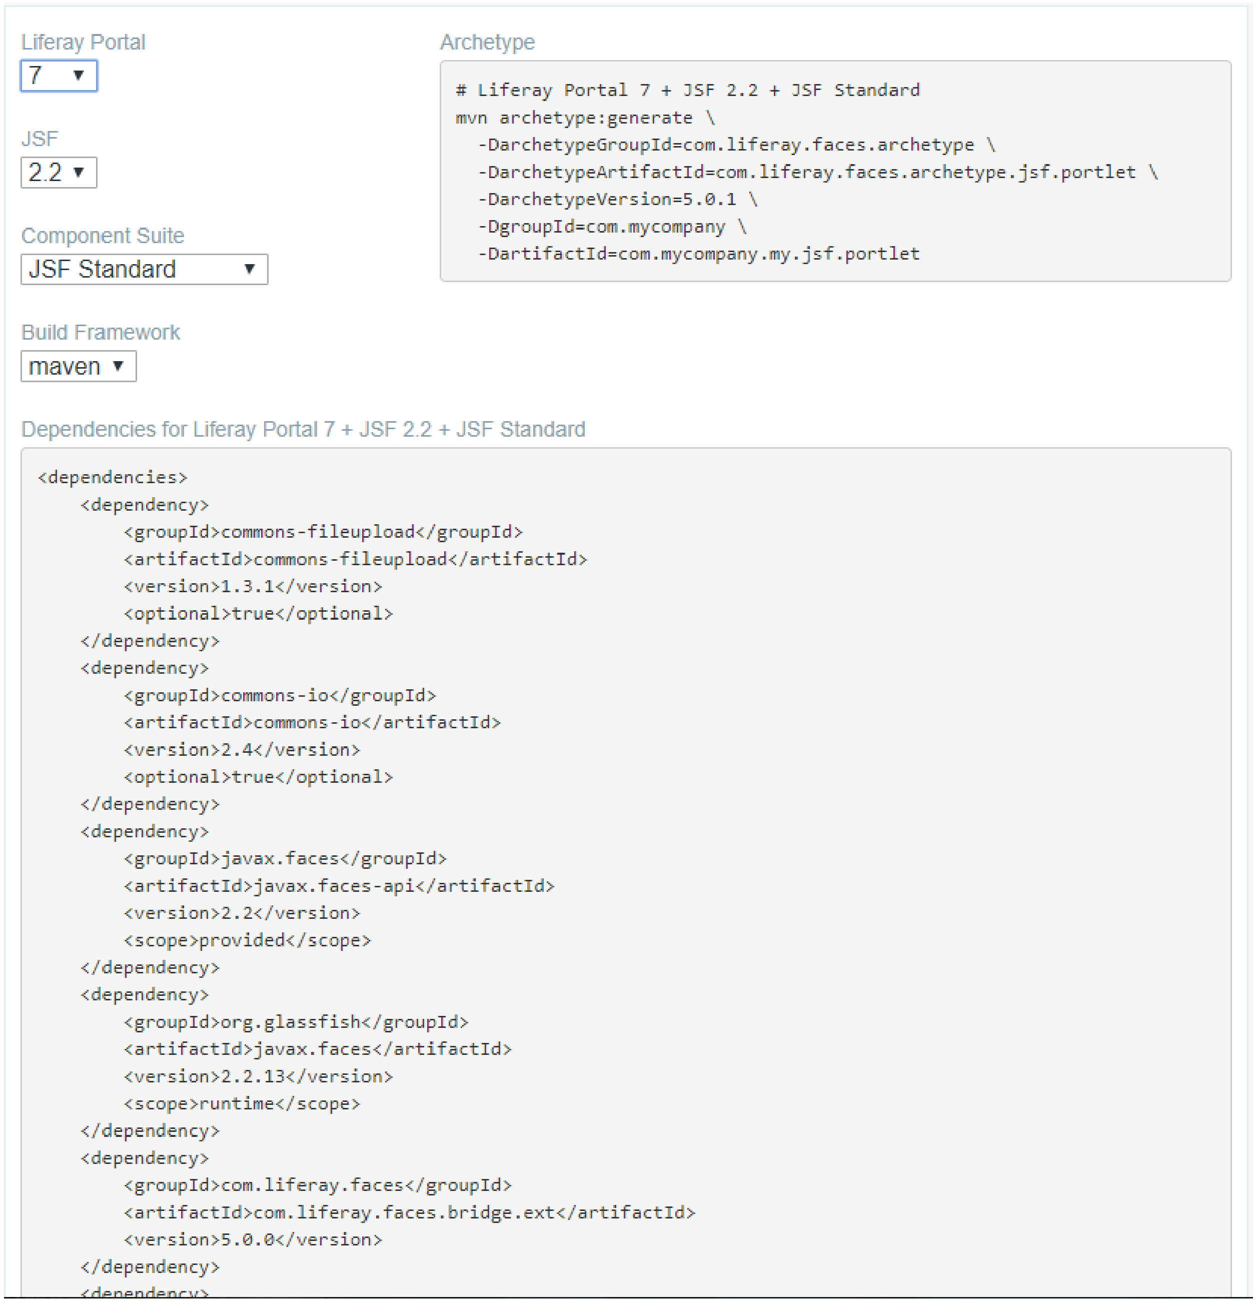
Figure 16.6: The JSF Applicant portlet provides a job application for users to submit.

For reference, you can download the pre-upgraded portlet code and the upgrade portlet code. This sample project uses Maven.

Follow these steps to upgrade your Liferay JSF portlet.

1. Open your Liferay JSF portlet's build file (e.g., `pom.xml`, `build.gradle`) to where the dependencies are configured.

2. Navigate to the http://liferayfaces.org/ site and generate a dependency list by choosing the environment to which you want to upgrade your portlet.



Liferay Portal: 7

JSF: 2.2

Component Suite: JSF Standard

Build Framework: maven

Archetype

```
# Liferay Portal 7 + JSF 2.2 + JSF Standard
mvn archetype:generate \
  -DarchetypeGroupId=com.liferay.faces.archetype \
  -DarchetypeArtifactId=com.liferay.faces.archetype.jsf.portlet \
  -DarchetypeVersion=5.0.1 \
  -DgroupId=com.mycompany \
  -DartifactId=com.mycompany.my.jsf.portlet
```

Dependencies for Liferay Portal 7 + JSF 2.2 + JSF Standard

```
<dependencies>
    <dependency>
        <groupId>commons-fileupload</groupId>
        <artifactId>commons-fileupload</artifactId>
        <version>1.3.1</version>
        <optional>true</optional>
    </dependency>
    <dependency>
        <groupId>commons-io</groupId>
        <artifactId>commons-io</artifactId>
        <version>2.4</version>
        <optional>true</optional>
    </dependency>
    <dependency>
        <groupId>javax.faces</groupId>
        <artifactId>javax.faces-api</artifactId>
        <version>2.2</version>
        <scope>provided</scope>
    </dependency>
    <dependency>
        <groupId>org.glassfish</groupId>
        <artifactId>javax.faces</artifactId>
        <version>2.2.13</version>
        <scope>runtime</scope>
    </dependency>
    <dependency>
        <groupId>com.liferay.faces</groupId>
        <artifactId>com.liferay.faces.bridge.ext</artifactId>
        <version>5.0.0</version>
    </dependency>
    <dependency>
```

Figure 16.7: The Liferay Faces site gives you options to generate dependencies for many environments.

3. Compare the generated dependencies with your portlet's dependencies and make any necessary updates. For the sample JSF Applicant portlet, only one Liferay Faces dependency requires updating:

   ```
   <dependency>
       <groupId>com.liferay.faces</groupId>
       <artifactId>com.liferay.faces.bridge.ext</artifactId>
       <version>3.0.0</version>
   </dependency>
   ```

   The Liferay Faces Bridge EXT dependency must be updated to version 5.0.0 for 7.0. The updated dependency should look like this:

   ```
   <dependency>
       <groupId>com.liferay.faces</groupId>
       <artifactId>com.liferay.faces.bridge.ext</artifactId>
       <version>5.0.0</version>
   </dependency>
   ```

That's it! Your Liferay JSF portlet is upgraded and deployable to 7.0!

You deploy a Liferay JSF portlet to 7.0 the same way you deploy to Portal 6.x. When the plugin WAR file lands in the `[Liferay_Home]/deploy` folder, Liferay DXP's Plugin Compatibility Layer converts the WAR to a Web Application Bundle (WAB) and installs the portlet as a WAB to Liferay DXP's OSGi runtime.

On deploying an upgraded portlet, the server prints messages that indicate the following portlet status:

- WAR processing
- WAB startup
- Availability to users

Deploying a Liferay JSF portlet produces messages like these:

```
13:41:43,690 INFO ... [com.liferay.portal.kernel.deploy.auto.AutoDeployScanner][AutoDeployDir:252] Processing com.liferay.faces.demo.jsf.applicant.portlet-
1.0.war
...
13:42:03,522 INFO  [fileinstall-C:/liferay-ce-portal-7.0-ga4/osgi/war][BundleStartStopLogger:35] STARTED com.liferay.faces.demo.jsf.applicant.portlet-
1.0_4.1.0 [503]
...
13:42:05,169 INFO  [fileinstall-C:/liferay-ce-portal-7.0-ga4/osgi/war][PortletHotDeployListener:293] 1 portlet for com.liferay.faces.demo.jsf.applicant.port
1.0 is available for use
```

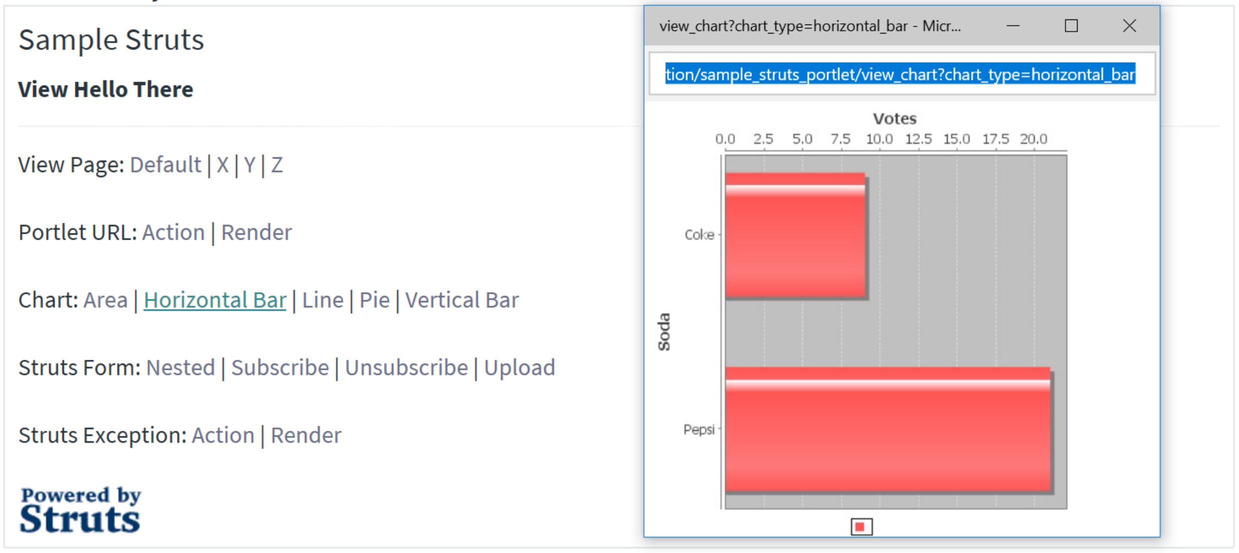
After the portlet deployment is complete, it's available on Liferay DXP.

You've learned how to upgrade and deploy a Liferay JSF portlet. You resolved dependencies and deployed the portlet as you always have. It's just that easy!

16.6 Upgrading a Struts Portlet

Struts is a stable, widely adopted framework that implements the Model View Controller (MVC) design pattern. If you have a Struts portlet for Liferay Portal 6.2, you can upgrade it to 7.0.

Upgrading Struts portlets to 7.0 is easier than you might think. Liferay DXP lets you continue working with Struts portlets as Java EE web applications. On deploying a Struts portlet Web Application aRchive (WAR), Liferay DXP's Web Application Bundle (WAB) Generator creates an OSGi module (bundle) for the portlet and installs it to Liferay's OSGi framework. The Struts portlet behaves just as it did in 6.2 on your 7.0 site.



Sample Struts
View Hello There
View Page: Default | X | Y | Z
Portlet URL: Action | Render
Chart: Area | Horizontal Bar | Line | Pie | Vertical Bar
Struts Form: Nested | Subscribe | Unsubscribe | Upload
Struts Exception: Action | Render
Powered by Struts

tion/sample_struts_portlet/view_chart?chart_type=horizontal_bar
Votes
0.0 2.5 5.0 7.5 10.0 12.5 15.0 17.5 20.0
Soda
Coke
Pepsi

Figure 16.8: The Sample Struts portlet's charts compare fictitious soft drink survey results.

This tutorial demonstrates how to upgrade a portlet that uses the Struts 1 Framework and refers to Liferay's Sample Struts portlet (Sample Struts) as an example. Sample Struts uses several Struts features to show page navigation, `Action` and `ActionForm` Controller classes, exceptions, and more.

Here are the sample portlet's characteristics:

- Model class (`Book`)
- View comprised of JSPs that leverage Struts tag libraries
- `Action` classes (Controllers) for handling requests and responses
- `ActionForm` classes for interacting with models and forwarding requests to `Action`s
- Visual component reuse with Tiles
- Internationalization using Action Messages and resource bundles
- Form validation using the Validator Framework
- Error management through Action Errors

You can follow this tutorial to upgrade your Struts portlet. Along the way, you can examine the Sample Struts portlet source code from before and after its upgrade:

- Liferay Portal 6.2 Sample Struts portlet code

- 7.0 Sample Struts portlet code

Here's the Sample Struts portlet's folder structure:

- `sample-struts-portlet`
  - `docroot/`
    * `html/portlet/sample_struts_portlet/` → JSPs
    * `WEB-INF/`
      · `lib/` → Required third-party libraries unavailable in the Liferay DXP system

- src/
- com/liferay/samplestruts/model/ → Model classes
- com/liferay/samplestruts/servlet/ → Test servlet and servlet context listener
- com/liferay/samplestruts/struts/
- action/ → Action classes that return View pages to the client
- form/ → ActionForm classes for model interaction
- render/ → Action classes that present additional pages and handle input
- SampleException.java → Exception class
- content/test/ → Resource bundles
- META-INF/ → Javadoc
- tld/ → Tag library definitions
- liferay-display.xml → Sets the application category
- liferay-plugin-package.properties → Sets metadata and portal dependencies
- liferay-portlet.xml → Maps descriptive role names to roles
- liferay-releng.properties → (internal) Release properties
- portlet.xml → Defines the portlet and its initialization parameters and security roles
- struts-config.xml → Struts configuration
- tiles-defs.xml → Struts Tile definitions
- validation.xml → Defines form inputs for validation
- validation-rules.xml → Struts validation rules
- web.xml → Web application descriptor

– build.xml → Apache Ant build file

Upgrading a Struts portlet involves these steps:

1. Adapt the code to Liferay 7.0's API
2. Resolve dependencies

Adapting the code to Liferay 7.0's API

Liferay's Upgrade Planner identifies code affected by the new API, explains the API changes and how to adapt to them, and in many cases, provides options for adapting the code automatically.

Adapting the Sample Struts portlet's code is straightforward. Resolving its dependencies is more involved.

Resolving dependencies

The Liferay Portal 6.2 Sample Struts portlet depends on Liferay Portal to provide required third-party libraries and tag library definitions (TLDs). The portal-dependency-jars and portal-dependency-tlds properties in the portlet's liferay-plugin-package.properties specifies them:

```
portal-dependency-jars=\
    antlr2.jar,\
    commons-beanutils.jar,\
    commons-collections.jar,\
    commons-digester.jar,\
    commons-fileupload.jar,\
    commons-io.jar,\
    commons-lang.jar,\
    commons-validator.jar,\
    jcommon.jar,\
    jfreechart.jar,\
    oro.jar,\
    portals-bridges.jar,\
    struts.jar

portal-dependency-tlds=\
    struts-bean.tld,\
    struts-bean-el.tld,\
    struts-html.tld,\
    struts-html-el.tld,\
    struts-logic.tld,\
    struts-logic-el.tld,\
    struts-nested.tld,\
    struts-tiles.tld,\
    struts-tiles-el.tld
```

Resolving the tag libraries is easy.

Resolving Tag Library Definitions

7.0 continues to provide many of the same TLDs Liferay Portal 6.2 provided.

If the 7.0 application's `WEB-INF/tld` folder contains a TLD you need, add it to your portlet's `portal-dependency-tlds` property in the `liferay-plugin-package.properties` file. If the folder doesn't contain the TLD, find the TLD on the web, download it, and add it to your portlet's `WEB-INF/tld` folder.

Resolving Third-Party Libraries

Third-party libraries listed as `portal-dependency-jars` in a 6.x portlet's `liferay-plugin-package.properties` file might not be provided by 7.0. Providing fewer libraries streamlines Liferay DXP. Liferay DXP has replaced some of its libraries with newer ones.

7.0 exposes (exports) Java packages instead of sharing JAR content wholesale. If you need packages Liferay DXP doesn't export, you can find and download the artifact (JAR) that provides them and add it to your portlet's `docroot/WEB-INF/lib` folder.

Here are steps for resolving the Sample Struts portlet's Java package dependencies:

1. Liferay DXP doesn't export Antlr packages. Replace the portlet's JAR file `antlr2.jar` with newer JAR `antlr.jar` from Maven Central.

2. Liferay DXP doesn't export packages from `portals-bridges.jar`. Replace the portlet's JAR file `portals-bridges.jar` with these JARs from Maven Central:

    - `portals-bridges-common.jar`
    - `portals-bridges-struts.jar`

3. Liferay DXP doesn't export packages from `struts.jar`. Replace the portlet's JAR file `struts.jar` with the following ones from Maven Central:

    - `struts-taglib.jar`
    - `struts-tiles.jar`

4. The `Import-Packages` heading in the `com.liferay.portal.bootstrap` module's `system.packages.extra.bnd` file lists the following JAR files Sample Struts requires. Since the bootstrap module exports packages from these JARs, add their names to the `portal-dependency-jars` property in the portlet's `liferay-plugin-package.properties` file. :

- `commons-beanutils.jar`
- `commons-collections.jar`
- `commons-lang.jar`

5. Add all the rest of the JARs the Sample Struts portlet depends on to the portlet's `WEB-INF/lib` folder.

The following table summarizes the sample portlet's Java dependency resolution.
Sample Struts Portlet's Dependency Resolution:
JAR | System exports the packages theportletneeds from this JAR? | Resolution | `antlr.jar` | No | add to `WEB-INF/lib` `commons-beanutils.jar` | Yes | List in `portal-dependency-jars` | `commons-collections.jar` | Yes | List in `portal-dependency-jars` | `commons-digester.jar` | No | add to `WEB-INF/lib` | `commons-fileupload.jar` | No | add to `WEB-INF/lib` | `commons-io.jar` | No | add to `WEB-INF/lib` | `commons-lang.jar` | Yes | List in `portal-dependency-jars` | `commons-validator.jar` | No | Add to `WEB-INF/lib` | `jcommon.jar` | No | Add to `WEB-INF/lib` | `jfreechart.jar` | No | Add to `WEB-INF/lib` | `oro.jar` | No | Add to `WEB-INF/lib` | `portals-bridges-common.jar` | No | Add to `WEB-INF/lib` | `portals-bridges-struts.jar` | No | Add to `WEB-INF/lib` | `struts-core.jar` | No | Add to `WEB-INF/lib` | `struts-extras.jar` | No | Add to `WEB-INF/lib` | `struts-taglib.jar` | No | Add to `WEB-INF/lib` | `struts-tiles.jar` | No | Add to `WEB-INF/lib` |

Note: The official Sample Struts portlet for 7.0 uses Apache Ant/Ivy to manage dependencies.

For more details on resolving dependencies, see the tutorial Resolving a Plugin's Dependencies.
You've resolved the Sample Struts portlet's dependencies. It's ready to deploy.

Important: Setting Portal property `jsp.page.context.force.get.attribute` (described in the JSP section) to `true` (default) forces calls to `com.liferay.taglib.servlet. PageContextWrapper#findAttribute(String)` to use `getAttribute(String)`. Although this improves performance by avoiding unnecessary fall-backs, it can cause attribute lookup problems in Struts portlets. To use Struts portlets in your sites, makes sure to set the Portal property `jsp.page.context.force.get.attribute` to `false` in a file `[Liferay-Home]/portal-ext.properties`.

```
jsp.page.context.force.get.attribute=false
```

Deploy the Struts portlet as you normally would. The server prints messages indicating the following portlet status:

- WAR processing
- WAB startup
- Availability to users

Deploying the Sample Struts portlet produces these messages:

```
00:15:20,344 INFO  [com.liferay.portal.kernel.deploy.auto.AutoDeployScanner][AutoDeployDir:252] Processing sample-struts-portlet-

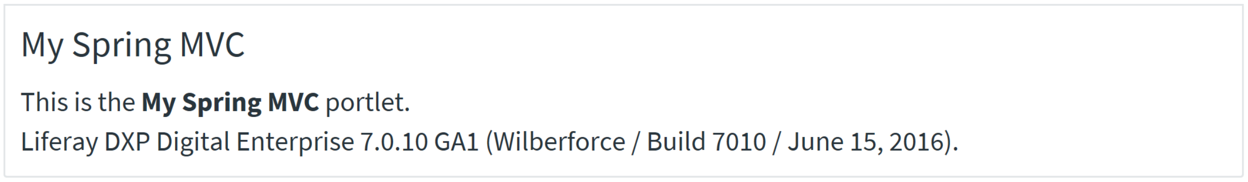
16.7 Upgrading a Spring MVC portlet

The Spring Portlet MVC framework facilitates injecting dependencies and implementing the Model View Controller pattern in portlets. If you use this framework in a portlet for Liferay Portal 6.x, you can upgrade it to 7.0.

This tutorial demonstrates upgrading a Spring MVC portlet called My Spring MVC (project `my-spring-mvc-portlet`). It's a bare-bones portlet created from the Plugins SDK's `spring_mvc` template.



My Spring MVC

This is the **My Spring MVC** portlet.
Liferay DXP Digital Enterprise 7.0.10 GA1 (Wilberforce / Build 7010 / June 15, 2016).

Figure 16.9: My Spring MVC portlet shows its name and Liferay DXP's information.

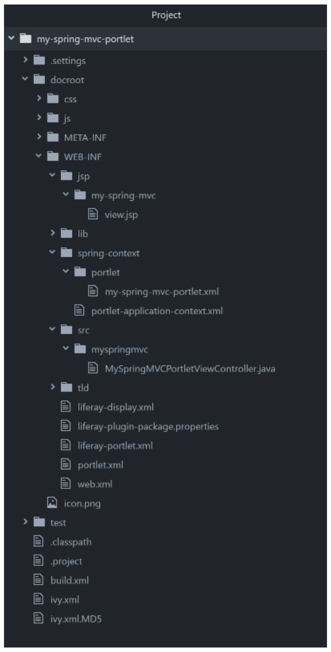
To follow along, download and refer to the original source code and the upgraded source code.

The figure below shows the `my-spring-mvc-portlet` project.

These files have Spring-related content:

- `view.jsp` → Shows the portlet's name and Liferay DXP's release information.
- `my-spring-mvc-portlet.xml` → Liferay DXP uses this context file for the portlet.
- `portlet-applications-context.xml` → Spring's `SpringContextLoaderListener` class uses this context file.
- `MySpringMVCPortletviewController` → Maps `VIEW` requests to the `view.jsp` and assigns Liferay DXP release information to a model attribute.
- `portlet.xml` → References context configuration file `my-spring-mvc-portlet.xml` and specifies a dispatcher for registered portlet request handlers.
- `web.xml` → References context configuration file `portlet-application-context.xml` and specifies a `ViewRendererServlet` to convert portlet requests and responses to HTTP servlet requests and responses.

Here are the Spring MVC portlet upgrade steps:



```
Project
my-spring-mvc-portlet
  .settings
  docroot
    css
    js
    META-INF
    WEB-INF
      jsp
        my-spring-mvc
          view.jsp
      lib
      spring-context
        portlet
          my-spring-mvc-portlet.xml
        portlet-application-context.xml
      src
        myspringmvc
          MySpringMVCPortletViewController.java
      tld
      liferay-display.xml
      liferay-plugin-package.properties
      liferay-portlet.xml
      portlet.xml
      web.xml
    icon.png
  test
  .classpath
  .project
  build.xml
  ivy.xml
  ivy.xml.MD5
```

Figure 16.10: The `my-spring-mvc-portlet` project has traditional Liferay plugin files, Spring Portlet MVC application contexts (in `spring-context/`), and a controller class `MySpringMVCPortletviewController`.

1. Adapt the code to Liferay 7.0's API
2. Resolve dependencies

Adapt the code to Liferay 7.0's API

The Upgrade Planner facilitates updating the code and resolving compilation issues quickly.

The Upgrade Planner detects if the value of the `liferay-versions` property in your plugin's `liferay-plugin-package.properties` file needs updating and it provides an option to fix it automatically. This is the only code adaptation required by `my-spring-mvc-portlet`.

Resolve Dependencies

In Liferay Portal 6.2, `my-spring-mvc-portlet` leveraged Portal's JARs by specifying them in the `liferay-plugin-package.properties` file's `portal-dependency-jars` property. Since the property is deprecated in 7.0, you should acquire dependencies using a dependency management framework, such as Gradle, Maven, or Apache Ant/Ivy.

Converting the sample portlet plugin from a traditional plugin to a Liferay Workspace web application facilitated resolving its dependencies.

Here's the updated `my-spring-mvc-portlet`'s `build.gradle` file:

```
dependencies {
    compileOnly group: 'aopalliance', name: 'aopalliance', version: '1.0'
    compileOnly group: 'commons-logging', name: 'commons-logging', version: '1.2'
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
    compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
    compile group: 'org.jboss.arquillian.junit', name: 'arquillian-junit-container', version: '1.1.3.Final'
    compile group: 'org.jboss.arquillian.container', name: 'arquillian-tomcat-remote-7', version: '1.0.0.CR6'
    compile group: 'com.liferay', name: 'com.liferay.ant.arquillian', version: '1.0.0-SNAPSHOT'
    compile group: 'org.springframework', name: 'spring-aop', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-beans', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-context', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-core', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-expression', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-web', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-webmvc', version: '4.1.9.RELEASE'
    compile group: 'org.springframework', name: 'spring-webmvc-portlet', version: '4.1.9.RELEASE'
}
```

Some of `my-spring-mvc-portlet`'s dependency artifacts have new names.

Old name	New name
`spring-web-portlet`	`spring-webmvc-portlet`
`spring-web-servlet`	`spring-webmvc`

Maven Central provides artifact dependency information.

Note: If the Spring Framework version you're using differs from the version Liferay DXP uses, you must name your Spring Framework JARs differently from Liferay DXP's Spring Framework JARs. If you don't rename your JARs, Liferay DXP assumes you're using its Spring Framework JARs and excludes yours from the generated WAB (Web Application Bundle). Portal property `module.framework.web.generator.excluded.paths` lists Liferay DXP's Spring Framework JARs. Understanding Excluded JARs explains how to detect the Spring Framework version Liferay DXP uses.

Note: If a dependency is an OSGi module JAR and Liferay DXP already exports your plugin's required packages, *exclude* the JAR from your plugin's WAR file. This prevents your plugin from exporting the same package(s) that Liferay is already exporting. This prevents class loader collisions. To exclude a JAR from deployment, add its name to the your project's `liferay-plugin-package.properties` file's `deploy-excludes` property.

```
deploy-excludes=\
    **/WEB-INF/lib/module-a.jar,\
    **/WEB-INF/lib/module-b.jar
```

Since `my-spring-mvc-portlet`'s dependencies aren't OSGi modules, no JARs must be excluded.

To import class packages referenced by your portlet's descriptor files, add the packages to an `Import-Package` header in the `liferay-plugin-package.properties` file. See Packaging a Spring MVC Portlet for details.

If you depend on a package from Java's `rt.jar` other than its `java.*` packages, override portal property `org.osgi.framework.bootdelegation` and add it to the property's list. Go here for details.

Note: Spring MVC portlets whose embedded JARs contain properties files (e.g., `spring.handlers`, `spring.schemas`, `spring.tooling`) might be affected by issue LPS-75212. The last JAR that has properties files is the only JAR whose properties are added to the resulting WAB's classpath. Properties in other JARs aren't added.

Packaging a Spring MVC Portlet explains how to add all the embedded JAR properties.

The portlet is ready to deploy. Deploy it as you always have.

Liferay DXP's WAB Generator converts the portlet WAR to a Web Application Bundle (WAB) and installs the WAB to Liferay's OSGi Runtime Framework.

Migrating Plugins SDK Projects to Workspace and Gradle

Using Dependency Management Tools

Using the WAB Generator

16.8 Upgrading Web Plugins

Web plugins are regular Java EE web modules designed to work with Liferay DXP. These plugins were stored in the `webs` folder of the legacy Plugins SDK.

Upgrading a Liferay web plugin involves these steps:

1. Adapt the plugin to 7.0's API using the Liferay Upgrade Planner. When running the planner's *Fix Upgrade Problems* step, many of the existing issues are autocorrected. For remaining issues, the planner identifies code affected by the new API and ways to adapt it.

2. Resolve its dependencies

3. Deploy it.

After deploying the upgraded portlet, the server prints messages that indicate the following portlet status:

- WAR processing
- WAB startup
- Availability to users

You've upgraded and deployed your Liferay web plugin on your 7.0 instance. Great job!

16.9 Upgrading Ext Plugins

Ext plugins let you use internal APIs and even let you overwrite Liferay DXP core files. This puts your deployment at risk of being incompatible with security, performance, or feature updates released by Liferay. When upgrading to a new version of Liferay DXP, you must review all changes and manually modify your Ext projects to merge your changes with Liferay DXP's.

During your upgrade to 7.0, it's highly recommended to leverage an extension point to customize Liferay DXP instead of using you existing Ext plugin, if possible. 7.0 provides many extension points that let you customize almost every detail of Liferay DXP. If there's a way to customize what you want with an extension point, do it that way instead. See the More Extensible, Easier to Maintain section for more details on the advantages of using Liferay DXP's extension points.

For more information on Ext projects, how to decide if you need one, and how to manage them, see the Customization with Ext section.

16.10 Upgrading the Liferay Maven Build

If you're an avid Maven user and have been using it for Liferay Portal 6.2 project development, you must upgrade your Maven build to be compatible with 7.0 development. There are two main parts of the Maven environment upgrade process that you must address:

- Upgrading to new 7.0 Maven plugins
- Updating Liferay Maven artifact dependencies

For more information on using Maven with 7.0, see the Maven tutorial section. For a guided and expedited upgrade process for your Maven build, try the Upgrade Planner.

You'll start off by upgrading your Maven environment's Liferay Maven plugins.

Upgrading to New 7.0 Maven Plugins

The biggest change for your project's build plugins is the removal of the `liferay-maven-plugin`. Liferay now provides several individual Maven plugins that accomplish specific tasks. For example, you can configure Maven plugins for Liferay's CSS Builder, Service Builder, Theme Builder, etc. With smaller plugins available to accomplish specific tasks in your project, you no longer have to rely on one large plugin that provides many things you may not want.

For example, suppose your Liferay Portal 6.2 project was using the `liferay-maven-plugin` for Liferay CSS Builder only. First, you should remove the legacy `liferay-maven-plugin` plugin dependency from your project's `pom.xml` file:

```
<plugin>
    <groupId>com.liferay.maven.plugins</groupId>
    <artifactId>liferay-maven-plugin</artifactId>
    <version>${liferay.version}</version>
    <configuration>
        <autoDeployDir>${liferay.auto.deploy.dir}</autoDeployDir>
        <liferayVersion>${liferay.version}</liferayVersion>
        <pluginType>portlet</pluginType>
    </configuration>
</plugin>
```

Then, add the CSS Builder plugin dependency to your project's `pom.xml` file:

```
<plugin>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.css.builder</artifactId>
    <version>1.0.21</version>
    <executions>
        <execution>
            <id>default-build</id>
            <phase>generate-sources</phase>
            <goals>
                <goal>build</goal>
            </goals>
        </execution>
    </executions>
        <configuration>
            <docrootDirName>src/main/webapp</docrootDirName>
        </configuration>
</plugin>
```

Some common Liferay Maven plugins are listed below, with their corresponding artifact IDs and tutorials explaining how to configure them:

Common Liferay Maven Plugins

Name	Artifact ID	Tutorial
CSS Builder	com.liferay.css.builder	Compiling SASS Files in a Maven Project
Lang Builder	com.liferay.lang.builder	Coming Soon
Service Builder	com.liferay.portal.tools.service.builder	Using Service Builder in a Maven Project
Theme Builder	com.liferay.portal.tools.theme.builder	Building Themes in a Maven Project

In Liferay Portal 6.2, you were also required to specify all your app server configuration settings. For example, your parent POM probably contained settings similar to these:

```
<properties>
    <liferay.app.server.deploy.dir>
        E:\liferay-portal-6.2.0-ce-ga1\tomcat-7.0.42\webapps
    </liferay.app.server.deploy.dir>

    <liferay.app.server.lib.global.dir>
        E:\liferay-portal-6.2.0-ce-ga1\tomcat-7.0.42\lib\ext
    </liferay.app.server.lib.global.dir>

    <liferay.app.server.portal.dir>
        E:\liferay-portal-6.2.0-ce-ga1\tomcat-7.0.42\webapps\root
    </liferay.app.server.portal.dir>

    <liferay.auto.deploy.dir>
        E:\liferay-portal-6.2.0-ce-ga1\deploy
    </liferay.auto.deploy.dir>

    <liferay.version>
        6.2.0
    </liferay.version>

    <liferay.maven.plugin.version>
        6.2.0
    </liferay.maven.plugin.version

</properties>
```

This is no longer required in 7.0 because Liferay's Maven tools no longer rely on your Liferay DXP installation's specific versions. You should remove them from your POM file.

Awesome! You've learned about the new Maven plugins available to you for 7.0 development. Next, you'll learn about updating your Liferay Maven artifacts.

Updating Liferay Maven Artifact Dependencies

Many Liferay Portal 6.2 artifact dependencies you were using have changed in 7.0. See the table below for popular Liferay Maven artifacts that have changed:

Liferay Portal 6.2 Artifact ID	7.0 Artifact ID
`portal-service`	`com.liferay.portal.kernel`
`util-bridges`	`com.liferay.util.bridges`
`util-java`	`com.liferay.util.java`
`util-slf4j`	`com.liferay.util.slf4j`
`util-taglib`	`com.liferay.util.taglib`

For more information on resolving dependencies in 7.0, see the Resolving a Plugin's Dependencies tutorial.

Of course, you must also update the artifacts you're referencing for your projects. If you're using the Central Repository to install Liferay Maven artifacts, you won't need to do anything more than update the artifacts in your POMs. If, however, you're working behind a proxy or don't have Internet access, you must update your company-shared or local repository with the latest 7.0 Maven artifacts. See the Installing Liferay Maven Artifacts tutorial for instructions.

With these updates, you can easily upgrade your Liferay Maven build so you can begin developing traditional plugin projects for 7.0.

Chapter 17

Optimizing Plugins for 7.0

Once you've upgraded your plugin to 7.0, you can optimize it to take advantage of all @product-ver@ offers. If you haven't yet familiarized yourself with what's changed from Liferay Portal 6, the new benefits for developers, OSGi and modularity, and the improved tooling, make sure to do so as they'll help you understand and appreciate the optional improvements for plugins and plugin development the optimization tutorials demonstrate.

Here are some common optimizations to consider:

- Migrating to environments that help you develop and test more quickly, such as the Liferay Theme Generator for themes and Liferay Workspace for modules and web applications.
- Adapting plugins to 7.0's modular architecture and updated frameworks, such as Service Builder.
- Styling your app consistently using Lexicon –the web implementation of Liferay's Lexicon Experience Language.
- Modularizing apps to reap the benefits of modularity and all that 7.0 offers.

Several optimization tutorials are here and more are coming soon.

17.1 Migrating Traditional Plugins to Workspace Web Applications

After you've adapted your traditional plugin to Liferay DXP's API, you can continue maintaining it in the Plugins SDK. The Plugins SDK, however, is deprecated as of 7.0. Maintaining plugins in the SDK will become increasingly difficult. Liferay Workspace replaces the Plugins SDK, providing a comprehensive Gradle development environment and more. A simple command migrates traditional plugins (such as portlets) to Gradle-based web application projects. From there you can build and deploy them to 7.0 as Web ARchives (WARs).

Running the Migration Command

Blade CLI's `convert` command migrates Plugins SDK plugins to web application projects in Workspace's `wars` folder. Plugin files are re-organized to follow the standard web application folder structure.

Standard Web Application Anatomy:

- `[project root]`

- `src`
    * `main`
        - `webapp`
        - `WEB-INF`
        - `classes`
        - `lib` → Libraries
        - descriptor files
        - `css` → CSS files
        - `js` → JavaScript files
        - `icons`
        - JSP files
    * `java` → Java source
- build files

In a terminal, navigate to the Liferay Workspace root folder. Then pass your Plugins SDK project's name to Blade's `convert` command:

```
blade convert [PLUGIN_PROJECT_NAME]
```

Blade extracts the plugin from the Plugins SDK and reorganizes it in a standard web application project in Workspace's `wars` folder.

Note: You can execute `blade convert -l` to show a list of projects that can be migrated in your Plugins SDK. Run `blade convert --all` to migrate all plugin projects in your Plugins SDK to Workspace.

The image below shows the plugin files before and after they're migrated to Workspace.

The following table maps traditional plugin source files to the standard web application folder structure Workspace uses.

Plugins SDK folders to web application folders:

Files	Plugins SDK folder (old)	Web app folder (new)
Java	`docroot/WEB-INF/src`	`src/main/java`
JSPs	`docroot`	`src/main/webapp`
icons	`docroot`	`src/main/webapp`
CSS	`docroot/css`	`src/main/webapp/css`
JS	`docroot/js`	`src/main/webapp/js`
descriptors	`docroot/WEB-INF`	`src/main/webapp/WEB-INF`
libraries	`docroot/WEB-INF/lib`	`src/main/webapp/lib`

From your plugin's new location, you can invoke Workspace Gradle tasks on it and build its `.war` file.

```
blade gw war
```

To deploy the `.war`, copy it from the plugin's `build/libs` folder to the `[LIFERAY_HOME]/deploy` folder.

Welcome to your plugin's new home in Workspace!

Workspace Gradle Tasks

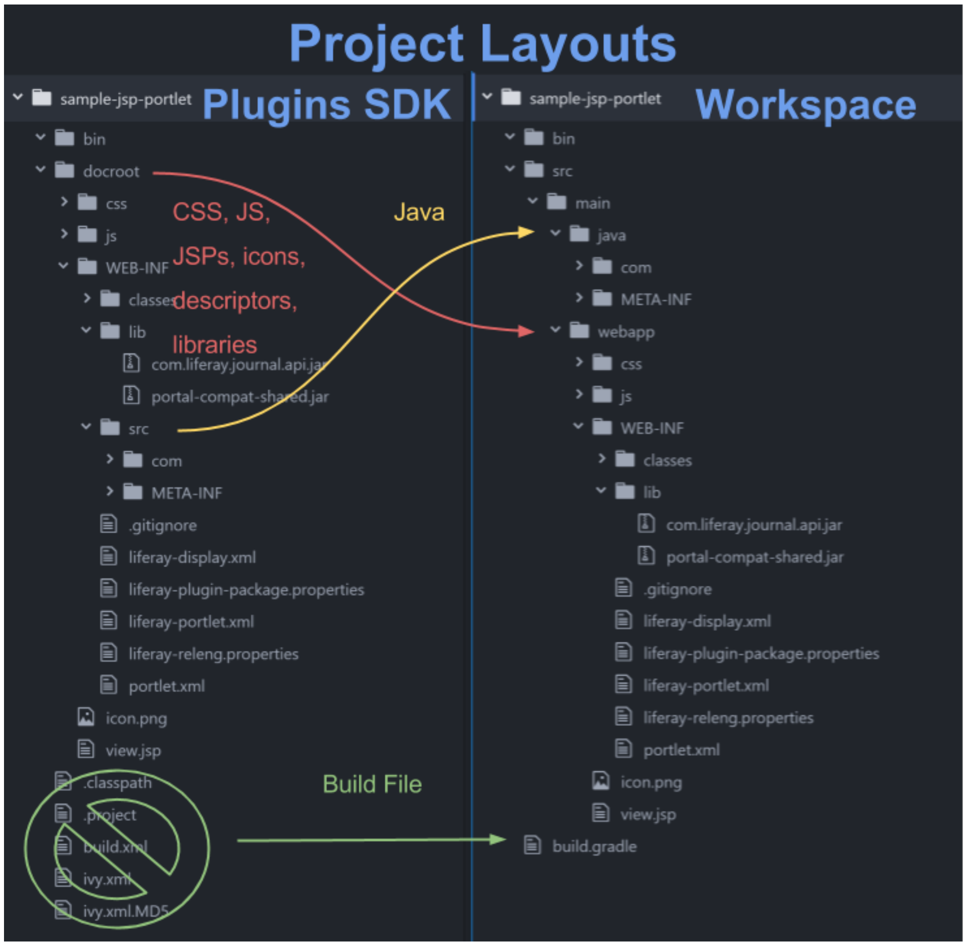

Figure 17.1: The `convert` command migrates a Plugins SDK project to a Workspace web application project. It moves Java source files to `src/main/java` and all other files/folders to `src/main/webapp`.

Chapter 18

Modularizing Plugins

As described in Benefits of Liferay 7 for Liferay 6 Developers, applications that comprise OSGi modules offer considerable advantages over monolithic applications.

The main benefit is that modular development practices structure code in ways that reduce maintenance costs. These practices involve, for example, defining contracts (such as APIs) more clearly, hiding internal classes, and handling dependencies more carefully. Related to this, module dependencies are explicitly listed within a module. Modules run only when all their dependencies are met–this can eliminate many obscure run time errors.

Splitting large applications into small independent modules lets you focus on smaller release cycles for those modules. Individual modules can be updated independently of the others. For instance, you might fix a JSP's security issue in an application's web (client) module. The issue only affects that module–none of the application's other modules need change.

The scenarios described below can help you decide whether to convert an application to modules.

When not to convert?

- You have a portlet that's JSR-168/286 compatible and you still want to be able to deploy it to another portlet container. In this case, it's best to stay with the traditional WAR model. (To eliminate this reason for not converting, Liferay is discussing with other vendors the possibility of making modular portlets a standard.)
- You're using a complex web framework that is heavily tied to the Java EE programming model and the amount of effort necessary to make it work with OSGi is more than you feel is necessary or warranted.
- You want to minimize effort to get your application to working on 7.0.

When to convert?

- You have a very large application with many lines of code. If you've got lots of developers making changes, separating the code into modules can make it easier and faster to get releases out.
- Your application has reusable parts that you want to consume outside of it. For instance, you have business logic that you're reusing in different projects. Modules let you consume their services from other modules.
- In general, you want to start reaping the benefits of modular development.

You can now make an informed decision on whether to stick with your upgraded traditional application as is or modularize it to leverage 7.0's modularity features.

18.1 Modularizing an Existing Portlet

An application with properly modularized plugins offers several benefits. You can release individually its plugins without releasing the entire application. External clients can consume services from particular plugins, without having to depend on an entire application. And by splitting up large amounts of code into concise modules, teams can more easily focus on particular areas of the application. These are just a few reasons to modularize application plugins.

In this tutorial, you'll learn how to convert your traditional application into modules. Before getting started, it's important to reiterate that the module structure shown in this tutorial is just one of many ways for structuring your application's modules. It's also important to remember that applications come in all different shapes and sizes. There may be special actions that some applications require. This tutorial provides the general process for converting to modules using Liferay's module structure.

Here's what's involved:

- Converting portlet classes and the UI
- Converting Service Builder interfaces and implementations
- Building and deploying modules

The instructions covered in this tutorial apply to both the commercial and open source versions of Liferay.

The first thing you'll do is create your application's web (client) module.

Converting Your Application's Portlet Classes and UI

The first thing you'll do is create your application's parent directory and the directory structure for your application's *web* client module. This module holds your application's portlet classes and is responsible for its UI. Before you start creating a skeleton structure for your application's modules, you should determine which modules will comprise this version of your application. If your application provides service and API classes (which is the case for all Liferay Service Builder applications), you should create separate modules for your service implementation and service API classes. This tutorial assumes the Maven project model, although any build tools or directory setup is permissible.

Note: It's recommended that you use the build plugin versions that support the latest OSGi features. The following Gradle or Maven build plugin versions should be used in their respective build frameworks:

Gradle - biz.aQute.bnd:biz.aQute.bnd.gradle:3.1.0 **or** - org.dm.gradle:gradle-bundle-plugin:0.8.1

Maven - biz.aQute.bnd:bnd-maven-plugin:3.1.0 **or** - org.apache.felix:maven-bundle-plugin:3.0.1

---

1. Create your application's parent folder. It is home for your application's independent modules and configuration files. For example, if your application's name is *Tasks*, then your parent folder could be *tasks*.

   If your application uses Liferay Service Builder, use the following Blade CLI command to generate the parent folder and service implementation and service API modules in it. If the parent folder already exists, it must be empty. This command names the parent folder after the `APPLICATION_NAME`:

   ```
   blade create -t service-builder -p [ROOT_PACKAGE] [APPLICATION_NAME]
   ```

   The `*-service` and `*-api` module folders are described later in this tutorial.

2. Create the folder structure for your web client module. You can do this automatically by using Blade CLI. The portlet tutorials demonstrate creating all different kinds of portlets.

   Navigate to your parent directory (e.g., tasks) and run the following Blade CLI command to generate a generic web client module structure:

   ```
   blade create -t mvc-portlet -p [ROOT_PACKAGE] [APPLICATION_NAME]-web
   ```

3. Replace the `/src/main/java/[APPLICATION_NAME]` folder with your root package. For instance, if your application's root package name is `com.liferay.tasks.web`, your class's directory should be `/src/main/java/com/liferay/tasks/web`. Also, remove the `init.jsp` and `view.jsp` files located in the `src/main/resources/META-INF/resources` folder. You'll insert your traditional application's Java code and JSPs, so the generated default code is not necessary.

4. Verify that your current directory structure for your application's `*-web` module matches the structure listed below:

   - `tasks`
     - `tasks-web`
       - `src`
         - `main`
         - `java`
         - `[ROOT_PACKAGE]`

         - `resources`
         - `content`
         - `Language.properties`

         - `META-INF`
         - `resources`
       - `bnd.bnd`
       - `build.gradle`

   The instructions in the rest of this sub-section only affect your application's web client module.

5. Open the `bnd.bnd` file. This is used to generate your module's `MANIFEST.MF` file that is generated when you build your project. Edit your module's `bnd.bnd` file to fit your application. For more information about configuring your module's `bnd.bnd`, visit http://bnd.bndtools.org/. You can view the `dictionary-web` module's `bnd.bnd` for a simple example below:

   ```
   Bundle-Name: Liferay Dictionary Web
   Bundle-SymbolicName: com.liferay.dictionary.web
   Bundle-Version: 1.0.6
   ```

   For a more advanced example, examine the `journal-web` module's `bnd.bnd`:

```
Bundle-Name: Liferay Journal Web
Bundle-SymbolicName: com.liferay.journal.web
Bundle-Version: 2.0.0
Export-Package:\
    com.liferay.journal.web.asset,\
    com.liferay.journal.web.dynamic.data.mapping.util,\
    com.liferay.journal.web.social,\
    com.liferay.journal.web.util
Liferay-JS-Config: /META-INF/resources/js/config.js
Liferay-Releng-Module-Group-Description:
Liferay-Releng-Module-Group-Title: Web Content
Web-ContextPath: /journal-web
```

6. Open the `build.gradle` file. This is used to specify all your module's dependencies. The `build.gradle` file that was generated for you is pre-populated with content and default dependencies related to OSGi and Liferay DXP. In the `dependencies {...}` block, you need to add the web client module's dependencies. To learn how to find and specify dependencies on Liferay API modules, refer to the reference document Finding Liferay API Modules. When deploying your module into the OSGi container, OSGi checks if the dependencies are available in the container. If the dependencies are not available in the container, your module will be unavailable. Therefore, your dependencies are not bundled with your module. Instead, they're available from Liferay's OSGi container.

7. Copy your traditional application's JSP files into the `/src/main/resources/META-INF/resources` directory. In most cases, all of your application's JSP files should reside in the web client module.

8. Your next task is to add your portlet classes, non-service classes, and non-implementation classes into your client module. Copy your portlet classes into their respective directories and ensure their package names within the class are specified correctly. Your client module can hold one class or many classes, depending on how large your application is. It's a good practice to organize your classes into sub-packages of the main package, to more easily manage them. You'll examine the `journal-web` module for an example of a client module holding many different Java classes:

- `journal-web`
    - ...
    - `src/main/java/com/liferay/journal/web/`
        - `asset`
            - [classes]
        - `configuration`
            - [classes]
        - `dynamic/data/mapping/util`
            - [classes]
        - `internal`
            - `application/list`
            - [classes]

            · custom/attributes
            · [classes]

            · dao/search
            · [classes]

            · ...

        * social

            · [classes]

        * util

            · [classes]

    - ...

```
**Note:** Many applications have service and API classes. These classes
need to live in separate implementation and API modules. You'll learn more
about creating these later in this tutorial.
```

---

9. Now that you have the necessary classes in your client module, you need to edit these classes to be compliant with OSGi. First, you need to choose a component framework to work with. Using a component framework lets you easily harness the power of OSGi. Liferay DXP uses the Declarative Services component framework and recommends that Liferay developers use it too. This tutorial assumes that you're using Declarative Services. You can, however, use any other OSGi component framework in Liferay DXP.

   Review your traditional application's XML files and migrate the configuration and metadata information to the portlet class as properties. You can do this by adding the `@Component` annotation to your portlet class and adding the necessary properties to that annotation. The end result should look similar to the following example:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.icon=/icon.png",
        "javax.portlet.name=1",
        "javax.portlet.display-name=Tasks Portlet",
        "javax.portlet.security-role-ref=administrator,guest,power-user",
        "javax.portlet.init-param.clear-request-parameters=true",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.expiration-cache=0",
        "javax.portlet.supports.mime-type=text/html",
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.info.title=Tasks Portlet",
        "javax.portlet.info.short-title=Tasks",
        "javax.portlet.info.keywords=Tasks",
    },
    service = Portlet.class
)
public class TasksPortlet extends MVCPortlet {
```

10. Convert all references of the `portletId` (e.g., `58_INSTANCE_4gtH`) to the class name of the portlet, replacing all periods with underscores (e.g., `com_liferay_web_proxy_portlet_WebProxyPortlet`).

11. If your traditional application has resource actions, you'll need to migrate those into your client module. Create the `/src/main/resources/resource-actions/default.xml` file, and copy your resource actions there. Make sure to create the `src/portlet.properties` file and add the following property:

    ```
    resource.actions.configs=resource-actions/default.xml
    ```

    As an example, you can view the Directory application's `default.xml` file.

12. Add any language keys that your application uses to the `src/main/resources/content/Language.properties` file. You should only include the language keys that are unique to your application. Your application will use the default language keys in Liferay when it is deployed.

Awesome! You've created your application's web client module and navigated through some of the most common tasks necessary to modularize your portlet classes and UI. There are certain parts of your application that may not be covered in this tutorial that you must account for. Liferay's Developer Network provides developer tutorials divided into popular areas so you can easily find the correct way to transform your legacy code to use Liferay DXP's updated best practices.

The table below serves as a quick reference guide. It summarizes the migration process for many of your application's directories, packages, and files. This is a sample table for a fictitious *tasks* applications.

Plugin Package	Module Package
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.asset`	`tasks-web/src/main/java/com.liferay.tasks.asset`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.portlet`	`tasks-web/src/main/java/com.liferay.tasks.portlet`
`tasks-portlet/docroot/WEB-INF/src/content`	`tasks-web/src/main/resources/content`
`tasks-portlet/docroot/WEB-INF/src/resource-actions`	`tasks-web/src/main/resources/resource-actions`
`tasks-portlet/docroot/WEB-INF/src/portlet.properties`	`tasks-web/src/main/resources/portlet.properties`
`tasks-portlet/docroot/init.jsp`	`tasks-web/src/main/resources/META-INF/resources/init.jsp`
`tasks-portlet/docroot/tasks`	`tasks-web/src/main/resources/META-INF/resources/tasks`
`tasks-portlet/docroot/upcoming_tasks`	`tasks-web/src/main/resources/META-INF/resources/upcoming_tasks`

Many applications only have a web client module. Larger, more complex applications, such as Liferay Service Builder applications, require additional modules to hold their service API and service implementation logic. You'll learn how to create these modules next.

Converting Your Application's Service Builder API and Implementation

In this section, you'll learn about converting a Liferay Portal 6 Service Builder application to a 7.0 style application. In the previous section, you learned how to generate your implementation and API modules. If you haven't yet run the `service-builder` Blade CLI command outlined in step 2 of the previous section, run it now. The API module holds your application's Service Builder generated API and the implementation module holds your application's Service Builder implementation.

Before you begin editing the API and implementation modules, you'll need to configure your root project (e.g., `tasks`) to recognize the multiple modules residing there. A multi-module Gradle project must have a `settings.gradle` file in the root project for building purposes. Luckily, when you generated your Service Builder project's modules using Blade CLI, the `settings.gradle` file was inserted and pre-configured for the `api` and `service` modules. You should add your `web` module into the Service Builder project's generated parent folder and define it in the `settings.gradle` file too. You'll configure your `web` module via Gradle settings later, but for now, go ahead and copy the module into the project generated by the `service-builder` template. For example, an example tasks project's root folder would look like this:

- `tasks`
    - `gradle`
    - `tasks-api`
    - `tasks-service`
    - `tasks-web`
    - `build.gradle`
    - `gradlew`
    - `settings.gradle`

Your root project directory should now be in good shape. Next, you'll learn how to use Service Builder to generate your application's service API and service implementation code.

1. Copy your traditional application's `service.xml` file and paste it into the implementation module's root directory (e.g., `tasks/tasks-service`).

2. Blade CLI generated a `bnd.bnd` file for your service implementation module. Make sure to edit this `bnd.bnd` file to fit your application. For an example of a service implementation module's BND file, examine the `export-import-service` module's BND below:

```
Bundle-Name: Liferay Export Import Service
Bundle-SymbolicName: com.liferay.exportimport.service
Bundle-Version: 4.0.0
Export-Package:\
    com.liferay.exportimport.content.processor.base,\
    com.liferay.exportimport.controller,\
    com.liferay.exportimport.data.handler.base,\
    com.liferay.exportimport.lar,\
    com.liferay.exportimport.lifecycle,\
    com.liferay.exportimport.messaging,\
    com.liferay.exportimport.portlet.preferences.processor.base,\
    com.liferay.exportimport.portlet.preferences.processor.capability,\
    com.liferay.exportimport.search,\
    com.liferay.exportimport.staged.model.repository.base,\
    com.liferay.exportimport.staging,\
    com.liferay.exportimport.xstream
Liferay-Releng-Module-Group-Description:
Liferay-Releng-Module-Group-Title: Data Management
Liferay-Require-SchemaVersion: 1.0.0
-includeresource: content=../../staging/staging-lang/src/main/resources/content
```

3. Blade CLI also generated your service implementation module's `build.gradle` file. In this file, Service Builder is already configured to generate code both in this module and in your service API module. When you run Service Builder, Java classes, interfaces, and related files are generated in your `*api` and `*service` modules. Open your service implementation module's `build.gradle` file to view the default configuration.

   As you've learned already, you don't have to accept the generated build files' defaults. Blade CLI simply generated some standard OSGi and Liferay configurations.

   For example, Service Builder is already available for you by default. Blade CLI applies the Service Builder plugin automatically when a project contains the `service.xml` file. With the Service Builder plugin already available, you don't have to worry about configuring it in your project.

4. Another important part of your service implementation module's `build.gradle` file is the `buildService{...}` block. This block configures how Service Builder runs for your project. The current configuration will generate your API module successfully, but extra configuration might be necessary in certain cases.

5. Open a terminal and navigate to your root project folder. Then run `gradlew buildService`.

   Your `service.xml` file's configuration is used to generate your application's service API and service implementation classes in their respective modules. You've also generated other custom files (related to SQL, Hibernate, Spring, etc.), depending on your `buildService {...)` block's configuration. For more information on configuration options for the Service Builder plugin, see the Service Builder Gradle Plugin reference article.

6. Now that you've run Service Builder, continue copying custom classes into your implementation module. The table below highlights popular Liferay Portal 6 classes and packages and where they should be placed in your application. This table is intended to aid in the organization of your classes and configuration files; however, remember to follow the organizational methodologies that make the most sense for your application. One size does not fit all with your modules' directory schemes.

Plugin Package	Module Package
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.model.impl`	`tasks-service/src/main/java/com.liferay.tasks.model.impl`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.service.impl`	`tasks-service/src/main/java/com.liferay.tasks.service.impl`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.service.permission`	`tasks-service/src/main/java/com.liferay.tasks.service.permission`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.service.persistence.impl`	`tasks-service/src/main/java/com.liferay.tasks.service.persistence.impl`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.social`	`tasks-service/src/main/java/com.liferay.tasks.social`
`tasks-portlet/docroot/WEB-INF/src/com.liferay.tasks.util`	`tasks-service/src/main/java/com.liferay.tasks.util`
`tasks-portlet/docroot/WEB-INF/src/custom-sql`	`tasks-service/src/main/resources/META-INF/custom-sql`

---

7. Once you've copied all of your custom classes over, run `gradlew buildService` again to generate the remaining services.

Now that your services are generated, you'll need to wire up your modules so they can reference each other when deployed to Liferay's OSGi container. Blade CLI has already partially completed this task. For example, it assumes that the service implementation module depends on the service API module.

You still need to associate the client module with the `api` and `service` modules, since they were generated separately. To do this, follow the steps below:

1. In your project's `settings.gradle` file, you must add the `web` module with the `api` and `service` modules so it's included in the Gradle build lifecycle:

```
include "tasks-api", "tasks-service", "tasks-web"
```

2. Add the `api` and `service` modules as dependencies in you client module:

```
dependencies {
    compileOnly  project(':tasks-api')
    compileOnly  project(':tasks-service')
}
```

Excellent! You've successfully generated your application's services using Service Builder. They now reside in modules, and can be deployed to 7.0.

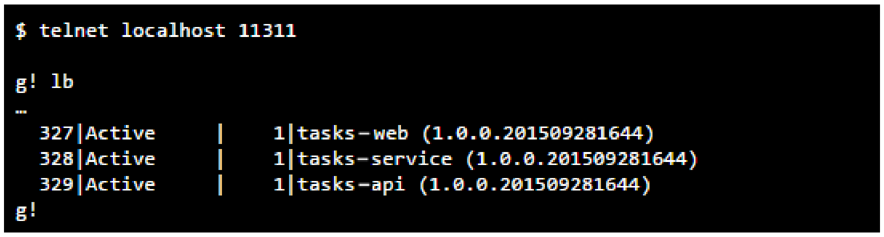
Building Your Module JARs for Deployment

Now it's time to build your modules and deploy them to your Liferay DXP instance. To build your project, run `gradlew build` from your project's root directory.

Once your project successfully builds, check all of your modules' `/build/libs` folders. There should be a newly generated JAR file in each, which is the file you'll need to deploy to Liferay DXP. You can deploy each JAR by running `blade deploy` from each module's root directory.

Note: If you deploy your modules out of order, you might receive error messages. For instance, if you try deploying your web client module first, you'll receive errors if it relies on the service implementation and service API modules. Once each module's dependencies are met, they will successfully be deployed for use in Liferay. For more information on checking each module's dependencies, see the Using the Felix Gogo Shell article.

Once you've successfully deployed your modules, you can list them from the Gogo shell as shown below.



```
$ telnet localhost 11311

g! lb
…
  327|Active     |    1|tasks-web (1.0.0.201509281644)
  328|Active     |    1|tasks-service (1.0.0.201509281644)
  329|Active     |    1|tasks-api (1.0.0.201509281644)
g!
```

Figure 18.1: Once you've connected to your Liferay instance in your Gogo shell prompt, run *lb* to list your new converted modules.

This tutorial explained how to convert your traditional application into the modular format of a 7.0 style applicaton. Specifically, you learned how to

- Create a web client (`*-web`) module that holds your application's portlet classes and UI.
- Create a service implementation module (`*-service`) and a service API module (`*-api`).
- Run Service Builder to generate code for your application's service and API modules.
- Wire your modules together by declaring their dependencies on each another.
- Build your modules and deploy them to your Liferay DXP installation.

Great job!

18.2 Migrating Data Upgrade Processes to the New Framework for Modules

When you make changes to your plugin that affect the database, you can use a *data upgrade process* to upgrade data to the new database schema. 7.0 has a new data upgrade framework for modules. While the old framework required several classes, the new framework lets you orchestrate the upgrade steps from a single class. Managing the steps from one class facilitates developing upgrade processes. The data upgrade framework you use depends on your development framework.

- If your upgraded plugin is a traditional WAR, you don't need to do anything special; existing upgrade processes adapted to 7.0's API work as is. The new data upgrade framework is for modules only.

- If you converted your upgraded plugin to a module or you have an upgraded module, you must migrate any upgrade processes you want to continue using to the new data upgrade framework.

You can migrate any number of old upgrade processes (starting with the most recent ones) to the new framework. For example, if your module has versions 1.0, 1.1, 1.2, and 1.3, but you only expect customers on versions 1.2 and newer to upgrade, you might migrate upgrade processes for versions 1.2 and 1.3 only. This tutorial shows you how to migrate to the new framework.

Before beginning, make sure you know how to create an upgrade process that uses the new framework. Click here to read the tutorial on creating these upgrade processes.

Note: Liferay Portal 6 plugins may also include verify processes. Although you can migrate the verify processes to 7.0 without any changes, it's a best practice to perform verification in your upgrade processes instead.

First, you'll review how Liferay Portal 6 upgrade processes work.

Understanding Liferay Portal 6 Upgrade Processes

Before getting started, it's important to understand how Liferay Portal 6 upgrade processes are structured. As an example, you'll use the Liferay Portal 6.2 upgrade process for the Knowledge Base Portlet. Click here to access it in GitHub.

In Liferay Portal 6 upgrade processes, the upgrade step classes for each schema version are in folders named after their schema version. For example, the Knowledge Base Portlet's upgrade step classes are in folders named `v1_0_0`, `v1_1_0`, `v1_2_0`, and so on. Each upgrade step class extends `UpgradeProcess` and overrides the `doUpgrade` method. The code in `doUpgrade` performs the upgrade. For example, the Knowledge Base Portlet's `v1_0_0/UpgradeRatingsEntry` upgrade step extends `UpgradeProcess` and performs the upgrade via the `updateRatingsEntries()` call in its `doUpgrade` method:

```
public class UpgradeRatingsEntry extends UpgradeProcess {

    @Override
    protected void doUpgrade() throws Exception {
        updateRatingsEntries();
    }

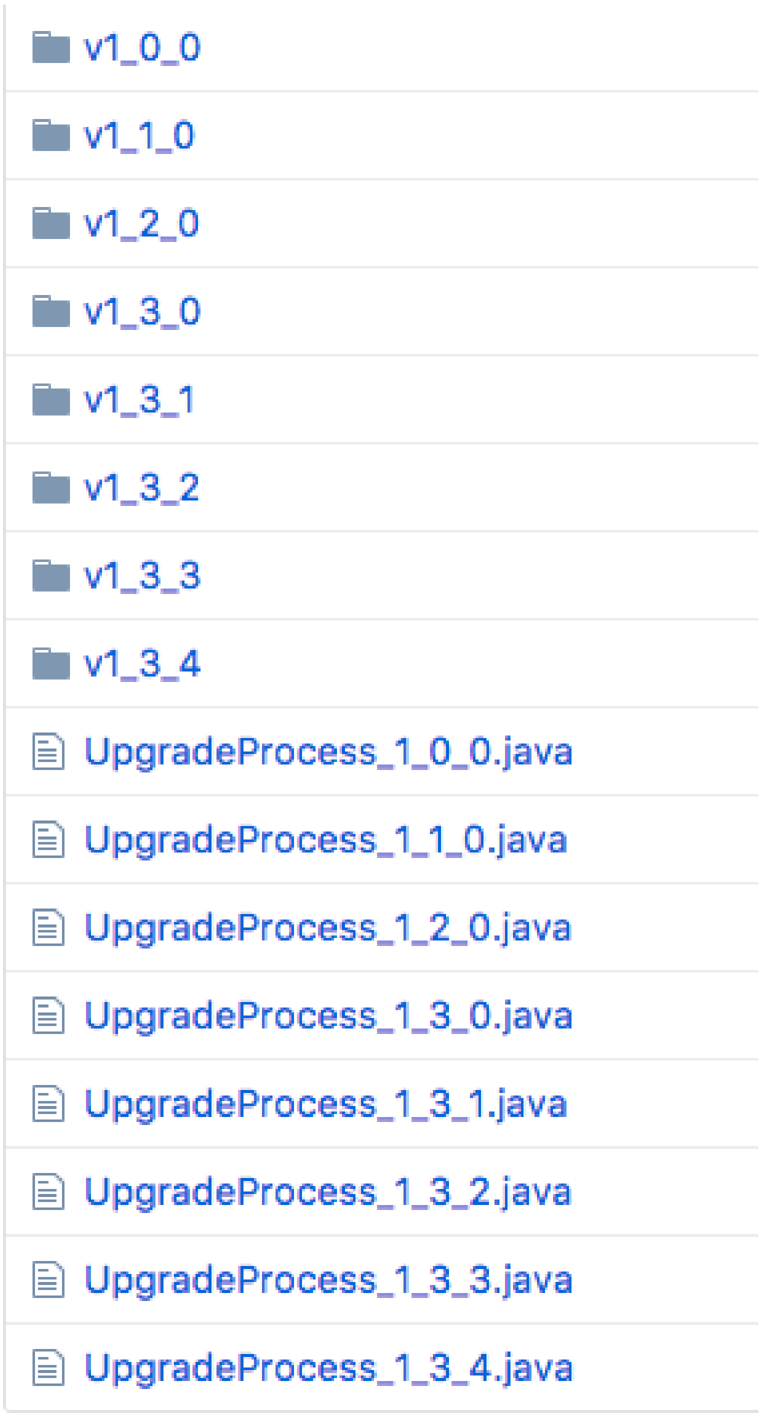
    ...

    protected void updateRatingsEntries() throws Exception {
        // Upgrade code
    }

    ...

}
```

The upgrade process classes are on the same level as the folders containing the upgrade steps and are also named after their schema version. For example, the Knowledge Base Portlet's upgrade process classes are named `UpgradeProcess_1_0_0`, `UpgradeProcess_1_1_0`, `UpgradeProcess_1_2_0`, and so on. Each upgrade process class also extends `UpgradeProcess` and runs the upgrade process in the `doUpgrade` method. It runs the upgrade process by passing the appropriate upgrade step to the `upgrade` method. For example,



v1_0_0
v1_1_0
v1_2_0
v1_3_0
v1_3_1
v1_3_2
v1_3_3
v1_3_4
UpgradeProcess_1_0_0.java
UpgradeProcess_1_1_0.java
UpgradeProcess_1_2_0.java
UpgradeProcess_1_3_0.java
UpgradeProcess_1_3_1.java
UpgradeProcess_1_3_2.java
UpgradeProcess_1_3_3.java
UpgradeProcess_1_3_4.java

Figure 18.2: The Knowledge Base Portlet's Liferay Portal 6.2 upgrade process.

the doUpgrade method in the Knowledge Base Portlet's UpgradeProcess_1_0_0 class runs the upgrade steps UpgradeRatingsEntry and UpgradeRatingsStats via the upgrade method:

```
@Override
protected void doUpgrade() throws Exception {
    upgrade(UpgradeRatingsEntry.class);
    upgrade(UpgradeRatingsStats.class);
}
```

Now that you know how Liferay Portal 6 upgrade processes are defined, you'll learn how to convert them to the new upgrade process framework in 7.0.

Converting your Liferay Portal 6 Upgrade Process to 7.0

So how do Liferay Portal 6 upgrade processes compare to those that use the new upgrade process framework in 7.0? First, the upgrade step classes are the same, so you can leave them unchanged. The big change in 7.0's new upgrade processes is that upgrade process classes no longer exist. Instead, you must combine your upgrade process classes' functionality into a single registrator class. Recall from the data upgrade process tutorial that registrators define an upgrade process that the upgrade process framework executes. Each registry.register call in the registrator registers the appropriate upgrade steps for each schema version. You must therefore transfer the functionality of your old upgrade process classes' doUpgrade methods into a registrator's registry.register calls.

For example, click here to see the Knowledge Base Portlet's new 7.0 upgrade process in GitHub.

Besides some additional upgrade step classes to handle changes made to the portlet for 7.0, the only difference in this upgrade process is that it contains a single registrator class, KnowledgeBaseServiceUpgrade, instead of multiple upgrade process classes. The KnowledgeBaseServiceUpgrade class, like all registrators, calls the appropriate upgrade steps for each schema version in its registry.register calls. For example, the first registry.register call registers the upgrade process for the 1.0.0 schema version:

```
registry.register(
        "com.liferay.knowledge.base.service", "0.0.1", "1.0.0",
        new com.liferay.knowledge.base.internal.upgrade.v1_0_0.
            UpgradeRatingsEntry(),
        new com.liferay.knowledge.base.internal.upgrade.v1_0_0.
            UpgradeRatingsStats());
```

Compare this to the above doUpgrade method from the corresponding Liferay Portal 6 upgrade process class UpgradeProcess_1_0_0. Both call the same upgrade steps. Click here to see the complete KnowledgeBaseServiceUpgrade registrator class and all its registry.register calls.

That's it! For instructions on creating new upgrade processes for 7.0, including complete steps on creating a registrator, click here.

18.3 Migrating a Theme from the Plugins SDK to the Liferay Theme Generator

After you've upgraded your Liferay Portal 6 theme to 7.0, the Themes Generator offers enhanced development features and tools for optimizing your theme and streamlining theme management. To introduce one of its most powerful features, we'll pose some questions.

Questions:

- Do you want to make a temporary change to your theme's UI?
- Do you want to add the same UI modification to all of your themes without duplicating code?
- Do you want to share your new theme designs with a colleague?
- Do you want to test a new design concept in your theme without altering its code?

Answer: Themelets are the answer! Themelets are small, extendable, reusable modular pieces of code that let you make changes to your theme quickly. Because they are modular, you can use the same themelet for multiple themes!

Themelets are just one of the features you gain from migrating your existing Ant-based theme project to a Liferay Theme Generator project. The Liferay Theme Generator is a Node.js-based tool that gives you access to an array of theme Gulp tasks that facilitate developing and managing themes.

The *upgrade* Gulp task upgrades Liferay Portal 6 themes to 7.0. For details, refer to the Upgrading Themes tutorial.

In addition to the *upgrade* task, there are tasks for building and deploying themes and for interacting with deployed themes. For instance, you can automatically redeploy your theme as you make changes to it.

Do you periodically need to make changes to your theme's settings? No problem. You can configure your theme's settings through the command-line wizard that the Liferay Theme Generator provides. All you have to do is answer a few questions about the settings.

As you can see, the Liferay Theme Generator, Node.js, and Gulp development tools offer a lot to a Liferay theme developer.

This tutorial assumes that you have already installed the Liferay Theme Generator and that your upgraded theme was developed with the Plugins SDK. There are two ways you can migrate your Plugins SDK theme to the Theme Generator: importing your theme manually into the Theme Generator or converting it to a Theme Generator project from a Liferay Workspace. You'll learn how to import it manually first.

Importing Your Theme

The Liferay Theme Generator uses Yeoman to equip theme projects with the new development tools. Follow the steps below to set up your existing theme in such a project:

1. Navigate to the directory you want to import your theme into and run the following command:

   ```
   yo liferay-theme:import
   ```

   This runs the import sub-generator for the themes generator.

2. Enter the absolute path of the theme you want to import and press `Enter`.

```
**Note:** you must specify an absolute path, as the themes import
sub-generator does not support relative paths.
```

```
The theme's modified files (the files it modified from the base theme) are
copied and reorganized in a newly created  `src` directory. A `gulpfile.js`,
`liferay-theme.json`, `package.json` file  and a `node_modules` directory
are also added.

Next, the `gulp init` task runs and prompts you with a couple questions.
```

3. Enter the path to your app server.

4. Enter your site's URL (this can be your production site, development site, etc.), or press `Enter` to accept the default `http://localhost:8080`.

Your theme is now set up to use the Node.js build tools and theme Gulp tasks!

Migrating Themes to the Theme Generator Using Workspace

If you're a theme developer who wants to use Liferay Workspace to migrate your Plugins SDK theme to the Theme Generator, you can execute a single command to convert the theme project. Before beginning, make sure your Plugins SDK has been converted to a Liferay Workspace.

1. Using a command line tool, navigate to the root folder of your workspace.
2. Execute the following command to migrate your Plugins SDK theme to a Theme Generator theme:

   ```
   blade convert [PLUGINS_SDK_THEME_NAME]
   ```

   Blade CLI extracts the theme from the nested Plugins SDK folder and reorganizes it into a standard Theme Generator project. The converted theme is available in the workspace's `themes` folder.

That's it! Your Plugins SDK theme is now available as a Liferay Theme Generator project residing in Liferay Workspace.

18.4 Migrating a Theme from the Plugins SDK to Workspace

After you've adapted your Plugins SDK theme to Liferay DXP's API, you can continue maintaining it in the Plugins SDK. The Plugins SDK, however, is deprecated as of 7.0. Maintaining plugins in the SDK will become increasingly difficult. Liferay Workspace replaces the Plugins SDK, providing a comprehensive Gradle development environment and more. A simple command migrates Plugins SDK (Ant-based) themes to Workspace (Gradle-based) themes. From there you can build and deploy them to 7.0 as Web ARchives (WARs).

Running the Migration Command

Blade CLI's `convert` command migrates Plugins SDK themes to Workspace themes in Workspace's `wars` folder. Theme files are re-organized to follow the standard 7.0 theme folder structure.

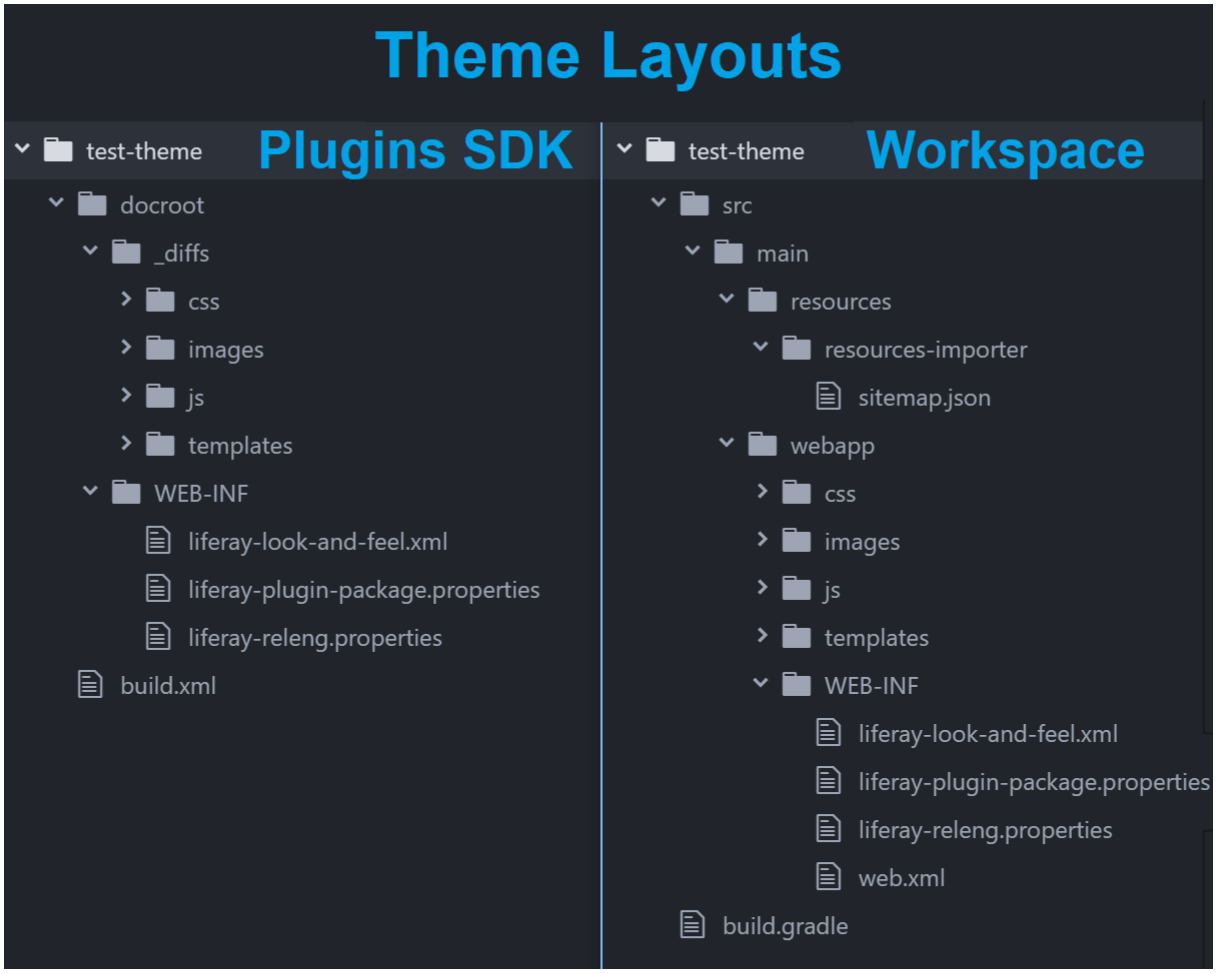
In a terminal, navigate to the Liferay Workspace root folder. Then pass your Plugins SDK theme's name to Blade CLI's `convert` command:

```
blade convert --themebuilder [THEME_PROJECT_NAME]
```

Blade CLI extracts the plugin from the Plugins SDK and reorganizes it in a standard web application project in Workspace's `wars` folder. Blade CLI uses the Theme Builder plugin to migrate your theme to a workspace. You can also migrate your Plugins SDK theme to a Liferay Theme Generator theme using Blade CLI. Follow the Migrating Themes to the Theme Generator Using Workspace tutorial for more information.

The image below shows the theme files before and after they're migrated to Workspace.

From your theme's new location, you can deploy it to 7.0 and maintain it using Workspace Gradle tasks. Welcome to your theme's new home in Workspace!



```
test-theme
  docroot
    _diffs
      css
      images
      js
      templates
    WEB-INF
      liferay-look-and-feel.xml
      liferay-plugin-package.properties
      liferay-releng.properties
  build.xml
```

```
test-theme
  src
    main
      resources
        resources-importer
          sitemap.json
      webapp
        css
        images
        js
        templates
        WEB-INF
          liferay-look-and-feel.xml
          liferay-plugin-package.properties
          liferay-releng.properties
          web.xml
  build.gradle
```

Workspace Gradle Tasks

18.5 Customization with Ext Plugins

Ext plugins are deprecated for 7.0 and should only be used if absolutely necessary. They are deployable to Liferay Portal 7.0 CE GA4+.

The following app servers should be used for Ext plugin development in Liferay DXP:

- Tomcat 8.0

In most cases, Ext plugins are no longer necessary. There are, however, certain cases that require the use of an Ext plugin. Liferay only supports the following Ext plugin use cases:

- Providing custom implementations for any beans declared in Liferay DXP's Spring files (when possible, use service wrappers instead of an Ext plugin). 7.0 removed many beans, so make sure your overridden beans are still relevant if converting your legacy Ext plugin.
- Overwriting a class in a 7.0 core JAR. For a list of core JARs, see the Finding Core Liferay DXP Artifacts section.
- Modifying Liferay DXP's `web.xml` file.
- Adding to Liferay DXP's `web.xml` file.

Ext plugins are powerful tools used to extend Liferay DXP. They, however, increase the complexity of your Liferay DXP instance and are not recommended unless there is absolutely no other way to accomplish your task. 7.0 provides many extension points that let you customize almost every detail of Liferay DXP. If there's a way to customize what you want with an extension point, do it that way instead. See the More Extensible, Easier to Maintain section for more details on the advantages of using Liferay DXP's extension points.

Before deciding to use an Ext plugin, weigh the cost. Ext plugins let you use internal APIs and even let you overwrite Liferay DXP core files. This puts your deployment at risk of being incompatible with security, performance, or feature updates released by Liferay. When upgrading to a new version of Liferay DXP (even if it's a maintenance version or a service pack), you have to review all changes and manually modify your Ext plugin to merge your changes with Liferay DXP's. Additionally, Ext plugins aren't hot deployable. To deploy an Ext plugin, you must restart your server. Additional steps are also required to deploy or redeploy to production systems.

In this tutorial, you'll learn how to

- Create an Ext plugin
- Develop an Ext plugin
- Deploy an Ext plugin in Production

Before diving into creating an Ext plugin, however, first consider if an Ext plugin is even necessary at all.

Making the Decision to Use Ext Plugins

There are many parts of Liferay DXP that now provide an extension point via OSGi bundle. You should follow this three step process to decide whether an Ext plugin is necessary:

1. Find the OSGi extension point that you need. You can follow the Finding Extension Points tutorial as a guide.

2. If an OSGi extension point does not exist, use an Ext plugin.

3. Research new extension points after every release of Liferay DXP. When a new version of Liferay DXP provides the extension point you need, always use the extension point to replace the existing Ext plugin.

So how do you find an OSGi extension point?

Your first step is to examine the custom module projects that extend popular Liferay DXP extension points stored in the Liferay Blade Samples repository. For more information on these sample projects, see the Liferay Sample Projects tutorial. Usable extension points are also documented throughout Liferay's Developer Network categorized by the Liferay DXP section involved. For example, Overriding MVC Commands and Customizing the Product Menu are articles describing how to extend a Liferay DXP extension point. Want to learn how to override module JSPs or Liferay DXP core JSPs? Those processes are documented too!

There are a few corner cases where you may need an Ext plugin to customize a part of Liferay DXP that does not provide an extension point. Refer to the top of this tutorial for Ext plugin use cases supported by Liferay.

Note: In previous versions of Liferay Portal, you needed an Ext plugin to specify classes as portal property values (e.g., `global.starup.events.my.custom.MyStartupAction`), since the custom class had to be added to the portal class loader. This is no longer the case in 7.0 since all lifecycle events can use OSGi services with no need to edit these legacy properties.

Now that you know how to make an informed decision on using Ext plugins, you'll learn how to create one next.

Creating an Ext Plugin

An Ext plugin is a powerful tool for extending Liferay DXP. Because it increases the complexity of your Liferay DXP installation, you should only use an Ext plugin if you're sure you can't accomplish your goal in a different way. You can only create Ext plugins from a Plugins SDK. If you're using a Liferay Workspace to create your @project@ projects, you can merge a Plugins SDK instance into the workspace.

Creating an Ext Plugin Using Liferay @ide@

Follow the steps below, replacing the project name with your own, to create a custom Ext plugin:

1. Go to *File → New → Liferay Plugin Project*.
2. Enter your project's name and its display name. In the figure below, *example* is used for both. Note that the Display name field is automatically filled in with the capitalized version of the Project name.
3. Select the *Ant (liferay-plugins-sdk)* option for your build type.
4. Select the *Ext* plugin type. Then click *Next*.
5. If you have not yet configured a Plugins SDK, select *Next* and choose the Plugins SDK for which you want to generate the Ext plugin. Once you have your Plugins SDK configured, click *Finish*.

The Plugins SDK automatically appends `-ext` to the plugin project name when it creates your Ext plugin's project folder. Your Ext plugin project is added to your configured Plugins SDK instance and is also available via @ide@'s Package Explorer for further development.

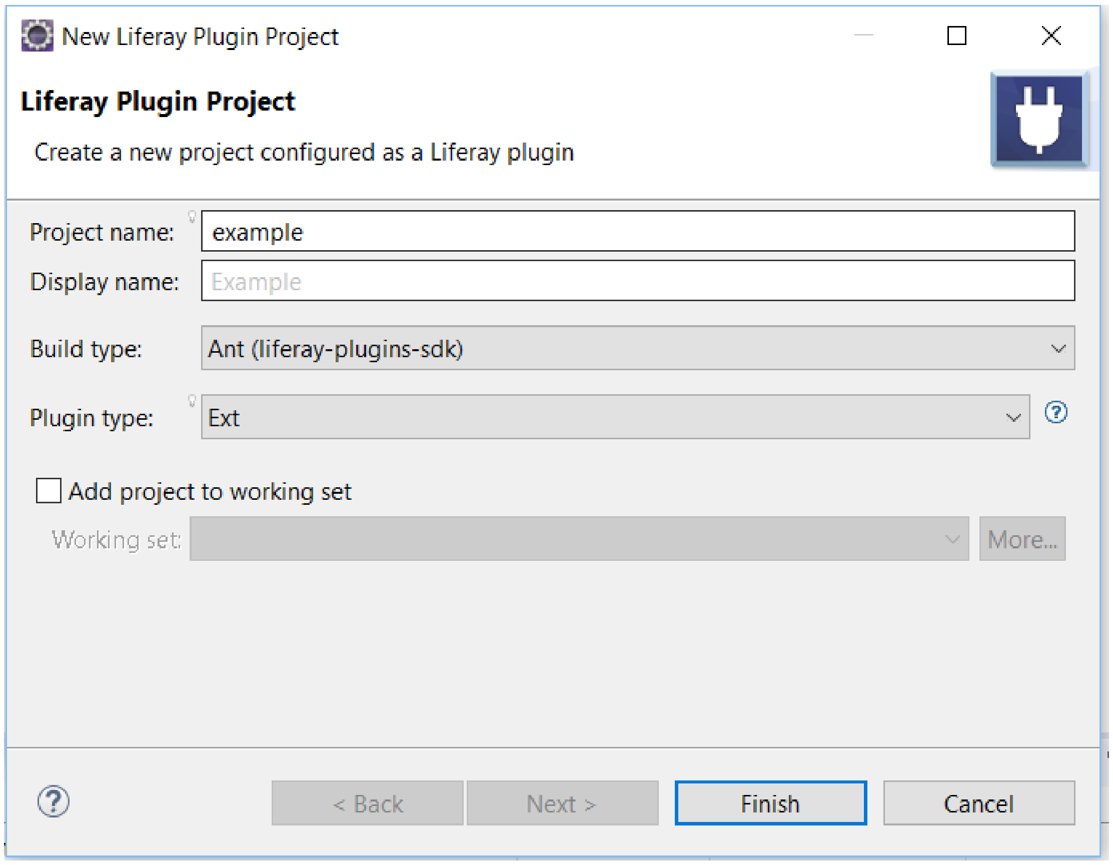
Creating an Ext Plugin Using the Command Line

To create a new Ext plugin from the command line, navigate to the `ext` folder in your Liferay Plugins SDK and enter the command below appropriate for your operating system. The two arguments after the `create` command are the project name and display name, respectively. The examples below use the project name *example* and the display name *Example*. Make sure to specify values you want to use for your Ext plugin's project name and display name.

In Linux or Mac OS, enter:

```
./create.sh example "Example"
```

In Windows, enter:



New Liferay Plugin Project

Liferay Plugin Project

Create a new project configured as a Liferay plugin

Project name: example

Display name: Example

Build type: Ant (liferay-plugins-sdk)

Plugin type: Ext

Add project to working set

Working set:

Figure 18.5: You can create an Ext plugin project with Liferay @ide@.

```
create.bat example "Example"
```

A BUILD SUCCESSFUL message from Ant tells you there's a new folder (e.g., folder example-ext for a project named *example*) inside your Plugins SDK's ext folder. The Plugins SDK automatically appends -ext to the project name.

Anatomy of an Ext Plugin

There are a few things to note about an Ext plugin's folder structure. Below is a listing of an Ext folder structure:

- [project name]-ext/
  - docroot/
    * WEB-INF/
      - ext-impl/
      - src/

      - ext-lib/
      - global/

· portal/

· ext-service/
· src/

· ext-util-bridges/
· src/

· ext-util-java/
· src/

· ext-util-taglib/
· src/

· ext-web/
· docroot/

Here are detailed explanations of the `/docroot/WEB-INF/` subfolders:

- `ext-impl/src`: Contains the custom implementation classes and classes that override core classes from `portal-impl.jar`.
- `ext-lib/global`: Contains libraries to be copied to the application server's global classloader upon deployment of the Ext plugin.
- `ext-lib/portal`: Contains libraries to be copied inside Liferay's main application. These libraries are usually necessary because they're invoked from classes you add in `ext-impl/src`.
- `ext-kernel/src`: Contains classes that should be available to other plugins. In advanced scenarios, this folder can be used to hold classes that overwrite classes from `portal-kernel.jar`.
- `ext-web/docroot`: Contains the web application's configuration files, including `WEB-INF/struts-config-ext.xml`, which lets you customize Liferay's core struts classes. Note that for 7.0, there are very few entities left to override in the `struts-config.xml` file. Any JSPs that you're customizing also belong here.
- `ext-util-bridges`, `ext-util-java` and `ext-util-taglib`: These folders are needed only in scenarios where you must customize these Liferay libraries: `util-bridges.jar`, `util-java.jar` and `util-taglib.jar`, respectively. If you're not customizing any of these libraries, you can ignore these folders.

By default, several files are also added to the plugin. Here are the most significant files:

- `build.xml`: The Ant build file for the Ext plugin project.
- `docroot/WEB-INF/liferay-plugin-package.properties`: Contains plugin-specific properties, including the plugin's display name, version, author, and license type.
- `docroot/WEB-INF/ext-web/docroot/WEB-INF` files:

- `portlet-ext.xml`: Used to overwrite the definition of a build-in portlet. The `portlet.xml` file contains very few portlet configurations in 7.0 because portlets were modularized and moved out of core. To override this file, copy the complete definition of the desired portlet from `portlet-custom.xml` in Liferay's source code, then apply the necessary changes.
- `liferay-portlet-ext.xml`: This file is similar to `portlet-ext.xml`, but is for additional definition elements specific to Liferay. The `liferay-portlet.xml` file contains very few definition elements in 7.0 because portlets were modularized and moved out of core. To override the remaining definition elements, copy the complete definition of the desired portlet from `liferay-portlet.xml` in Liferay's source code, then apply the necessary changes.
- `struts-config-ext.xml` and `tiles-defs-ext.xml`: These files are used to customize the struts actions used by core portlets. Since most portlets were modularized and moved out of core in 7.0, the `struts-config.xml` and `tiles-defs.xml` files are sparsely used.
- `web.xml`: Used to overwrite web application configurations and servlet information for 7.0.

Note: After creating an Ext plugin, remove the files from `docroot/WEB-INF/ext-web/docroot/WEB-INF` that you don't need to customize. Removing files you're not customizing prevents incompatibilities that could manifest from Liferay DXP updates.

Great! You've now created an Ext plugin and are familiar with its folder structure and its most significant files. Next, you'll use your Ext plugin to customize Liferay DXP.

Developing an Ext Plugin

An Ext plugin changes Liferay DXP itself when the plugin is deployed; it's not a separate component that you can easily remove at any time. For this reason, the Ext plugin development process is different from other plugin types. It's important to remember that once an Ext plugin is deployed, some of its files are copied *inside* the Liferay installation; the only way to remove the changes is by *redeploying* an unmodified Liferay application. You're also responsible for checking that patches and fix packs do not conflict with your Ext plugin.

The 7.0 compatible Plugins SDK is designed to only develop/deploy one Ext plugin. This means that all your customizations should live inside one Ext plugin. The Plugins SDK does not check for conflicts among multiple Ext plugins stored in the `/ext` folder, so do **not** develop/deploy multiple Ext plugins at once.

The Plugins SDK lets you deploy and redeploy your Ext plugin during your development phase. Redeployment involves *cleaning* (i.e., removing) your application server and unzipping your specified Liferay bundle to start from scratch. That way, any changes made to the Ext plugin during development are properly applied, and files removed from your plugin by previous changes aren't left behind in the Liferay DXP application. Because of this added complexity, you should use another plugin type to accomplish your goals whenever possible.

Before digging in to the details, here's an overview of the Ext plugin development processes described below:

- *Configure* your Plugins SDK environment to develop Ext plugins for Liferay DXP on your application server.
- *Deploy* and *publish* your Ext plugins for the first time.
- *Redeploy* normally or use a *clean redeployment* process after making changes to your Ext plugins.
- *Package* your Ext plugins for distribution.
- A list of advanced customization techniques.

It's time to learn each step of the development process.

Set Up the Build Environment

Before deploying an Ext plugin, you must edit the `build.[username].properties` file in the root folder of your Plugins SDK. If the file doesn't yet exist, create it now. Substitute `[username]` with your user ID on your computer. Once you've opened your build properties file, add the following properties–make sure the individual paths reflect the right locations on your system:

```
ext.work.dir=[work]

app.server.dir=[work]/liferay-ce-portal-[version]/[app server]

app.server.zip.name=[...]/liferay-ce-portal-[app server].zip
```

Your `app.server.zip.name` property must specify the path to your Liferay DXP `.zip` file. The `work` folder you specify for the `ext.work.dir` property is where you've unzipped your Liferay DXP runtime. The `app.server.dir` property must point to your application server's directory in your work folder. Look in your Liferay DXP bundle at the path to the application server to determine the value to use for your `app.server.dir` property.

For example, if your work folder is `C:/work`, specify it as your `ext.work.dir` property's value. If your Liferay DXP bundle .zip file is `C:/downloads/liferay-ce-portal-tomcat-7.0-ga4-[timestamp].zip`, set the `app.server.zip.name` property to that file's path. If the *relative path* to the application server *within* the Liferay DXP bundle `.zip` file is `liferay-ce-portal-7.0-ga4\tomcat-8.0.32`, specify an `app.server.dir` property value `C:/work/liferay-ce-portal-7.0-ga4/tomcat-8.0.32`.

Next you'll modify the Ext plugin you created and deploy it.

Initial Deployment

Your environment is set up and you're ready to start customizing. Once you're finished, you can deploy the plugin.

Deploy the Plugin Now you'll learn how to deploy your plugin using Liferay @ide@ or the command line.

Deploying in Liferay @ide@ Drag your Ext plugin project from your Package Explorer onto your server to deploy your plugin. Liferay @ide@ automatically restarts the server for the server to detect and publish your Ext plugin.

After deploying, if you don't see your customizations in the portal, your Ext plugin may not have successfully deployed. To confirm whether the Ext plugin deploys successfully, try deploying from the command line; the Ant deployment targets report success or failure.

Deploying via the Command Line

1. Open a command line window in your Ext plugin project folder and enter one of these commands:

   ```
   ant deploy

   ant direct-deploy
   ```

   The `direct-deploy` target deploys all changes directly to the appropriate folders in the Liferay application. The `deploy` target creates a `.war` file with your changes and then deploys it to your server. Either way, your server must be restarted after the deployment. Using `direct-deploy` is preferred for deploying an Ext plugin during development if your application server supports it. Direct deploy doesn't work in WebLogic or WebSphere application server environments.

A `BUILD SUCCESSFUL` message indicates your plugin is now being deployed. Your console window running Liferay DXP shows a message like this:

```
Extension environment for [your project]-ext has been applied. You must
reboot the server and redeploy all other plugins
```

If any changes applied through the Ext plugin affect the deployment process itself, you must redeploy all other plugins. Even if the Ext plugin doesn't affect the deployment process, it's a best practice to redeploy all your other plugins following initial deployment of the Ext plugin.

The `ant deploy` target builds a `.war` file with your changes and copies them to the auto-deploy folder inside the Liferay DXP installation. When the server starts, it detects the `.war` file, inspects it, and copies its contents to the appropriate destinations inside the deployed and running Liferay application.

2. Restart the server so that it detects and publishes your Ext plugin.

   Once your server restarts, open Liferay DXP to see the customizations you made with your Ext plugin.

Frequently, you'll want to add further customizations to your original Ext plugin. You can make unlimited customizations to an Ext plugin that has already been deployed, but the redeployment process is different from other project types. You'll learn more on redeploying your Ext plugin next.

Redeployment

So far, Ext plugin development has been similar to the development of other plugin types. You've now reached the point of divergence. When the plugin is first deployed, some of its files are copied into the Liferay DXP installation. After changing an Ext plugin, you'll either *clean redeploy* or *redeploy*, depending on the modifications you made to your plugin following the initial deployment. You'll learn about each redeployment method and when to use each one.

Clean Redeployment If you removed part(s) of your plugin, if there are changes to your plugin that can affect plugin deployment, or if you want to start with a clean Liferay DXP environment, *undeploy* your plugin and *clean* your application server before redeploying your Ext plugin. By cleaning the application server, the existing Liferay DXP installation is removed and the bundle specified in your Plugins SDK environment is unzipped in its place. See the instructions below to learn more about this process.

Using Liferay @ide@

1. Remove the plugin from the server. While selecting the Ext plugin in the *Servers* view, select the plugin's *Remove* option.

2. Clean the application server. Remember to shut down the application server before cleaning it. This is required on Windows because the server process locks the installed Liferay bundle's files.

   While selecting the Ext plugin project in the *Package Explorer* view, select the plugin's *Liferay → Clean App Server...* option.

3. Start the Liferay server.

4. Drag the Ext plugin and drop it onto the Liferay server.

5. While selecting the Liferay server in the *Servers* view, click the *Publish* option.

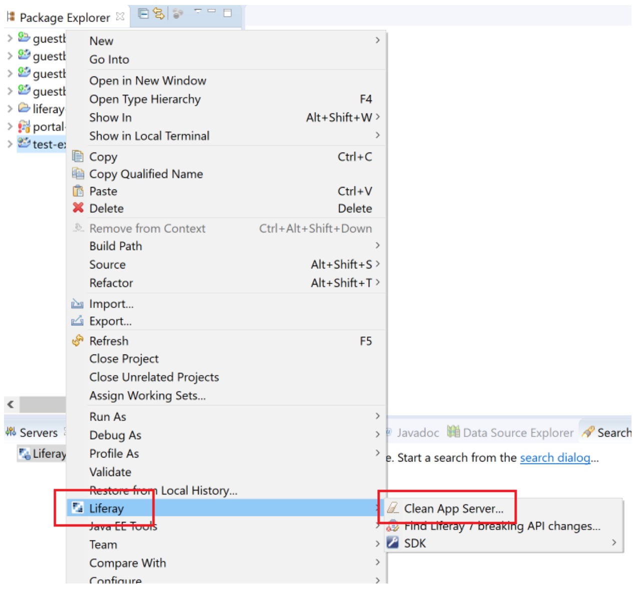


Figure 18.6: How to clean your app server

Using the Command Line

1. Stop the Liferay DXP server.

2. To deploy your Ext plugin, enter the following commands into your console:

```
cd [your-plugin-ext]
ant clean-app-server
ant direct-deploy
```

3. Start the Liferay DXP server.

Redeployment If you only added to your plugin or made modifications that don't affect the plugin deployment process, you can redeploy the Ext plugin. Follow the steps based on the tool you're using.

Using Liferay @ide@ Right-click your plugin located underneath your server and select *Redeploy*.

Using the Command Line Using the same procedure as for initial deployment. Open a command line window in your Ext plugin project's directory and execute either `ant deploy` or `ant direct-deploy`.

After your plugin is published to Liferay DXP, verify that your customizations are available.

Next you'll learn how to package an Ext plugin for distribution and production.

Distribution

Once you're finished developing an Ext plugin, you can package it in a `.war` file for distribution and production deployment.

Using Liferay @ide@ With your Ext plugin project selected in the *Package Explorer* view, select the project's *Liferay* → *SDK* → *war* option.

Using the Command Line From your Ext plugin's directory execute

```
ant war
```

The `.war` file is written to your `[liferay-plugins]/dist` directory.

Now that you've learned the basics of Ext plugin development, you'll look at some advanced customizations.

Using Advanced Configuration Files

Liferay DXP uses several internal configuration files for its own architecture; in addition, there are configuration files for the libraries and frameworks Liferay DXP depends on, like Struts and Spring. Configuration could be accomplished using fewer files with more properties in each, but maintenance and use is made easier by splitting up the configuration properties into several files. For advanced customization needs, it may be useful to override the configuration specified in multiple configuration files. Liferay DXP provides a clean way to do this from an Ext plugin without modifying the original files.

All the configuration files in Liferay DXP are listed below by their path in an Ext plugin folder. Here are descriptions of what each file is for and the path to the original file in Liferay DXP:

- `ext-impl/src/META-INF/ext-model-hints.xml`
  - **Description:** Overrides the default properties of the fields of the data models used by Liferay DXP's core portlets. These properties determine how the form fields for each model are rendered.
  - **Original file in Liferay DXP:** `portal-impl/src/META-INF/portal-model-hints.xml`
- `ext-impl/src/META-INF/ext-spring.xml`
  - **Description:** Overrides the Spring configuration used by Liferay DXP and any of its core portlets. It's most commonly used to configure specific data sources or swap the implementation of a default service with a custom one.
  - **Original file in Liferay DXP:** `portal-impl/src/META-INF/*-spring.xml`
- `ext-impl/src/META-INF/portal-log4j-ext.xml`
  - **Description:** Allows overriding the Log4j configuration. It can be used to configure appenders for log file location, naming, and rotation. See the Log4j XML Configuration Primer. Increasing or decreasing the log level of a class or class hierarchy is best done outside of an Ext plugin, in Liferay DXP's' UI or a Log4j XML file in a module or the `osgi/log4j` folder.
  - **Original file in Liferay:** `portal-impl/src/META-INF/portal-log4j.xml`
- `ext-web/docroot/WEB-INF/portlet-ext.xml`
  - **Description:** Overrides the core portlets' declarations. It's most commonly used to change the init parameters or the roles specified.
  - **Original file in Liferay DXP:** `portal-web/docroot/WEB-INF/portlet-custom.xml`
- `ext-web/docroot/WEB-INF/liferay-portlet-ext.xml`
  - **Description:** Overrides the Liferay-specific core portlets' declarations. It core portlets included in Liferay DXP. Refer to the liferay-portlet-app_7_0_0.dtd file for details on all the available options. Use this file with care; the code of the portlets may be assuming some of these options to be set to certain values.

    - **Original file in Liferay DXP:** `portal-web/docroot/WEB-INF/liferay-portlet.xml`

- `ext-web/docroot/WEB-INF/liferay-display.xml`
    - **Description:** Overrides the portlets that are shown in the interface for adding applications and the categories in which they're organized.
    - **Original file in Liferay DXP:** `portal-web/docroot/WEB-INF/liferay-display.xml`

You'll learn how to deploy your Ext plugin in production next.

Deploying in Production

Often, you can't use Ant to deploy web applications in production or pre-production environments. Additionally, some application servers such as WebSphere or WebLogic have their own deployment tools and don't work with Liferay DXP's auto-deployment process. Here are two methods to consider for deploying and redeploying an Ext plugin in production.

Method 1: Redeploying Liferay's Web Application

You can use this method in any application server that supports auto-deployment; What's the benefit? The only artifact that needs to be transferred to the production system is your Ext plugin's `.war` file, produced using the `ant war` target. This `.war` file is usually small and easy to transport. Execute these steps on the server:

1. Redeploy Liferay DXP:

   If this is your first time deploying your Ext plugin to this server, skip this step. Otherwise, start by executing the same steps you first used to deploy Liferay DXP on your app server. If you're using a bundle, unzip it again. If you installed Liferay DXP manually on an existing application server, you must redeploy the Liferay DXP `.war` file and copy both the libraries required globally by Liferay DXP and your Ext plugin to the appropriate folder within the application server.

2. Copy the Ext plugin `.war` into the auto-deploy folder. For a bundled Liferay DXP distribution, the `deploy` folder is in Liferay's *root* folder of your bundle (e.g., `liferay-ce-portal-[version]/`).

3. Once the Ext plugin is detected and deployed by Liferay DXP, restart your Liferay DXP server.

Method 2: Generate an Aggregated WAR File

Some application servers don't support auto-deploy; WebSphere and WebLogic are two examples. With an aggregated `.war` file, the Ext plugin is merged before deployment to production. A single `.war` file then contains Liferay DXP plus the changes from your Ext plugin. Before you deploy the aggregated Liferay DXP `.war` file, copy the dependency `.jar` files for Liferay DXP and your Ext plugin to the global application server class loader in the production server. The precise location varies from server to server; refer to Deployment to get the details for your application server.

To create the aggregated `.war` file, deploy the Ext plugin first to the Liferay DXP bundle you are using in your development environment. Once it's deployed, restart the server so that the plugin is fully deployed and shut it down again. Now the aggregated file is ready.

Create a `.war` file by zipping the Liferay web application folder from within the app server. Copy into your application server's global classpath all of the libraries on which your Ext plugin depends.

Now, perform these actions on your server:

1. Redeploy Liferay DXP using the aggregated `.war` file.

2. Stop the server and copy the new version of the global libraries to the appropriate directory in the application server.

Next, you'll learn about Liferay's licensing and contributing standards.

Licensing and Contributing

Liferay DXP is Open Source software licensed under the LGPL 2.1 license. If you reuse any code snippet and redistribute it, whether publicly or to a specific customer, make sure your modifications are compliant with the license. One common way is to make the source code of your modifications are available to the community under the same license. Make sure you read the license text yourself to find the option that best fits your needs.

If your goal in making changes is fixing a bug or improving Liferay DXP, it could be of interest to a broader audience. Consider contributing it back to the project. That benefits all users of the product including you, since you won't have to maintain the changes with each newly released version of Liferay DXP. You can notify Liferay of bugs or improvements at issues.liferay.com. Check out the Participate section of portal.liferay.dev, to learn all the ways that you can contribute to the Liferay Portal project.

In summary, an Ext plugin is a powerful way to extend Liferay DXP. There are no limits to what you can customize, so use it carefully. Before using an Ext plugin, see if you can implement all or part of the desired functionality through Application Display Templates or a different plugin type. OSGi modules offer you a lot of extension capabilities themselves, without introducing the complexity that's inherent with Ext plugins. If you need to use an Ext plugin, make your customization as small as possible and follow the instructions in this tutorial carefully to avoid issues.

Chapter 19

Developing a Web Application

In this Learning Path, you'll create the Liferay Guestbook Web Application from scratch using tools like Liferay @ide@ and BLADE tools. As you create this application, you'll learn how to create a back-end database, web services, a security model, UI, and more using all the best practices and standards for Liferay DXP. Completing this Learning Path will prepare you to write your own application and further explore Liferay's APIs.

To develop a web application with Liferay, start at the beginning: setting up a Liferay development environment. Though you can use anything from a text editor and the command line, to your Java IDE of choice, Liferay provides Liferay @ide@ to optimize development on Liferay's platform. It integrates Liferay's BLADE tools for modular development.

Once your development environment is set up, you'll begin creating the application. From modeling data to Service Builder, you'll learn everything you need to know to create and run your application.

From there you'll see everything from UI standards to providing remote services. Once everything is completed and wrapped up with a bow, you can distribute the application on Marketplace.

Let's Go!

19.1 Development Setup Overview

```
<p>Development Setup Overview<br>Step 1 of 1</p>
```

Liferay's development tools aim to help you get started fast. The basic steps for installing Liferay @ide@ are

- Download a Liferay @ide@ bundle.
- Unzip the downloaded package to a location on your system.
- Start @ide@.

You'll follow these steps, and then generate an environment for developing your first Liferay DXP application.

Installing a Liferay @ide@ Bundle

To install Liferay @ide@, follow these steps:

1. Download and install the Java Development Kit (JDK). Liferay DXP runs on Java. The JDK is required because you'll be developing Liferay DXP apps in Liferay @ide@. The JDK is an enhanced version of the Java Environment used for developing new Java technology.

2. Download Liferay @ide@. Installing it is easy: unzip it to a convenient location on your system.

3. To run Liferay @ide@, execute the `eclipse` executable.

The first time you start Liferay @ide@, it prompts you to select an Eclipse workspace. If you specify a folder where no workspace currently exists, Liferay @ide@ creates a new workspace in that folder. Follow these steps to create a new workspace:

1. When prompted, indicate your workspace's path. Name your new workspace `guestbook-workspace` and click *OK*.

2. When Liferay @ide@ first launches, it presents a welcome page. Click the *Workbench* icon to continue.

Nice job! Your development environment is installed and your workspace is set up.

Creating a Liferay Workspace

Now you'll create another kind of workspace–a Liferay Workspace. By holding and managing your Liferay DXP projects, a Liferay Workspace provides a simplified, straightforward way to develop Liferay DXP applications. In the background, a Liferay Workspace uses Blade CLI and Gradle to manage dependencies and organize your build environment. Note that to avoid configuration issues, you can only create one Liferay Workspace for each Eclipse Workspace.

Follow these steps to create a Liferay Workspace in Liferay @ide@:

1. Select *File* → *New* → *Liferay Workspace Project*. Note: you may have to select *File* → *New* → *Other*, then choose *Liferay Workspace Project* in the *Liferay* category.

   A *New Liferay Workspace* dialog appears, which presents several configuration options.

2. Give your workspace the name `com-liferay-docs-guestbook`.

3. Next, choose your workspace's location. Leave the default setting checked. This places your Liferay Workspace inside your Eclipse workspace.

4. Check the *Download Liferay bundle* checkbox to automatically download and unzip a Liferay DXP instance in your workspace. When prompted, name the server `liferay-tomcat-bundle`.

5. Click *Finish* to create your Liferay Workspace. This may take a while because Liferay Liferay DXP downloads the Liferay DXP bundle in the background.

A dialog appears prompting you to open the Liferay Workspace perspective. Click *Yes*, and your perspective switches to Liferay Workspace.

Congratulations! Your development environment is ready! Next, you'll get started developing your first Liferay DXP application.

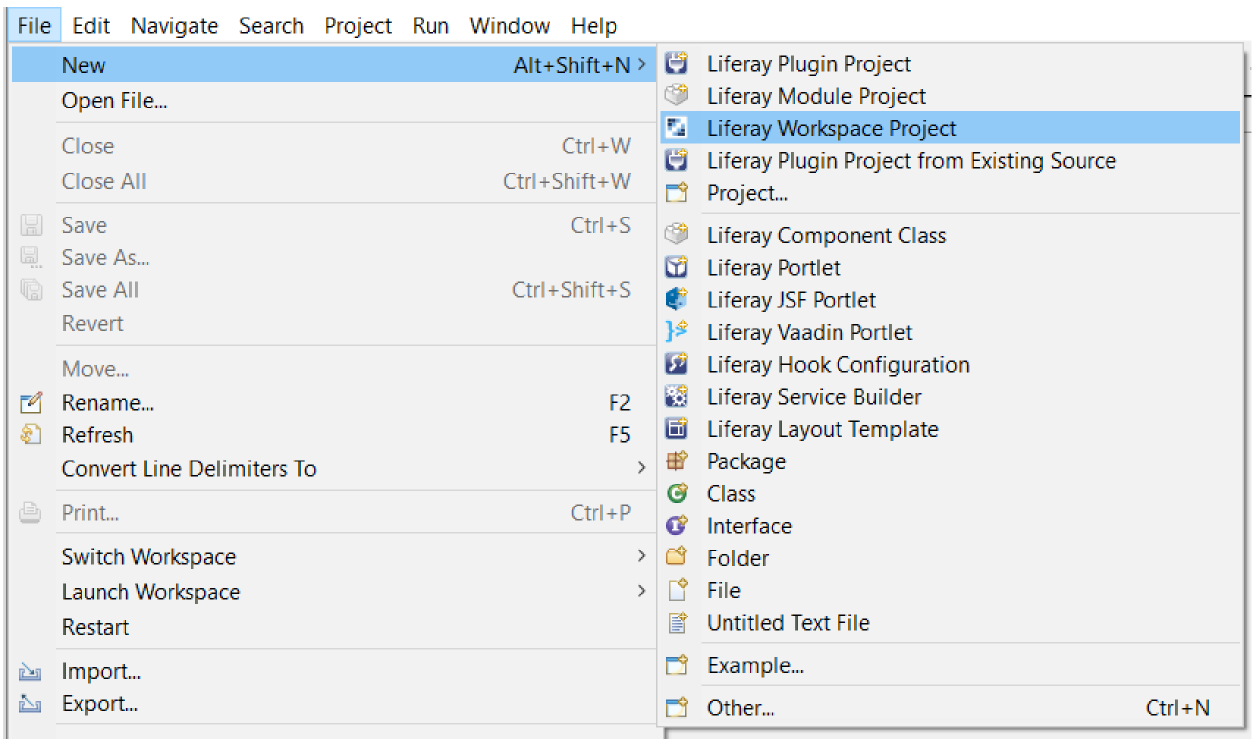

Figure 19.1: By selecting *Liferay Workspace*, you begin the process of creating a new workspace for your Liferay DXP projects.

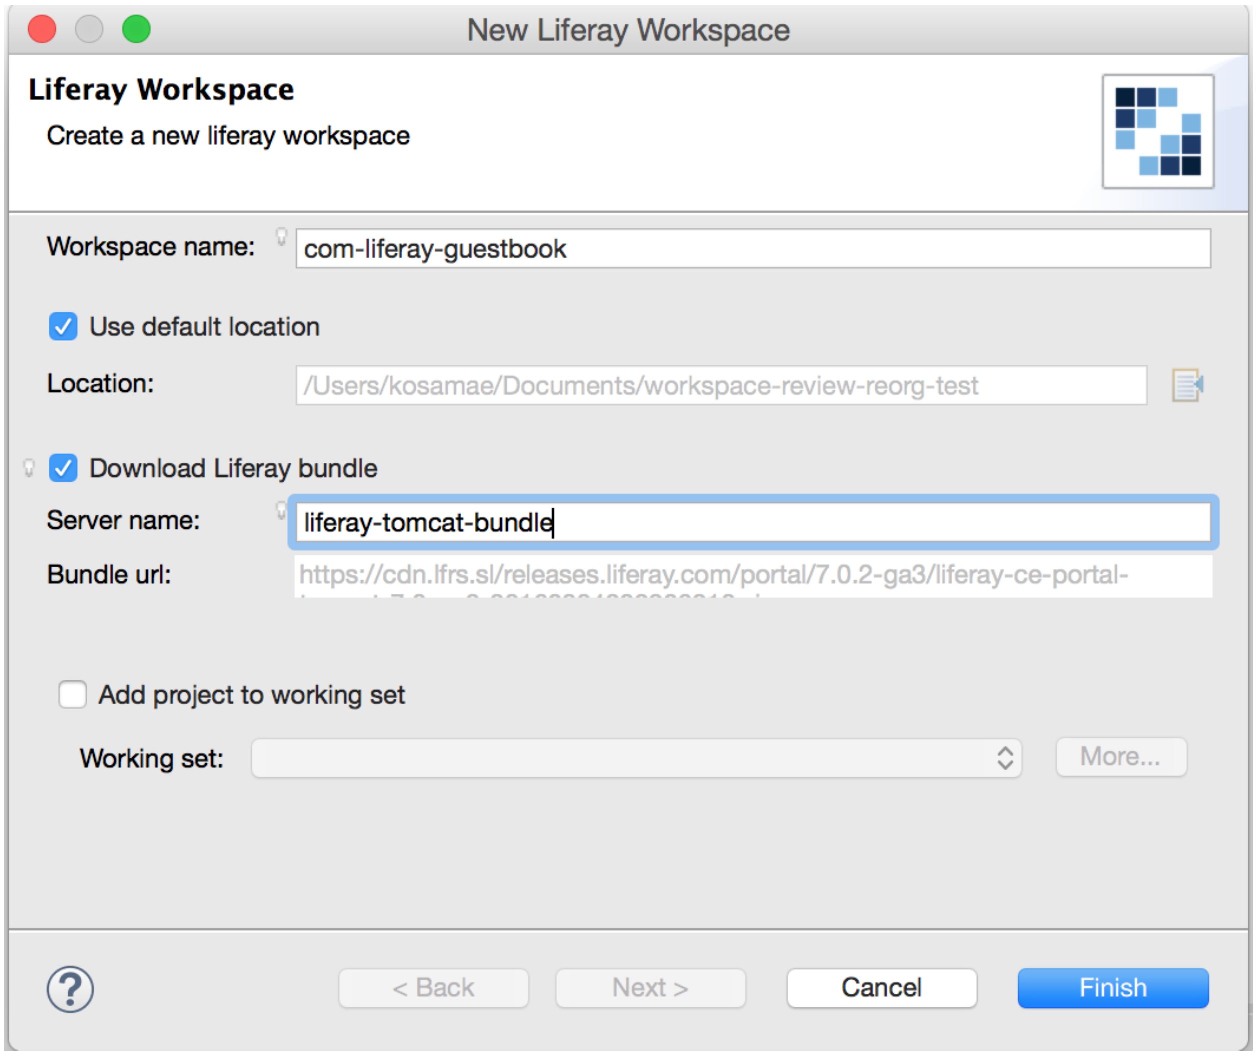


Workspace name: com-liferay-guestbook

✓ Use default location

Location: /Users/kosamae/Documents/workspace-review-reorg-test

✓ Download Liferay bundle

Server name: liferay-tomcat-bundle

Bundle url: https://cdn.lfrs.sl/releases.liferay.com/portal/7.0.2-ga3/liferay-ce-portal-

Add project to working set

Working set:

Figure 19.2: Liferay @ide@ provides an easy-to-follow menu to create your Liferay Workspace.

Chapter 20

Creating a Working Prototype

So far, you've installed and set up Liferay @ide@, and created a Liferay Workspace. Next, you'll create your application and start adding basic features to it. Here's what you'll do:

- Create your application and deploy it to your Liferay DXP instance.
- Create a functional button for adding and removing guestbook entries.
- Create a form for users to create and edit guestbook entries.
- Create a UI for displaying guestbook entries.
- Implement a prototype storage system (to be replaced later) for storing guestbook entries.

At the end, you'll have a fully functional prototype application ready to be enhanced later! There's no time like now to get started.

Let's Go!

20.1 Writing Your First Liferay DXP Application

`<p>Developing Your First Portlet<br>Step 1 of 8</p>`

It's easy to get started developing your first Liferay DXP application. Here, you'll learn step-by-step how to create your project and deploy your application to Liferay DXP. Before you know it, you'll have your application deployed alongside those that come with Liferay DXP.

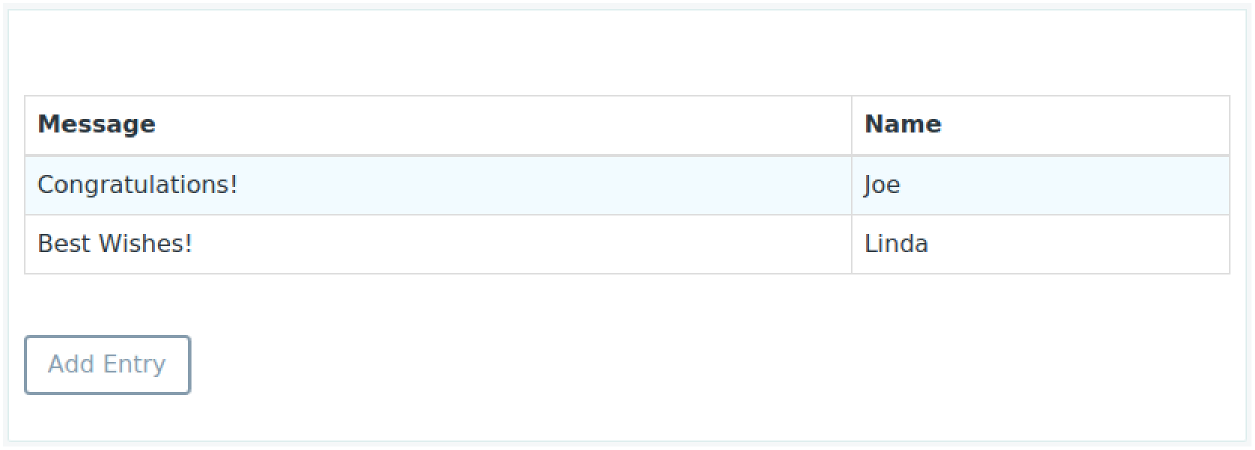
Your first application is simple: you'll build a guestbook application that looks like this:

By default, it shows guestbook messages that various users leave on your website. To add a message, you click the *Add Entry* button to show a form that lets you enter and save a message.

Ready to write your first Liferay DXP application?

Creating Your First Liferay DXP Application

Your first step is to create a *Liferay Module Project*. Modules are the core building blocks of Liferay DXP applications. Every application is made from one or more modules. Each module encapsulates a functional piece of an application, and then multiple modules form a complete application. There's good reason for this: modules let you swap out code implementations more or less at will. This makes your applications easy to maintain and upgrade.



Message	Name
Congratulations!	Joe
Best Wishes!	Linda

Figure 20.1: You'll create this simple application.

These modules are OSGi modules. The OSGi container in Liferay DXP can run any OSGi module. Each module is packaged as a JAR file that contains a manifest file. The manifest is needed for the container to recognize the module. Technically, a module that contains only a manifest is still valid. Of course, such a module wouldn't be very interesting.

Now you'll create your first module. For the purpose of this Learning Path, you'll create your modules inside your Liferay Workspace. Follow these instructions to create your first Liferay Module Project:

1. In the Project Explorer in Liferay @ide@, right click on your Liferay Workspace and select *New → Liferay Module Project*.

2. Complete the first screen of the wizard with the following information:

    - Enter `guestbook-web` for the Project name.
    - Use the *Gradle* Build type.
    - Select `mvc-portlet` for the Project Template.

    Click *Next*.

3. On the second screen of the wizard, enter `Guestbook` for the component class name, and `com.liferay.docs.guestbook.portlet` for the package name. Click *Finish*.

Note that it may take a while for @ide@ to create your project, because Gradle downloads your project's dependencies for you during project creation. Once this is done, you have a module project named `guestbook-web`. The `mvc-portlet` template configured the project with the proper dependencies and generated all the files you need to get started:

- The portlet class (in the package you specified)
- JSP files (in `/src/main/resources`)
- Language properties (also in `/src/main/resources`)

Your new module project is a *portlet* application. Next, you'll learn exactly what a portlet is.

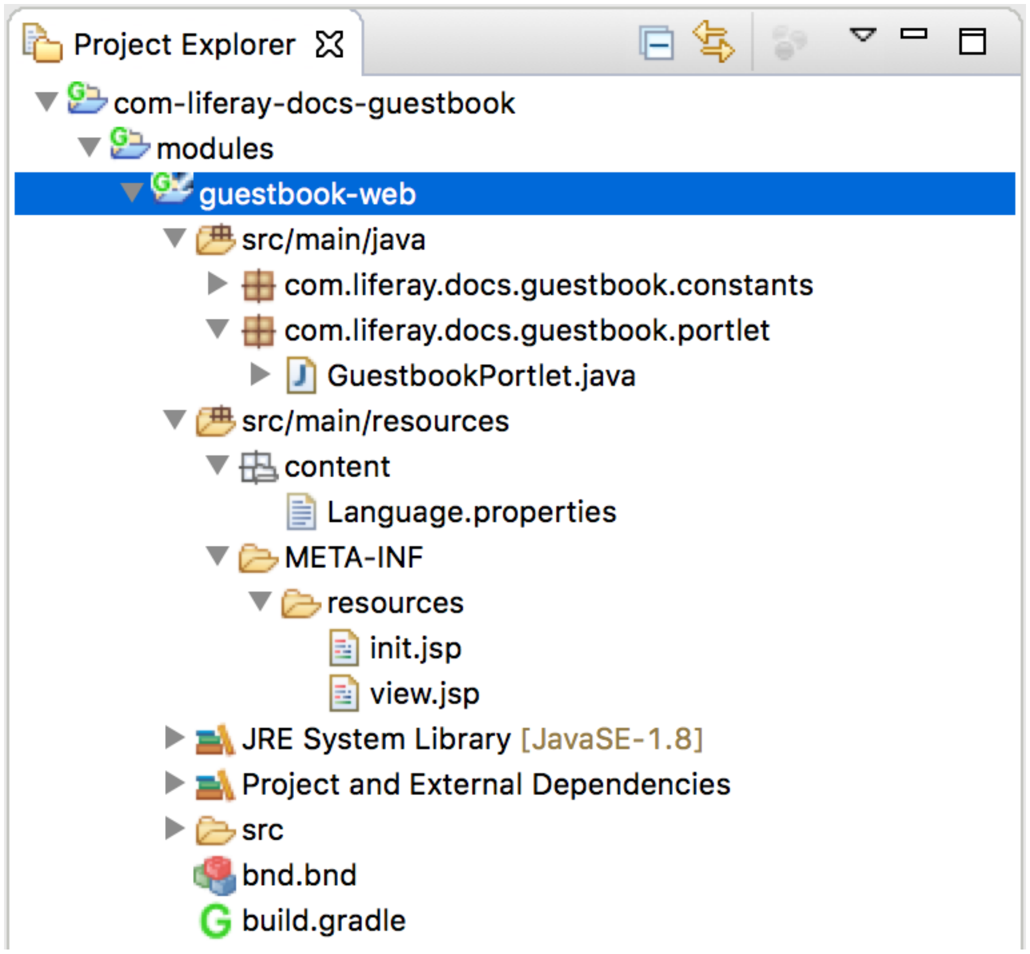


Figure 20.2: Your new module project appears in your Liferay Workspace's `modules` folder.

What is a Portlet?

When you access a web site, you interact with an application. That application could be simple: it might only show you one piece of information, such as an article. The application might be complex: you could be doing your taxes, entering lots of data into an application that calculates whether you owe or are due a refund. These applications run on a *platform* that provides application developers the building blocks they need to make applications.

Liferay DXP provides a platform that contains common features needed by today's applications, including user management, security, user interfaces, services, and more. Portlets are one of those basic building blocks. Often a web application takes up the entire page. If you want, you can do this with applications in Liferay DXP as well. Portlets, however, allow Liferay DXP to serve many applications on the same page at the same time. Liferay DXP's framework takes this into account at every step. For example, features like platform-generated URLs exist to support Liferay's ability to serve multiple applications on the same page.

What is a Component?

Portlets created in Liferay Module Projects are generated as *Components*. If the module (sometimes also called a *bundle*) encapsulates pieces of your application, the component is the object that contains the core functionality. A Component is an object that is managed by a component framework or container.

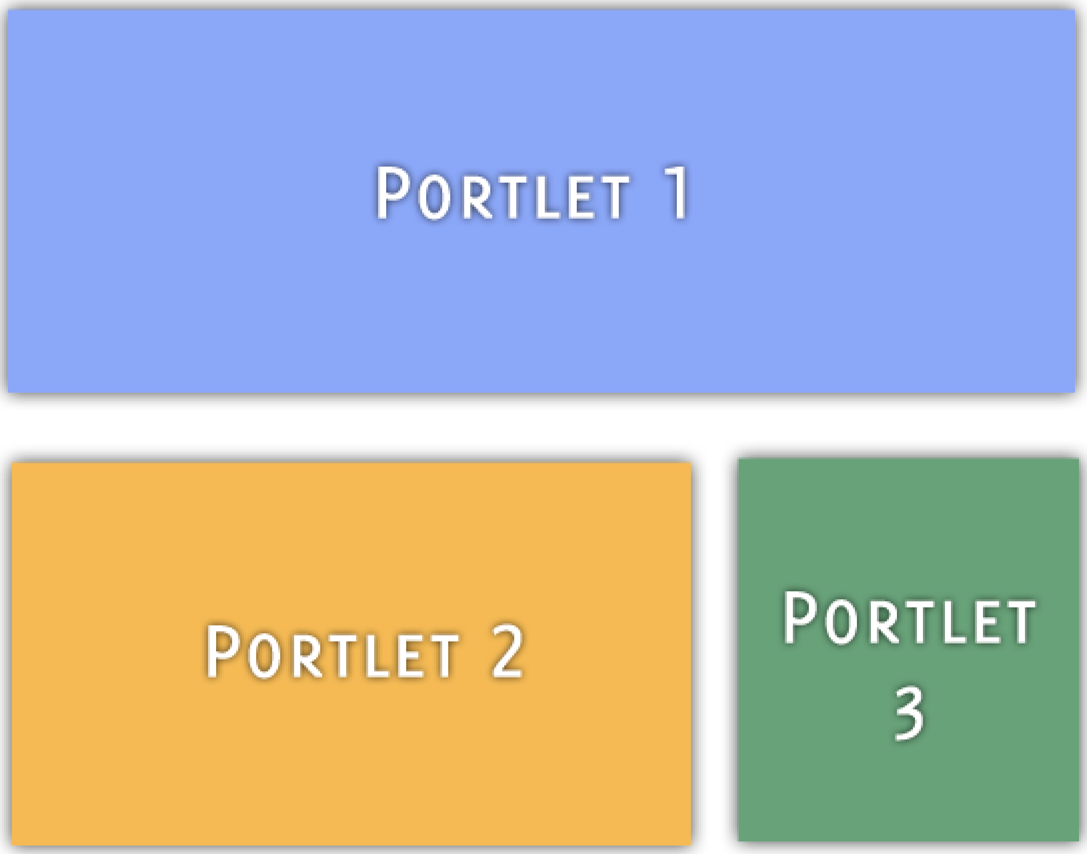

Figure 20.3: Many Liferay applications can run at the same time on the same page.

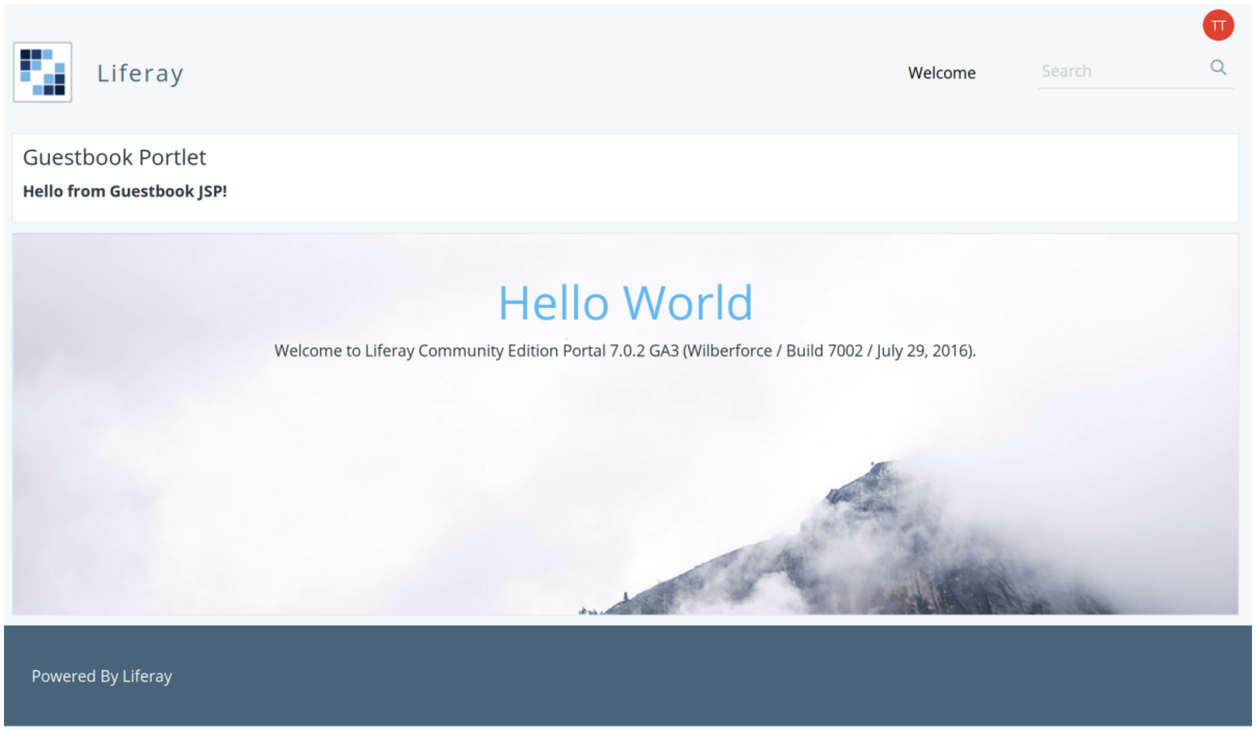
Components are deployed inside modules, and they're created, started, stopped, and destroyed as needed by the container. What a perfect model for a web application! It can be made available only when needed, and when it's not, the container can make sure it doesn't use any resources needed by other components.

In this case, you created a Declarative Services (DS) component. With Declarative Services, you declare that an object is a component, and you define some data about the component so the container knows how to manage it. A default configuration was created for you; you'll examine it later.

Deploying the Application

Even though all you've done is generate it, the `guestbook-web` project is ready to be built and deployed to Liferay DXP. Make sure that your server is running, and if it isn't, select it in @ide@'s Servers pane and click the start button. After it starts, drag and drop the `guestbook-web` project from the Project Explorer to the server. If this is your first time starting Liferay DXP, you'll go through a short wizard to set up your server. In this wizard, make sure you use the default database (Hypersonic). Although this database isn't intended for production use, it works fine for development and testing.

Next, check that your application is available in Liferay DXP. Open a browser, navigate to your portal (http://localhost:8080 by default), and add your application to a page. To add an application to a page, click the *Add* button in the upper right hand corner (it looks like a plus sign), and then select *Applications*. In the Applications list, your application should appear in the Sample category. Its name should be `guestbook-web-module Portlet`.



Liferay
Welcome
Search
Guestbook Portlet
Hello from Guestbook JSP!
Hello World
Welcome to Liferay Community Edition Portal 7.0.2 GA3 (Wilberforce / Build 7002 / July 29, 2016).
Powered By Liferay

Figure 20.4: This is the default Liferay homepage. It contains several portlets, including the initial version of the Guestbook application that you created.

Now you're ready to jump in and start developing your Guestbook portlet.

20.2 Creating an Add Entry Button

```
<p>Developing Your First Portlet<br>Step 2 of 8</p>
```

A guestbook application is pretty simple, right? People come to your site and post their names and brief messages. Other users can read these entries and post their own.

When you created your project, it generated a file named `view.jsp` in your project's `src/main/resources/META-INF/resources` folder. This file creates the default view for users when the portlet is added to the page. Right now it only contains some sample content:

```
<%@ include file="/init.jsp" %>

<p>
    <b><liferay-ui:message key="guestbook-web.caption"/></b>
</p>
```

First, `view.jsp` imports `init.jsp`. By convention, imports and tag library declarations in Liferay DXP portlet applications should be in an `init.jsp` file. The other JSP files in the application import `init.jsp`. This lets you handle JSP dependency management in a single file.

Besides importing `init.jsp`, `view.jsp` displays a message defined by a language key. This key and its value are declared in your project's `src/main/resources/content/Language.properties` file.

It's time to start developing the Guestbook application. First, users need a way to add a guestbook entry. In `view.jsp`, follow these steps to add this button:

1. Remove everything under the include for `init.jsp`.

2. Below the include, add the following AlloyUI tags to display an Add Entry button inside of a button row:

   ```
   <aui:button-row>
       <aui:button value="Add Entry"></aui:button>
   </aui:button-row>
   ```

You can use aui tags in `view.jsp` since `init.jsp` declares the AlloyUI tag library by default (as well as other important imports and tags):

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
<%@ taglib uri="http://java.sun.com/portlet_2_0" prefix="portlet" %>

<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>
<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>
<%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

<portlet:defineObjects />

<liferay-theme:defineObjects />
```

Your application now displays a button instead of a message, but the button doesn't do anything. Next, you'll create a URL for your button.

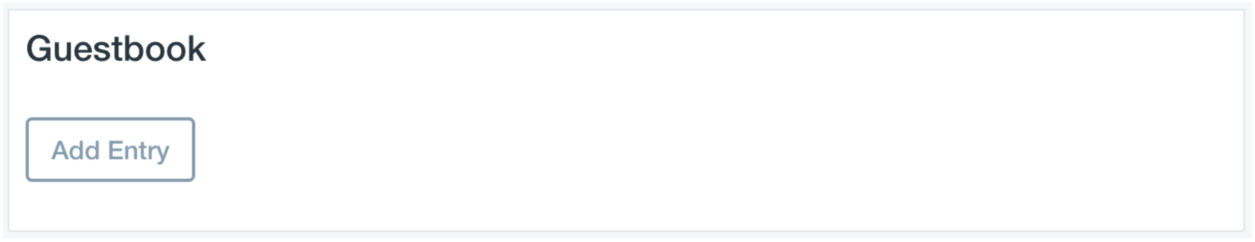


Figure 20.5: Your new button is awesome, but it doesn't work yet.

20.3 Generating Portlet URLs

```
<p>Developing Your First Portlet<br>Step 3 of 8</p>
```

Recall that users can place multiple portlets on a single page. As a developer, you have no idea what other portlets will share a page with yours. This means that you can't define URLs for various functions in your application like you may be used to.

For example, consider a Calendar application that a user puts on the same page as a Blog application. To implement the functionality for deleting calendar events and blog entries in the respective application, both application developers append the del parameter to the URL, and give it a primary key value so the application can look up and delete the calendar event or blog entry. Since both applications read this parameter, their delete functionality clashes.

System-generated URLs are Liferay DXP's solution to this. By generating a unique URL parameter for each piece of functionality, Liferay DXP lets multiple applications with the same or similar functionality coexist in perfect harmony. Unfortunately, for this to work in your portlet you must manually add support for it. Fortunately, doing so is very straightforward.

In view.jsp, follow these steps to enable system-generated URLs in your portlet:

1. Add these tags below <%@ include file="/init.jsp" %>, but above the <aui:button-row> tag:

```
<portlet:renderURL var="addEntryURL">
    <portlet:param name="mvcPath" value="/edit_entry.jsp"></portlet:param>
</portlet:renderURL>
```

2. Add this attribute to the <aui:button> tag, before value="Add Entry":

```
onClick="<%= addEntryURL.toString() %>"
```

   Your view.jsp page should now look like this:

```
<%@ include file="/init.jsp" %>

<portlet:renderURL var="addEntryURL">
    <portlet:param name="mvcPath" value="/edit_entry.jsp"></portlet:param>
</portlet:renderURL>

<aui:button-row>
    <aui:button onClick="<%= addEntryURL.toString() %>" value="Add Entry"></aui:button>
</aui:button-row>
```

The <portlet:renderURL> tag's var attribute creates the addEntryURL variable to hold the system-generated URL. The <portlet:param> tag defines a URL parameter to append to the URL. In this example, a URL parameter named mvcPath with a value of /edit_entry is appended to the URL.

Note that your GuestbookPortlet class (located in your guestbook-web module's com.liferay.docs.guestbook.portlet package) extends Liferay's MVCPortlet class. In a Liferay MVC portlet, the mvcPath URL parameter indicates a page within your portlet. To navigate to another page in your portlet, use a portal URL with the parameter mvcPath to link to the specific page.

In the example above, you created a renderURL that points to your application's edit_entry.jsp page, which you haven't yet created. Note that using an AlloyUI button to follow the generated URL isn't required. You can use any HTML construct that contains a link. Users can click your button to access your application's edit_entry.jsp page. This currently produces an error since no edit_entry.jsp exists yet. Creating edit_entry.jsp is your next step.

20.4 Linking to Another Page

```
<p>Developing Your First Portlet<br>Step 4 of 8</p>
```

In the same folder your view.jsp is in, create the edit_entry.jsp file:

1. Right-click your project's src/main/resources/META-INF/resources folder and choose *New → File*.

2. Name the file `edit_entry.jsp` and click *Finish*.

3. Add this line to the top of the file:

   ```
   <%@ include file="init.jsp" %>
   ```

   Remember, it's a best practice to add all JSP imports and tag library declarations to a single file that's imported by your application's other JSP files. For `edit_entry.jsp`, you need these imports to access the portlet tags that create URLs and the Alloy tags that create the form.

4. You'll create two URLs: one to submit the form and one to go back to the `view.jsp`. To create the URL to go back to `view.jsp`, add the following tag below the first line you added:

   ```
   <portlet:renderURL var="viewURL">
       <portlet:param name="mvcPath" value="/view.jsp"></portlet:param>
   </portlet:renderURL>
   ```

Next, you must create a new URL for submitting the form. Before you do, some explanation is in order.

20.5 Triggering Portlet Actions

```
<p>Developing Your First Portlet<br>Step 5 of 8</p>
```

Recall that portlets run in a portion of a page, and a page can contain multiple portlets. Because of this, portlets have *phases* of operation. Here, you'll learn about the most important two. The first phase is the one you've already used: the *render* phase. All this means is that the portlet draws itself, using the JSPs you write for it.

The other phase is called the *action* phase. This phase runs once, when a user triggers a portlet action. The portlet performs whatever action the user triggered, such as performing a search or adding a record to a database. Then, based on what happened in the action, the portlet goes back to the render phase and re-renders itself according to its new state.

To save a guestbook entry, you must trigger a portlet action. For this, you'll create an action URL.

Add the following tag in `edit_entry.jsp` after the closing `</portlet:renderURL>` tag:

```
<portlet:actionURL name="addEntry" var="addEntryURL"></portlet:actionURL>
```

You now have the two required URLs for your form.

20.6 Creating a Form

```
<p>Developing Your First Portlet<br>Step 6 of 8</p>
```

The form for creating guestbook entries is pretty simple. All you need are two fields: one for the name of the person submitting the entry, and one for the entry itself.

Add the following tags to the end of your `edit_entry.jsp` file:

```
<aui:form action="<%= addEntryURL %>" name="<portlet:namespace />fm">
        <aui:fieldset>
            <aui:input name="name"></aui:input>
            <aui:input name="message"></aui:input>
        </aui:fieldset>

        <aui:button-row>
            <aui:button type="submit"></aui:button>
            <aui:button type="cancel" onClick="<%= viewURL.toString() %>"></aui:button>
        </aui:button-row>
</aui:form>
```

Save `edit_entry.jsp` and redeploy your application. If you refresh the page and click the *Add Entry* button, your form appears. If you click the *Cancel* button, it works! However, don't try the *Save* button yet. You haven't yet created the action that saves a guestbook entry, so clicking *Save* produces an error.

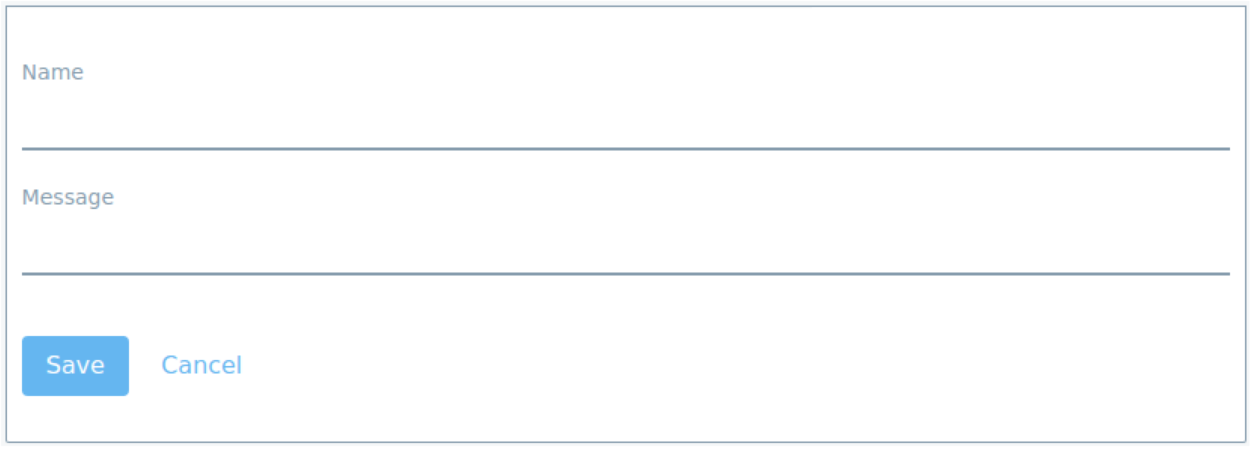

Figure 20.6: This is the Guestbook application's form for adding entries.

Implementing the portlet action (what happens when the user clicks *Save*) is your next task.

20.7 Implementing Portlet Actions

```
<p>Developing Your First Portlet<br>Step 7 of 8</p>
```

When users submit the form, your application stores the form data for display in the guestbook. To keep this first application simple, you'll implement this using a part of the Portlet API called Portlet Preferences. Normally, of course, you'd use a database. Liferay DXP's Service Builder tool eliminates a great deal of complexity when working with databases. For now, however, you can create the first iteration of your guestbook application using portlet preferences.

To make your portlet do anything other than re-render itself, you must implement portlet actions. An action defines some processing, usually based on user input, that the portlet must perform before it renders itself. In the case of the guestbook portlet, the action you'll implement next saves a guestbook entry that a user typed into the form. Saved guestbook entries can be retrieved and displayed later.

Since you're using Liferay's MVC Portlet framework, you have an easy way to implement actions. Portlet actions are implemented in the portlet class, which acts as the controller. In the form you just created, you made an action URL, and you called it `addEntry`. To create a portlet action, you create a method in the portlet class with the same name. `MVCPortlet` calls that method when a user triggers its matching URL.

1. Open GuestbookPortlet. The project template generated this class when you created the portlet project.

2. Create a method with the following signature:

   ```
   public void addEntry(ActionRequest request, ActionResponse response) {

   }
   ```

3. Press [CTRL]+[SHIFT]+O to organize imports and import the required javax.portlet.ActionRequest and javax.portlet.ActionResponse classes.

You've now created a portlet action. It doesn't do anything, but at least you won't get an error now if you submit your form. Next, you should make the action save the form data.

Because of the limitations of the portlet preferences API, you must store each guestbook entry as a String in a string array. Since your form has two fields, you must use a delimiter to determine where the user name ends and the guestbook entry begins. The caret symbol (^) makes a good delimiter because users are highly unlikely to use that symbol in a guestbook entry.

Note: The portlet preferences API is used here for prototyping purposes only. In most cases, you'll need a more robust solution for storing data. You'll learn how to implement such a solution later in the *Service Builder* section.

The following method implements adding a guestbook entry to a portlet preference called guestbook-entries:

```
public void addEntry(ActionRequest request, ActionResponse response) {
    try {
        PortletPreferences prefs = request.getPreferences();

        String[] guestbookEntries = prefs.getValues("guestbook-entries",
                new String[1]);

        ArrayList<String> entries = new ArrayList<String>();

        if (guestbookEntries[0] != null) {
            entries = new ArrayList<String>(Arrays.asList(prefs.getValues(
                    "guestbook-entries", new String[1])));
        }

        String userName = ParamUtil.getString(request, "name");
        String message = ParamUtil.getString(request, "message");
        String entry = userName + "^" + message;

        entries.add(entry);

        String[] array = entries.toArray(new String[entries.size()]);

        prefs.setValues("guestbook-entries", array);

        try {
            prefs.store();
        }
        catch (IOException ex) {
            Logger.getLogger(GuestbookPortlet.class.getName()).log(
                    Level.SEVERE, null, ex);
        }
        catch (ValidatorException ex) {
            Logger.getLogger(GuestbookPortlet.class.getName()).log(
                    Level.SEVERE, null, ex);
```

```
        }

    }
    catch (ReadOnlyException ex) {
        Logger.getLogger(GuestbookPortlet.class.getName()).log(
                Level.SEVERE, null, ex);
    }
}
```

1. Replace your existing addEntry method with the above method.

2. Press [CTRL]+[SHIFT]+O to organize imports and select the javax.portlet.PortletPreferences and java.util.logging.Logger when prompted (not their Liferay equivalents).

First, the preferences are retrieved. Then the guestbook-entries preference is retrieved and converted to an ArrayList so that you can add an entry without worrying about exceeding the size of the array. Next, the name and message fields from your form are retrieved. Note that Liferay's ParamUtil class makes it very easy to retrieve URL parameters.

Finally, the fields are combined into a String delimited by a caret, and the new entry is added to the ArrayList, which is then converted back to an array so it can be stored as a preference. The try/catch blocks are required by the portlet preferences API.

This isn't the normal way to use portlet preferences, but it provides a quick and easy way for you to store guestbook entries in this first version of your application. In a later step, you'll implement a robust way to store guestbook entries in a database.

The next and final feature to implement is a mechanism for viewing guestbook entries.

20.8 Displaying Guestbook Entries

```
<p>Developing Your First Portlet<br>Step 8 of 8</p>
```

To display guestbook entries, you must do the reverse of what you did to store them: retrieve them from portlet preferences, loop through them, and present them on the page. The best way to do this with MVC Portlet is to use the Model-View-Controller paradigm. You already have the view (your JSP files) and your controller (your portlet class). Now you need your model.

Creating Your Model

1. Create a new package called com.liferay.docs.guestbook.model. To do this, right-click your src/main/java folder and select *New → Package*. Then enter the package name in the dialog box that appears.

2. Next, create your model class. This is a simple class that models a guestbook entry. To do this, right-click your new package and select *New → Class*. Name the class Entry, and click *Finish*.

   You now have a Java class for your guestbook entries. Next, you'll give it the fields you need to store entries.

3. Create two private String variables: name and message.

```
private String name;
private String message;
```

4. Right-click a blank area of the editor and select *Source → Generate Getters and Setters*. Click *Select All* in the dialog that pops up, and then click *OK*.

5. Next, provide two constructors: one that initializes the class with no values for the two fields, and one that takes the two fields as parameters and sets their values:

   ```
   public Entry() {
      this.name = null;
      this.message = null;
   }

   public Entry(String name, String message) {
      setName(name);
      setMessage(message);
   }
   ```

Your completed model class looks like this:

```
package com.liferay.docs.guestbook.model;

public class Entry {

    private String name;
    private String message;

    public Entry() {
        this.name = null;
        this.message = null;
    }

    public Entry(String name, String message) {
        setName(name);
        setMessage(message);
    }

    public String getName() {
        return name;
    }

    public String getMessage() {
        return message;
    }

    public void setName(String name) {
        this.name = name;
    }

    public void setMessage(String message) {
        this.message = message;
    }

}
```

Now that you have your model, you have an easy way of encapsulating guestbook entries so they can be processed by the controller layer and displayed by the view layer. Your next step is to enhance the controller (your portlet class) so that guestbook entries are processed and ready to display when users see the guestbook application.

Customizing How Your Application is Rendered

As mentioned earlier, your application is using two portlet phases: render and action. To make the guestbook show the saved guestbook entries when users view the application, you need to customize your portlet's render functionality, which it's currently inheriting from its parent class, `MVCPortlet`.

1. Open GuestbookPortlet and add the following method below your addEntry method:

   ```
   @Override
   public void render(RenderRequest renderRequest, RenderResponse renderResponse)
       throws PortletException, IOException {

       PortletPreferences prefs = renderRequest.getPreferences();
       String[] guestbookEntries = prefs.getValues("guestbook-entries", new String[1]);

       if (guestbookEntries[0] ≠ null) {
           List<Entry> entries = parseEntries(guestbookEntries);
           renderRequest.setAttribute("entries", entries);
       }

       super.render(renderRequest, renderResponse);
   }
   ```

   This method retrieves the guestbook entries from the configuration, converts it to a List of Entry objects, and places that List into the request object. It then calls the parent class's render method.

2. Beneath the render method, add the following method that converts the array to a List of your model objects:

   ```
   private List<Entry> parseEntries(String[] guestbookEntries) {
       List<Entry> entries = new ArrayList<Entry>();

       for (String entry : guestbookEntries) {
           String[] parts = entry.split("\\^", 2);
           Entry gbEntry = new Entry(parts[0], parts[1]);
           entries.add(gbEntry);
       }

       return entries;
   }
   ```

3. Press [CTRL]+[SHIFT]+O to organize imports.

Note: When you are prompted to choose imports, here are some guidelines:

- Always use org.osgi... packages instead of aQute.bnd...
- Generally use java.util... or javax.portlet... packages.
- You never use java.awt... in this project.
- Only use com.liferay... when it is for a Liferay specific implementation or your custom implementation of a concept.

For example:

- If you are given the choice between javax.portlet.Portlet and com.liferay.portlet.Portlet choose javax.portlet.Portlet.
- If you are given the choice between org.osgi.component and aQute.bnd.annotation.component choose org.osgi.component

- However, if you are given the choice between `java.util.Map.Entry` and `com.liferay.docs.guestbook.model.Entry` (the custom class you created) choose `com.liferay.docs.guestbook.model.Entry`

If at some point you think you chose an incorrect import, but you're not sure what it might be, you can erase all of the imports from the file and press [CTRL]+[SHIFT]+O again and see if you can identify where you went wrong.

As you can see, this method splits the entries in the `String` array into two parts based on the caret (^) character.

Now that you have your controller preparing your data for display, your next step is to implement the view so users can see guestbook entries.

Displaying Guestbook Entries

Liferay's development framework makes it easy to loop through data and display it nicely to the end user. You'll use a Liferay UI construct called *Search Container* to make this happen.

1. Add these tags to your `view.jsp` in between the `</portlet:renderURL>` and `<aui:button-row>` tags:

```
<jsp:useBean id="entries" class="java.util.ArrayList" scope="request"/>

<liferay-ui:search-container>
    <liferay-ui:search-container-results results="<%= entries %>" />

    <liferay-ui:search-container-row
        className="com.liferay.docs.guestbook.model.Entry"
        modelVar="entry"
    >
        <liferay-ui:search-container-column-text property="message" />

        <liferay-ui:search-container-column-text property="name" />
    </liferay-ui:search-container-row>

    <liferay-ui:search-iterator />
</liferay-ui:search-container>
```

Save your work, deploy your application, and try adding some guestbook entries.

Awesome! You've finished your working prototype! You have a working application that adds and saves guestbook entries.

The way you're saving the entries isn't the best way to persist data in your application. Next, you'll use Service Builder to generate your persistence classes and the methods you need to store your application data in the database.

Chapter 21

Generating the Back-end

So far, you have a prototype application that uses Liferay's Model-View-Controller (MVC) portlet framework. MVC is a great design pattern for web applications because it splits your application into three parts (the model, the view, and the controller). This lets you swap out those parts if necessary.

A *persistence* layer and a *service* layer are added to these three parts of your application. To get the prototype working, you used Portlet Properties to create a rudimentary persistence layer. Since this isn't a long-term solution, you'll now replace that layer by persisting your guestbooks and their entries to a database.

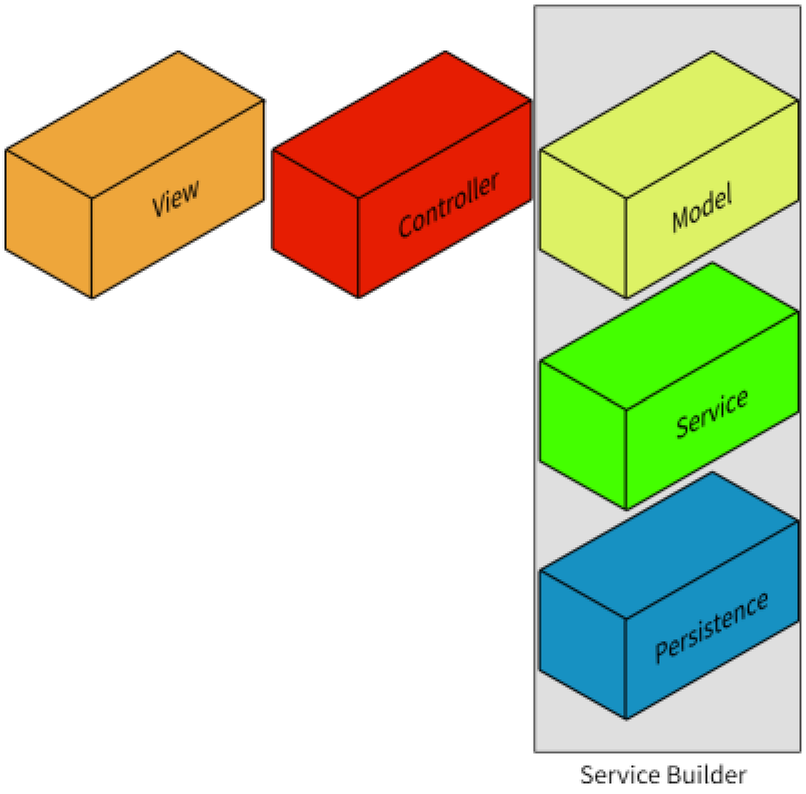

Figure 21.1: Service Builder generates the shaded layers of your application.

Service Builder is Liferay's code generation tool for defining object models and mapping those models to

SQL databases. By defining your model in a single XML file, you can generate your object model (the M in MVC), your service layer, and your persistence layer all in one shot. At the same time, you can generate web services (more on that later) and support every database Liferay DXP supports.

Ready to begin?

Let's Go!

21.1 What is Service Builder?

`<p>Generating the Back-end<br>Step 1 of 3</p>`

Now you'll use Service Builder to generate create, read, update, delete, and find operations for your application. You'll also use Service Builder to generate the necessary model, persistence, and service layers for your application. Then you can add your application's necessary business logic.

Guestbook Application Design

In the prototype application, you defined a single guestbook's entries and displayed them in a list. The full application will handle multiple Guestbooks and their entries. To make this work, you'll create two tables in the database: one for guestbooks, and one for guestbook entries.

Service Layer

This application is data-driven. It uses services for storing and retrieving data. The application asks for data, and the service fetches it. The application can then display this data to the user, who reads or modifies it. If the data is modified, the application passes it back to the service, and the service stores it. The application doesn't need to know anything about how the service does what it does.

To get started, you'll create a Service Builder project and populate its `service.xml` file with all the necessary entities to generate this code:

1. In Liferay @ide@, click *File → New → Liferay Module Project*.
2. Name the project `guestbook`.
3. Select `service-builder` for the Project Template Name.
4. Click *Next*.
5. Enter `com.liferay.docs.guestbook` for the *Package Name*.
6. Click *Finish*.

This creates two modules: an API module (`guestbook-api`) and a service module (`guestbook-service`). Next, you'll learn how to use them.

21.2 Generating Model, Service, and Persistence Layers

Figure 21.2: Your current project structure.

The persistence layer saves and retrieves your model data. The service layer is a buffer between your application and persistence layers: having it lets you swap out your persistence layer for a different implementation without modifying anything but the calls in the service layer.

To model the guestbooks and entries, you'll create guestbook and entry model classes. But you won't do this directly in Java. Instead, you'll define them in Service Builder, which generates your object model and maps it to all the SQL databases Liferay DXP supports.

This application's design lets you create multiple guestbooks, each containing different sets of entries. All users with permission to access the application can add entries, but only administrative users can add guestbooks.

It's time to get started. You'll create the `Guestbook` entity first:

1. In your `guestbook-service` project, open `service.xml`.

2. When Liferay @ide@ generated your project, it filled this file with dummy entities, which you'll replace. First replace the file's opening contents (below the `DOCTYPE`) with the following code:

```
<service-builder auto-namespace-tables="true" package-path="com.liferay.docs.guestbook">
    <author>liferay</author>
    <namespace>GB</namespace>
    <entity name="Guestbook" local-service="true" uuid="true">
```

   This defines the author, namespace, and the entity name. The namespace keeps the database field names from conflicting. The last tag is the opening tag for the `Guestbook` entity definition. In this tag, you enable local services for the entity, define its name, and specify that it should have a universally unique identifier (UUID).

3. Next, replace the PK fields section:

   ```
   <column name="guestbookId" primary="true" type="long" />
   ```

   This defines `guestbookId` as the entity's primary key, of the type `long`.

4. The group instance can be left alone.

   ```
   <column name="groupId" type="long" />
   ```

   This defines the ID of the site in Liferay DXP that the entity instance belongs to (more on this in a moment).

5. Leave the Audit Fields section alone. Add status fields:

   ```
   <!-- Status fields -->

   <column name="status" type="int" />
   <column name="statusByUserId" type="long" />
   <column name="statusByUserName" type="String" />
   <column name="statusDate" type="Date" />
   ```

   The Audit section defines Liferay DXP metadata. The `companyId` is the primary key of a portal instance. The `userId` is the primary key of a user. The `createDate` and `modifiedDate` store the respective dates on which the entity instance is created and modified. The Status section is used later to implement workflow.

6. In the Other fields section, remove all the generated fields and put this one in their place:

   ```
    <column name="name" type="String" />
   ```

7. Next, remove everything else from the Guestbook entity. Before the closing `</entity>` tag, add this finder definition:

   ```
       <finder name="GroupId" return-type="Collection">
           <finder-column name="groupId" />
       </finder>
   ```

   This defines a finder that generates a `get` method you'll use to retrieve Guestbook entities. The fields used by the finder define the scope of the data retrieved. This finder gets all Guestbooks by their `groupId`, which corresponds to the site the application is on. This lets administrators put Guestbooks on multiple sites, and each `Guestbook` has its own data scoped to its site.

The `Guestbook` entity is finished for now. Next, you'll create the `Entry` entity:

1. Add the opening entity tag:

   ```
   <entity name="Entry" local-service="true" uuid="true">
   ```

As with the `Guestbook` entity, you enable local services, define the entity's name, and specify that it should have a UUID.

2. Add the tag to define the primary key and the `groupId`:

```
<column name="entryId" primary="true" type="long" />

<column name="groupId" type="long" />
```

3. Add the audit fields as you did with the `Guestbook` entity:

```
<column name="companyId" type="long" />
<column name="userId" type="long" />
<column name="userName" type="String" />
<column name="createDate" type="Date" />
<column name="modifiedDate" type="Date" />
```

4. Add status fields like you did for the guestbook:

```
 <!-- Status fields -->

 <column name="status" type="int" />
 <column name="statusByUserId" type="long" />
 <column name="statusByUserName" type="String" />
 <column name="statusDate" type="Date" />
```

5. Add the fields that define an `Entry`:

```
<column name="name" type="String" />
<column name="email" type="String" />
<column name="message" type="String" />
<column name="guestbookId" type="long" />
```

The `name`, `email`, and `message` fields comprise an `Entry`. These fields define the name of the person creating the entry, their email address, and the Guestbook message, respectively. The `guestbookId` is assigned automatically by code you'll write, and is a `Guestbook` foreign key. This ties the `Entry` to a specific `Guestbook`.

6. Add your finder and closing entity tag:

```
    <finder name="G_G" return-type="Collection">
        <finder-column name="groupId" />
        <finder-column name="guestbookId" />
    </finder>
</entity>
```

Here, you define a finder that gets guestbook entries by `groupId` and `guestbookId`. As before, the `groupId` corresponds to the site the application is on. The `guestbookId` defines the guestbook the entries come from. This finder returns a `Collection` of entries.

7. Define your exception types outside the `<entity>` tags, just before the closing `</service-builder>` tag:

```
<exceptions>
    <exception>EntryEmail</exception>
    <exception>EntryMessage</exception>
    <exception>EntryName</exception>
    <exception>GuestbookName</exception>
</exceptions>
```

These generate exception classes you'll use later in try/catch statements.

8. Save your `service.xml` file.

Now you're ready to run Service Builder to generate your model, service, and persistence layers!

1. In the Gradle Tasks pane on the right side of @ide@, open `guestbook-service` → `build`.
2. Run `buildService` by right-clicking it and selecting *Run Gradle Tasks*. Make sure you're connected to the Internet, as Gradle downloads dependencies the first time you run it.
3. In the Project Explorer, right-click the `guestbook-service` module and select *Refresh*. Repeat this step for the `guestbook-api` module. This ensures that the new classes and interfaces generated by Service Builder show up in @ide@.
4. In the Project Explorer, right-click the `guestbook-service` module and select *Gradle → Refresh Gradle Project*. Repeat this step for the `guestbook-api` module. This ensures that your modules' Gradle dependencies are up to date.

Service Builder is based on a design philosophy called loose coupling. It generates three layers of your application: the model, the service, and the persistence layers. Loose coupling means you can swap out the persistence layer with little to no change in the model and service layers. The model is in the `-api` module, and the service and persistence layers are in the `-service` module.

Each layer is implemented using Java Interfaces and implementations of those interfaces. Rather than have one `Entry` class that represents your model, Service Builder generates a system of classes that include a `Guestbook` interface, a `GuestbookBaseImpl` abstract class that Service Builder manages, and a `GuestbookImpl` class that you can customize. This design lets you customize your model, while Service Builder generates code that's tedious to write. That's why Service Builder is a code generator for code generator haters.

Next, you'll create the service implementations.

21.3 Implementing Service Methods

```
<p>Generating the Back-end<br>Step 3 of 3</p>
```

When you use Service Builder, you implement the services in the service module. Because your application's projects are components, you can reference your service layer from your web module.

You'll implement services for guestbooks and entries in the `guestbook-service` module's `GuestbookLocalServiceImpl` and `EntryLocalServiceImpl`, respectively.

Follow these steps to implement services for guestbooks in `GuestbookLocalServiceImpl`:

1. In the `com.liferay.docs.guestbook.service.impl` package, open `GuestbookLocalServiceImpl`. Then add this `addGuestbook` method:

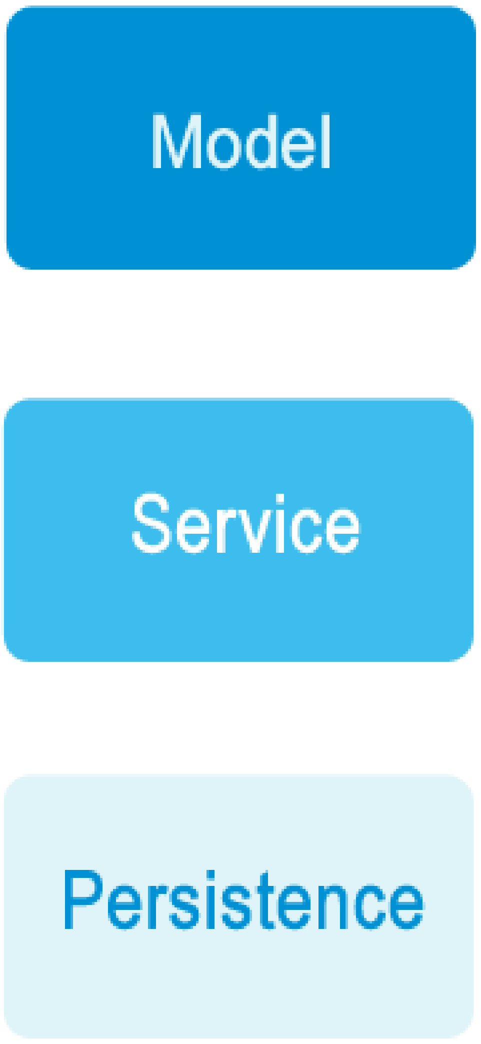

Figure 21.3: The Model, Service, and Persistence Layer.

```
public Guestbook addGuestbook(
    long userId, String name, ServiceContext serviceContext)
    throws PortalException {

    long groupId = serviceContext.getScopeGroupId();

    User user = userLocalService.getUserById(userId);

    Date now = new Date();

    validate(name);

    long guestbookId = counterLocalService.increment();

    Guestbook guestbook = guestbookPersistence.create(guestbookId);

    guestbook.setUuid(serviceContext.getUuid());
    guestbook.setUserId(userId);
    guestbook.setGroupId(groupId);
    guestbook.setCompanyId(user.getCompanyId());
    guestbook.setUserName(user.getFullName());
    guestbook.setCreateDate(serviceContext.getCreateDate(now));
    guestbook.setModifiedDate(serviceContext.getModifiedDate(now));
    guestbook.setName(name);
    guestbook.setExpandoBridgeAttributes(serviceContext);

    guestbookPersistence.update(guestbook);

    return guestbook;

}
```

This method adds a guestbook to the database. It retrieves metadata from the environment (such as the current user's ID, the group ID, etc.), along with data passed from the user. It validates this data and uses it to construct a `Guestbook` object. The method then persists this object to the database and returns the object. You only implement the business logic here because Service Builder already generated the model and all the code that maps that model to the database.

2. Add the methods for getting `Guestbook` objects:

```
public List<Guestbook> getGuestbooks(long groupId) {

    return guestbookPersistence.findByGroupId(groupId);
}

public List<Guestbook> getGuestbooks(long groupId, int start, int end,
    OrderByComparator<Guestbook> obc) {

    return guestbookPersistence.findByGroupId(groupId, start, end, obc);
}

public List<Guestbook> getGuestbooks(long groupId, int start, int end) {

    return guestbookPersistence.findByGroupId(groupId, start, end);
}

public int getGuestbooksCount(long groupId) {

    return guestbookPersistence.countByGroupId(groupId);
}
```

These call the finders you generated with Service Builder. The first method retrieves a list of guestbooks from the site specified by `groupId`. The next two methods get paginated lists, optionally in a particular order. The final method gives you the total number of guestbooks for a given site.

3. Finally, add the guestbook validator method:

```
protected void validate(String name) throws PortalException {
    if (Validator.isNull(name)) {
        throw new GuestbookNameException();
    }
}
```

   This method uses Liferay DXP's `Validator` to make sure the user entered text for the guestbook name.

4. Press [CTRL]+[SHIFT]+O to organize imports and select the following when prompted:

   - `java.util.Date`
   - `com.liferay.portal.kernel.service.ServiceContext`
   - `com.liferay.docs.guestbook.model.Entry`
   - `com.liferay.portal.kernel.util.Validator`

Now you're ready to implement services for entries in `EntryLocalServiceImpl`. Do so now by following these steps:

1. In the `com.liferay.docs.guestbook.service.impl` package, open `EntryLocalServiceImpl`. Add this `addEntry` method:

```
public Entry addEntry(
    long userId, long guestbookId, String name, String email,
    String message, ServiceContext serviceContext)
    throws PortalException {

    long groupId = serviceContext.getScopeGroupId();

    User user = userLocalService.getUserById(userId);

    Date now = new Date();

    validate(name, email, message);

    long entryId = counterLocalService.increment();

    Entry entry = entryPersistence.create(entryId);

    entry.setUuid(serviceContext.getUuid());
    entry.setUserId(userId);
    entry.setGroupId(groupId);
    entry.setCompanyId(user.getCompanyId());
    entry.setUserName(user.getFullName());
    entry.setCreateDate(serviceContext.getCreateDate(now));
    entry.setModifiedDate(serviceContext.getModifiedDate(now));
    entry.setExpandoBridgeAttributes(serviceContext);
    entry.setGuestbookId(guestbookId);
    entry.setName(name);
    entry.setEmail(email);
    entry.setMessage(message);

    entryPersistence.update(entry);

    return entry;
}
```

Like the addGuestbook method, addEntry takes data from the current context along with data the user entered, validates it, and creates a model object. That object is then persisted to the database and returned.

2. Add this updateEntry method:

```
public Entry updateEntry (
    long userId, long guestbookId, long entryId, String name, String email,
    String message, ServiceContext serviceContext)
    throws PortalException, SystemException {

    Date now = new Date();

    validate(name, email, message);

    Entry entry = getEntry(entryId);

    User user = userLocalService.getUserById(userId);

    entry.setUserId(userId);
    entry.setUserName(user.getFullName());
    entry.setModifiedDate(serviceContext.getModifiedDate(now));
    entry.setName(name);
    entry.setEmail(email);
    entry.setMessage(message);
    entry.setExpandoBridgeAttributes(serviceContext);

    entryPersistence.update(entry);

    return entry;
}
```

This method first retrieves the entry and updates its data to reflect what the user submitted, including its date modified.

3. Add this deleteEntry method:

```
public Entry deleteEntry (long entryId, ServiceContext serviceContext)
    throws PortalException {

    Entry entry = getEntry(entryId);

    entry = deleteEntry(entryId);

    return entry;
}
```

This method retrieves the entry object defined by entryId, deletes it from the database, and then returns the deleted object.

4. Add the methods for getting Entry objects:

```
public List<Entry> getEntries(long groupId, long guestbookId) {
    return entryPersistence.findByG_G(groupId, guestbookId);
}

public List<Entry> getEntries(long groupId, long guestbookId, int start, int end)
    throws SystemException {

    return entryPersistence.findByG_G(groupId, guestbookId, start, end);
}
```

```
public List<Entry> getEntries(
    long groupId, long guestbookId, int start, int end, OrderByComparator<Entry> obc) {

    return entryPersistence.findByG_G(groupId, guestbookId, start, end, obc);
}

public int getEntriesCount(long groupId, long guestbookId) {
    return entryPersistence.countByG_G(groupId, guestbookId);
}
```

These methods, like the getters in `GuestbookLocalServiceImpl`, call the finders you generated with Service Builder. These `getEntries*` methods, however, retrieve entries from a specified guestbook and site. The first method gets a list of entries. The next method gets a paginated list. The third method sorts the paginated list, and the last method gets the total number of entries as an integer.

5. Add the `validate` method:

```
protected void validate(String name, String email, String entry)
    throws PortalException {

    if (Validator.isNull(name)) {
        throw new EntryNameException();
    }

    if (!Validator.isEmailAddress(email)) {
        throw new EntryEmailException();
    }

    if (Validator.isNull(entry)) {
        throw new EntryMessageException();
    }
}
```

   This method makes sure the user entered relevant data when creating an entry.

6. Press [CTRL]+[SHIFT]+O to organize imports and select the following when prompted:

   - `java.util.Date`
   - `com.liferay.portal.kernel.service.ServiceContext`
   - `com.liferay.docs.guestbook.model.Entry`
   - `com.liferay.portal.kernel.util.Validator`

Nice work! These local service methods implement the services that are referenced in the portlet class.

Updating Generated Classes

Now that you've implemented the service methods, you must make them available to the rest of your application. To do this, run `buildService` again:

1. In *Gradle Tasks → guestbook-service → build*, right-click `buildService` and select *Run Gradle Tasks*. In the utility classes, Service Builder populates calls to your newly created service methods.

2. In the Project Explorer, right-click the `guestbook-service` module and select *Refresh*. Repeat this step for the `guestbook-api` module. This ensures that the changes made by Service Builder show up in Liferay @ide@.

3. In the Project Explorer, right-click the `guestbook-service` module and select *Gradle → Refresh Gradle Project*. Repeat this step for the `guestbook-api` module. This ensures that your modules' Gradle dependencies are up to date.

Tip: If something goes awry when working with Service Builder, repeat these steps to run Service Builder again and refresh your api and service modules.

Excellent! Your new back-end has been generated. Now it's time to refactor your prototype to use it.

Chapter 22

Refactoring the Prototype

In an earlier section of this Learning Path, you created a Guestbook portlet prototype. Then you wrote a `service.xml` file to define your application's data model, and used Service Builder to generate the back-end code (the model, service, and persistence layers). You also added service methods using the appropriate extension points: your entities' `*LocalServiceImpl` classes. Now you need to integrate the original prototype with the new back-end to create a fully functional application.

There are many differences between the prototype and the application you'll create. In the back-end, you've already accounted for one big difference: users can create multiple Guestbooks that each have their own entries. In the front-end, however, only site administrators should be able to create guestbooks. Therefore, you'll create another portlet called Guestbook Admin and place it in the Content menu for sites.

To turn this application from a prototype into a full-fledged Liferay web application, you'll make these changes:

- Modify your view layer's folder structure to account for the administrative portlet
- Set the Display Category so users can find the application more easily
- Create a file to store the application's text keys
- Change the controller to call your new Service Builder-based back-end
- Update the view so it can display multiple Guestbooks in tabs

Ready to begin?
Let's Go!

22.1 Organizing Folders for Larger Applications

`<p>Refactoring the Prototype<br>Step 1 of 6</p>`

Currently, all your JSPs sit in your web module's `src/main/resources/META-INF/resources` folder, which serves as the context root folder. To make a clear separation between the Guestbook portlet and the Guestbook Admin portlet, you must place the files that make up their view layers in separate folders:

1. In the `guestbook-web` project, right click the `src/main/resources/META-INF/resources` folder and select *New → Folder*. Name the new folder `guestbookwebportlet` and click *Finish*.

2. Copy `view.jsp` and `edit_entry.jsp` into the new folder by dragging and dropping them there.

3. Open both files and change the `init.jsp` location at the top of the file:

   ```
   <%@include file="../init.jsp"%>
   ```

4. Check the other references to JSPs within the files to make sure that they point to the new locations.

As you update your view layer to take full advantage of the new back-end, you'll update any references to the old paths. In addition, you must update the resource location in your component properties. In the next step, you'll update all of those properties, including the one that defines the resource location.

22.2 Defining the Component Metadata Properties

<p>Refactoring the Prototype<br>Step 2 of 6</p>

When users add applications to a page, they pick them from a list of *display categories*.

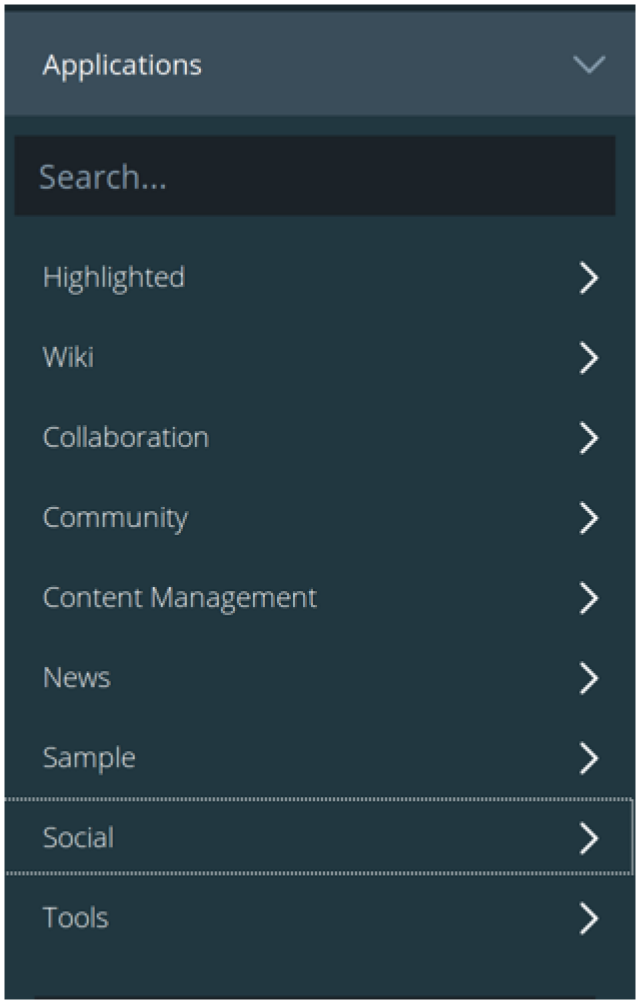

Figure 22.1: Users choose applications from a list of display categories.

A portlet's display category is defined in its component class as a metadata property. Since the Guestbook portlet lets users communicate with each other, you'll add it to the Social category. Only one Guestbook portlet should be added to a page, so you'll also define it as a *non-instanceable* portlet. Such a portlet can appear only once on a page or site, depending on its scope.

Open the `GuestbookPortlet` class and update the component class metadata properties to match this configuration:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.social",
        "com.liferay.portlet.instanceable=false",
        "com.liferay.portlet.scopeable=true",
        "javax.portlet.display-name=Guestbook",
        "javax.portlet.expiration-cache=0",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/guestbookwebportlet/view.jsp",
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=power-user,user",
        "javax.portlet.supports.mime-type=text/html"
    },
    service = Portlet.class
)
```

The `com.liferay.portlet.display-category=category.social` property sets the Guestbook portlet's display category to *Social*. The `com.liferay.portlet.instanceable=false` property specifies that the Guestbook portlet is non-instanceable, so only one instance of the portlet can be added to a page. In the property `javax.portlet.init-param.view-template`, you also update the location of the main `view.jsp` to its new location in `/guestbookwebportlet`.

Since you edited the portlet's metadata, you must remove and re-add the portlet to the page before continuing:

1. Go to `localhost:8080` in your web browser.

2. Sign in to your administrative account.

3. The Guestbook portlet now shows an error on the page. Click its portlet menu (at the top-right of the portlet), then select *Remove* and click *OK* to confirm.

4. Open the *Add* menu and select *Applications*.

5. Open the *Social* category and drag and drop the *Guestbook* application onto the page.

Great! Now the Guestbook portlet appears in an appropriate category. Though you were able to add it to the page before, the user experience is better.

22.3 Creating Portlet Keys

```
<p>Refactoring the Prototype<br>Step 3 of 6</p>
```

`PortletKeys` let you manage important things like the portlet name or other repeatable, commonly used variables in one place. This way, if you need to change the portlet's name, you can do it in one place, and then reference it in every class that needs it. Keys must be referenced first as a component property, and then as a class.

Follow these steps to create your application's `PortletKeys`:

1. In your guestbook-web module, open the GuestbookPortlet class and update the component class metadata properties by adding one new property:

   ```
   "javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK,
   ```

   Note that you need the trailing comma if you've added the property to the middle of the list. If you've added it to the end of the last, leave it off.

2. Save GuestbookPortlet. It now shows an error because you haven't added the key to the class.

3. Open the com.liferay.docs.guestbook.constants package.

4. Open GuestbookPortletKeys and create a public, static, final String called GUESTBOOK with a value of com_liferay_docs_guestbook_portlet_GuestbookPortlet:

   ```
   public static final String GUESTBOOK =
           "com_liferay_docs_guestbook_portlet_GuestbookPortlet";
   ```

5. Save the file.

Now GuestbookPortlet's error has disappeared, and your application can be deployed again. Nice job! Next, you'll integrate your application with the new back-end you generated with Service Builder.

22.4 Integrating the New Back-end

```
<p>Refactoring the Prototype<br>Step 4 of 6</p>
```

It's a good practice to start with a working prototype as a proof of concept, but eventually that prototype must transform into a real application. Up to this point, you've made all the preparations to do that, and now it's time to replace the prototype back-end with the real, database-driven back-end you created with Service Builder.

For the prototype, you manually created the application's model. The first thing you want to do is remove it, because Service Builder generated a new one:

1. Find the com.liferay.docs.guestbook.model package in the guestbook-web module.

2. Delete it. You'll see errors in your project, but that's because you haven't replaced the model yet.

Now you get to do some dependency management. For the web module to access the generated services, you must make it aware of the API and service modules. Then you can update the addEntry method in GuestbookPortlet to use the new services:

1. First, open guestbook-web's build.gradle file and add these dependencies:

   ```
   compileOnly project(":modules:guestbook:guestbook-api")
   compileOnly project(":modules:guestbook:guestbook-service")
   ```

2. Right-click on the guestbook-web project and select *Gradle → Refresh Gradle Project*.

3. Now you must add *references* to the Service Builder services you need. To do this, add them as class variables with `@Reference` annotations on their setter methods. Open `GuestbookPortlet` and add these references to the bottom of the file:

```
    @Reference(unbind = "-")
    protected void setEntryService(EntryLocalService entryLocalService) {
        _entryLocalService = entryLocalService;
    }

    @Reference(unbind = "-")
    protected void setGuestbookService(GuestbookLocalService guestbookLocalService) {
        _guestbookLocalService = guestbookLocalService;
    }

    private EntryLocalService _entryLocalService;
    private GuestbookLocalService _guestbookLocalService;
```

   Note that it's Liferay's code style to add class variables this way. The `@Reference` annotation on the setters allows Liferay's OSGi container to inject references to your generated services so you can use them. The `unbind` parameter tells the container there's no method for unbinding these services: the references can die with the class during garbage collection when they're no longer needed.

4. Now you can modify the `addEntry` method to use these service references:

```
public void addEntry(ActionRequest request, ActionResponse response)
            throws PortalException {

        ServiceContext serviceContext = ServiceContextFactory.getInstance(
            Entry.class.getName(), request);

        String userName = ParamUtil.getString(request, "name");
        String email = ParamUtil.getString(request, "email");
        String message = ParamUtil.getString(request, "message");
        long guestbookId = ParamUtil.getLong(request, "guestbookId");
        long entryId = ParamUtil.getLong(request, "entryId");

    if (entryId > 0) {

        try {

            _entryLocalService.updateEntry(
                serviceContext.getUserId(), guestbookId, entryId, userName,
                email, message, serviceContext);

            SessionMessages.add(request, "entryAdded");

            response.setRenderParameter(
                "guestbookId", Long.toString(guestbookId));

        }
        catch (Exception e) {
            System.out.println(e);

            SessionErrors.add(request, e.getClass().getName());

            PortalUtil.copyRequestParameters(request, response);

            response.setRenderParameter(
                "mvcPath", "/guestbookwebportlet/edit_entry.jsp");
        }

    }
    else {
        try {
            _entryLocalService.addEntry(
                serviceContext.getUserId(), guestbookId, userName, email,
                message, serviceContext);

            SessionMessages.add(request, "entryAdded");

            response.setRenderParameter(
                "guestbookId", Long.toString(guestbookId));

        }
        catch (Exception e) {
            SessionErrors.add(request, e.getClass().getName());

            PortalUtil.copyRequestParameters(request, response);

            response.setRenderParameter(
                "mvcPath", "/guestbookwebportlet/edit_entry.jsp");
        }
    }
}
```

This `addEntry` method gets the name, message, and email fields that the user submits in the JSP and passes them to the service to be stored as entry data. The `if-else` logic checks whether there's an existing `entryId`. If there is, the update service method is called, and if not, the add service method is called. In both cases, it sets a render parameter with the Guestbook ID so the application can display the guestbook's entries after this one has been added. This is all done in `try`...`catch` statements.

5. Now add `deleteEntry`, which you didn't have before:

```
public void deleteEntry(ActionRequest request, ActionResponse response) throws PortalException {
        long entryId = ParamUtil.getLong(request, "entryId");
        long guestbookId = ParamUtil.getLong(request, "guestbookId");

        ServiceContext serviceContext = ServiceContextFactory.getInstance(
            Entry.class.getName(), request);

        try {

            response.setRenderParameter(
                "guestbookId", Long.toString(guestbookId));

            _entryLocalService.deleteEntry(entryId, serviceContext);
        }

        catch (Exception e) {
            Logger.getLogger(GuestbookPortlet.class.getName()).log(
                Level.SEVERE, null, e);
        }
}
```

This method retrieves the entry object (using its ID from the request) and calls the service to delete it.

6. Next you must replace the `render` method:

```
@Override
public void render(RenderRequest renderRequest, RenderResponse renderResponse)
        throws IOException, PortletException {

        try {
            ServiceContext serviceContext = ServiceContextFactory.getInstance(
                Guestbook.class.getName(), renderRequest);

            long groupId = serviceContext.getScopeGroupId();

            long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");

            List<Guestbook> guestbooks = _guestbookLocalService.getGuestbooks(
                groupId);

            if (guestbooks.isEmpty()) {
                Guestbook guestbook = _guestbookLocalService.addGuestbook(
                    serviceContext.getUserId(), "Main", serviceContext);

                guestbookId = guestbook.getGuestbookId();
            }

            if (guestbookId == 0) {
                guestbookId = guestbooks.get(0).getGuestbookId();
            }

            renderRequest.setAttribute("guestbookId", guestbookId);
        }
        catch (Exception e) {
            throw new PortletException(e);
        }

        super.render(renderRequest, renderResponse);
}
```

This new render method checks for any guestbooks in the current site. If there aren't any, it creates one. Either way, it grabs the first guestbook so its entries can be displayed by your view layer.

7. Remove the parseEntries method. It's a remnant of the prototype application.

8. Hit Ctrl-Shift-O to organize your imports.

Awesome! You've updated your controller to use services. Next, you'll tackle the view.

22.5 Updating the View

```
<p>Refactoring the Prototype<br>Step 5 of 6</p>
```

You updated more than just the basic mechanism behind creating the entry–you completely changed its method and structure. You must, therefore, update the UI as well. To do that, you must create a new JSP for managing guestbooks, and update the existing JSPs.

1. First, you must update your dependencies. In your `guestbook-web` module, open `init.jsp` from `/src/main/resources/META-INF/resources/`. In this file, add the following additional dependencies:

```
<%@ taglib uri="http://liferay.com/tld/frontend" prefix="liferay-frontend" %>
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
<%@ taglib uri="http://liferay.com/tld/security" prefix="liferay-security" %>
<%@ page import="java.util.List" %>
<%@ page import="com.liferay.portal.kernel.util.ParamUtil" %>
<%@ page import="com.liferay.portal.kernel.util.HtmlUtil" %>
<%@ page import="com.liferay.portal.kernel.util.StringPool" %>
<%@ page import="com.liferay.portal.kernel.model.PersistedModel" %>
<%@ page import="com.liferay.portal.kernel.dao.search.SearchEntry" %>
<%@ page import="com.liferay.portal.kernel.dao.search.ResultRow" %>
<%@ page import="com.liferay.docs.guestbook.model.Guestbook" %>
<%@ page import="com.liferay.docs.guestbook.service.EntryLocalServiceUtil" %>
<%@ page import="com.liferay.docs.guestbook.service.GuestbookLocalServiceUtil" %>
<%@ page import="com.liferay.docs.guestbook.model.Entry" %>
```

2. Open the `view.jsp` file found in `/resources/META-INF/resources/guestbookwebportlet`. Replace this file's contents with the following code:

```
<%@include file="../init.jsp"%>

<%
long guestbookId = Long.valueOf((Long) renderRequest
        .getAttribute("guestbookId"));
%>

<aui:button-row cssClass="guestbook-buttons">

    <portlet:renderURL var="addEntryURL">
        <portlet:param name="mvcPath" value="/guestbookwebportlet/edit_entry.jsp" />
        <portlet:param name="guestbookId"
            value="<%=String.valueOf(guestbookId)%>" />
    </portlet:renderURL>

    <aui:button onClick="<%=addEntryURL.toString()%>" value="Add Entry"></aui:button>

</aui:button-row>

<liferay-ui:search-container total="<%=EntryLocalServiceUtil.getEntriesCount()%>">
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId.longValue(),
                    guestbookId, searchContainer.getStart(),
                    searchContainer.getEnd())%>" />

<liferay-ui:search-container-row
    className="com.liferay.docs.guestbook.model.Entry" modelVar="entry">

    <liferay-ui:search-container-column-text property="message" />

    <liferay-ui:search-container-column-text property="name" />

</liferay-ui:search-container-row>

<liferay-ui:search-iterator />

</liferay-ui:search-container>
```

This `view.jsp` now retrieves the entries from the guestbook it gets from the `render` method. It does this inside a Liferay DXP construct called a *Search Container*. This is a front-end component that makes it easy to display data in rows and columns. The `EntryLocalServiceUtil` call retrieves the data from your new Service Builder-based back-end. Otherwise, this JSP is much the same: you still have an *Add Entry* button with its corresponding URL.

Next, you need to edit the `edit_entry.jsp`:

1. Open `edit_entry.jsp` and replace the existing code with this:

```
<%@include file="../init.jsp" %>

<%

long entryId = ParamUtil.getLong(renderRequest, "entryId");

Entry entry = null;
```

```
if (entryId > 0) {
  entry = EntryLocalServiceUtil.getEntry(entryId);
}

long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");

%>

<portlet:renderURL var="viewURL">

<portlet:param name="mvcPath" value="/guestbookwebportlet/view.jsp"></portlet:param>

</portlet:renderURL>

<portlet:actionURL name="addEntry" var="addEntryURL"></portlet:actionURL>

<aui:form action="<%= addEntryURL %>" name="<portlet:namespace />fm">

<aui:model-context bean="<%= entry %>" model="<%= Entry.class %>" />

    <aui:fieldset>

        <aui:input name="name" />
        <aui:input name="email" />
        <aui:input name="message" />
        <aui:input name="entryId" type="hidden" />
        <aui:input name="guestbookId" type="hidden" value='<%= entry == null ? guestbookId : entry.getGuestbookId() %>'/>

    </aui:fieldset>

    <aui:button-row>

        <aui:button type="submit"></aui:button>
        <aui:button type="cancel" onClick="<%= viewURL.toString() %>"></aui:button>

    </aui:button-row>
</aui:form>
```

This is much the same form, though there are more fields now. Using some AlloyUI tags, the form is linked to your `Entry` entity. The two hidden fields contain the new `entryId` and the `guestbookId` for the guestbook the new entry belongs to. The submit button is an `ActionURL` that executes the `addEntry` method in the controller (your portlet class).

Congratulations! You've now successfully replaced your prototype back-end with a real, database-driven back-end. Next, you'll do a quick review and deploy your application.

22.6 Fitting it All Together

```
<p>Refactoring the Prototype<br>Step 6 of 6</p>
```

You've created a complete data-driven application from the back-end to the display. It's a great time to review how everything connects together.

The Entry

First, you defined your model in Service Builder's configuration file, `service.xml`. The main part of this is your `Entry` object:

```
<entity local-service="true" name="Entry" uuid="true">

    <!-- PK fields -->

    <column name="entryId" primary="true" type="long" />

    <!-- Group instance -->

    <column name="groupId" type="long" />

    <!-- Audit fields -->

    <column name="companyId" type="long" />
    <column name="userId" type="long" />
    <column name="userName" type="String" />
    <column name="createDate" type="Date" />
    <column name="modifiedDate" type="Date" />
    <column name="name" type="String" />
    <column name="email" type="String" />
    <column name="message" type="String" />
    <column name="guestbookId" type="long" />

    <finder name="G_G" return-type="Collection">
        <finder-column name="groupId" />
        <finder-column name="guestbookId" />
    </finder>
</entity>
```

Next, you created a service implementation in `EntryLocalServiceImpl` that defined how to get and store the entry. Every field you defined was accounted for in the `addEntry` method.

```
public Entry addEntry(long userId, long guestbookId, String name, String email,
        String message, ServiceContext serviceContext)
        throws PortalException {

        long groupId = serviceContext.getScopeGroupId();

        User user = userLocalService.getUserById(userId);

        Date now = new Date();

        validate(name, email, message);

        long entryId = counterLocalService.increment();

        Entry entry = entryPersistence.create(entryId);

        entry.setUuid(serviceContext.getUuid());
        entry.setUserId(userId);
        entry.setGroupId(groupId);
        entry.setCompanyId(user.getCompanyId());
        entry.setUserName(user.getFullName());
        entry.setCreateDate(serviceContext.getCreateDate(now));
        entry.setModifiedDate(serviceContext.getModifiedDate(now));
        entry.setExpandoBridgeAttributes(serviceContext);
        entry.setGuestbookId(guestbookId);
        entry.setName(name);
        entry.setEmail(email);
        entry.setMessage(message);

        entryPersistence.update(entry);

        return entry;
}
```

Notice that all the fields you described in Service Builder (including things like the `uuid`) are present here.

You also added ways to get entries:

```
public List<Entry> getEntries(long groupId, long guestbookId) {
    return entryPersistence.findByG_G(groupId, guestbookId);
}

public List<Entry> getEntries(
    long groupId, long guestbookId, int start, int end, OrderByComparator<Entry> obc) {

    return entryPersistence.findByG_G(groupId, guestbookId, start, end, obc);
}

public List<Entry> getEntries(long groupId, long guestbookId, int start, int end)
    throws SystemException {

    return entryPersistence.findByG_G(groupId, guestbookId, start, end);
}
```

In `service.xml` you defined `groupId` and `guestbookId` as the two finder fields, and in these methods you called methods generated to the persistence layer.

After you implemented all that, Service Builder propagated your implementation to the interfaces, so they could be called. Then, in the portlet class, you created references to the service classes that Service Builder generated, and used those references to access the service to add an entry:

```
_entryLocalService.addEntry( serviceContext.getUserId(), guestbookId,
    userName, email,message, serviceContext);
```

Finally, you wrapped all this up in a user interface that lets users enter the information they want, and displays the data they've entered.

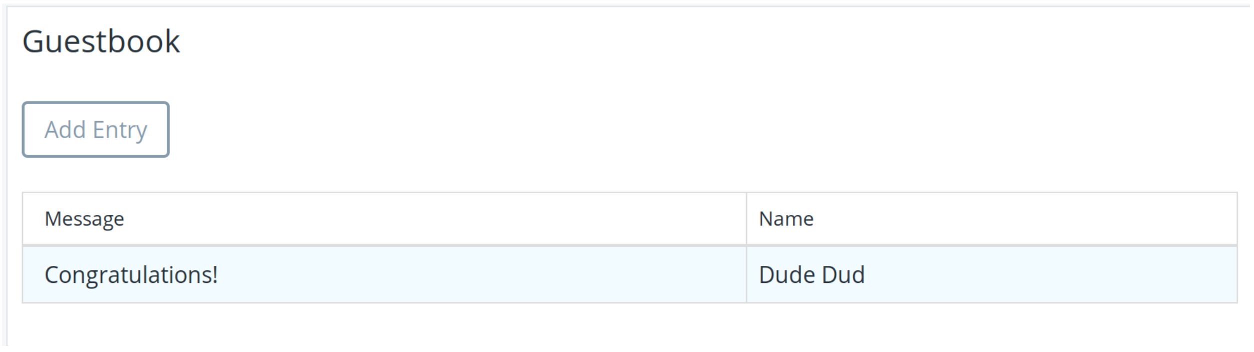
Now that you've built the application, and you can see a clear picture of how it all works, it's time to test it.

Deploying and Testing the Application

1. Drag and drop the `guestbook-api` module onto the server.
2. Drag and drop the `guestbook-service` module onto the server.
3. Look for the STARTED messages from the console.
4. Go to your Liferay DXP instance at `localhost:8080` in your browser to test your updated application.
5. Click *Add Entry*.
6. Enter a *Name*, *Message*, and *Email Address*.
7. Click *Submit*.
8. Verify that your entry appears.

What's Next?

You've created a working web application and deployed it on Liferay DXP. If you've created web applications before, though, you know that it's missing some important features: security, front-end validation, and an interface for administrators to create multiple guestbooks per portlet. In the next section, you'll begin adding these (and more) features.



Guestbook

Message	Name
Congratulations!	Dude Dud

Figure 22.2: A new guestbook and entry.

Chapter 23

Writing an Administrative Portlet

Like the prototype, the real application lets users add and view guestbook entries. The application's back-end, however, is much more powerful. It can support many guestbooks and their associated entries. Despite this, there's no UI to support these added features. When you create this UI, you must also make sure that only administrators can add guestbooks.

To accomplish this, you must create a Guestbook Admin portlet and place it in Liferay DXP's administrative interface–specifically, within the Content menu. This way, the Guestbook Admin portlet is accessible only to Site Administrators, and users can use the Guestbook portlet to create entries.

In short, this is a simple application with a simple interface:

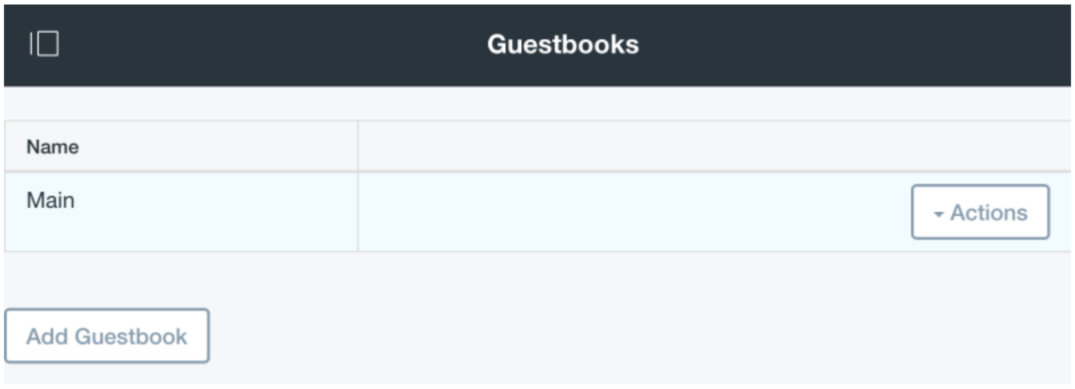


Figure 23.1: The Guestbook Admin portlet lets administrators manage Guestbooks.

Are you ready to begin?

Let's Go!

23.1 Creating the Classes

```
<p>Writing the Guestbook Admin App<br>Step 1 of 5</p>
```

Because the Guestbook and Guestbook Admin applications should be bundled together, you'll create the new application manually inside the `guestbook-web` project, rather than by using a wizard. If you disagree with this design decision, you can create a separate project for Guestbook Admin; the project template you'd use is *panel-app*. For now, however, it's better to go through the process manually to learn how it all works:

1. Right-click the `com.liferay.docs.guestbook.portlet` package in the `guestbook-web` project and select *New → Class*.

2. Name the class `GuestbookAdminPortlet`.

3. Click *Browse* next to the Superclass and search for `MVCPortlet`. Click it and select *OK*.

4. Click *Finish*.

You now have your Guestbook Admin application's portlet class. For an administrative application, however, you need at least one more component.

Panels and Categories

As described in the product menu tutorial, there are three sections of the product menu as illustrated below.

Each section is called a *panel category*. A panel category can hold various menu items called *panel apps*. In the illustration above, the Sites menu is open to reveal its panel apps and categories (yes, you can nest them).

The most natural place for the Guestbook Admin portlet is in the *Content* panel category with Liferay DXP's other content-based apps. This integrates it nicely in the spot where site administrators expect it to be. This also means you don't have to create a new category for it: you can just create the panel entry, which is what you'll do next. If you'd like to learn more about panel categories and apps after this, see the product menu tutorial and the control menu tutorial.

Follow these steps to create the panel entry for the Guestbook Admin portlet:

1. Add the dependency you need to extend Liferay DXP's panel categories and apps. To do this, open `guestbook-web`'s `build.gradle` file and add this dependency:

   ```
   compileOnly group: "com.liferay", name: "com.liferay.application.list.api", version: "2.0.0"
   ```

2. Right-click `guestbook-web` and select *Gradle → Refresh Gradle Project*.

3. Right-click `src/main/java` in the `guestbook-web` project and select *New → Package*. Name the package `com.liferay.docs.guestbook.application.list` and click *Finish*.

4. Right-click your new package and select *New → Class*. Name the class `GuestbookAdminPanelApp`. Click *Browse* next to Superclass, search for `BasePanelApp`, select it, and click *OK*. Then click *Finish*.

Great! You've created the classes you need, and you're ready to begin working on them.

23.2 Adding Metadata

```
<p>Writing the Guestbook Admin App<br>Step 2 of 5</p>
```

Now that you've generated the classes, you must turn them into OSGi components. Remember that because components are container-managed objects, you must provide metadata that tells Liferay DXP's OSGi container how to manage their lifecycles.

Follow these steps:

1. Add the following portlet key to the `GuestbookPortletKeys` class:

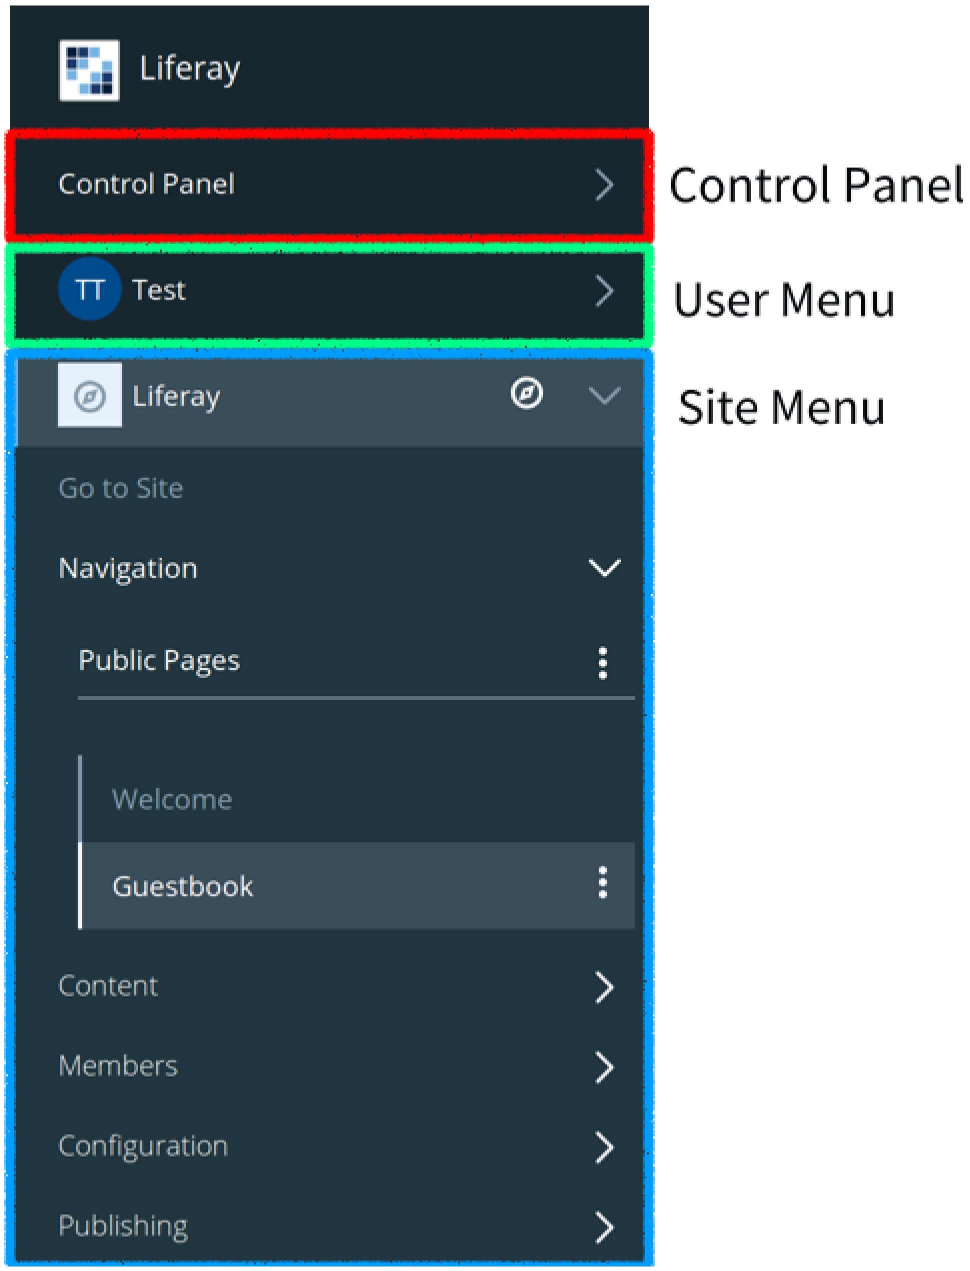

Figure 23.2: The product menu is split into three sections: the Control Panel, the User menu, and the Sites menu.

```
public static final String GUESTBOOK_ADMIN =
  "com_liferay_docs_guestbook_portlet_GuestbookAdminPortlet";
```

2. Open the `GuestbookAdminPortlet` class and add the `@Component` annotation immediately above the class declaration:

   ```
   @Component(
       immediate = true,
       property = {
               "com.liferay.portlet.display-category=category.hidden",
               "com.liferay.portlet.scopeable=true",
               "javax.portlet.display-name=Guestbooks",
               "javax.portlet.expiration-cache=0",
               "javax.portlet.init-param.portlet-title-based-navigation=true",
               "javax.portlet.init-param.template-path=/",
               "javax.portlet.init-param.view-template=/guestbookadminportlet/view.jsp",
               "javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK_ADMIN,
               "javax.portlet.resource-bundle=content.Language",
               "javax.portlet.security-role-ref=administrator",
               "javax.portlet.supports.mime-type=text/html",
               "com.liferay.portlet.add-default-resource=true"
       },
       service = Portlet.class
   )
   ```

3. Hit [CTRL]+[SHIFT]+O to add the `javax.portlet.Portlet` and other imports.

There are only a few new things here. Note the value of the `javax.portlet.display-name` property: `Guestbooks`. This is the name that appears in the Site menu. Also note the value of the `javax.portlet.name` property: `+ GuestbookPortletKeys.GUESTBOOK_ADMIN`. This specifies the portlet's title via the `GUESTBOOK_ADMIN` portlet key that you just created.

Pay special attention to the following metadata property:

```
com.liferay.portlet.display-category=category.hidden
```

This is the same property you used before with the Guestbook portlet. You placed that portlet in the Social category. The value `category.hidden` specifies a special category that doesn't appear anywhere. You're putting the Guestbook Admin portlet here because it'll be part of the Site menu, and you don't want users adding it to a page. This prevents them from doing that.

Next, you can configure the Panel app class. Follow these steps:

1. Open the `GuestbookAdminPanelApp` class and add the `@Component` annotation immediately above the class declaration:

   ```
   @Component(
       immediate = true,
       property = {
           "panel.app.order:Integer=300",
           "panel.category.key=" + PanelCategoryKeys.SITE_ADMINISTRATION_CONTENT
       },
       service = PanelApp.class
   )
   ```

   The `panel.category.key` metadata property determines where to place the Guestbook Admin portlet in the Product Menu. Remember that the Product Menu is divided into three main sections: the Control Panel, the User Menu, and the Site Administration area. The value of the `panel.category.key` property is PanelCategoryKeys.SITE_ADMINISTRATION_CONTENT, which means Guestbook Admin is in *Site Administration → Content*. The key is provided by the PanelCategoryKeys class. The panel.app.order value determines the rank for the Guestbook Admin portlet in the list.

2. Finally, update the class to use the proper name and portlet keys:

```
public class GuestbookAdminPanelApp extends BasePanelApp {

    @Override
    public String getPortletId() {
        return GuestbookPortletKeys.GUESTBOOK_ADMIN;
    }

    @Override
    @Reference(
        target = "(javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK_ADMIN + ")",
        unbind = "-"
    )
    public void setPortlet(Portlet portlet) {
        super.setPortlet(portlet);
    }

}
```

3. Hit [CTRL]+[SHIFT]+O to organize imports. This time, import com.liferay.portal.kernel.model.Portlet instead of javax.portlet.Portlet.

Now that the configuration is out of the way, you're free to implement the app's functionality: adding, editing, and deleting guestbooks. That's the next step.

23.3 Updating Your Service Layer

<p>Writing the Guestbook Admin App<br>Step 3 of 5</p>

In an earlier section, you wrote an addGuestbook service method in GuestbookLocalServiceImpl, but you never used it. To have full functionality over guestbooks, you must also add methods for updating and deleting guestbooks, as well as for returning the number of guestbooks in a site.

Adding Guestbook Service Methods

Remember that when working with Service Builder, you define your service in the *Impl classes. After you add or remove a method from an *Impl class, or change the signature of a method in an *Impl class, you must run Service Builder. Service Builder updates the affected interfaces and any other generated code.

Follow these steps to add the required guestbook service methods:

1. Go to the guestbook-service project and open GuestbookLocalServiceImpl.java in the com.liferay.docs.guestbook.serv package. Add the following method for updating a guestbook:

```
public Guestbook updateGuestbook(long userId, long guestbookId,
    String name, ServiceContext serviceContext) throws PortalException,
                SystemException {

        Date now = new Date();

        validate(name);
        Guestbook guestbook = getGuestbook(guestbookId);

        User user = userLocalService.getUser(userId);

        guestbook.setUserId(userId);
        guestbook.setUserName(user.getFullName());
        guestbook.setModifiedDate(serviceContext.getModifiedDate(now));
        guestbook.setName(name);
        guestbook.setExpandoBridgeAttributes(serviceContext);

        guestbookPersistence.update(guestbook);

        return guestbook;
}
```

The `updateGuestbook` method retrieves the `Guestbook` by its ID, replaces its data with what the user entered, and then calls the persistence layer to save it back to the database.

2. Next, add the following method for deleting a guestbook:

```
public Guestbook deleteGuestbook(long guestbookId,
                ServiceContext serviceContext) throws PortalException,
                SystemException {

        Guestbook guestbook = getGuestbook(guestbookId);

        List<Entry> entries = entryLocalService.getEntries(
                        serviceContext.getScopeGroupId(), guestbookId);

        for (Entry entry : entries) {
                entryLocalService.deleteEntry(entry.getEntryId());
        }

        guestbook = deleteGuestbook(guestbook);

        return guestbook;
}
```

It's important to consider what should happen if you delete a guestbook that has existing entries. If you just deleted the guestbook, the guestbook's entries would still exist in the database, but they'd be orphaned. Your `deleteGuestbook` service method makes a service call to delete a guestbook's entries before deleting that guestbook. This way, guestbook entries are never orphaned.

3. Use [CTRL]+[SHIFT]+O to update your imports, then save `GuestbookLocalServiceImpl.java`.

4. In the Gradle Tasks pane on the right side in Liferay @ide@, run Service Builder by opening the `guestbook-service` module and double-clicking `buildService`.

Now that you've finished updating the service layer, it's time to work on the Guestbook Admin portlet itself.

23.4 Defining Portlet Actions

```
<p>Writing the Guestbook Admin App<br>Step 4 of 5</p>
```

The Guestbook Admin portlet now needs action methods for adding, updating, and deleting guestbooks. As with the Guestbook portlet, action methods call the corresponding service methods. Note that since your services and applications are all running in the same container, any application can call the Guestbook services. This is an advantage of Liferay DXP's OSGi-based architecture: different applications or modules can call services published by other modules. If a service is published, it can be used via `@Reference`. You'll take advantage of this here in the Guestbook Admin portlet to consume one of the same services consumed by the Guestbook portlet (the `addGuestbook` service).

Adding Three Portlet Actions

The Guestbook Admin portlet must let administrators add, update, and delete `Guestbook` objects. You'll create portlet actions to meet these requirements. Open `GuestbookAdminPortlet.java` and follow these steps:

1. Add the following action method and instance variables needed for adding a new guestbook:

```
public void addGuestbook(ActionRequest request, ActionResponse response)
    throws PortalException {

    ServiceContext serviceContext = ServiceContextFactory.getInstance(
        Guestbook.class.getName(), request);

    String name = ParamUtil.getString(request, "name");

    try {
        _guestbookLocalService.addGuestbook(
            serviceContext.getUserId(), name, serviceContext);
    }
    catch (PortalException pe) {

        Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
            Level.SEVERE, null, pe);

        response.setRenderParameter(
            "mvcPath", "/guestbookadminportlet/edit_guestbook.jsp");
    }
}

private GuestbookLocalService _guestbookLocalService;

@Reference(unbind = "-")
protected void setGuestbookService(GuestbookLocalService guestbookLocalService) {
    _guestbookLocalService = guestbookLocalService;
}
```

   Since `addGuestbook` is a portlet action method, it takes `ActionRequest` and `ActionResponse` parameters. To make the service call to add a new guestbook, the guestbook's name must be retrieved from the request. The `serviceContext` must also be retrieved from the request and passed as an argument in the service call. If an exception is thrown, you should display the Add Guestbook form and not the default view. That's why you add this line in the `catch` block:

```
response.setRenderParameter("mvcPath",
        "/guestbookadminportlet/edit_guestbook.jsp");
```

   Later, you'll use this for field validation and to show error messages to the user. Note that `/guestbookadminportlet/edit_guestbook.jsp` doesn't exist yet; you'll create it in the next section when you're designing the Guestbook Admin portlet's user interface.

2. Add the following action method for updating an existing guestbook:

```
public void updateGuestbook(ActionRequest request, ActionResponse response)
    throws PortalException {

    ServiceContext serviceContext = ServiceContextFactory.getInstance(
        Guestbook.class.getName(), request);

    String name = ParamUtil.getString(request, "name");
    long guestbookId = ParamUtil.getLong(request, "guestbookId");

    try {
        _guestbookLocalService.updateGuestbook(
            serviceContext.getUserId(), guestbookId, name, serviceContext);

    } catch (PortalException pe) {

        Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
            Level.SEVERE, null, pe);

        response.setRenderParameter(
            "mvcPath", "/guestbookadminportlet/edit_guestbook.jsp");
    }
}
```

This method retrieves the guestbook name, ID, and the `serviceContext` from the request. The `updateGuestbook` service call uses the guestbook's ID to identify the guestbook to update. If there's a problem with the service call, the Guestbook Admin portlet displays the Edit Guestbook form again so that the user can edit the form and resubmit:

```
response.setRenderParameter("mvcPath",
        "/guestbookadminportlet/edit_guestbook.jsp");
```

Note that the Edit Guestbook form uses the same JSP as the Add Guestbook form to avoid duplication of code.

3. Add the following action method for deleting a guestbook:

```
public void deleteGuestbook(ActionRequest request, ActionResponse response)
    throws PortalException {

    ServiceContext serviceContext = ServiceContextFactory.getInstance(
        Guestbook.class.getName(), request);

    long guestbookId = ParamUtil.getLong(request, "guestbookId");

    try {
        _guestbookLocalService.deleteGuestbook(guestbookId, serviceContext);
    }
    catch (PortalException pe) {

        Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
            Level.SEVERE, null, pe);
    }
}
```

This method uses the service layer to delete the guestbook by its ID. Since the `deleteGuestbook` action is invoked from the Guestbook Admin portlet's default view, there's no need to set the `mvcPath` render parameter to point to a particular JSP if there was a problem with the `deleteGuestbook` service call.

4. Hit [CTRL]+[SHIFT]+O to organize imports. Save the file.

You now have your service methods and portlet action methods in place. Your last task is to implement the Guestbook Admin portlet's user interface.

23.5 Creating a User Interface

<p>Writing the Guestbook Admin App<br>Step 5 of 5</p>

It's time to create the Guestbook Admin portlet's user interface. The portlet's default view has a button for adding new guestbooks. It must also display the guestbooks that already exist.

Each guestbook's name is displayed along with an Actions button. The Actions button reveals options for editing the guestbook, configuring its permissions, or deleting it.

Creating JSPs for the Guestbook Admin Portlet's User Interface

The Guestbook Admin portlet's user interface is made up of three JSPs: the default view, the Actions button, and the form for adding or editing a guestbook.

Create the default view first:

1. Create a folder for the Guestbook Admin portlet's JSPs. In `src/main/resources/META-INF/resources`, create a folder called `guestbookadminportlet`.

2. Create a file in this folder called `view.jsp` and fill it with this code:

```
<%@include file="../init.jsp"%>

<liferay-ui:search-container
    total="<%= GuestbookLocalServiceUtil.getGuestbooksCount(scopeGroupId) %>">
    <liferay-ui:search-container-results
        results="<%= GuestbookLocalServiceUtil.getGuestbooks(scopeGroupId,
            searchContainer.getStart(), searchContainer.getEnd()) %>" />

    <liferay-ui:search-container-row
        className="com.liferay.docs.guestbook.model.Guestbook" modelVar="guestbook">

        <liferay-ui:search-container-column-text property="name" />

        <liferay-ui:search-container-column-jsp
            align="right"
            path="/guestbookadminportlet/guestbook_actions.jsp" />

    </liferay-ui:search-container-row>

    <liferay-ui:search-iterator />
</liferay-ui:search-container>

<aui:button-row cssClass="guestbook-admin-buttons">
    <portlet:renderURL var="addGuestbookURL">
        <portlet:param name="mvcPath"
            value="/guestbookadminportlet/edit_guestbook.jsp" />
        <portlet:param name="redirect" value="<%= "currentURL" %>" />
    </portlet:renderURL>

    <aui:button onClick="<%= addGuestbookURL.toString() %>"
        value="Add Guestbook" />
</aui:button-row>
```

First is the standard `init.jsp` include to gain access to the imports.

Next is a button row with a single button for adding new guestbooks: `<aui:button-row cssClass="guestbook-admin-buttons">`. The `cssClass` attribute lets you specify a custom CSS class for additional styling. The `<portlet:renderURL>` tag constructs a URL that points to the edit_guestbook.jsp. You haven't created this JSP yet, but you'll use it for adding a new guestbook and editing an existing one.

Finally, a Liferay search container is used to display the list of guestbooks. Three sub-tags define the search container:

- <liferay-ui:search-container-results>
- <liferay-ui:search-container-row>
- <liferay-ui:search-iterator>

The <liferay-ui:search-container-results> tag's results attribute uses a service call to retrieve the guestbooks in the scope. The total attribute uses another service call to get a count of guestbooks.

The <liferay-ui:search-container-row> tag defines what rows contain. In this case, the className attribute defines com.liferay.docs.guestbook.model.Guestbook". The modelVar attribute defines guestbook as the variable for the currently iterated guestbook. In the search container row, two columns are defined. The <liferay-ui:search-container-column-text property="name" /> tag specifies the first column. This tag displays text. Its property="name" attribute specifies that the text to be displayed is the current guestbook object's name attribute. The tag <liferay-ui:search-container-column-jsp path="/guestbookadminportlet/guestbook_actions.jsp" align="right" /> specifies the second (and last) column. This tag includes another JSP file within a search container column. Its path attribute specifies the path to the JSP file that should be displayed: guestbook_actions.jsp.

Finally, the <liferay-ui:search-iterator /> tag iterates through and displays the list of guestbooks. Using Liferay's search container makes the Guestbook Admin portlet look like a native Liferay DXP portlet. It also provides built-in pagination so that your portlet can automatically display large numbers of guestbooks on one site.

Your next step is to add the guestbook_actions.jsp file that's responsible for displaying the list of possible actions for each guestbook.

3. Create a new file called guestbook_actions.jsp in your project's /guestbookadminportlet folder. Paste in this code:

```
<%@include file="../init.jsp"%>

<%
    String mvcPath = ParamUtil.getString(request, "mvcPath");

    ResultRow row = (ResultRow) request
                    .getAttribute("SEARCH_CONTAINER_RESULT_ROW");

    Guestbook guestbook = (Guestbook) row.getObject();
%>

<liferay-ui:icon-menu>

    <portlet:renderURL var="editURL">
        <portlet:param name="guestbookId"
            value="<%=String.valueOf(guestbook.getGuestbookId()) %>" />
        <portlet:param name="mvcPath"
            value="/guestbookadminportlet/edit_guestbook.jsp" />
    </portlet:renderURL>

    <liferay-ui:icon image="edit" message="Edit"
            url="<%=editURL.toString() %>" />
    <portlet:actionURL name="deleteGuestbook" var="deleteURL">
            <portlet:param name="guestbookId"
                value="<%= String.valueOf(guestbook.getGuestbookId()) %>" />
    </portlet:actionURL>

    <liferay-ui:icon-delete url="<%=deleteURL.toString() %>" />

</liferay-ui:icon-menu>
```

This JSP comprises the pop-up actions menu that shows the possible actions users can perform on a guestbook: editing it or deleting it. First, `init.jsp` is included because it contains all the JSP imports. Because `guestbook_actions.jsp` is included for every Search Container row, it retrieves the guestbook in the current iteration. The scriptlet grabs that guestbook so its ID can be supplied to the menu tags.

The `<liferay-ui:icon-menu` tag dominates `guestbook_actions.jsp`. It's a container for menu items, of which there are currently only two (you'll add more later). The Edit menu item displays the Edit icon and the message *Edit*:

```
<liferay-ui:icon image="edit" message="Edit"
        url="<%=editURL.toString() %>" />
```

The `editURL` variable comes from the `<portlet:renderURL var="editURL">` tag with two parameters: `guestbookId` and `mvcPath`. The `guestbookId` parameter specifies the guestbook to edit (it's the one from the selected search container result row), and the `mvcPath` parameter specifies the Edit Guestbook form's path.

The Delete menu item displays a delete icon and the default message *Delete*:

```
<liferay-ui:icon-delete url="<%=deleteURL.toString() %>" />
```

Unlike the `editURL`, which is a render URL that links to the `edit_guestbook.jsp`, the `deleteURL` is an action URL that invokes the portlet's `deleteGuestbook` action. The tag `<portlet:actionURL name="deleteGuestbook" var="deleteURL">` creates this action URL, which only takes one parameter: the `guestbookId` of the guestbook to be deleted.

Now there's just one more JSP file left to create: the `edit_guestbook.jsp` that contains the form for adding a new guestbook and editing an existing one.

4. Create a new file called `edit_guestbook.jsp` in your project's `/guestbookadminportlet` directory. Then add the following code to it:

```
<%@include file = "../init.jsp" %>

<%
        long guestbookId = ParamUtil.getLong(request, "guestbookId");

        Guestbook guestbook = null;

        if (guestbookId > 0) {
                guestbook = GuestbookLocalServiceUtil.getGuestbook(guestbookId);
        }
%>

<portlet:renderURL var="viewURL">
        <portlet:param name="mvcPath" value="/guestbookadminportlet/view.jsp" />
</portlet:renderURL>
```

```
<portlet:actionURL name='<%= guestbook == null ? "addGuestbook" : "updateGuestbook" %>' var="editGuestbookURL" />

<aui:form action="<%= editGuestbookURL %>" name="fm">

        <aui:model-context bean="<%= guestbook %>" model="<%= Guestbook.class %>" />

        <aui:input type="hidden" name="guestbookId"
            value='<%= guestbook == null ? "" : guestbook.getGuestbookId() %>' />

        <aui:fieldset>
             <aui:input name="name" />
        </aui:fieldset>

        <aui:button-row>
             <aui:button type="submit" />
             <aui:button onClick="<%= viewURL %>" type="cancel"  />
        </aui:button-row>
</aui:form>
```

After the `init.jsp` import, you declare a `null` guestbook variable. If there's a `guestbookId` parameter in the request, then you know that you're editing an existing guestbook, and you use the `guestbookId` to retrieve the corresponding guestbook via a service call. Otherwise, you know that you're adding a new guestbook.

Next is a view URL that points to the Guestbook Admin portlet's default view. This URL is invoked if the user clicks *Cancel* on the Add Guestbook or Edit Guestbook form. After that, you create an action URL that invokes either the Guestbook Admin portlet's `addGuestbook` method or its `updateGuestbook` method, depending on whether the `guestbook` variable is null.

If a guestbook is being edited, the current guestbook's name should appear in the form's name field. You use the following tag to define a model of the guestbook that can be used in the AlloyUI form:

```
<aui:model-context bean="<%= guestbook %>" model="<%= Guestbook.class %>" />
```

The form itself is created with the following tag:

```
<aui:form action="<%= editGuestbookURL %>" name="<portlet:namespace />fm">
```

When the form is submitted, the `editGuestbookURL` is invoked, which calls the Guestbook Admin portlet's `addGuestbook` or `updateGuestbook` method, as discussed above.

The `guestbookId` must appear on the form so that it can be submitted. The user, however, doesn't need to see it. Thus, you specify `type="hidden"`:

```
<aui:input type="hidden" name="guestbookId"
        value='<%= guestbook == null ? "" : guestbook.getGuestbookId() %>' />
```

The name, of course, should be editable by the user so it's not hidden.

The last item on the form is a button row with two buttons. The *Submit* button submits the form, invoking the `editGuestbookURL` which, in turn, invokes either the `addGuestbook` or `updateGuestbook` method. The *Cancel* button invokes the `viewURL` which displays the default view.

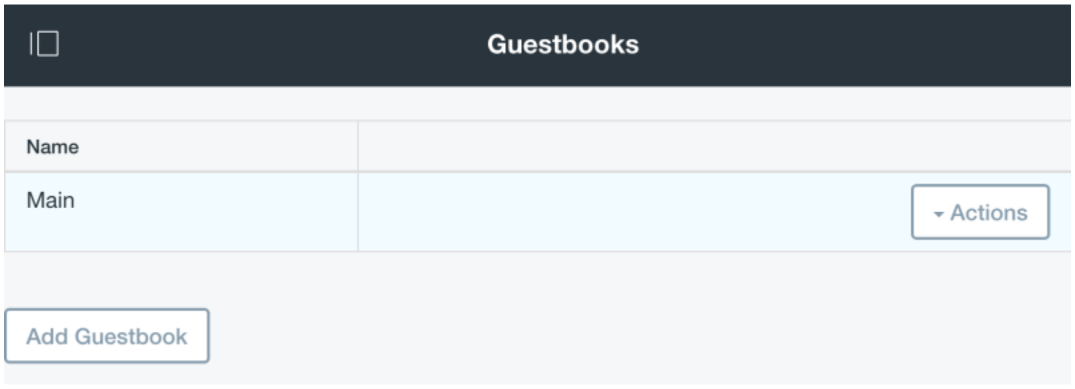

Figure 23.3: The Guestbook Admin portlet lets administrators add or edit guestbooks, configure their permissions, or delete them.

Excellent! You've now finished creating the UI for the Guestbook Admin portlet. It should now match the figure below:

Test out the Guestbook Admin portlet! Try adding, editing, and deleting guestbooks.

Now all the Guestbook application's primary functions work. There are still many missing features, however. For example, if there's ever an error, users never see it: all the code written so far just prints messages in the logs. Next, you'll learn how to display those errors to the user.

Chapter 24

Using Resources and Permissions

You now have an application that uses the database for data storage. This is a great foundation to build on. What comes next? What if users want a Guestbook that's limited to certain trusted people? To do that, you have to implement permissions.

Thankfully, with Liferay DXP you don't have to write an entire permissions system from scratch: the framework provides a robust and well-tested permissions system that you can implement quickly.

Ready to start?

Let's Go!

24.1 Configuring Your Permissions Scheme

<p>Implementing Permissions<br>Step 1 of 4</p>

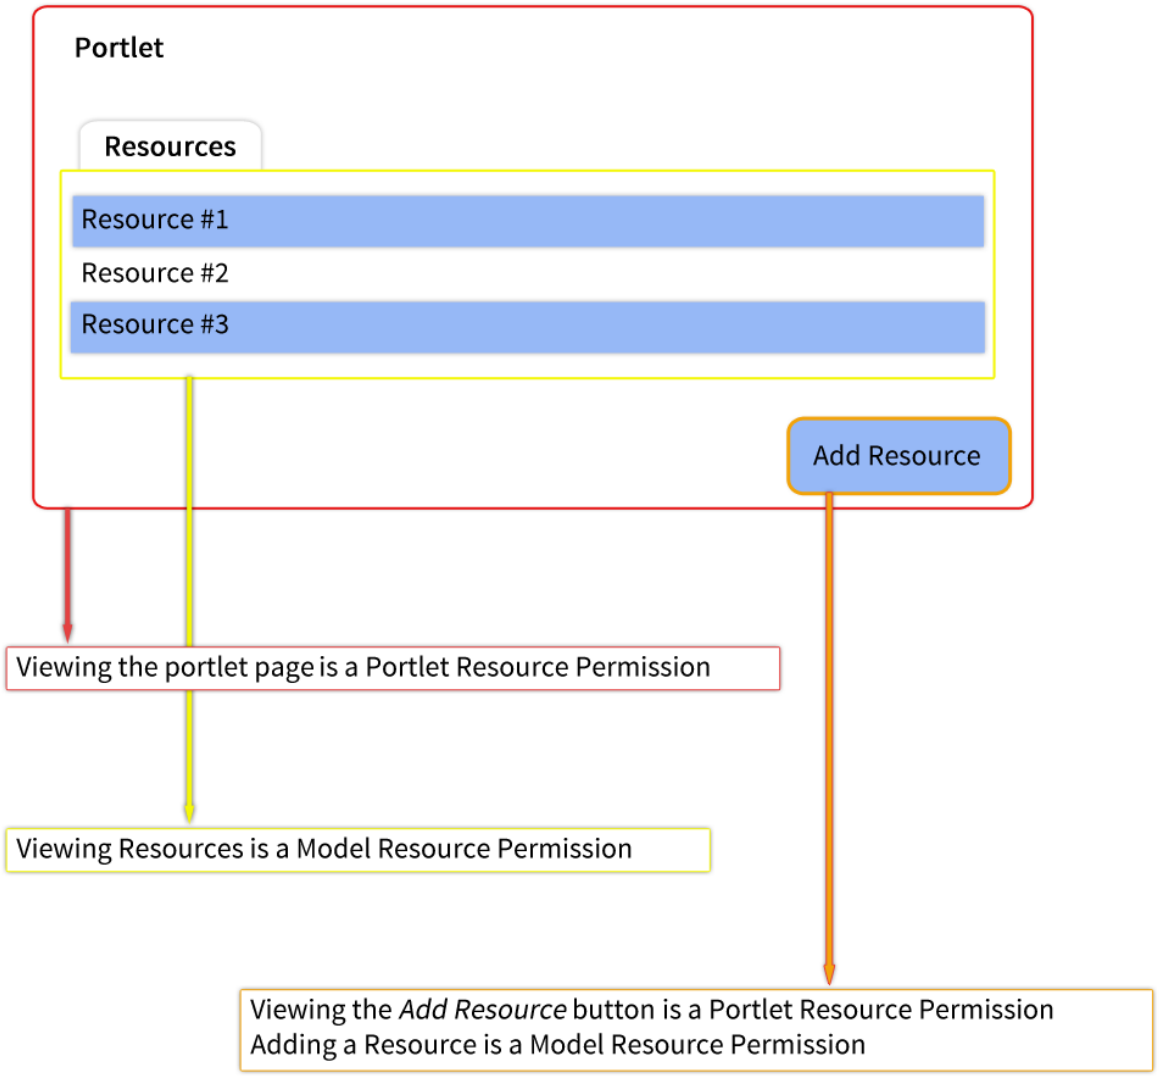
Liferay DXP's permissions framework is configured declaratively, like Service Builder. You define all your permissions in an XML file that by convention is called `default.xml` (but you could really call it whatever you want). Then you implement permissions checks in the following places in your code:

- In the view layer, when showing links or buttons to protected functionality
- In the actions, before performing a protected action
- Later, in your service, before calling the local service

You should first define the permissions you want. To get started, think of your application's use cases and how access to that functionality should be controlled:

- The Add Guestbook button should be available only to administrators.
- The Guestbook tabs should be filtered by permissions so administrators can control who can see them.
- To prevent anonymous users from spamming the guestbook, the Add Entry button should be available only to site members.
- Users should be able to set permissions on their own entries.

Now you're ready to create the permissions configuration. Objects in your application (such as Guestbook and Entry) are defined as *resources*, and *resource actions* manage how users can interact with those resources. There are therefore two kinds of permissions: portlet permissions and resource (or model) permissions. Portlet permissions protect access to global functions, such as *Add Entry*. If users don't have permission to access that global function, they're missing a portlet permission. Resource permissions protect access to objects, such as Guestbook and Entry. A user may have permission to view one Entry, view and edit another Entry, and may not be able to access another Entry at all. This is due to a resource permission.



Portlet
Resources
Resource #1
Resource #2
Resource #3
Add Resource
Viewing the portlet page is a Portlet Resource Permission
Viewing Resources is a Model Resource Permission
Viewing the *Add Resource* button is a Portlet Resource Permission
Adding a Resource is a Model Resource Permission

Figure 24.1: Portlet permissions and resource permissions cover different parts of the application.

The first thing you must do is tell the framework where your permissions are defined. You'll define resource and model permissions in the module where your model is defined:

1. In guestbook-service's src/main/resources folder, create a file called portlet.properties.

2. In this file, place the following property:

```
resource.actions.configs=META-INF/resource-actions/default.xml
```

This property defines the name and location of your permissions definition file.
Next, create the permissions file:

1. In the META-INF folder, create a subfolder called resource-actions.

2. Create a new file in this folder called default.xml.

3. Click the *Source* tab. Add the following DOCTYPE declaration to the top of the file:

```
<?xml version="1.0"?>
<!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action
Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-resource-action-mapping_7_0_0.dtd">
```

4. Place the following wrapper tags into your default.xml file, below the DOCTYPE declaration:

```
<resource-action-mapping>

</resource-action-mapping>
```

   You'll define your resource and model permissions inside these tags.

5. Next, place the permissions for your com.liferay.docs.guestbook package between the <resource-action-mapping> tags:

```
<model-resource>
    <model-name>com.liferay.docs.guestbook</model-name>
    <portlet-ref>
        <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookPortlet</portlet-name>
        <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookAdminPortlet</portlet-name>
    </portlet-ref>
    <root>true</root>
    <permissions>
        <supports>
            <action-key>ADD_GUESTBOOK</action-key>
            <action-key>ADD_ENTRY</action-key>
            <action-key>VIEW</action-key>
        </supports>
        <site-member-defaults>
            <action-key>ADD_ENTRY</action-key>
        </site-member-defaults>
        <guest-defaults>
            <action-key>VIEW</action-key>
        </guest-defaults>
        <guest-unsupported>
            <action-key>ADD_GUESTBOOK</action-key>
            <action-key>ADD_ENTRY</action-key>
        </guest-unsupported>
    </permissions>
</model-resource>
```

   This defines the baseline configuration for the Guestbook and Entry entities. The supported actions are ADD_GUESTBOOK, ADD_ENTRY, and VIEW. Site members can ADD_ENTRY by default, while guests can't perform either add action (but they can view).

6. Below that, but above the closing `</resource-action-mapping>`, place the `Guestbook` model permissions:

```
<model-resource>
    <model-name>com.liferay.docs.guestbook.model.Guestbook</model-name>
    <portlet-ref>
        <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookPortlet</portlet-name>
        <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookAdminPortlet</portlet-name>
    </portlet-ref>
    <permissions>
        <supports>
            <action-key>ADD_ENTRY</action-key>
            <action-key>DELETE</action-key>
            <action-key>PERMISSIONS</action-key>
            <action-key>UPDATE</action-key>
            <action-key>VIEW</action-key>
        </supports>
        <site-member-defaults>
            <action-key>ADD_ENTRY</action-key>
            <action-key>VIEW</action-key>
        </site-member-defaults>
        <guest-defaults>
            <action-key>VIEW</action-key>
        </guest-defaults>
        <guest-unsupported>
            <action-key>UPDATE</action-key>
        </guest-unsupported>
    </permissions>
</model-resource>
```

   This defines the `Guestbook` specific actions, including adding, deleting, updating, and viewing. By default, site members and guests can view guestbooks, but guests can't update them.

7. Below the `Guestbook` model permissions, but still above the closing `</resource-action-mapping>`, place the `Entry` model permissions:

```
<model-resource>
    <model-name>com.liferay.docs.guestbook.model.Entry</model-name>
    <portlet-ref>
        <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookPortlet</portlet-name>
    </portlet-ref>
    <permissions>
        <supports>
            <action-key>DELETE</action-key>
            <action-key>PERMISSIONS</action-key>
            <action-key>UPDATE</action-key>
            <action-key>VIEW</action-key>
        </supports>
        <site-member-defaults>
            <action-key>VIEW</action-key>
        </site-member-defaults>
        <guest-defaults>
            <action-key>VIEW</action-key>
        </guest-defaults>
        <guest-unsupported>
            <action-key>UPDATE</action-key>
        </guest-unsupported>
    </permissions>
</model-resource>
```

   This defines `Entry` specific actions. By default, a site member can add or view an entry, and a guest can only view an entry.

8. Save the file.

This defines permissions at the model level, but you must also define portlet permissions. These are managed in the `guestbook-web` module, which contains the portlet class. Follow these steps to add the portlet permissions in the `guestbook-web` module:

1. In `guestbook-web`'s `src/main/resources` folder, create a file called `portlet.properties`.

2. In this file, place the following property:

   ```
   resource.actions.configs=META-INF/resource-actions/default.xml
   ```

3. Create a subfolder called `resource-actions` in the `src/main/resources/META-INF` folder.

4. Create a new file in this folder called `default.xml`.

5. Add the following `DOCTYPE` declaration to the top of the file:

   ```
   <?xml version="1.0"?>
   <!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action
   Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-resource-action-mapping_7_0_0.dtd">
   ```

6. Below the `DOCTYPE` declaration, add the following `resource-action-mapping` tags:

   ```
   <resource-action-mapping>

   </resource-action-mapping>
   ```

   You'll define your portlet permissions inside these tags.

7. Insert this block of code inside the `resource-action-mapping` tags:

   ```
   <portlet-resource>
       <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookAdminPortlet</portlet-name>
       <permissions>
           <supports>
               <action-key>ACCESS_IN_CONTROL_PANEL</action-key>
               <action-key>CONFIGURATION</action-key>
               <action-key>VIEW</action-key>
           </supports>
           <site-member-defaults>
               <action-key>VIEW</action-key>
           </site-member-defaults>
           <guest-defaults>
               <action-key>VIEW</action-key>
           </guest-defaults>
           <guest-unsupported>
               <action-key>ACCESS_IN_CONTROL_PANEL</action-key>
               <action-key>CONFIGURATION</action-key>
           </guest-unsupported>
       </permissions>
   </portlet-resource>
   ```

   This defines the default permissions for the Guestbook Admin portlet. It supports the actions `ACCESS_IN_CONTROL_PANEL`, `CONFIGURATION`, and `VIEW`. While anyone can view the app, guests and site members can't configure it or access it in the Control Panel. Since it's a Control Panel portlet, this effectively means that only administrators are able to access it.

8. Below the Guestbook Admin permissions, insert this block of code:

```
<portlet-resource>
    <portlet-name>com_liferay_docs_guestbook_portlet_GuestbookPortlet</portlet-name>
    <permissions>
        <supports>
            <action-key>ADD_TO_PAGE</action-key>
            <action-key>CONFIGURATION</action-key>
            <action-key>VIEW</action-key>
        </supports>
        <site-member-defaults>
            <action-key>VIEW</action-key>
        </site-member-defaults>
        <guest-defaults>
            <action-key>VIEW</action-key>
        </guest-defaults>
        <guest-unsupported />
    </permissions>
</portlet-resource>
```

This defines permissions for the Guestbook portlet. It supports the actions `ADD_TO_PAGE`, `CONFIGURATION`, and `VIEW`. Site members and guests get the `VIEW` permission by default.

9. Save the file.

Great job! You've now successfully designed and implemented a permissions scheme for your application. Next, you'll create the Java code to support permissions in the service layer.

24.2 Permissions in the Service Layer

```
<p>Implementing Permissions<br>Step 2 of 4</p>
```

The last step introduced the concept of *resources*. Resources are data stored with your entities that define how they can be accessed. For example, when the configuration in your `default.xml` files is applied to your application's entities in the database, resources are created. These resources are then used in conjunction with Liferay DXP's permissions system to determine who can do what to the entities.

Liferay DXP provides a complete API for managing resources that's integrated with Service Builder. This API is injected into your implementation classes automatically. To manage the resources, all you must do is call the API in the service's add and delete methods. Follow these steps to do this in your application:

1. In your `guestbook-service` module, open `GuestbookLocalServiceImpl.java` from the `com.liferay.docs.guestbook.servic` package.

2. Just before the `addGuestbook` method's `return` statement, add this code:

   ```
   resourceLocalService.addResources(user.getCompanyId(), groupId, userId,
       Guestbook.class.getName(), guestbookId, false, true, true);
   ```

   Note that the `resourceLocalService` object is already there, ready for you to use. This is one of several utilities that are injected automatically by Service Builder. You'll see the rest in the future.

   This code adds a resource to Liferay DXP's database to correspond with your entity (note that the `guestbookId` is included in the call). The three booleans at the end are settings. The first is whether to add portlet action permissions. This should only be `true` if the permission is for a portlet resource. Since this permission is for a model resource (an entity), it's `false`. The other two are settings for adding group and guest permissions. If you set these to `true`, you'll add the default permissions you defined in the permissions configuration file (`default.xml`) in the previous step. Since you definitely want to do this, these booleans are set to `true`.

3. Next, go to the `updateGuestbook` method. Add a similar bit of code in between `guestbookPersistence.update(guestbook);` and the `return` statement:

```
resourceLocalService.updateResources(serviceContext.getCompanyId(),
                serviceContext.getScopeGroupId(),
                Guestbook.class.getName(), guestbookId,
                serviceContext.getGroupPermissions(),
                serviceContext.getGuestPermissions());
```

4. Now you'll do the same for `deleteGuestbook`. Add this code in between `guestbook = deleteGuestbook(guestbook);` and the `return` statement:

```
resourceLocalService.deleteResource(serviceContext.getCompanyId(),
                Guestbook.class.getName(), ResourceConstants.SCOPE_INDIVIDUAL,
                guestbookId);
```

5. Hit [CTRL]+[SHIFT]+O to organize the imports and save the file.

6. Now you'll add resources for the `Entry` entity. Open `EntryLocalServiceImpl.java` from the same package. For `addEntry`, add a line of code that adds resources for this entity, just before the `return` statement:

```
resourceLocalService.addResources(user.getCompanyId(), groupId, userId,
    Entry.class.getName(), entryId, false, true, true);
```

7. For `deleteEntry`, add this code just before the `return` statement:

```
resourceLocalService.deleteResource(
               serviceContext.getCompanyId(), Entry.class.getName(),
               ResourceConstants.SCOPE_INDIVIDUAL, entryId);
```

8. Finally, find `updateEntry` and add its resource action, also just before the `return` statement:

```
resourceLocalService.updateResources(
      user.getCompanyId(), serviceContext.getScopeGroupId(),
      Entry.class.getName(), entryId, serviceContext.getGroupPermissions(),
      serviceContext.getGuestPermissions());
```

That's all it takes to add permissions resources. Future entities added to the database are fully permissions-enabled. Note, however, that any entities you've already added to your Guestbook application in the portal don't have resources and thus can't be protected by permissions. You'll fix this at the end of this section.

Next, you'll create helper classes to make it easier to check permissions.

24.3 Creating Permissions Helper Classes

```
<p>Implementing Permissions<br>Step 3 of 4</p>
```

You've now defined your permissions and made sure resources are added to the database so permissions can be checked. Now you'll create the helper classes needed to check permissions.

Here's how it works. You have a permission, such as `ADD_ENTRY`, and a resource, such as a `Guestbook`. For a user to add an entry to a guestbook, you must check whether that user has the `ADD_ENTRY` permission for that guestbook. Creating helper classes to check permissions on particular models and entities makes these checks more efficient. Creating such classes is therefore a best practice. Now you'll create these classes for the Guestbook application:

1. Right-click the guestbook-service module and select *New → Package*. Name the package com.liferay.docs.guestbook.service.permission. This is where you'll place your helper classes.

2. Right-click the new package and select *New → Class*. Name the class GuestbookModelPermission.

3. Replace this class's contents with the following code:

```
package com.liferay.docs.guestbook.service.permission;

import org.osgi.service.component.annotations.Component;

import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.security.auth.PrincipalException;
import com.liferay.portal.kernel.security.permission.BaseResourcePermissionChecker;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import com.liferay.portal.kernel.security.permission.ResourcePermissionChecker;

@Component(immediate = true, property = {
    "resource.name=" + GuestbookModelPermission.RESOURCE_NAME
}, service = ResourcePermissionChecker.class)

public class GuestbookModelPermission extends BaseResourcePermissionChecker {

    public static final String RESOURCE_NAME = "com.liferay.docs.guestbook";

    public static void check(
        PermissionChecker permissionChecker, long groupId, String actionId)
        throws PortalException {

        if (!contains(permissionChecker, groupId, actionId)) {
            throw new PrincipalException.MustHavePermission(
                permissionChecker, RESOURCE_NAME, groupId, actionId);
        }
    }

    public static boolean contains(
        PermissionChecker permissionChecker, long groupId, String actionId) {

        return permissionChecker.hasPermission(
            groupId, RESOURCE_NAME, groupId, actionId);
    }

    @Override
    public Boolean checkResource(
        PermissionChecker permissionChecker, long classPK, String actionId) {

        return contains(permissionChecker, classPK, actionId);
    }
}
```

This class is a component that extends BaseResourcePermissionChecker and defines two static methods (so you don't have to instantiate the class) that encapsulate the model you're checking permissions for. It also contains a boolean method that checks your resources. Liferay's PermissionChecker class does most of the work: you only need feed it the proper resource and action, such as ADD_ENTRY, and it returns whether the permission exists or not.

There are three implementations here: a check method that throws an exception if the user doesn't have permission, a contains method that returns a boolean that's true if the user has permission and false if not, and a checkResource method that calls the contains method.

Next, you'll create helpers for your two entities. Follow these steps to do so:

1. Create a class in the same package called GuestbookPermission.java.

2. Replace this class's contents with the following code:

```
package com.liferay.docs.guestbook.service.permission;

import com.liferay.docs.guestbook.model.Guestbook;
import com.liferay.docs.guestbook.service.GuestbookLocalService;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.exception.SystemException;
import com.liferay.portal.kernel.security.auth.PrincipalException;
import com.liferay.portal.kernel.security.permission.BaseModelPermissionChecker;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

@Component(
    immediate = true,
    property = {"model.class.name=com.liferay.docs.guestbook.model.Guestbook"}
)
public class GuestbookPermission implements BaseModelPermissionChecker {

    public static void check(
        PermissionChecker permissionChecker, long guestbookId, String actionId)
        throws PortalException, SystemException {

        if (!contains(permissionChecker, guestbookId, actionId)) {
            throw new PrincipalException();
        }
    }

    public static void check(
        PermissionChecker permissionChecker, long groupId, long guestbookId,
        String actionId)
        throws PortalException {

        if (!contains(permissionChecker, groupId, actionId)) {
            throw new PrincipalException.MustHavePermission(
                permissionChecker, Guestbook.class.getName(), guestbookId,
                actionId);
        }
    }

    public static boolean contains(
        PermissionChecker permissionChecker, long groupId, long guestbookId, String actionId)
            throws PortalException {

        Guestbook guestbook = _guestbookLocalService.getGuestbook(guestbookId);

        return GuestbookModelPermission.contains(permissionChecker, groupId, actionId);
    }

    public static boolean contains(
        PermissionChecker permissionChecker, long guestbookId, String actionId)
        throws PortalException, SystemException {

        Guestbook guestbook
            = _guestbookLocalService.getGuestbook(guestbookId);
        return contains(permissionChecker, guestbook, actionId);
    }

    public static boolean contains(
        PermissionChecker permissionChecker, Guestbook guestbook, String actionId)
            throws PortalException, SystemException {

        return permissionChecker.hasPermission(
        guestbook.getGroupId(), Guestbook.class.getName(), guestbook.getGuestbookId(), actionId);

    }
    @Reference(unbind = "-")
    protected void setGuestbookLocalService(GuestbookLocalService guestbookLocalService) {
        _guestbookLocalService = guestbookLocalService;
    }

    private static GuestbookLocalService _guestbookLocalService;

    @Override
    public void checkBaseModel(
        PermissionChecker permissionChecker, long groupId, long guestbookId, String actionId) throws PortalException {
            check(permissionChecker, guestbookId, actionId);
    }
}
```

As you can see, this class is similar to GuestbookModelPermission. The difference is that GuestbookPermission is for the model/resource permission, so you supply the primary key of the entity you're checking permissions for (guestbookId). The check and contains methods in GuestbookPermission are also similar to those in GuestbookModelPermission. In both classes, the check method throws an exception if there's no permission, while the contains method returns a boolean denoting whether the current user has permission. The contains method in GuestbookPermission, however, also retrieves the entity to verify that it exists (if it doesn't, an exception is thrown).

Your final class is almost identical to GuestbookPermission, but it's for the Entry entity. Follow these steps to create it:

1. Create a class in the same package called EntryPermission.java.

2. Replace this class's contents with the following code:

```
package com.liferay.docs.guestbook.service.permission;

import com.liferay.docs.guestbook.model.Entry;
import com.liferay.docs.guestbook.service.EntryLocalService;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.exception.SystemException;
import com.liferay.portal.kernel.security.auth.PrincipalException;
import com.liferay.portal.kernel.security.permission.BaseModelPermissionChecker;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

@Component(
    immediate = true,
    property = {"model.class.name=com.liferay.docs.guestbook.model.Entry"}
)
public class EntryPermission implements BaseModelPermissionChecker {

    public static void check(
        PermissionChecker permissionChecker, long entryId, String actionId)
        throws PortalException, SystemException {

        if (!contains(permissionChecker, entryId, actionId)) {
            throw new PrincipalException();
        }
    }

    public static boolean contains(
        PermissionChecker permissionChecker, long entryId, String actionId)
        throws PortalException, SystemException {

        Entry entry = _entryLocalService.getEntry(entryId);
```

```
            return contains (permissionChecker, entry, actionId);

        }

        public static boolean contains(
            PermissionChecker permissionChecker, Entry entry, String actionId) throws
            PortalException, SystemException {

            return permissionChecker.hasPermission(entry.getGroupId(), Entry.class.getName(), entry.getEntryId(), actionId);
        }

        @Reference(unbind = "-")
        protected void setEntryLocalService (EntryLocalService entryLocalService) {

            _entryLocalService = entryLocalService;
        }

        private static EntryLocalService _entryLocalService;

        @Override
        public void checkBaseModel(
            PermissionChecker permissionChecker, long groupId, long primaryKey, String actionId) throws PortalException {
                check(permissionChecker, primaryKey, actionId);
        }
    }
```

This class is almost identical to `GuestbookPermission`. The only difference is that `EntryPermission` is for the `Entry` entity.

Now that you have these classes, you must build services and export the permissions package so that other modules can access it. Follow these steps to do so:

1. Save the permissions helper classes you just created. From the Gradle Tasks panel on the right side of Liferay @ide@, run `buildService` from the `guestbook-service` module's `build` folder.

2. In the Project Explorer, open the `bnd.bnd` file from the root folder of the `guestbook-service` module.

3. In the graphical view, under the *Export Packages* section, click the plus button to add an export.

4. Select `com.liferay.docs.guestbook.service.permission` and click `OK`.

5. Save the file.

Congratulations! You've now created helper classes for your permissions. The only thing left is to implement permission checks in the application's view layer. You'll do this next.

24.4 Permissions in JSPs

```
<p>Implementing Permissions<br>Step 4 of 4</p>
```

User interface components can be wrapped in permission checks pretty easily. In this step, you'll learn how.

First go to the `init.jsp` in your `guestbook-web` project. Add the following imports to the file:

```
<%@ page import="com.liferay.docs.guestbook.service.permission.GuestbookModelPermission" %>
<%@ page import="com.liferay.docs.guestbook.service.permission.GuestbookPermission" %>
<%@ page import="com.liferay.docs.guestbook.service.permission.EntryPermission" %>
<%@ page import="com.liferay.portal.kernel.util.WebKeys" %>
<%@ page import="com.liferay.portal.kernel.security.permission.ActionKeys" %>
```

The first three are the permissions helper classes you just created. Now it's time to implement permission checks.

Checking Permissions in the UI

Recall that you want to restrict access to three areas in your application:

- The guestbook tabs across the top of your application
- The Add Guestbook button
- The Add Entry button

First, you'll create the guestbook tabs and check permissions for them. Follow these steps to do so:

1. Open `/guestbookwebportlet/view.jsp` and find the scriptlet that gets the `guestbookId` from the request. Just below this, add the following code:

```
<aui:nav cssClass="nav-tabs">

    <%
        List<Guestbook> guestbooks = GuestbookLocalServiceUtil.getGuestbooks(scopeGroupId);

            for (int i = 0; i < guestbooks.size(); i++) {

                Guestbook curGuestbook = (Guestbook) guestbooks.get(i);
                String cssClass = StringPool.BLANK;

                if (curGuestbook.getGuestbookId() == guestbookId) {
                    cssClass = "active";
                }

                if (GuestbookPermission.contains(
                    permissionChecker, curGuestbook.getGuestbookId(), "VIEW")) {

    %>

    <portlet:renderURL var="viewPageURL">
        <portlet:param name="mvcPath" value="/guestbookwebportlet/view.jsp" />
        <portlet:param name="guestbookId"
            value="<%=String.valueOf(curGuestbook.getGuestbookId())%>" />
    </portlet:renderURL>

    <aui:nav-item cssClass="<%=cssClass%>" href="<%=viewPageURL%>"
        label="<%=HtmlUtil.escape(curGuestbook.getName())%>" />

    <%
                }

            }
    %>

</aui:nav>
```

   This code gets a list of guestbooks from the database, iterates through them, checks the permission for each against the current user's roles, and adds the guestbooks the user can access to a list of tabs.

   You've now implemented your first permission check. As you can see, it's relatively straightforward thanks to the static methods in your helper classes. The code above shows the tab only if the current user has the `VIEW` permission for the guestbook.

   Next, you'll add permission checks to the Add Entry button.

2. Scroll down to the line that reads `<aui:button-row cssClass="guestbook-buttons">`. Just below this line, add the following line of code to check for the `ADD_ENTRY` permission:

```
<c:if test='<%= GuestbookPermission.contains(permissionChecker, guestbookId, "ADD_ENTRY") %>'>
```

3. After this is the code that creates the `addEntryURL` and the Add Entry button. After the `aui:button` tag and above the `</aui:button-row>` tag, add the closing tag for the `<c:if>` statement:

```
</c:if>
```

You've now implemented your permission check for the Add Entry button by using JSTL tags.

Next, you'll implement an `entry_actions.jsp` that's much like the one in the Guestbook Admin portlet. This will determine what options appear for logged in users who can see the actions menu in the portlet. Just like before, you'll wrap each `renderURL` in a `if` statement that checks the permissions against available actions. To do this, follow these steps:

1. In `src/main/resources/META-INF/resources/guestbookwebportlet`, create a file called `entry_actions.jsp`.

2. In this file, add the following code:

```
<%@include file="../init.jsp"%>

<%
String mvcPath = ParamUtil.getString(request, "mvcPath");

ResultRow row = (ResultRow)request.getAttribute(WebKeys.SEARCH_CONTAINER_RESULT_ROW);

Entry entry = (Entry)row.getObject();
%>

<liferay-ui:icon-menu>

    <portlet:renderURL var="viewEntryURL">
        <portlet:param name="entryId" value="<%= String.valueOf(entry.getEntryId()) %>" />
        <portlet:param name="mvcPath" value="/guestbookwebportlet/view_entry.jsp" />
    </portlet:renderURL>

    <liferay-ui:icon
        message="View"
        url="<%= viewEntryURL.toString() %>"
    />

    <c:if
        test="<%= EntryPermission.contains(permissionChecker, entry.getEntryId(), ActionKeys.UPDATE) %>">
        <portlet:renderURL var="editURL">
            <portlet:param name="entryId"
                value="<%= String.valueOf(entry.getEntryId()) %>" />
            <portlet:param name="mvcPath" value="/guestbookwebportlet/edit_entry.jsp" />
        </portlet:renderURL>

        <liferay-ui:icon image="edit" message="Edit"
            url="<%=editURL.toString() %>" />
    </c:if>

    <c:if
    test="<%=EntryPermission.contains(permissionChecker, entry.getEntryId(), ActionKeys.PERMISSIONS) %>">

        <liferay-security:permissionsURL
            modelResource="<%= Entry.class.getName() %>"
            modelResourceDescription="<%= entry.getMessage() %>"
            resourcePrimKey="<%= String.valueOf(entry.getEntryId()) %>"
            var="permissionsURL" />

        <liferay-ui:icon image="permissions" url="<%= permissionsURL %>" />

    </c:if>

    <c:if
        test="<%=EntryPermission.contains(permissionChecker, entry.getEntryId(), ActionKeys.DELETE) %>">

        <portlet:actionURL name="deleteEntry" var="deleteURL">
            <portlet:param name="entryId"
                value="<%= String.valueOf(entry.getEntryId()) %>" />
            <portlet:param name="guestbookId"
                value="<%= String.valueOf(entry.getGuestbookId()) %>" />
        </portlet:actionURL>

        <liferay-ui:icon-delete url="<%=deleteURL.toString() %>" />
    </c:if>

</liferay-ui:icon-menu>
```

This code defines several action buttons for viewing, updating, setting permissions on, and deleting entities. Each button is protected by a permissions check. If the current user can't perform the given action, the action doesn't appear.

3. Finally, in `view.jsp`, you must add the `entry_actions.jsp` as the last column in the Search Container. Find the line defining the Search Container row. It looks like this:

```
<liferay-ui:search-container-row
    className="com.liferay.docs.guestbook.model.Entry" modelVar="entry">
```

Below that line are two columns. After the second column, add a third:

```
<liferay-ui:search-container-column-jsp path="/guestbookwebportlet/entry_actions.jsp" align="right" />
```

4. Save all JSP files.

Excellent! You've now implemented all the permissions checks for the Guestbook portlet.

When testing the application, remember that any guestbook entries you created without resources won't work with permissions. Add new guestbooks and entries to test your application with different users. Administrative users see all the buttons, regular users see the Add Entry button, and guests see no buttons at all (but can navigate).

Note: You may see an error where the Guestbook portlet doesn't appear at all, and you see this error in the log:

```
Someone may be trying to circumvent the permission checker.
```

This is because any data you currently have in the Guestbook application doesn't have resources. In this case, you must drop and re-create your database. To do this, find your Liferay Workspace on your file system (it should be inside your Eclipse workspace). Inside the `bundles/data` folder is a `hypersonic` folder. Shut down Liferay DXP, remove everything from this folder, and then restart. After adding guestbook to a page, the portlet will work normally.

Now see if you can do the same for the Guestbook Admin portlet. Don't worry if you can't: at the end of this Learning Path is a link to the completed project for you to examine.

Great! You're all done with permissions. The next step is to integrate search and indexing into your application. This is a prerequisite for the much more powerful stuff to come.

Chapter 25

Displaying Messages and Errors

When users interact with your application, they perform tasks it defines, like saving or editing things. The Guestbook application is no different. Your application should also provide feedback on these operations so users can know if they worked. Up to now, you've been placing this information in logs that only administrators can access. Wouldn't it be better to show users these messages?

That's exactly what you'll do next, in three steps:

1. Create language keys for your messages.
2. Add the error messages to your action methods.
3. Report those error messages in your JSPs.

Ready to get started?

Let's Go!

25.1 Creating Language Keys

`<p>Displaying Messages and Errors<br>Step 1 of 3</p>`

Any modern application should place its messages and form field labels in a language keys file that can be duplicated and then translated into multiple languages. Here, you'll learn how to provide a *default* set of English language keys for your application. For more information on language keys and providing automatically translated language keys, see this tutorial.

Language keys are stored in the `Language.properties` file included in your `guestbook-web` module. `Language.properties` is the default, but you can create a number of translations by appending the ISO-639 language code to the file name (e.g., `Language_en.properties` for English or `Language_de.properties` for German). For now, stick to the default language keys.

Follow these steps to create your language keys:

1. Open `/src/main/resources/content/Language.properties` in your `guestbook-web` module. Remove the default keys in this file.

2. Paste in the following keys:

```
entry-added=Entry added successfully.
entry-deleted=Entry deleted successfully.
guestbook-added=Guestbook added successfully.
guestbook-updated=Guestbook updated successfully.
guestbook-deleted=Guestbook deleted successfully.
```

3. Save the file.

Your messages are now in place, and your application can use them. Next, you'll add them to your action methods.

25.2 Adding Failure and Success Messages

<p>Displaying Messages and Errors<br>Step 2 of 3</p>

To display correct feedback to users properly, you must edit your portlet classes to use Liferay DXP's `SessionMessages` and `SessionErrors` classes. These classes collect messages that the view layer shows to the user by using a simple tag.

You'll add these messages to code that runs when the user triggers a system function that can succeed or fail, such as creating, editing, or deleting an entry or guestbook. This generally happens in action methods. You must update these methods to handle failure and success states in `GuestbookPortlet.java` and `GuestbookAdminPortlet.java`. Start by updating `addEntry` and `deleteEntry` in `GuestbookPortlet.java`:

1. Find the `addEntry` method in `GuestbookPortlet.java`. In the first `try...catch` block's `try` section, add a success message just before the closing }:

   ```
   SessionMessages.add(request, "entryAdded");
   ```

   This uses Liferay's `SessionMessages` API to add a success message whenever a Guestbook is successfully added. It looks up the message you placed in the `Language.properties` file and inserts the message for the key `entry-added` (it automatically converts the key to camel case).

2. Below that, in the `catch` block, find the following code:

   ```
   System.out.println(e);
   ```

3. Beneath it, paste this line:

   ```
   SessionErrors.add(request, e.getClass().getName());
   ```

   Now you not only log the message to the console, you also use the `SessionErrors` object to show the message to the user.

Next, do the same for the `deleteEntry` method:

1. After the logic to delete the entry, add a success message:

   ```
   SessionMessages.add(request, "entryDeleted");
   ```

2. Find the same `Logger...` block of code in the `deleteEntry` method and after it, paste this line:

```
SessionErrors.add(request, e.getClass().getName());
```

3. Hit [CTRL]+[SHIFT]+O to import `com.liferay.portal.kernel.servlet.SessionErrors` and `com.liferay.portal.kernel.servlet.SessionMessages`. Save the file.

Well done! You've added the messages to `GuestbookPortlet`. Now you must update `GuestbookAdminPortlet.java`:

1. Open `GuestbookAdminPortlet.java` and look for the same cues.

2. Add the appropriate success messages to the try section of the `try...catch` in `addGuestbook`, `updateGuestbook`, and `deleteGuestbook`, respectively:

   ```
   SessionMessages.add(request, "guestbookAdded");
   ```

   ```
   SessionMessages.add(request, "guestbookUpdated");
   ```

   ```
   SessionMessages.add(request, "guestbookDeleted");
   ```

3. In the `catch` section of those same methods, find `Logger.getlogger...` and paste the `SessionErrors` block beneath it:

   ```
   SessionErrors.add(request, pe.getClass().getName());
   ```

4. Hit [CTRL]+[SHIFT]+O to import `SessionErrors` and `SessionMessages`. Save the file.

Great! The controller now makes relevant and detailed feedback available. Now all you need to do is publish this feedback in the view layer.

25.3 Adding Messages to JSPs

```
<p>Displaying Messages and Errors<br>Step 3 of 3</p>
```

Any messages the user should see are now stored in either `SessionMessages` or `SessionErrors`. Next, you'll make these messages appear in your JSPs.

1. In the `guestbook-web` module, open `guestbookwebportlet/view.jsp`. Add the following block of success messages to the top of the file, just below the `init.jsp` include statement:

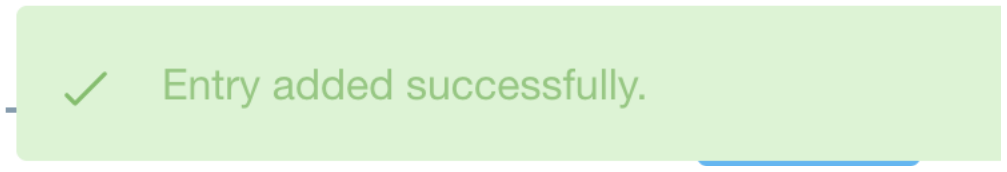
   ```
   <liferay-ui:success key="entryAdded" message="entry-added" />
   <liferay-ui:success key="guestbookAdded" message="guestbook-added" />
   <liferay-ui:success key="entryDeleted" message="entry-deleted" />
   ```

   This tag accesses what's stored in `SessionMessages`. It has two attributes. The first is the `SessionMessages` key that you provided in the `GuestbookPortlet.java` class's add and delete methods. The second looks up the specified key in the `Language.properties` file. You could have specified a hard-coded message here, but it's far better to provide a localized key.

2. Now open `guestbookadminportlet/view.jsp`. Add the following block of success messages in the same spot below the include:

```
<liferay-ui:success key="guestbookAdded" message="guestbook-added" />
<liferay-ui:success key="guestbookUpdated" message="guestbook-updated" />
<liferay-ui:success key="guestbookDeleted" message="guestbook-deleted" />
```

Note that one of the `message` values is the same for both portlets. There's no need to write redundant messages–language keys are reusable.



Entry added successfully.

Figure 25.1: Now the message will display the value you specified in `Language.properties`.

Congratulations! You've added useful feedback for operations in your application. Next, you'll add permission checking for your guestbooks and entries.

Chapter 26

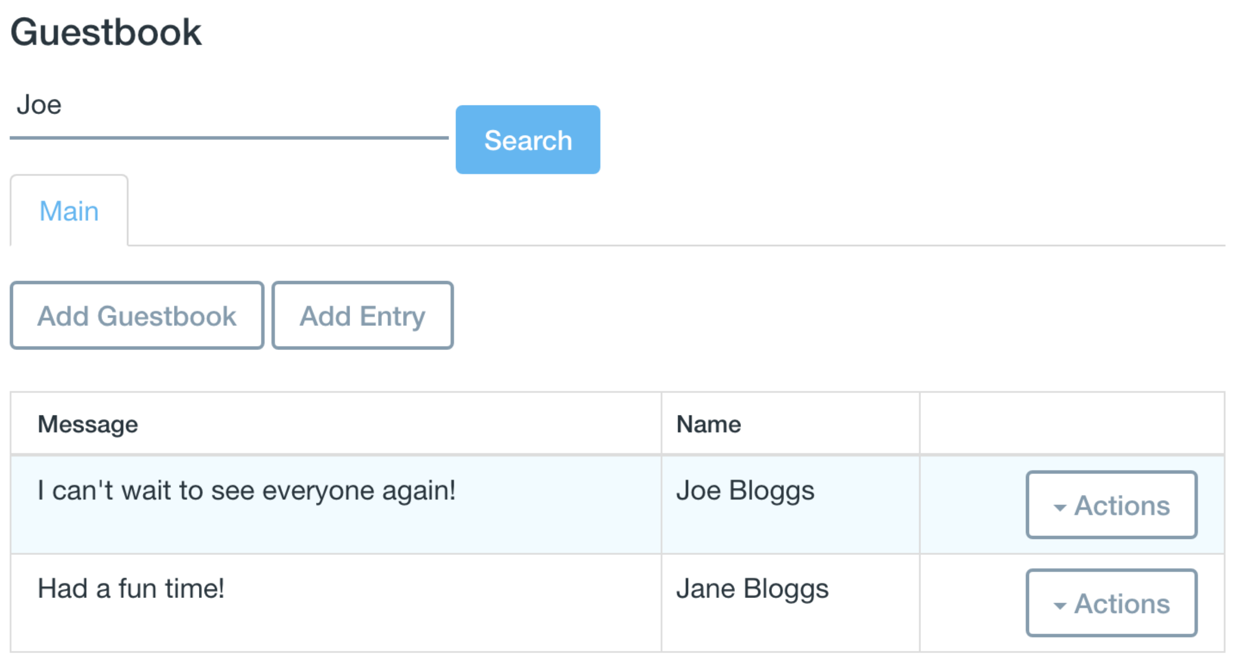
Leveraging Search

Now you have working Guestbook and Guestbook Admin portlets. The Guestbook portlet lets users add, edit, delete, and configure permissions for guestbook entries. The Guestbook Admin portlet lets site administrators create, edit, delete, and configure permissions for guestbooks. In the case of a very popular event (maybe a *Lunar Luau* dinner at the Lunar Resort), there could be many guestbook entries in the portlet, and users might want to search for entries that mentioned the delicious low-gravity ham that was served (melts in your mouth). Searching for the word *ham* should display these entries. In short, guestbook entries must be searchable via a search bar in the Guestbook portlet.

To enable search, you'll add an indexer for guestbooks and their entries. Although you probably won't have enough guestbooks in a site to warrant searching the Guestbook Admin portlet, creating a guestbook indexer has other benefits. In a later section, you'll asset-enable guestbooks and guestbook entries so Liferay DXP's Asset Publisher can display them. Enabling search is a prerequisite for this–you must index any entity that you want to make an asset.

But assets are for later. Right now it's time to create those indexers. Ready?

Let's Go!



Joe

Message	Name	
I can't wait to see everyone again!	Joe Bloggs	Actions
Had a fun time!	Jane Bloggs	Actions

Figure 26.1: You'll add a search bar to the Guestbook portlet so that users can search for guestbook entries. If a guestbook entry's message or name matches the search query, the entry is displayed in the search results.

Chapter 27

Enabling Search and Indexing for Guestbooks

In this section, you first create an indexer for guestbooks. You then modify the service layer to use this indexer to update the search index when a guestbook is persisted:

1. Create a `GuestbookIndexer` class that extends Liferay's `BaseIndexer` abstract class.

2. Update `GuestbookLocalServiceImpl`'s `addGuestbook`, `updateGuestbook`, and `deleteGuestbook` methods to invoke the guestbook indexer.

Since there's no reason to search for guestbooks in the UI, only the back-end work is necessary.
Let's Go!

27.1 Understanding Search and Indexing

`<p>Enabling Search and Indexing for Guestbooks<br>Step 1 of 3</p>`

By default, Liferay DXP uses Elasticsearch, a search engine backed by the popular Lucene search library, to implement its search and indexing functionality. To avoid the resource-hogging table merges necessary to search the database, using a search engine like Elasticsearch lets you convert searchable entities into *documents*. In Elasticsearch, documents are searchable database entities converted into JSON objects. After you implement an indexer for guestbook entries, Liferay DXP creates a document for each entry. This indexer specifies which guestbook entry fields to add to each guestbook entry document. All the guestbook entry documents are then added to an index. When the index is searched, a *hits* object is returned that contains pointers to the documents matching the search query. Searching for entities with a search engine via an index is faster than searching for entities in the database. Elasticsearch provides some additional features like relevancy scoring and fuzzy search queries.

Along with the search engine, Liferay DXP has its own search infrastructure. Liferay DXP adds to the existing Elasticsearch API for a few reasons:

- To ensure indexed documents include the fields needed by Liferay DXP (e.g., `entryClassName`, `entryClassPK`, `assetTagNames`, `assetCategories`, `companyId`, `groupId`, staging status).

- To ensure the scope of returned search results is appropriate by applying the right filters to search requests.
- To provide permission checking and hit summaries to display in the search portlet.

Next, you'll create the indexer for guestbooks.

27.2 Creating a Guestbook Indexer

<p>Enabling Search and Indexing for Guestbooks<br>Step 2 of 3</p>

First, update your `build.gradle` to have all of the necessary imports.

1. Open the `build.gradle` file in your `guestbook-service` project.
2. Add the following line below the other imports:

```
compileOnly group: "com.liferay", name: "com.liferay.registry.api", version: "1.0.0"
compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
```

3. Save the file and run `Refresh Gradle Project`.

Now that you have the additional dependencies configured, follow these steps to create the indexer for guestbooks:

1. Create a new package in the `guestbook-service` module project's `src/main/java` folder called `com.liferay.docs.guestbook.search`. In this package, create a new class called `GuestbookIndexer` that extends `com.liferay.portal.kernel.search.BaseIndexer` with `Guestbook` as a type argument. Add an `@Component` annotation to declare that the `GuestbookIndexer` class provides an implementation of the Indexer service. Also, define the `CLASS_NAME` variable by getting the name of the `Guestbook` model class. This is necessary to override the `getClassName` method from `BaseIndexer`. Liferay DXP uses this method to determine the object this Indexer indexes:

```
@Component(
    immediate = true,
    service = Indexer.class
)
public class GuestbookIndexer extends BaseIndexer<Guestbook> {

    public static final String CLASS_NAME = Guestbook.class.getName();
}
```

2. Add the `GuestbookIndexer` constructor:

```
public GuestbookIndexer() {
    setDefaultSelectedFieldNames(
        Field.ASSET_TAG_NAMES, Field.COMPANY_ID, Field.CONTENT,
        Field.ENTRY_CLASS_NAME, Field.ENTRY_CLASS_PK, Field.GROUP_ID,
        Field.MODIFIED_DATE, Field.SCOPE_GROUP_ID, Field.TITLE, Field.UID);
    setPermissionAware(true);
    setFilterSearch(true);
}
```

This constructor does several things:

- Sets the default selected field names. These fields are used to retrieve results documents from the search engine.
- Sets the default selected localized field names. This ensures that the localized version of the field is searched and returned.
- Makes the search results permissions-aware at search time, as well as in the index. Without this, a search query returns *all* matching guestbooks regardless of the user's permissions on the resource.
- Sets filter search to `true`, enabling a document-by-document check of the search results' `VIEW` permissions. This is redundant most of the time, but safeguards against unexpected problems like the search index becoming stale, or if permission inheritance doesn't happen fast enough. Most of Liferay DXP's internal apps use this setting. If not set, the indexer relies on the permissions information indexed in the search engine.

3. Since you extend the abstract class `BaseIndexer` instead of implementing the `Indexer` interface directly, you must override its abstract methods. In the `getClassName` method, return the `CLASS_NAME` constant defined at the top of the class:

```
@Override
public String getClassName() {
    return CLASS_NAME;
}
```

   This returns `com.liferay.docs.guestbook.model.Guestbook`.

4. Next, you must override `hasPermission`. Call the `contains` method of the `GuestbookPermission` helper class that you created in an earlier Learning Path section:

```
@Override
public boolean hasPermission(
        PermissionChecker permissionChecker, String entryClassName,
        long entryClassPK, String actionId)
    throws Exception {

    return GuestbookPermission.contains(
        permissionChecker, entryClassPK, ActionKeys.VIEW);
}
```

   Here, you ensure that the `VIEW` permission on guestbooks can be used to find and display appropriate search results.

5. Override the `postProcessContextBooleanFilter` method:

```
@Override
public void postProcessContextBooleanFilter(
        BooleanFilter contextBooleanFilter, SearchContext searchContext)
throws Exception {
    addStatus(contextBooleanFilter, searchContext);
}
```

   This method is invoked while the main search query is being constructed. The base implementation of `addStatus` in `BaseIndexer` adds the workflow status to the filter. This ensures that entities with the status `STATUS_IN_TRASH` aren't added to the query. You'll learn more about workflow later.

6. Override postProcessSearchQuery to add clauses to the ongoing search query. It's best to add the localized value of any full text fields that might contribute to search relevance. By specifying the localized search term, you ensure that the regular search term has the locale appended (e.g., title_en_US). For the guestbook entity, add the title field (Field.TITLE):

   ```
   @Override
   public void postProcessSearchQuery(
       BooleanQuery searchQuery, BooleanFilter fullQueryBooleanFilter,
       SearchContext searchContext)
       throws Exception {

       addSearchLocalizedTerm(searchQuery, searchContext, Field.TITLE, false);
   }
   ```

7. Override the doDelete() method, which deletes the document corresponding to the Guestbook object parameter. Call BaseIndexer's deleteDocument method with the guestbook's company ID and guestbook ID:

   ```
   @Override
   protected void doDelete(Guestbook guestbook) throws Exception {
       deleteDocument(guestbook.getCompanyId(), guestbook.getGuestbookId());
   }
   ```

8. Implement the doGetDocument method to select the entity's fields to build a search document that's indexed by the search engine. The main searchable field for guestbooks is the guestbook name, which is stored in a guestbook search document's title field:

   ```
   @Override
   protected Document doGetDocument(Guestbook guestbook)
       throws Exception {

       Document document = getBaseModelDocument(CLASS_NAME, guestbook);

       document.addDate(Field.MODIFIED_DATE, guestbook.getModifiedDate());

       Locale defaultLocale =
           PortalUtil.getSiteDefaultLocale(guestbook.getGroupId());
       String localizedField = LocalizationUtil.getLocalizedName(
           Field.TITLE, defaultLocale.toString());

       document.addText(localizedField, guestbook.getName());
       return document;
   }
   ```

   Because Liferay DXP supports localization, you should too. The above code gets the default locale from the site by passing the Guestbook's group ID to the getSiteDefaultLocale method, then using it to get the localized name of the guestbook's title field. The retrieved site locale is appended to the field (e.g., title_en_US), so the field gets passed to the search engine and goes through the right analysis and tokenization.

9. Implement the doGetSummary method to return a *summary*. A summary is a condensed, text-based version of the entity that can be displayed generically. You create it by combining key parts of the entity's data so users can browse through search results to find the entity they want. Call BaseIndexer's createSummary method, then use summary.setMaxContentLength to set the summary content's maximum size. Most Liferay DXP applications use a value of 200, so it's a good idea to use the same to ensure uniform result summaries:

```
@Override
protected Summary doGetSummary(
    Document document, Locale locale, String snippet,
    PortletRequest portletRequest, PortletResponse portletResponse) {

    Summary summary = createSummary(document);
    summary.setMaxContentLength(200);
    return summary;
}
```

10. Override the overloaded `doReindex` method, which gets called when an entity is updated or a user explicitly triggers a reindex. The first `doReindex` method takes a single object argument. Retrieve the associated document with `BaseIndexer`'s `getDocument` method, then invoke `IndexWriterHelper`'s `updateDocument` method to update (reindex) the document:

```
@Override
protected void doReindex(Guestbook guestbook)
    throws Exception {

    Document document = getDocument(guestbook);
    indexWriterHelper.updateDocument(
        getSearchEngineId(), guestbook.getCompanyId(), document,
        isCommitImmediately());
}
```

11. The second `doReindex` method takes two arguments: a `className` string, and a `classPK` long. In this method, you retrieve the guestbook corresponding to the primary key by calling `GuestbookLocalService`'s `getGuestbook` method, passing in the `classPK` parameter. Then pass the guestbook to the first `doReindex` method (see above):

```
@Override
protected void doReindex(String className, long classPK)
    throws Exception {

    Guestbook guestbook = _guestbookLocalService.getGuestbook(classPK);
    doReindex(guestbook);
}
```

12. The third (and final) `doReindex` method indexes all entities in the current Liferay DXP instance (`companyId`). It takes a string array (`ids`) as an argument. `GetterUtil.getLong(ids[0])` retrieves the first string in the array, casts it to a `long`, stores it in a `companyId` variable, and passes it as an argument to the `reindexGuestbooks` helper method:

```
@Override
protected void doReindex(String[] ids)
    throws Exception {

    long companyId = GetterUtil.getLong(ids[0]);
    reindexGuestbooks(companyId);
}
```

13. To reindex guestbooks, provide the helper method `reindexGuestbooks`. In this method, use an actionable dynamic query helper method to retrieve all the guestbooks in the Liferay DXP instance. Service Builder generated this query method for you when you built the services. Each guestbook's document is then retrieved and added to a collection:

```
protected void reindexGuestbooks(long companyId)
  throws PortalException {

  final IndexableActionableDynamicQuery indexableActionableDynamicQuery =
    _guestbookLocalService.getIndexableActionableDynamicQuery();

  indexableActionableDynamicQuery.setCompanyId(companyId);

  indexableActionableDynamicQuery.setPerformActionMethod(

    new ActionableDynamicQuery.PerformActionMethod<Guestbook>() {
      @Override
      public void performAction(Guestbook guestbook) {
        try {
          Document document = getDocument(guestbook);
          indexableActionableDynamicQuery.addDocuments(document);
        }
        catch (PortalException pe) {
          if (_log.isWarnEnabled()) {
            _log.warn(
              "Unable to index guestbook " +
                guestbook.getGuestbookId(),
              pe);
          }
        }
      }
    });
  indexableActionableDynamicQuery.setSearchEngineId(getSearchEngineId());
  indexableActionableDynamicQuery.performActions();
}
```

14. Get the log for the guestbook model and add the necessary service references at the bottom of the file:

```
private static final Log _log =
  LogFactoryUtil.getLog(GuestbookIndexer.class);

@Reference
protected IndexWriterHelper indexWriterHelper;

@Reference
private GuestbookLocalService _guestbookLocalService;
```

15. Organize your imports ([CTRL]+[SHIFT]+O), and save the file. It will have errors.

16. Export the `com.liferay.docs.guestbook.search` package in the `guestbook-service` module's `bnd.bnd` file. The export section should look like this:

```
Export-Package:
  com.liferay.docs.guestbook.service.permission,\
  com.liferay.docs.guestbook.search
```

The guestbook indexer class is complete! Next, you can update the service layer.

27.3 Handling Indexing in the Guestbook Service Layer

<p>Enabling Search and Indexing for Guestbooks<br>Step 3 of 3</p>

Whenever a guestbook database entity is added, updated, or deleted, the search index must be updated accordingly. The Liferay DXP annotations `@Indexable` and `@IndexableType` mark your service methods so documents can be updated or deleted. You must update the `addGuestbook`, `updateGuestbook`, and `deleteGuestbook` service methods with these annotations.

1. Open GuestbookLocalServiceImpl in the guestbook-service module's com.liferay.docs.guestbook.service.impl package, and add the following annotation above the method signature for the addGuestbook and updateGuestbook methods:

   ```
   @Indexable(type = IndexableType.REINDEX)
   public Guestbook addGuestbook(...)

   @Indexable(type = IndexableType.REINDEX)
   public Guestbook updateGuestbook(...)
   ```

   The @Indexable annotation indicates that an index update is required following the method execution. The GuestbookIndexer controls exactly how the indexing happens. Setting the @Indexable annotation type to IndexableType.REINDEX updates the document in the index that corresponds to the updated guestbook.

2. Add the following annotation above the method signature for the deleteGuestbook method:

   ```
   @Indexable(type = IndexableType.DELETE)
   public Guestbook deleteGuestbook(...)
   ```

   When a guestbook is deleted from the database, its document shouldn't remain in the search index. This ensures that it is deleted.

3. Add the necessary imports:

   ```
   import com.liferay.portal.kernel.search.Indexable;
   import com.liferay.portal.kernel.search.IndexableType;
   ```

   Save the file.

4. In the Gradle Tasks pane on the right-hand side of Liferay @ide@, double-click buildService in guestbook-service → build. This re-runs Service Builder to incorporate your changes to GuestbookLocalServiceImpl.

Great! Next, you'll enable search and indexing for guestbook entries.

Chapter 28

Enabling Search and Indexing for Guestbook Entries

Enabling search for guestbook entries in the Guestbook portlet takes two steps:

1. Create an EntryIndexer class that extends Liferay DXP's BaseIndexer abstract class.

2. Update EntryLocalServiceImpl's addEntry and deleteEntry methods to invoke the guestbook entry indexer.

When you finish, all the back-end search and indexing work for both entities will be complete, leaving only the UI changes to complete.

Let's Go!

28.1 Creating an Entry Indexer

<p>Enabling Search and Indexing for Guestbook Entries<br>Step 1 of 2</p>

The EntryIndexer class you'll complete here is very similar to the GuestbookIndexer class you completed in the previous section. Therefore, the instructions here only point out differences between the indexing of guestbooks and entries.

Follow these steps to create the entry indexer:

1. In the com.liferay.docs.guestbook.search package of your guestbook-service module project's src/main/java folder, create a new
   class called EntryIndexer that extends com.liferay.portal.kernel.search.BaseIndexer. Replace the default contents of EntryIndexer.java with the following code:

```
package com.liferay.docs.guestbook.search;

@Component(immediate = true, service = Indexer.class)
public class EntryIndexer extends BaseIndexer<Entry> {

    public static final String CLASS_NAME = Entry.class.getName();

    public EntryIndexer() {
```

```
    setDefaultSelectedFieldNames(
        Field.COMPANY_ID, Field.ENTRY_CLASS_NAME, Field.ENTRY_CLASS_PK,
        Field.UID, Field.SCOPE_GROUP_ID, Field.GROUP_ID);
    setDefaultSelectedLocalizedFieldNames(Field.TITLE, Field.CONTENT);
    setFilterSearch(true);
    setPermissionAware(true);
}

@Override
public String getClassName() {

    return CLASS_NAME;
}

@Override
public boolean hasPermission(
    PermissionChecker permissionChecker, String entryClassName,
    long entryClassPK, String actionId)
    throws Exception {

    return EntryPermission.contains(
        permissionChecker, entryClassPK, ActionKeys.VIEW);
}

@Override
public void postProcessContextBooleanFilter(
    BooleanFilter contextBooleanFilter, SearchContext searchContext)
    throws Exception {

    addStatus(contextBooleanFilter, searchContext);
}

@Override
public void postProcessSearchQuery(
    BooleanQuery searchQuery, BooleanFilter fullQueryBooleanFilter,
    SearchContext searchContext)
    throws Exception {

    addSearchLocalizedTerm(searchQuery, searchContext, "guestbookName", false);
    addSearchLocalizedTerm(searchQuery, searchContext, Field.TITLE, false);
    addSearchLocalizedTerm(searchQuery, searchContext, Field.CONTENT, false);
}

@Override
protected void doDelete(Entry entry)
    throws Exception {

    deleteDocument(entry.getCompanyId(), entry.getEntryId());
}

@Override
protected Document doGetDocument(Entry entry)
    throws Exception {

    Document document = getBaseModelDocument(CLASS_NAME, entry);
    document.addDate(Field.MODIFIED_DATE, entry.getModifiedDate());
    document.addText("email", entry.getEmail());

    Locale defaultLocale =
        PortalUtil.getSiteDefaultLocale(entry.getGroupId());
    String localizedTitle = LocalizationUtil.getLocalizedName(
        Field.TITLE, defaultLocale.toString());
    String localizedMessage = LocalizationUtil.getLocalizedName(
        Field.CONTENT, defaultLocale.toString());

    document.addText(localizedTitle, entry.getName());
    document.addText(localizedMessage, entry.getMessage());
```

```
        long guestbookId = entry.getGuestbookId();
        Guestbook guestbook = _guestbookLocalService.getGuestbook(guestbookId);
        String guestbookName= guestbook.getName();
        String localizedGbName = LocalizationUtil.getLocalizedName(
            "guestbookName", defaultLocale.toString());

        document.addText(localizedGbName, guestbookName);

        return document;
    }
```

This is not all the code, but it contains the heart of the functionality: the `doGetDocument` method and its helper methods. The email, date, localized title, and message fields (based on the site's default language) are indexed. Finally, you get the entry's guestbook and index the localized version of the `guestbookName` field. Always support localization where possible–this ensures your entities are searchable in any language.

2. The rest of the code is very similar to the `GuestbookIndexer`. Paste in the following code to finish the entry indexer class:

```
    @Override
    protected Summary doGetSummary(
        Document document, Locale locale, String snippet,
        PortletRequest portletRequest, PortletResponse portletResponse)
        throws Exception {

        Summary summary = createSummary(document);

        summary.setMaxContentLength(200);

        return summary;
    }

    @Override
    protected void doReindex(Entry entry)
        throws Exception {

        Document document = getDocument(entry);
        indexWriterHelper.updateDocument(
            getSearchEngineId(), entry.getCompanyId(), document,
            isCommitImmediately());
    }

    @Override
    protected void doReindex(String className, long classPK)
        throws Exception {

        Entry entry = _entryLocalService.getEntry(classPK);
        doReindex(entry);
    }

    @Override
    protected void doReindex(String[] ids)
        throws Exception {

        long companyId = GetterUtil.getLong(ids[0]);
        reindexEntries(companyId);
    }

    protected void reindexEntries(long companyId)
        throws PortalException {

        final IndexableActionableDynamicQuery indexableActionableDynamicQuery =
                _entryLocalService.getIndexableActionableDynamicQuery();

            indexableActionableDynamicQuery.setCompanyId(companyId);

            indexableActionableDynamicQuery.setPerformActionMethod(
                new ActionableDynamicQuery.PerformActionMethod<Entry>() {

                    @Override
                    public void performAction(Entry entry) {

                        try {
                            Document document = getDocument(entry);
                            indexableActionableDynamicQuery.addDocuments(document);
                        }
                        catch (PortalException pe) {
                            if (_log.isWarnEnabled()) {
                                _log.warn(
                                    "Unable to index entry " + entry.getEntryId(),
                                    pe);
                            }
                        }
                    }
                });
            indexableActionableDynamicQuery.setSearchEngineId(getSearchEngineId());
            indexableActionableDynamicQuery.performActions();
        }

        private static final Log _log = LogFactoryUtil.getLog(EntryIndexer.class);

        @Reference
        protected IndexWriterHelper indexWriterHelper;

        @Reference
        private EntryLocalService _entryLocalService;

        @Reference
        private GuestbookLocalService _guestbookLocalService;

    }
```

As with the guestbook, you must update the entry's service layer to support indexing when its service methods are called. That's your next step.

28.2 Handling Indexing in the Entry Service Layer

<p>Enabling Search and Indexing for Guestbook Entries<br>Step 2 of 2</p>

Whenever a guestbook entry is added, updated, or deleted, the corresponding document should also be updated or deleted. A minor update to each of the `addEntry`, `updateEntry`, and `deleteEntry` service methods for guestbook entries is all it takes.

Follow these steps to update the methods:

1. Open `EntryLocalServiceImpl` in the `guestbook-service` module's `com.liferay.docs.guestbook.service.impl` package, and add the annotation `@Indexable(type = IndexableType.REINDEX)` above the signature for the `addEntry` and `updateEntry` methods:

   ```
   @Indexable(type = IndexableType.REINDEX)
   public Entry addEntry(...)

   @Indexable(type = IndexableType.REINDEX)
   public Entry updateEntry(...)
   ```

The @Indexable annotation indicates that an index update is required following method execution. The EntryIndexer controls exactly how the indexing happens. Setting the @Indexable annotation's type to IndexableType.REINDEX updates the document in the index that corresponds to the updated entry.

2. Add the @Indexable(type = IndexableType.DELETE) annotation above the signature for the deleteEntry method. The indexable type IndexableType.DELETE ensures that the entry is deleted from the index:

   ```
   @Indexable(type = IndexableType.DELETE)
   public Entry deleteEntry(...)
   ```

3. Add the required imports:

   ```
   import com.liferay.portal.kernel.search.Indexable;
   import com.liferay.portal.kernel.search.IndexableType;
   ```

   Save the file.

4. In the Gradle Tasks pane on the right-hand side of Liferay @ide@, double-click buildService in guestbook-service → build. This re-runs Service Builder to incorporate your changes to EntryLocalServiceImpl.

Awesome! Both guestbooks and their entries now have search and indexing support in the back-end. Next, you'll enable search in the Guestbook portlet's front-end.

Chapter 29

Updating Your User Interface For Search

Updating the Guestbook portlet's user interface for search takes two steps:

1. Update the Guestbook portlet's default view JSP to display a search bar for submitting queries.
2. Create a new JSP for the Guestbook portlet to display search results.

You'll start by updating the Guestbook portlet's view JSP.
Let's Go!

29.1 Adding a Search Bar to the Guestbook Portlet

<p>Updating Your UI for Search<br>Step 1 of 2</p>

Follow these steps to create the search bar UI for the Guestbook portlet:

1. In `guestbook-web`, open the file `src/main/resources/META-INF/resources/guestbookwebportlet/view.jsp`. Add a render URL near the top of the file, just after the scriptlet that gets the `guestbookId` from the request:

   ```
   <liferay-portlet:renderURL varImpl="searchURL">
       <portlet:param name="mvcPath"
       value="/guestbookwebportlet/view_search.jsp" />
   </liferay-portlet:renderURL>
   ```

   The render URL points to `/guestbookwebportlet/view_search.jsp` (created in the next step). You construct the URL first because you must specify what happens when the user submits a search query.

2. Right after the render URL, create an AUI form that directs the user to the `view_search.jsp` page for viewing search results:

   ```
   <aui:form action="<%= searchURL %>" method="get" name="fm">
       <liferay-portlet:renderURLParams varImpl="searchURL" />

       <div class="search-form">
           <span class="aui-search-bar">
               <aui:input inlineField="<%= true %>" label=""
   ```

```
            name="keywords" size="30" title="search-entries" type="text"
            />

            <aui:button type="submit" value="search" />
        </span>
    </div>
</aui:form>
```

The tag `<liferay-portlet:renderURLParams varImpl="searchURL" />` includes the URL parameters of the `searchURL` as hidden input fields in the AUI form. This is important since the parameters of the `searchURL` are overwritten when the search query is submitted as a URL parameter.

The body of the search form consists of a `<div>` containing a `<span>` that contains two elements: the search bar and the search button. The `<aui:input>` tag defines the search bar. Its `name="keywords"` attribute specifies the name of the URL parameter that contains the search query. The `<aui:button>` tag defines the search button. The `type="submit"` attribute specifies that when the button is clicked (or the *Enter* key is pressed), the AUI form is submitted. The `value="search"` attribute specifies the name that appears on the button.

That's all there is to the search form! When the form is submitted, the `mvcPath` parameter pointing to the `view_search.jsp` is included in the URL along with the `keywords` parameter containing the search query. Now it's time to create the `view_search.jsp` form to display the search results.

29.2 Creating a Search Results JSP for the Guestbook Portlet

```
<p>Updating Your UI for Search<br>Step 2 of 2</p>
```

There are several design goals to implement in the search results JSP:

- Use a search container to display guestbook entries matching a search query.
- Make the Actions button available for each guestbook entry in the results, like it is in the main view's search container.
- Include the search bar so that users can edit and resubmit their queries without having to click the back link to go to the portlet's default view.

Follow these steps to create the search results JSP:

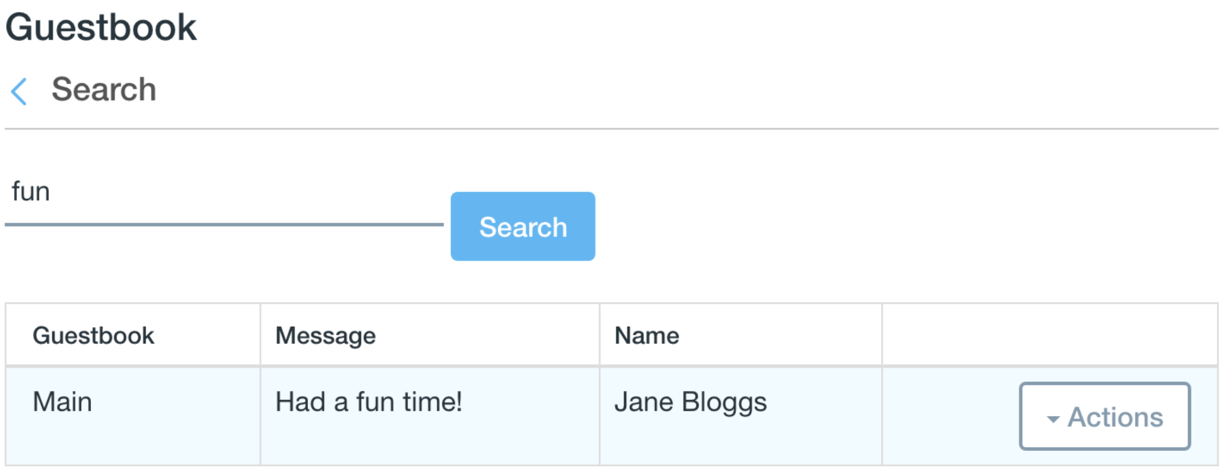
1. Create a new file called `view_search.jsp` in your `guestbook-web` module's `/guestbookwebportlet` folder. In this file, include the `init.jsp`:

   ```
   <%@include file="../init.jsp"%>
   ```

2. Extract the `keywords` and `guestbookId` parameters from the request. The `keywords` parameter contains the search query, and the `guestbookId` parameter contains the ID of the guestbook being searched:

   ```
   <%
     String keywords = ParamUtil.getString(request, "keywords");
     long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");
   %>
   ```

3. Define the `searchURL` and `viewURL` as `renderURL`s. Both use the `mvcPath` parameter that's available to Liferay MVC Portlets:



Guestbook	Message	Name	
Main	Had a fun time!	Jane Bloggs	Actions

Figure 29.1: The search results should appear in a search container, and the Actions button should appear for each entry. The search bar should also be displayed.

```
<liferay-portlet:renderURL varImpl="searchURL">
        <portlet:param name="mvcPath"
        value="/guestbookwebportlet/view_search.jsp" />
</liferay-portlet:renderURL>

<portlet:renderURL var="viewURL">
    <portlet:param
        name="mvcPath"
        value="/guestbookwebportlet/view.jsp"
    />
</portlet:renderURL>
```

The `searchURL` points to the current JSP: `view_search.jsp`. The `viewURL` points back to the Guestbook portlet's main view. These URLs are used in the AUI form that you'll create next.

4. Add this AUI form:

```
<aui:form action="<%= searchURL %>" method="get" name="fm">
    <liferay-portlet:renderURLParams varImpl="searchURL" />

<liferay-ui:header
    backURL="<%= viewURL.toString() %>"
    title="search"
/>

    <div class="search-form">
        <span class="aui-search-bar">
            <aui:input inlineField="<%= true %>" label="" name="keywords"
            size="30" title="search-entries" type="text" />

            <aui:button type="submit" value="search" />
        </span>
    </div>
</aui:form>
```

This form is identical to the one that you added to the Guestbook portlet's `view.jsp`, except that this one contains a `<liferay-ui:header>` tag that displays the Back icon next to the word *Search*. The `backURL` attribute in the header uses the viewURL defined above. Submitting the form invokes the searchURL with the user's search query added to the URL in the keywords parameter.

5. Start a scriptlet to get a search context and set some attributes in it:

```
<%
    SearchContext searchContext = SearchContextFactory
    .getInstance(request);

    searchContext.setKeywords(keywords);
    searchContext.setAttribute("paginationType", "more");
    searchContext.setStart(0);
    searchContext.setEnd(10);
```

   To execute a search, you need a SearchContext object. SearchContextFactory lets you create a SearchContext from the request object. Add the user's search query to the SearchContext by passing the keywords URL parameter to the setKeywords method. Then specify details about pagination and how the search results should be displayed.

6. Still in the scriptlet, obtain an Indexer to run a search. Retrieve the entry indexer from the map in Liferay DXP's indexer registry by passing in the indexer's class or class name:

```
Indexer indexer = IndexerRegistryUtil.getIndexer(Entry.class);
```

7. In the same scriptlet, use the indexer and the search context to run a search:

```
Hits hits = indexer.search(searchContext);

List<Entry> entries = new ArrayList<Entry>();

    for (int i = 0; i < hits.getDocs().length; i++) {
            Document doc = hits.doc(i);

            long entryId = GetterUtil
            .getLong(doc.get(Field.ENTRY_CLASS_PK));

            Entry entry = null;

            try {
                    entry = EntryLocalServiceUtil.getEntry(entryId);
            } catch (PortalException pe) {
                    _log.error(pe.getLocalizedMessage());
            } catch (SystemException se) {
                    _log.error(se.getLocalizedMessage());
            }

            entries.add(entry);
    }
```

   The search results return as Hits objects containing pointers to documents that correspond to guestbook entries. You then loop through the hit documents, retrieving the corresponding guestbook entries and adding them to a list.

8. Finish the scriptlet by retrieving a list of all the guestbooks that exist in the current site. Create a map between the guestbook IDs and the guestbook names.

```
        List<Guestbook> guestbooks = GuestbookLocalServiceUtil.getGuestbooks(scopeGroupId);

        Map<String, String> guestbookMap = new HashMap<String, String>();

        for (Guestbook guestbook : guestbooks) {
                guestbookMap.put(Long.toString(guestbook.getGuestbookId()), guestbook.getName());
        }
%>
```

Making this single service call and creating a map is more efficient than making separate service calls for each guestbook.

9. Display the search results in a search container:

```
<liferay-ui:search-container delta="10"
    emptyResultsMessage="no-entries-were-found"
    total="<%= entries.size() %>">
        <liferay-ui:search-container-results
                results="<%= entries %>"
/>
```

This specifies three attributes for the `<liferay-ui:search-container>` tag:

- `delta="10"`: specifies that at most, 10 entries can appear per page.
- `emptyResultsMessage`: specifies the message indicating there are no results.
- `total`: specifies the number of search results.

The `results` attribute of the tag `<liferay-ui:search-container-results>` specifies the search results. This is easy since you stored the entries resulting from the search in the `entries` list.

10. Use the `<liferay-ui:search-container-row>` tag to set the name of the class whose properties are displayed in each row:

```
<liferay-ui:search-container-row
        className="com.liferay.docs.guestbook.model.Entry"
        keyProperty="entryId" modelVar="entry" escapedModel="<%=true%>">
```

This uses the `className` attribute for the class name and specifies the entity's primary key attribute in the `keyProperty` attribute. The `modelVar` property specifies the name of the `Entry` variable that's available to each search container row. To ensure that each field of the `Entry` variable is escaped (sanitized), the `escapedModel` is `true`. This prevents potential hacks that could occur if users submitted malicious code into the Add Guestbook form, for example.

11. Inside the `<liferay-ui:search-container-row>` tag, specify the four columns to display: the guestbook entry's guestbook name, message, entry name, and the actions JSP. The guestbook name is retrieved from the map created in the scriptlet:

```
    <liferay-ui:search-container-column-text name="guestbook"
        value="<%=guestbookMap.get(Long.toString(entry.getGuestbookId()))%>" />

    <liferay-ui:search-container-column-text property="message" />

    <liferay-ui:search-container-column-text property="name" />

    <liferay-ui:search-container-column-jsp
        path="/guestbookwebportlet/entry_actions.jsp"
        align="right" />
</liferay-ui:search-container-row>
```

12. Use the `<liferay-ui:search-iterator>` tag to iterate through the search results and handle pagination. Close the search container tag:

```
        <liferay-ui:search-iterator />
</liferay-ui:search-container>
```

13. At the bottom of `view_search.jsp`, declare a `Log` object. You used this log in the `catch` clauses of the `try` clause that calls the `EntryLocalServiceUtil.getEntry` method to retrieve the guestbook entries. If this service call throws an exception, it's best to log the error so a server administrator can determine what went wrong. Liferay DXP's convention is to declare custom logs for individual classes or JSPs at the bottom of the file:

```
<%!
        private static Log _log = LogFactoryUtil.getLog("html.guestbookwebportlet.view_search_jsp");
%>
```

14. Finally, your `view_search.jsp` requires some extra imports. Add the following imports to `init.jsp`:

```
<%@ page import="com.liferay.portal.kernel.dao.search.SearchContainer" %>
<%@ page import="com.liferay.portal.kernel.exception.PortalException" %>
<%@ page import="com.liferay.portal.kernel.exception.SystemException" %>
<%@ page import="com.liferay.portal.kernel.language.LanguageUtil" %>
<%@ page import="com.liferay.portal.kernel.log.Log" %>
<%@ page import="com.liferay.portal.kernel.log.LogFactoryUtil" %>
<%@ page import="com.liferay.portal.kernel.search.Indexer" %>
<%@ page import="com.liferay.portal.kernel.search.IndexerRegistryUtil" %>
<%@ page import="com.liferay.portal.kernel.search.SearchContext" %>
<%@ page import="com.liferay.portal.kernel.search.SearchContextFactory" %>
<%@ page import="com.liferay.portal.kernel.search.Hits" %>
<%@ page import="com.liferay.portal.kernel.search.Document" %>
<%@ page import="com.liferay.portal.kernel.search.Field" %>
<%@ page import="com.liferay.portal.kernel.util.StringPool" %>
<%@ page import="com.liferay.portal.kernel.util.GetterUtil" %>
<%@ page import="com.liferay.portal.kernel.util.Validator" %>
<%@ page import="com.liferay.portal.kernel.util.PortalUtil" %>

<%@ page import="java.util.ArrayList" %>
<%@ page import="java.util.Map" %>
<%@ page import="java.util.HashMap" %>

<%@ page import="javax.portlet.PortletURL" %>
```

Good work! The Guestbook portlet now supports search! Now your users can find those Guestbook entries they were looking for.

The next section goes over Liferay DXP's asset framework, which provides shared functionality across different types of content like blog posts, message board posts, wiki articles, and more. This is the heart of integration with Liferay DXP's development platform.

Chapter 30

Assets: Integrating with Liferay's Framework

Liferay DXP's asset framework transforms entities into a common format that can be published anywhere in your site. Web content articles, blog posts, wiki articles, and documents are some asset-enabled entities that come out-of-the-box. By asset-enabling your own applications, you can take advantage of Liferay DXP's functionality for publishing your application's data across your site in the form of asset publisher entries, notifications, social activities, and more.

Liferay DXP's asset framework includes the following features:

- Tags and categories
- Comments and ratings
- Related assets (a.k.a. asset links)
- Faceted search
- Integration with Liferay DXP's Asset Publisher portlet
- Integration with Liferay DXP's Search portlet
- Integration with Liferay DXP's Tags Navigation, Tag Cloud, and Categories Navigation portlets

In this section, you'll asset-enable the guestbook and guestbook entry entities. You'll implement tags, categories, and related assets for guestbooks and guestbook entries. You'll implement comments and ratings in guestbook entries. You'll also learn how asset-enabled guestbooks and guestbook entries integrate with Liferay DXP core portlets like the Asset Publisher, Tags Navigation, Tag Cloud, and Categories Navigation portlets. Ready to start?

Let's Go!

Chapter 31

Enabling Assets at the Service Layer

<p>Enabling Assets at the Service Layer<br>Step 1 of 3</p>

Each row in the AssetEntry table represents an asset and has an entryId primary key, and classNameId and classPK foreign keys. The classNameId specifies the asset's type. For example, an asset with a classNameId of JournalArticle means that the asset represents a web content article (in Liferay DXP, JournalArticle is the back-end name for a web content article). An asset's classPK is the primary key of the entity represented by the asset.

Follow these steps to make Liferay DXP's asset services available to your entities' service layers:

1. In the guestbook-service module's service.xml file, add the following references directly above the closing </entity> tags for Guestbook and Entry:

   ```
   <reference package-path="com.liferay.portlet.asset" entity="AssetEntry" />
   <reference package-path="com.liferay.portlet.asset" entity="AssetLink" />
   ```

   As mentioned above, you must use Liferay DXP's AssetEntry service for your application to add asset entries that correspond to guestbooks and guestbook entries. You also use Liferay DXP's AssetLink service for your application to support related assets. *Asset links* are Liferay DXP's back-end term for related assets.

2. You must add finders–two for Guestbooks and two for Entitys–so your assets show in Asset Publisher. Add these below the existing finders for the Guestbook entity:

   ```
   <finder name="Status" return-type="Collection">
       <finder-column name="status" />
   </finder>

   <finder name="G_S" return-type="Collection">
       <finder-column name="groupId" />
       <finder-column name="status" />
   </finder>
   ```

   Add these below the existing finders for the Entry entity:

```
<finder name="Status" return-type="Collection">
    <finder-column name="status" />
</finder>
<finder name="G_S" return-type="Collection">
    <finder-column name="groupId" />
    <finder-column name="status" />
</finder>
```

3. Right-click `build.gradle` and select *Gradle → Refresh Gradle Project*.

4. Run the `buildService` Gradle task. This task causes the objects referenced above to be injected into your services for use.

Great! Next, you'll handle assets in your service layer.

31.1 Handling Assets at the Guestbook Service Layer

<p>Enabling Assets at the Service Layer<br>Step 2 of 3</p>

In this section, you'll update the guestbook service layer to use assets. You must update the add, update, and delete methods of your project's `GuestbookLocalServiceImpl`. Follow these steps to do so:

1. Open your project's `GuestbookLocalServiceImpl` class and find the `addGuestbook` method. Add the call to add the asset entries below the call that adds resources:

```
AssetEntry assetEntry = assetEntryLocalService.updateEntry(userId,
                groupId, guestbook.getCreateDate(),
                guestbook.getModifiedDate(), Guestbook.class.getName(),
                guestbookId, guestbook.getUuid(), 0,
                serviceContext.getAssetCategoryIds(),
                serviceContext.getAssetTagNames(), true, true, null, null, null, null,
                ContentTypes.TEXT_HTML, guestbook.getName(), null, null, null,
                null, 0, 0, null);

assetLinkLocalService.updateLinks(userId, assetEntry.getEntryId(),
                serviceContext.getAssetLinkEntryIds(),
                AssetLinkConstants.TYPE_RELATED);
```

   Calling `assetEntryLocalService.updateEntry` adds a new row (corresponding to the guestbook that's being added) to the `AssetEntry` table in Liferay DXP's database. `AssetEntryLocalServiceImpl`'s `updateEntry` method both adds and updates asset entries because it checks to see whether the asset entry already exists in the database and then takes the appropriate action. If you check the Javadoc for Liferay DXP's `AssetEntryLocalServiceUtil.updateEntry`, you'll see that this method is overloaded. Now, why did you use a version of this method with such a long method signature? Because there's only one version of `updateEntry` that takes a `title` parameter (to set the asset entry's title). Since you want to set the asset title to `guestbook.getName()`, that's the version you use.

   Later, you'll update the Guestbook Admin portlet's form for adding guestbooks to allow the selection of related assets, which are stored in the database's `AssetLink` table. The `assetLinkLocalService.updateLinks` call adds the appropriate entries to the table so related assets work for your guestbook entities. The `updateEntry` method adds and updates asset entries the same way `updateLink` adds and updates asset links.

2. Next, add the asset calls to `GuestbookLocalServiceImpl`'s `updateGuestbook` method, directly after the resource call:

```
AssetEntry assetEntry = assetEntryLocalService.updateEntry(guestbook.getUserId(),
                guestbook.getGroupId(), guestbook.getCreateDate(),
                guestbook.getModifiedDate(), Guestbook.class.getName(),
                guestbookId, guestbook.getUuid(), 0,
                serviceContext.getAssetCategoryIds(),
                serviceContext.getAssetTagNames(), true, true, guestbook.getCreateDate(),
                null, null, null, ContentTypes.TEXT_HTML, guestbook.getName(), null, null,
                null, null, 0, 0, serviceContext.getAssetPriority());

assetLinkLocalService.updateLinks(serviceContext.getUserId(),
                assetEntry.getEntryId(), serviceContext.getAssetLinkEntryIds(),
                AssetLinkConstants.TYPE_RELATED);
```

Here, `assetEntryLocalService.updateEntry` updates an existing asset entry and `assetLinkLocalService.updateLinks` adds or updates that entry's asset links (related assets).

3. Next, add the asset calls to the `deleteGuestbook` method, directly after the resource calls:

```
AssetEntry assetEntry = assetEntryLocalService.fetchEntry(
                Guestbook.class.getName(), guestbookId);

assetLinkLocalService.deleteLinks(assetEntry.getEntryId());

assetEntryLocalService.deleteEntry(assetEntry);
```

Here, you use the guestbook's class name and ID to retrieve the corresponding asset entry. Then you delete that asset entry's asset links and the asset entry itself.

4. Finally, organize your imports, save the file, and run Service Builder to apply the changes.

Next, you'll do the same thing for guestbook entries.

31.2 Handling Assets at the Entry Service Layer

<p>Enabling Assets at the Service Layer<br>Step 3 of 3</p>

Now you must update the guestbook entry entity's service methods. In these methods, the calls you'll make to `assetEntryLocalService` and `assetLinkLocalService` are identical to the ones you made in the guestbook entity's service methods. Follow these steps:

1. Open `EntryLocalServiceImpl` and add the asset calls to the `addEntry` method after the resource calls:

```
AssetEntry assetEntry = assetEntryLocalService.updateEntry(userId,
                groupId, entry.getCreateDate(), entry.getModifiedDate(),
                Entry.class.getName(), entryId, entry.getUuid(), 0,
                serviceContext.getAssetCategoryIds(),
                serviceContext.getAssetTagNames(), true, true, null, null, null, null,
                ContentTypes.TEXT_HTML, entry.getMessage(), null, null, null,
                null, 0, 0, null);

assetLinkLocalService.updateLinks(userId, assetEntry.getEntryId(),
                serviceContext.getAssetLinkEntryIds(),
                AssetLinkConstants.TYPE_RELATED);
```

2. Next, add the asset calls to the `updateEntry` method after the resource calls:

```
        AssetEntry assetEntry = assetEntryLocalService.updateEntry(userId,
                        serviceContext.getScopeGroupId(),
                        entry.getCreateDate(), entry.getModifiedDate(),
                        Entry.class.getName(), entryId, entry.getUuid(),
                        0, serviceContext.getAssetCategoryIds(),
                        serviceContext.getAssetTagNames(), true, true,
                        entry.getCreateDate(), null, null, null,
                        ContentTypes.TEXT_HTML, entry.getMessage(), null,
                        null, null, null, 0, 0,
                        serviceContext.getAssetPriority());

        assetLinkLocalService.updateLinks(userId, assetEntry.getEntryId(),
                        serviceContext.getAssetLinkEntryIds(),
                        AssetLinkConstants.TYPE_RELATED);
```

3. Add the asset calls to the `deleteEntry` method after the resource calls:

```
AssetEntry assetEntry = assetEntryLocalService.fetchEntry(
                Entry.class.getName(), entryId);

assetLinkLocalService.deleteLinks(assetEntry.getEntryId());

assetEntryLocalService.deleteEntry(assetEntry);
```

4. Organize your imports, save the file, and run Service Builder.

5. Finally, add these language keys to the `guestbook-web/src/main/resource/content/Language.properties` file:

```
model.resource.com.liferay.docs.guestbook.model.Guestbook=Guestbook
model.resource.com.liferay.docs.guestbook.model.Entry=Guestbook Entry
```

Excellent! You've asset-enabled your guestbook and guestbook entry entities at the service layer. Your next step is to implement asset renderers for these entities so they can be fully integrated into Liferay DXP's asset framework. Every asset needs an asset renderer class so the Asset Publisher portlet can display it.

Chapter 32

Implementing Asset Renderers

Assets are generic versions of entities, so they contain fields like `title`, `description`, and `summary`. Liferay DXP uses these fields to display assets. Asset Renderers translate an entity into an asset via these fields. For Liferay DXP to display your entities as assets, you must therefore create and register Asset Renderer classes for your guestbook and guestbook entry entities. Without these classes, Liferay DXP can't display your entities in Asset Publisher, Notifications, Activities, or anywhere else that displays assets.

Your next task is to create these Asset Renderers. Ready to begin?

Let's Go!

32.1 Implementing a Guestbook Asset Renderer

`<p>Implementing Asset Renderers<br>Step 1 of 2</p>`

Liferay DXP's asset renderers follow the factory pattern, so you must create a `GuestbookAssetRendererFactory` that instantiates the `GuestbookAssetRenderer`'s private guestbook object. Here, you'll create both classes.

Get started by creating the Asset Renderer class first.

Creating the AssetRenderer Class

Follow these steps to create the `GuestbookAssetRenderer` class:

1. Create a new package called `com.liferay.docs.guestbook.asset` in the `guestbook-service` module's `src/main/java` folder. In this package, create a `GuestbookAssetRenderer` class that extends Liferay DXP's `BaseJSPAssetRenderer` class. Extending this class gives you a head-start on implementing the `AssetRenderer` interface. Start with this code:

```
package com.liferay.docs.guestbook.asset;

import com.liferay.asset.kernel.model.BaseJSPAssetRenderer;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.exception.SystemException;
import com.liferay.portal.kernel.model.LayoutConstants;
import com.liferay.portal.kernel.portlet.LiferayPortletRequest;
import com.liferay.portal.kernel.portlet.LiferayPortletResponse;
import com.liferay.portal.kernel.portlet.PortletURLFactoryUtil;
import com.liferay.portal.kernel.security.permission.ActionKeys;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import com.liferay.portal.kernel.util.HtmlUtil;
import com.liferay.portal.kernel.util.PortalUtil;
import com.liferay.portal.kernel.util.StringUtil;
import com.liferay.docs.guestbook.portlet.constants.GuestbookPortletKeys;
import com.liferay.docs.guestbook.model.Guestbook;
import com.liferay.docs.guestbook.service.permission.GuestbookPermission;
import java.util.Locale;
import javax.portlet.PortletRequest;
import javax.portlet.PortletResponse;
import javax.portlet.PortletURL;
import javax.portlet.WindowState;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class GuestbookAssetRenderer extends BaseJSPAssetRenderer<Guestbook> {

}
```

2. Add the constructor and the guestbook class variable next. Most of the methods in this class are simply getters that return fields from this private guestbook object:

```
public GuestbookAssetRenderer(Guestbook guestbook) {

            _guestbook = guestbook;
}

private Guestbook _guestbook;
```

3. The `BaseJSPAssetRenderer` abstract class that you're extending contains dummy implementations of the `hasEditPermission` and `hasViewPermission` methods that you must override. Override these dummy implementations with actual permission checks using the `GuestbookPermission` class that you created earlier:

```
@Override
public boolean hasEditPermission(PermissionChecker permissionChecker)
throws PortalException {

  long guestbookId = _guestbook.getGuestbookId();
  return GuestbookPermission.contains(permissionChecker, guestbookId,
  ActionKeys.UPDATE);
}

@Override
public boolean hasViewPermission(PermissionChecker permissionChecker)
throws PortalException {

  long guestbookId = _guestbook.getGuestbookId();
  return GuestbookPermission.contains(permissionChecker, guestbookId,
  ActionKeys.VIEW);
}
```

4. Add the following getter methods to retrieve information about the guestbook asset:

```
@Override
public Guestbook getAssetObject() {
  return _guestbook;
}

@Override
public long getGroupId() {
  return _guestbook.getGroupId();
}

@Override
public long getUserId() {

  return _guestbook.getUserId();
}

@Override
public String getUserName() {
  return _guestbook.getUserName();
}

@Override
public String getUuid() {
  return _guestbook.getUuid();
}

@Override
public String getClassName() {
  return Guestbook.class.getName();
}

@Override
public long getClassPK() {
  return _guestbook.getGuestbookId();
}

@Override
public String getSummary(PortletRequest portletRequest, PortletResponse
  portletResponse) {
    return "Name: " + _guestbook.getName();
}

@Override
public String getTitle(Locale locale) {
  return _guestbook.getName();
}

@Override
public boolean include(HttpServletRequest request, HttpServletResponse
  response, String template) throws Exception {
    request.setAttribute("GUESTBOOK", _guestbook);
    request.setAttribute("HtmlUtil", HtmlUtil.getHtml());
    request.setAttribute("StringUtil", new StringUtil());
    return super.include(request, response, template);
}
```

The final method makes several utilities, as well as the `Guestbook` entity, available to Liferay DXP in the `HttpServletRequest` object.

5. Override the `getJspPath` method. This method returns a string that represents the path to the JSP that renders the guestbook asset. When the Asset Publisher displays an asset's full content, it invokes the asset renderer class's `getJspPath` method and passes a `template` string parameter that equals `"full_content"`. This returns `/asset/guestbook/full_content.jsp` when the `full_content` template string is passed as a parameter. You'll create this JSP later when updating your application's user interface:

```
  @Override
  public String getJspPath(HttpServletRequest request, String template) {

    if (template.equals(TEMPLATE_FULL_CONTENT)) {
      request.setAttribute("gb_guestbook", _guestbook);
      return "/asset/guestbook/" + template + ".jsp";
    } else {
      return null;
    }
  }
```

6. Override the getURLEdit method. This method returns a URL for editing the asset:

```
@Override
public PortletURL getURLEdit(LiferayPortletRequest liferayPortletRequest,
    LiferayPortletResponse liferayPortletResponse) throws Exception {
  PortletURL portletURL = liferayPortletResponse.createLiferayPortletURL(
      getControlPanelPlid(liferayPortletRequest), GuestbookPortletKeys.GUESTBOOK,
      PortletRequest.RENDER_PHASE);
  portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/edit_guestbook");
  portletURL.setParameter("guestbookId", String.valueOf(_guestbook.getGuestbookId()));
  portletURL.setParameter("showback", Boolean.FALSE.toString());

  return portletURL;
}
```

7. Override the getURLViewInContext method. This method returns a URL to view the asset in its native application:

```
@Override
public String getURLViewInContext(LiferayPortletRequest liferayPortletRequest,
    LiferayPortletResponse liferayPortletResponse, String noSuchEntryRedirect) throws Exception {
  try {
    long plid = PortalUtil.getPlidFromPortletId(_guestbook.getGroupId(),
        GuestbookPortletKeys.GUESTBOOK);

    PortletURL portletURL;
    if (plid == LayoutConstants.DEFAULT_PLID) {
      portletURL = liferayPortletResponse.createLiferayPortletURL(getControlPanelPlid(liferayPortletRequest),
          GuestbookPortletKeys.GUESTBOOK, PortletRequest.RENDER_PHASE);
    } else {
      portletURL = PortletURLFactoryUtil.create(liferayPortletRequest,
          GuestbookPortletKeys.GUESTBOOK, plid, PortletRequest.RENDER_PHASE);
    }

    portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/view");
    portletURL.setParameter("guestbookId", String.valueOf(_guestbook.getGuestbookId()));

    String currentUrl = PortalUtil.getCurrentURL(liferayPortletRequest);

    portletURL.setParameter("redirect", currentUrl);

    return portletURL.toString();

  } catch (PortalException e) {

  } catch (SystemException e) {
  }

  return noSuchEntryRedirect;
}
```

8. Override the getURLView method. This method returns a URL to view the asset from within the Asset Publisher:

```
@Override
public String getURLView(LiferayPortletResponse liferayPortletResponse,
WindowState windowState) throws Exception {

  return super.getURLView(liferayPortletResponse, windowState);
}
```

9. Save the class.

10. You have an error in your class, because the `guestbook-service` project doesn't have access to the `GuestbookPortletKeys` object that's in the `guestbook-web` project.

    It is logical to think this could be corrected by including the project as a dependency in `guestbook-service`'s `build.gradle` file, but that creates a circular dependency. `guestbook-web` already depends on `guestbook-service`, so you can't make `guestbook-service` depend circularly on `guestbook-web`.

    So now what do you do?

    Make sure you've opened both `guestbook-api` and `guestbook-web` projects. Drag the `com.liferay.docs.guestbook.portlet` package from the `guestbook-web` project and drop it on the `guestbook-api` project's `src/main/java` folder. Blamo! You fixed the problem. `guestbook-service` depends on `guestbook-api` and implements its interfaces. `guestbook-web` depends on both. Now you have only linear dependencies.

Next you can create the `AssetRendererFactory` class.

Creating the GuestbookAssetRendererFactory Class

Follow these steps to create the `GuestbookAssetRendererFactory`:

1. In the `com.liferay.docs.guestbook.asset` package, create a class called `GuestbookAssetRendererFactory` that extends Liferay DXP's `BaseAssetRendererFactory` class. Replace its code with this starter code:

```
package com.liferay.docs.guestbook.asset;

import com.liferay.asset.kernel.model.AssetRenderer;
import com.liferay.asset.kernel.model.AssetRendererFactory;
import com.liferay.asset.kernel.model.BaseAssetRendererFactory;
import com.liferay.docs.guestbook.model.Guestbook;
import com.liferay.docs.guestbook.service.EntryLocalService;
import com.liferay.docs.guestbook.service.GuestbookLocalService;
import com.liferay.docs.guestbook.service.permission.GuestbookPermission;
import com.liferay.docs.guestbook.constants.GuestbookPortletKeys;
import com.liferay.portal.kernel.util.WebKeys;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.portlet.LiferayPortletRequest;
import com.liferay.portal.kernel.portlet.LiferayPortletResponse;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import com.liferay.portal.kernel.theme.ThemeDisplay;

import javax.portlet.PortletRequest;
import javax.portlet.PortletURL;
import javax.servlet.ServletContext;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

@Component(immediate = true,
  property = {"javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK},
  service = AssetRendererFactory.class
  )
```

```
public class GuestbookAssetRendererFactory extends
  BaseAssetRendererFactory<Guestbook> {

  public GuestbookAssetRendererFactory() {
    setClassName(CLASS_NAME);
    setLinkable(_LINKABLE);
    setPortletId(GuestbookPortletKeys.GUESTBOOK);
    setSearchable(true);
    setSelectable(true);
  }
```

This code contains the class declaration and the constructor. It sets the class name it creates an `AssetRenderer` for, a portlet ID, and a boolean (`_LINKABLE`) set to `true`. The boolean denotes the methods that provide URLs in the generated `AssetRenderer` are implemented.

2. Implement the `getAssetRenderer` method, which constructs new `GuestbookAssetRenderer` instances for specific guestbooks. It uses the `classPK` (primary key) parameter to retrieve the guestbook from the database. It then calls the `GuestbookAssetRenderer`'s constructor, passing the retrieved guestbook as an argument:

```
@Override
public AssetRenderer<Guestbook> getAssetRenderer(long classPK, int type)
throws PortalException {

  Guestbook guestbook = _guestbookLocalService.getGuestbook(classPK);

  GuestbookAssetRenderer guestbookAssetRenderer =
  new GuestbookAssetRenderer(guestbook);

  guestbookAssetRenderer.setAssetRendererType(type);
  guestbookAssetRenderer.setServletContext(_servletContext);

  return guestbookAssetRenderer;
}
```

3. You're extending `BaseAssetRendererFactory`, an abstract class that implements the `AssetRendererFactory` interface. To ensure that your custom asset is associated with the correct entity, each asset renderer factory must implement the `getClassName` and `getType` methods (among others):

```
  @Override
  public String getClassName() {
    return CLASS_NAME;
  }

  @Override
  public String getType() {
    return TYPE;
  }
```

4. Implement the `hasPermission` method via the `GuestbookPermission` class:

```
@Override
public boolean hasPermission(PermissionChecker permissionChecker,
long classPK, String actionId) throws Exception {

  Guestbook guestbook = _guestbookLocalService.getGuestbook(classPK);
  return GuestbookPermission.contains(permissionChecker, guestbook,
  actionId);
}
```

5. Add the remaining code to create the portlet URL for the asset and specify whether it's linkable:

```
        @Override
        public PortletURL getURLAdd(LiferayPortletRequest liferayPortletRequest,
            LiferayPortletResponse liferayPortletResponse, long classTypeId) {
          PortletURL portletURL = null;

          try {
            ThemeDisplay themeDisplay = (ThemeDisplay)
            liferayPortletRequest.getAttribute(WebKeys.THEME_DISPLAY);

            portletURL = liferayPortletResponse.createLiferayPortletURL(getControlPanelPlid(themeDisplay),
                GuestbookPortletKeys.GUESTBOOK, PortletRequest.RENDER_PHASE);
            portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/edit_guestbook");
            portletURL.setParameter("showback", Boolean.FALSE.toString());
          } catch (PortalException e) {
          }

          return portletURL;
        }

        @Override
        public boolean isLinkable() {
          return _LINKABLE;
        }

        @Override
        public String getIconCssClass() {
            return "bookmarks";
        }

      @Reference(target = "(osgi.web.symbolicname=com.liferay.docs.guestbook.portlet)",
              unbind = "-")
      public void setServletContext(ServletContext servletContext) {
              _servletContext = servletContext;
          }
          private ServletContext _servletContext;

      @Reference(unbind = "-")
          protected void setGuestbookLocalService(GuestbookLocalService guestbookLocalService) {
              _guestbookLocalService = guestbookLocalService;
      }

      private GuestbookLocalService _guestbookLocalService;
      private static final boolean _LINKABLE = true;
      public static final String CLASS_NAME = Guestbook.class.getName();
      public static final String TYPE = "guestbook";
  }
```

6. Organize imports (Ctrl-Shift-O) and save the file.

Great! The guestbook asset renderer is complete. Next, you'll create the entry asset renderer.

32.2 Implementing an Entry Asset Renderer

<p>Implementing Asset Renderers<br>Step 2 of 2</p>

The classes you'll create here are nearly identical to the `GuestbookAssetRenderer` and `GuestbookAssetRendererFactory` classes you created for guestbooks in the previous step. This step provides the code needed for guestbook entries. Please review the previous sections for more information on this code.

Creating the EntryAssetRenderer Class

In the `com.liferay.docs.guestbook.asset` package, create an `EntryAssetRenderer` class that extends Liferay DXP's `BaseJSPAssetRenderer` class. Replace the contents of your `EntryAssetRenderer` class with the following code:

```
package com.liferay.docs.guestbook.asset;

import com.liferay.asset.kernel.model.BaseJSPAssetRenderer;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.exception.SystemException;
import com.liferay.portal.kernel.model.LayoutConstants;
import com.liferay.portal.kernel.portlet.LiferayPortletRequest;
import com.liferay.portal.kernel.portlet.LiferayPortletResponse;
import com.liferay.portal.kernel.portlet.PortletURLFactoryUtil;
import com.liferay.portal.kernel.security.permission.ActionKeys;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import com.liferay.portal.kernel.util.HtmlUtil;
import com.liferay.portal.kernel.util.PortalUtil;
import com.liferay.portal.kernel.util.StringUtil;
import com.liferay.docs.guestbook.portlet.constants.GuestbookPortletKeys;
import com.liferay.docs.guestbook.model.Entry;
import com.liferay.docs.guestbook.service.permission.EntryPermission;
import java.util.Locale;
import javax.portlet.PortletRequest;
import javax.portlet.PortletResponse;
import javax.portlet.PortletURL;
import javax.portlet.WindowState;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class EntryAssetRenderer extends BaseJSPAssetRenderer<Entry> {

  public EntryAssetRenderer(Entry entry) {

    _entry = entry;
  }

  @Override
  public boolean hasViewPermission(PermissionChecker permissionChecker)
  throws PortalException {

    long entryId = _entry.getEntryId();
    return EntryPermission.contains(permissionChecker, entryId,
    ActionKeys.VIEW);
  }

  @Override
  public Entry getAssetObject() {
    return _entry;
  }

  @Override
  public long getGroupId() {
    return _entry.getGroupId();
  }

  @Override
  public long getUserId() {

    return _entry.getUserId();
  }

  @Override
  public String getUserName() {
    return _entry.getUserName();
  }
```

```
@Override
public String getUuid() {
  return _entry.getUuid();
}

@Override
public String getClassName() {
  return Entry.class.getName();
}

@Override
public long getClassPK() {
  return _entry.getEntryId();
}

@Override
public String getSummary(PortletRequest portletRequest,
PortletResponse portletResponse) {
  return "Name: " + _entry.getName() + ". Message: " + _entry.getMessage();
}

@Override
public String getTitle(Locale locale) {
  return _entry.getMessage();
}

@Override
public boolean include(HttpServletRequest request,
HttpServletResponse response, String template) throws Exception {
  request.setAttribute("ENTRY", _entry);
  request.setAttribute("HtmlUtil", HtmlUtil.getHtml());
  request.setAttribute("StringUtil", new StringUtil());
  return super.include(request, response, template);
}

@Override
public String getJspPath(HttpServletRequest request, String template) {

  if (template.equals(TEMPLATE_FULL_CONTENT)) {
    request.setAttribute("gb_entry", _entry);

    return "/asset/entry/" + template + ".jsp";
  } else {
    return null;
  }
}

@Override
public PortletURL getURLEdit(LiferayPortletRequest liferayPortletRequest,
    LiferayPortletResponse liferayPortletResponse) throws Exception {
  PortletURL portletURL = liferayPortletResponse.createLiferayPortletURL(
      getControlPanelPlid(liferayPortletRequest), GuestbookPortletKeys.GUESTBOOK,
      PortletRequest.RENDER_PHASE);
  portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/edit_entry");
  portletURL.setParameter("entryId", String.valueOf(_entry.getEntryId()));
  portletURL.setParameter("showback", Boolean.FALSE.toString());

  return portletURL;
}

@Override
public String getURLViewInContext(LiferayPortletRequest liferayPortletRequest,
    LiferayPortletResponse liferayPortletResponse, String noSuchEntryRedirect)
    throws Exception {
  try {
    long plid = PortalUtil.getPlidFromPortletId(_entry.getGroupId(),
        GuestbookPortletKeys.GUESTBOOK);
      PortletURL portletURL;
      if (plid == LayoutConstants.DEFAULT_PLID) {
        portletURL = liferayPortletResponse.createLiferayPortletURL(getControlPanelPlid(liferayPortletRequest),
            GuestbookPortletKeys.GUESTBOOK, PortletRequest.RENDER_PHASE);
      } else {
        portletURL = PortletURLFactoryUtil.create(liferayPortletRequest,
            GuestbookPortletKeys.GUESTBOOK, plid, PortletRequest.RENDER_PHASE);
      }

      portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/view");
      portletURL.setParameter("entryId", String.valueOf(_entry.getEntryId()));

      String currentUrl = PortalUtil.getCurrentURL(liferayPortletRequest);

      portletURL.setParameter("redirect", currentUrl);

      return portletURL.toString();

    } catch (PortalException e) {

    } catch (SystemException e) {
    }

    return noSuchEntryRedirect;
  }

  @Override
  public String getURLView(LiferayPortletResponse liferayPortletResponse,
  WindowState windowState) throws Exception {

    return super.getURLView(liferayPortletResponse, windowState);
  }

  @Override
  public boolean isPrintable() {
        return true;
  }

  private Entry _entry;
}
```

This class is similar to the `GuestbookAssetRenderer` class. For the `EntryAssetRenderer.getSummary` method, you return a summary that displays the entry name (the name of the user who created the entry) and the entry message.

`GuestbookAssetRenderer.getSummary` returns a summary that displays the guestbook name. `EntryAssetRenderer.getTitle` returns the entry message. `GuestbookAssetRenderer.getTitle` returns the guestbook name. The rest of the methods of `EntryAssetRenderer` are nearly identical to those of `GuestbookAssetRenderer`.

Creating the EntryAssetRendererFactory Class

Next, you must create the guestbook entry asset renderer's factory class. In the `com.liferay.docs.guestbook.asset` package, create a class called `EntryAssetRendererFactory` that extends Liferay DXP's `BaseAssetRendererFactory` class. Replace its contents with the following code:

```
package com.liferay.docs.guestbook.asset;

import com.liferay.asset.kernel.model.AssetRenderer;
import com.liferay.asset.kernel.model.AssetRendererFactory;
import com.liferay.asset.kernel.model.BaseAssetRendererFactory;
import com.liferay.docs.guestbook.model.Entry;
import com.liferay.docs.guestbook.service.EntryLocalService;
import com.liferay.docs.guestbook.service.permission.EntryPermission;
import com.liferay.docs.guestbook.portlet.constants.GuestbookPortletKeys;
import com.liferay.portal.kernel.util.WebKeys;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.portlet.LiferayPortletRequest;
import com.liferay.portal.kernel.portlet.LiferayPortletResponse;
import com.liferay.portal.kernel.portlet.LiferayPortletURL;
import com.liferay.portal.kernel.security.permission.PermissionChecker;
import com.liferay.portal.kernel.theme.ThemeDisplay;

import javax.portlet.PortletRequest;
import javax.portlet.PortletURL;
import javax.portlet.WindowState;
import javax.portlet.WindowStateException;
import javax.servlet.ServletContext;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

@Component(
    immediate = true,
    property = {"javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK},
    service = AssetRendererFactory.class
)
public class EntryAssetRendererFactory extends BaseAssetRendererFactory<Entry> {

    public EntryAssetRendererFactory() {
        setClassName(CLASS_NAME);
        setLinkable(_LINKABLE);
        setPortletId(GuestbookPortletKeys.GUESTBOOK);
        setSearchable(true);
        setSelectable(true);
    }

    @Override
    public AssetRenderer<Entry> getAssetRenderer(long classPK, int type)
        throws PortalException {

        Entry entry = _entryLocalService.getEntry(classPK);

        EntryAssetRenderer entryAssetRenderer = new EntryAssetRenderer(entry);

        entryAssetRenderer.setAssetRendererType(type);
        entryAssetRenderer.setServletContext(_servletContext);

        return entryAssetRenderer;
    }

    @Override
    public String getClassName() {
        return CLASS_NAME;
    }

    @Override
    public String getType() {
        return TYPE;
    }

    @Override
    public boolean hasPermission(PermissionChecker permissionChecker,
        long classPK, String actionId) throws Exception {

        Entry entry = _entryLocalService.getEntry(classPK);
        return EntryPermission.contains(permissionChecker, entry, actionId);
    }

    @Override
    public PortletURL getURLAdd(LiferayPortletRequest liferayPortletRequest,
        LiferayPortletResponse liferayPortletResponse, long classTypeId) {

        PortletURL portletURL = null;

        try {
            ThemeDisplay themeDisplay = (ThemeDisplay) liferayPortletRequest.getAttribute(WebKeys.THEME_DISPLAY);

            portletURL = liferayPortletResponse.createLiferayPortletURL(getControlPanelPlid(themeDisplay),
                GuestbookPortletKeys.GUESTBOOK, PortletRequest.RENDER_PHASE);
            portletURL.setParameter("mvcRenderCommandName", "/guestbookwebportlet/edit_entry");
            portletURL.setParameter("showback", Boolean.FALSE.toString());
        } catch (PortalException e) {
        }

        return portletURL;
    }

    @Override
    public PortletURL getURLView(LiferayPortletResponse liferayPortletResponse, WindowState windowState) {

        LiferayPortletURL liferayPortletURL
            = liferayPortletResponse.createLiferayPortletURL(
                GuestbookPortletKeys.GUESTBOOK, PortletRequest.RENDER_PHASE);

        try {
            liferayPortletURL.setWindowState(windowState);
        } catch (WindowStateException wse) {

        }
        return liferayPortletURL;
    }

    @Override
    public boolean isLinkable() {
        return _LINKABLE;
    }

    @Override
    public String getIconCssClass() {
        return "pencil";
    }

    @Reference(target = "(osgi.web.symbolicname=com.liferay.docs.guestbook.portlet)",
        unbind = "-")
    public void setServletContext (ServletContext servletContext) {
        _servletContext = servletContext;
    }

    @Reference(unbind = "-")
    protected void setEntryLocalService(EntryLocalService entryLocalService) {
        _entryLocalService = entryLocalService;
    }

    private EntryLocalService _entryLocalService;
    private ServletContext _servletContext;
    private static final boolean _LINKABLE = true;
    public static final String CLASS_NAME = Entry.class.getName();
    public static final String TYPE = "entry";

}
```

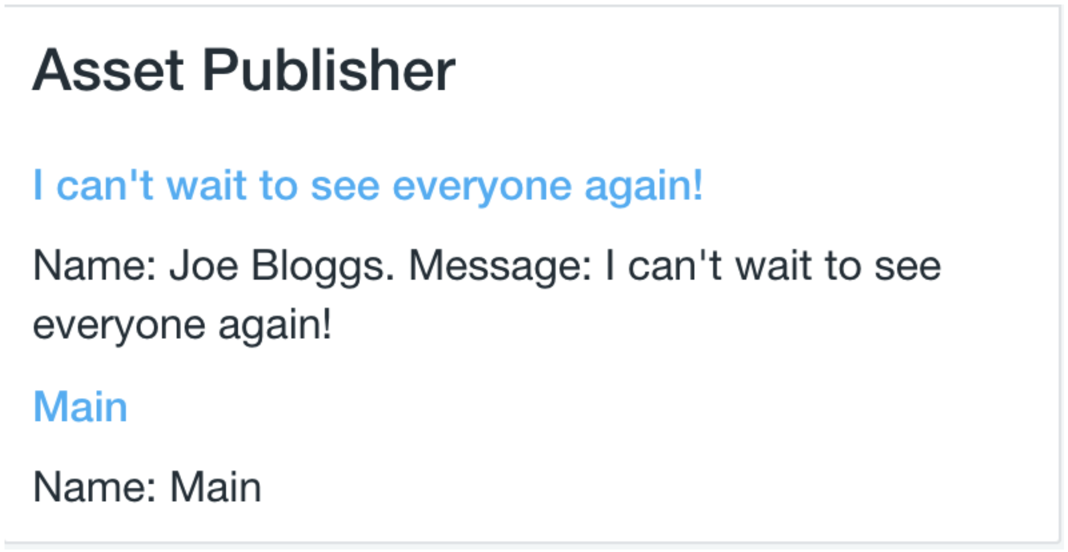
Exporting the Asset Package

The container needs to make the asset renderers and their factories available to Liferay DXP when it needs them. To do this, you must export the package.

Open the `guestbook-service` module's `bnd.bnd` file and add the asset package to the `Export-Package` declaration. When you're finished, it should look like this:

```
Export-Package: com.liferay.docs.guestbook.asset,\
                com.liferay.docs.guestbook.service.permission,\
                com.liferay.docs.guestbook.search
```

Now your guestbook project's entities are fully asset-enabled. To test the functionality, add the Asset Publisher portlet to a page and add a few guestbooks and guestbook entries. Edit a few of them, too. Then, check the Asset Publisher portlet. The Asset Publisher, by default, dynamically displays assets of any kind from the current site.



Asset Publisher

I can't wait to see everyone again!

Name: Joe Bloggs. Message: I can't wait to see everyone again!

Main

Name: Main

Figure 32.1: After you've implemented and registered your asset renderers for your custom entities, the Asset Publisher can display your entities.

Confirm that the Asset Publisher displays the guestbooks and guestbook entries that you added.

Great! In the next section, you'll update your portlets' user interfaces to use several features of Liferay DXP's asset framework: comments, ratings, tags, categories, and related assets.

Chapter 33

Adding Asset Features to Your User Interface

```
<p>Adding Asset Features to Your UI<br>Step 1 of 5</p>
```

Now that your guestbook and guestbook entry entities are asset-enabled, you're ready to use Liferay DXP's asset functionality in your application. You'll start by implementing comments, ratings, tags, categories, and related assets for guestbooks. Then you'll do the same for guestbook entries. All the back-end support for these features is provided by Liferay DXP. Your only task is to update your applications' user interfaces to use these features.

In this section, you'll create several new JSPs that need new imports. Add the following imports to the `guestbook-web` module project's `init.jsp` file:

```
<%@ page import="java.util.Map" %>
<%@ page import="java.util.HashMap" %>

<%@ page import="com.liferay.asset.kernel.service.AssetEntryLocalServiceUtil" %>
<%@ page import="com.liferay.asset.kernel.service.AssetTagLocalServiceUtil" %>

<%@ page import="com.liferay.asset.kernel.model.AssetEntry" %>
<%@ page import="com.liferay.asset.kernel.model.AssetTag" %>

<%@ page import="com.liferay.portal.kernel.util.ListUtil" %>
```

It's simpler to add these imports now so you don't run into errors as you're working through this section.

33.1 Creating JSPs for Displaying Custom Assets in the Asset Publisher

```
<p>Adding Asset Features to Your UI<br>Step 2 of 5</p>
```

Before proceeding, you must tie up a loose end from the previous step. Remember that you implemented `getJspPath` methods in your `GuestbookAssetRenderer` and `EntryAssetRenderer` classes. These methods return paths to the JSPs the Asset Publisher uses to display the assets' full content. The `getJspPath` method of `GuestbookAssetRenderer` returns `"/asset/guestbook/full_content.jsp"`, and the `getJspPath` method of `EntryAssetRenderer` returns `"/asset/entry/full_content.jsp"`. It's time to create these JSPs.

Follow these steps:

1. In the `guestbook-web` module project, create a new folder called `asset` under the `resources/META-INF/resources` folder. Add two folders to this new folder: `entry` and `guestbook`.

2. Create a new file called `full_content.jsp` in the `/asset/guestbook` folder. This JSP displays a guestbook asset's full content. Add the following code to this file:

   ```
   <%@include file="../../init.jsp"%>

   <%
   Guestbook guestbook = (Guestbook)request.getAttribute("gb_guestbook");

   guestbook = guestbook.toEscapedModel();
   %>

   <dl>
           <dt>Name</dt>
           <dd><%= guestbook.getName() %></dd>
   </dl>
   ```

   This JSP grabs the guestbook object from the request and displays the guestbook's name. In `GuestbookAssetRenderer`, the `getJspPath` method used the following to add the `gb_guestbook` request attribute:

   ```
   request.setAttribute("gb_guestbook", _guestbook);
   ```

   The guestbook's `toEscapedModel` method belongs to the `GuestbookModelImpl` class, which was generated by Service Builder. This method returns a *safe* guestbook object (a guestbook in which each field is HTML-escaped). Calling `guestbook = guestbook.toEscapedModel()` before displaying the guestbook name ensures that your JSP won't display malicious code that's masquerading as a guestbook name.

3. Next, in the `/asset/entry` folder, create a `full_content.jsp` for displaying a guestbook entry asset's full content. Add the following code to this file:

   ```
   <%@include file="../../init.jsp"%>

   <%
   Entry entry = (Entry)request.getAttribute("gb_entry");

   entry = entry.toEscapedModel();
   %>

   <dl>
           <dt>Guestbook</dt>
           <dd><%= GuestbookLocalServiceUtil.getGuestbook(entry.getGuestbookId()).getName() %></dd>
           <dt>Name</dt>
           <dd><%= entry.getName() %></dd>
           <dt>Message</dt>
           <dd><%= entry.getMessage() %></dd>
   </dl>
   ```

This JSP is almost as simple as the one for guestbooks. The only difference is that you're displaying three fields of the guestbook entry entity as opposed to one field of the guestbook entity.

Test your new JSPs by clicking a guestbook's or guestbook entry's title in the Asset Publisher. The Asset Publisher renders `full_content.jsp`:

By default, when displaying an asset's full view, the Asset Publisher displays additional links for Twitter, Facebook, and Google Plus. These links publicize your asset on social media. The *Back* icon and the *View in Context* link return you to the Asset Publisher's default view.

I can't wait to see everyone again!

Figure 33.1: When you click the title for a guestbook or guestbook entry in the Asset Publisher, your `full_content.jsp` should be displayed.

33.2 Enabling Tags, Categories, and Related Assets for Guestbooks

`<p>Adding Asset Features to Your UI<br>Step 3 of 5</p>`

Since you already asset-enabled guestbooks at the service layer, guestbook entities can now use Liferay DXP's back-end support for tags and categories. All that's left is to enable tags and categories in the UI. In this step, you'll update the Guestbook Admin portlet's `edit_guestbook.jsp` so admins can add, edit, or remove tags and categories when adding or updating a guestbook.

Enabling Asset Features

Follow these steps:

1. In the `guestbook-web` module's `/guestbookadminportlet/edit_guestbook.jsp`, add the tags `<liferay-ui:asset-categories-error />` and `<liferay-ui:asset-tags-error/>` to the `aui:form` below the closing `</aui:fieldset>` tag:

   ```
   <liferay-ui:asset-categories-error />
   <liferay-ui:asset-tags-error />
   ```

   These tags display error messages if an error occurs with the tags or categories submitted in the form.

2. Below the error tags, add a `<liferay-ui:panel>` tag with the following attributes:

```
<liferay-ui:panel defaultState="closed" extended="<%= false %>"
  id="guestbookCategorizationPanel" persistState="<%= true %>"
  title="categorization">

</liferay-ui:panel>
```

The `<liferay-ui:panel>` tag generates a collapsible section.

3. Add input fields for tags and categories inside the panel section you just created. Specify the `assetCategories` and `assetTags` types for the `<aui:input />` tags to tell Liferay DXP that these input tags represent asset categories and asset tags. You can group related input fields together with an `<aui:fieldset>` tag. Liferay DXP shows the appropriate selectors for tags and categories and displays the tags and categories that have already been added to the guestbook:

```
<aui:fieldset>
  <aui:input name="categories" type="assetCategories" />

  <aui:input name="tags" type="assetTags" />
</aui:fieldset>
```

4. Add a second `<liferay-ui:panel>` tag under the existing one. In this new tag, add an `<aui:fieldset>` tag containing a `<liferay-ui:asset-links>` tag. To display the correct asset links (the selected guestbook's related assets), set the `className` and `classPK` attributes:

```
<liferay-ui:panel defaultState="closed" extended="<%= false %>"
  id="guestbookAssetLinksPanel" persistState="<%= true %>"
  title="related-assets">
  <aui:fieldset>
    <liferay-ui:input-asset-links
      className="<%= Guestbook.class.getName() %>"
      classPK="<%= guestbookId %>" />
  </aui:fieldset>
</liferay-ui:panel>
```

Test the updated `edit_guestbook.jsp` page by navigating to the Guestbook Admin portlet in the Control Panel and clicking *Add Guestbook*. You'll see a field for adding tags and a selector for selecting related assets.

Don't do anything with these fields yet, because you're not done implementing assets. Next, you'll enable tags and categories for guestbook entries.

33.3 Enabling Tags, Categories, and Related Assets for Guestbook Entries

<p>Adding Asset Features to Your UI<br>Step 4 of 5</p>

Enabling tags, categories, and related assets for guestbook entries is similar to enabling them for guestbooks. It's so similar, you can refer back to the previous step for a detailed explanation.

Open your `guestbook-web` module's `guestbookwebportlet/edit_entry.jsp` file. Replace its content with the following code:

```
<%@ include file="../init.jsp" %>

<%
long entryId = ParamUtil.getLong(renderRequest, "entryId");
```

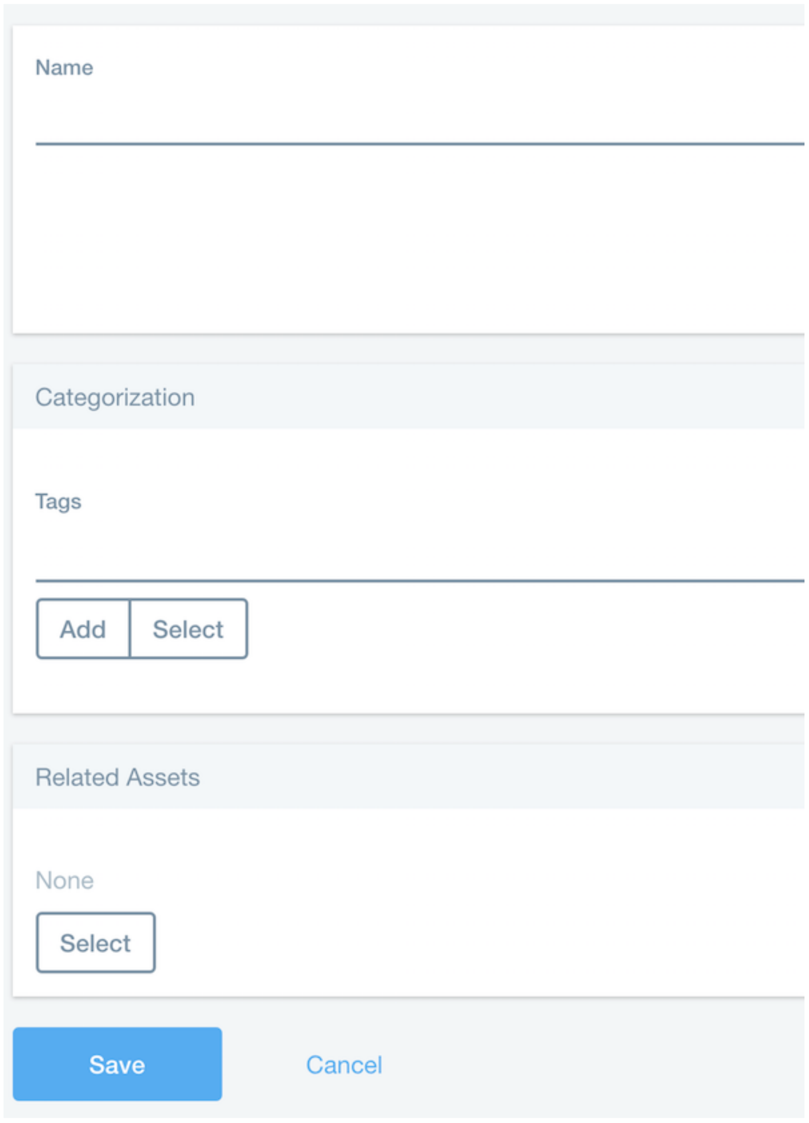

Figure 33.2: Once you've updated your Guestbook Admin portlet's `edit_guestbook.jsp` page, you'll see forms for adding tags and selecting related assets.

```
Entry entry = null;

if (entryId > 0) {
    entry = EntryLocalServiceUtil.getEntry(entryId);
}

long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");
%>

<portlet:renderURL var="viewURL">
    <portlet:param
        name="mvcPath"
        value="/guestbookwebportlet/view.jsp"
    />
</portlet:renderURL>

<liferay-ui:header
    backURL="<%= viewURL.toString() %>"
    title="<%= entry == null ? "Add Entry" : entry.getName() %>"
```

```
/>

<portlet:actionURL name="addEntry" var="addEntryURL" />

<aui:form action="<%= addEntryURL %>" name="fm">
    <aui:model-context bean="<%= entry %>" model="<%= Entry.class %>" />

        <aui:fieldset>
            <aui:input name="name" />

            <aui:input name="email" />

            <aui:input name="message" />

            <aui:input name="entryId" type="hidden" />

            <aui:input name="guestbookId" type="hidden"
            value=
            "<%= entry == null ? guestbookId : entry.getGuestbookId() %>" />
        </aui:fieldset>

<liferay-ui:asset-categories-error />
                    <liferay-ui:asset-tags-error />
                    <liferay-ui:panel defaultState="closed"
                    extended="<%= false %>" id="entryCategorizationPanel"
                    persistState="<%= true %>" title="categorization">
                            <aui:fieldset>
                                    <aui:input name="categories"
                                    type="assetCategories" />

                                    <aui:input name="tags" type="assetTags" />
                            </aui:fieldset>
                    </liferay-ui:panel>

                    <liferay-ui:panel defaultState="closed"
                    extended="<%= false %>" id="entryAssetLinksPanel"
                    persistState="<%= true %>" title="related-assets">
                            <aui:fieldset>
                                    <liferay-ui:input-asset-links
                                            className=
                                            "<%= Entry.class.getName() %>"
                                            classPK="<%= entryId %>"
                                    />
                            </aui:fieldset>
                    </liferay-ui:panel>

    <aui:button-row>
        <aui:button type="submit" />

        <aui:button onClick="<%= viewURL.toString() %>" type="cancel" />
    </aui:button-row>
</aui:form>
```

Test your JSP by using the Guestbook portlet to add and update Guestbook entries. Try adding and removing tags, categories, and related assets. All these operations should work.

Well done! Next, you'll enable comments and ratings for guestbook entries.

33.4 Enabling Comments and Ratings for Guestbook Entries

```
<p>Adding Asset Features to Your UI<br>Step 5 of 5</p>
```

Liferay DXP's asset framework lets users comment on and rate assets. As with tags, categories, and related assets, you must update the user interface to expose these features. It's best to separate the page where users comment on and rate assets from the page where users edit assets. You shouldn't have to edit an entry to comment on it; that not only makes no sense, it's a security problem. Comments and ratings should be added in a view mode only.

Follow these steps to enable comments and ratings on guestbook entries:

1. Create a new file called `view_entry.jsp` in your `guestbook-web` module project's `/guestbookwebportlet` folder.

2. Add a Java scriptlet to the file you just created. In this scriptlet, use an `entryId` request attribute to get an entry object. For security reasons, convert this object to an escaped model as discussed in the earlier step Creating JSPs for Displaying Customs Assets in the Asset Publisher:

```
<%@ include file="../init.jsp"%>

<%
  long entryId = ParamUtil.getLong(renderRequest, "entryId");

  long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");

  Entry entry = null;

  if (entryId > 0) {
    entry = EntryLocalServiceUtil.getEntry(entryId);

    entryId = entry.getEntryId();
  }

  entry = EntryLocalServiceUtil.getEntry(entryId);
  entry = entry.toEscapedModel();

  AssetEntry assetEntry =
  AssetEntryLocalServiceUtil.getEntry(Entry.class.getName(),
  entry.getEntryId());
```

3. Next, update the breadcrumb entry with the the current entry's name:

```
String currentURL = PortalUtil.getCurrentURL(request);
PortalUtil.addPortletBreadcrumbEntry(request, entry.getMessage(),
currentURL);
```

4. At the end of the scriptlet, add the names of the current entry's existing asset tags as keywords to the portal page. These tag names appear in a `<meta content="[tag names here]" lang="en-US" name="keywords" />` element in your portal page's `<head>` section. These keywords can help search engines find and index your page:

```
  PortalUtil.setPageSubtitle(entry.getMessage(), request);
  PortalUtil.setPageDescription(entry.getMessage(), request);

  List<AssetTag> assetTags =
  AssetTagLocalServiceUtil.getTags(Entry.class.getName(),
  entry.getEntryId());
  PortalUtil.setPageKeywords(ListUtil.toString(assetTags, "name"),
  request);
%>
```

5. After the scriptlet, specify the URLs for the page and back link:

```
<liferay-portlet:renderURL varImpl="viewEntryURL">
  <portlet:param name="mvcPath"
    value="/guestbookwebportlet/view_entry.jsp" />
  <portlet:param name="entryId" value="<%=String.valueOf(entryId)%>" />
</liferay-portlet:renderURL>

<liferay-portlet:renderURL varImpl="viewURL">
  <portlet:param name="mvcPath"
    value="/guestbookwebportlet/view.jsp" />
</liferay-portlet:renderURL>

<liferay-ui:header backURL="<%=viewURL.toString()%>"
  title="<%=entry.getName()%>"
/>
```

6. Next, define the page's main content. Display the guestbook's name, and the entry's name and message with the `<dl>`, `<dt>`, and `<dd>` tags:

```
<dl>
  <dt>Guestbook</dt>
  <dd><%=GuestbookLocalServiceUtil.getGuestbook(entry.getGuestbookId()).getName()%></dd>
  <dt>Name</dt>
  <dd><%=entry.getName()%></dd>
  <dt>Message</dt>
  <dd><%=entry.getMessage()%></dd>
</dl>
```

   This is the same way you defined the page's main content in `/guestbookwebportlet/full_content.jsp`.

7. Next, use a `<liferay-ui:panel-container>` tag to create a panel container. Inside this tag, use a `<liferay-ui:panel>` tag to create a panel to display the comments and ratings components:

```
<liferay-ui:panel-container extended="<%=false%>"
  id="guestbookCollaborationPanelContainer" persistState="<%=true%>">
  <liferay-ui:panel collapsible="<%=true%>" extended="<%=true%>"
    id="guestbookCollaborationPanel" persistState="<%=true%>"
    title="Collaboration">
```

8. Add the ratings and comments components via the `<liferay-ui:ratings>` and `<liferay-ui:discussion>` tags, respectively. The latter tag needs an action URL (in this case, `invokeTaglibDiscussion`) for its `formAction` attribute. The action URL adds the comment after the user enters a comment and clicks *Reply*:

```
    <liferay-ui:ratings className="<%=Entry.class.getName()%>"
      classPK="<%=entry.getEntryId()%>" type="stars" />

    <br />

    <portlet:actionURL name="invokeTaglibDiscussion"
    var="discussionURL" />

    <liferay-ui:discussion className="<%=Entry.class.getName()%>"
      classPK="<%=entry.getEntryId()%>"
      formAction="<%=discussionURL%>" formName="fm2"
      ratingsEnabled="<%=true%>" redirect="<%=currentURL%>"
      userId="<%=entry.getUserId()%>" />

  </liferay-ui:panel>
</liferay-ui:panel-container>
```

9. To restrict comments and ratings access to logged-in users, wrap the whole panel container in a `<c:if>` tag that tests the expression `themeDisplay.isSignedIn()`:

   ```
   <c:if test="<%= themeDisplay.isSignedIn() %>">
       ... your panel container ...
   </c:if>
   ```

   Make sure you add the closing `</c:if>` tag after the closing `</liferay-ui:panel-container>` tag.

```
**Note:** Discussions (comments) are implemented as message board messages
in Liferay DXP. In the `MBMessage` table, there's a `classPK` column. This
`classPK` represents the `entryId` of the guestbook entry the comment
belongs to. Ratings are stored in the `RatingsEntry` table. Similarly, the
`RatingsEntry` table contains a `classPK` column. This `classPK` represents
the `entryId` of the guestbook entry the rating belongs to. Using a
`classPK` foreign key in one table to represent the primary key of another
table is a common pattern that's used throughout Liferay DXP.
```

Next, you'll update the guestbook actions to use the new view.

Updating the Entry Actions JSP

Nothing links to your `view_entry.jsp` page—it's currently orphaned. Fix this by adding the *View* option to the Actions Menu. Open the `/guestbookwebportlet/entry_actions.jsp` and find the following line:

```
<liferay-ui:icon-menu>
```

Add the following lines below it:

```
<portlet:renderURL var="viewEntryURL">
  <portlet:param name="entryId"
    value="<%= String.valueOf(entry.getEntryId()) %>" />
  <portlet:param name="mvcPath"
    value="/guestbookwebportlet/view_entry.jsp" />
</portlet:renderURL>

<liferay-ui:icon message="View" url="<%= viewEntryURL.toString() %>" />
```

Here, you create a URL that points to `view_entry.jsp`. Test this link by selecting the *View* option in a guestbook entry's Actions Menu. Then test that comments and ratings work as expected.

Excellent! You've asset-enabled the guestbook and guestbook entry entities, and enabled tags, categories, and related assets for both entities. You've also enabled comments and ratings for guestbook entry entities! Great job!

Your next task is to generate web services. This makes it possible to write other clients (such as mobile applications) for the Guestbook application.

Chapter 34

Generating Web Services

Assets opened the door to support many features of Liferay DXP's development framework. There's more to cover, but the Guestbook app's back-end is now mature enough to widen its appeal.

Right now, the Guestbook app's back-end services can only be accessed by modules in the same OSGi container. If you want to read or post Guestbook entries, you have to write and deploy native code on the server. This is fine for some, but others want more: web clients on a different platform; standalone applications using Electron or some other framework; or mobile apps for Android or iOS. Web services power all of these.

You now have an application with back-end services and a front-end web client running in the same container. Web services make it possible to have multiple front-end clients on multiple platforms that access the same back-end. This makes it possible to build *headless* applications on Liferay DXP, with multiple front-ends elsewhere.

Next, you'll use Service Builder to create the Guestbook app's web services. When you finish, authorized clients can then consume these web services.

Ready to start?

Let's Go!

34.1 Creating Remote Services with Service Builder

`<p>Creating Remote Services<br>Step 1 of 1</p>`

Earlier, you used Service Builder to generate the Guestbook's model, persistence, and service layers. Services generated by Service Builder can come in two flavors: local and remote. The local services you already used can only be invoked locally from the same OSGi container. Remote services can be invoked by any application with permission to access your server via the web. Remote services are published as JSON or SOAP.

For more information, click here to see the Service Builder Web Services section of tutorials.

Creating web services for the Guestbook application takes two steps:

1. Generate the web services with Service Builder.

2. Expose the services you want and wrap them in permission checks.

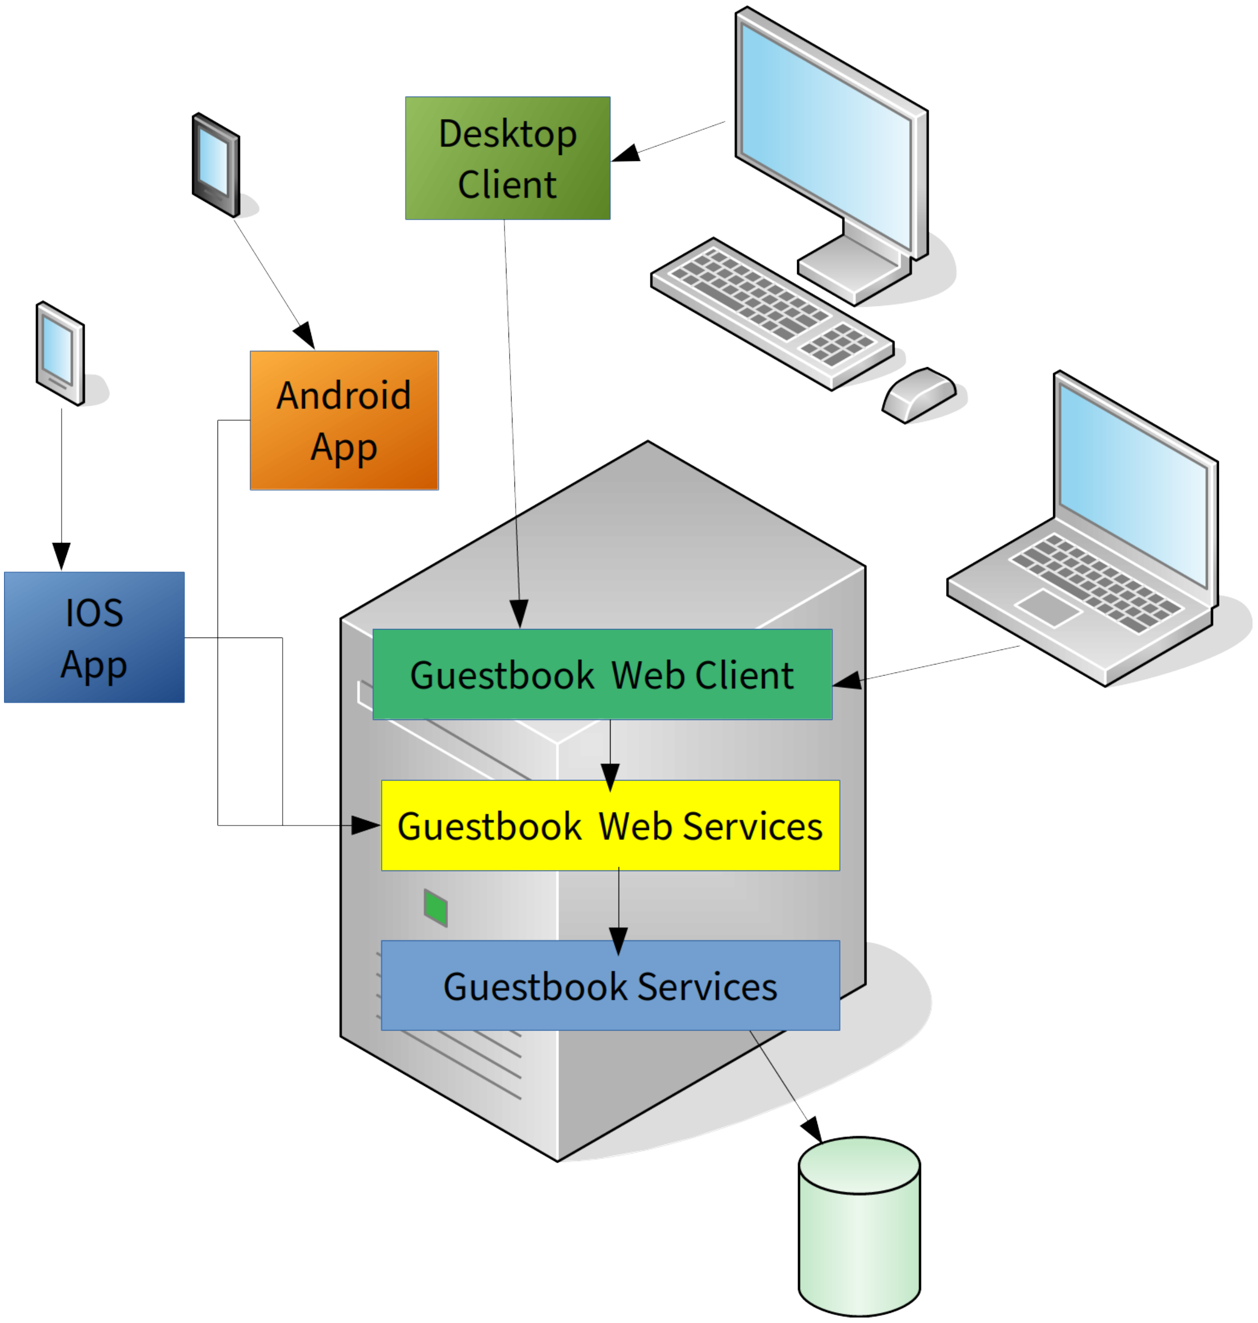

Figure 34.1: Liferay DXP makes it easy to write multi-client applications.

There's a level of security in the assumption that local services can only be called by other services in the container. For example, the web app does permission and validation checks before calling services. To access these services, developers must be able to deploy their modules on the server. You don't have these assurances when you expose services to the web, so you must check for permission before calling a service.

But first you must tell Service Builder to generate web services. Follow these steps:

1. Open `service.xml` from the `guestbook-service` module. Find the tags for the `Guestbook` and `Entry` entities:

   ```
   <entity name="Guestbook" local-service="true" uuid="true">

   <entity name="Entry" local-service="true" uuid="true">
   ```

2. As described in the `service.xml` DTD, `local-service` defaults to `false` and `remote-service` defaults to `true`. It helps other developers who read your code to specify what services are generated. Therefore, add `remote-service="true"` to the entity tags of the `Guestbook` and `Entry` entities:

   ```
   <entity name="Guestbook" local-service="true" remote-service="true" uuid="true">

   <entity name="Entry" local-service="true" remote-service="true" uuid="true">
   ```

3. In the *Gradle Tasks* window on the right-hand side of Liferay @ide@, expand the service module's build folder. Run Service Builder by double-clicking *buildService*. When Service Builder finishes, refresh the `guestbook-api` and `guestbook-service` modules in the Project Explorer.

You may be interested to know that Service Builder did absolutely nothing. Since remote services are generated by default, you've always had their stubs in your project. All you did was make it explicit in the code.

By implementing local services, you separated concerns. Local services can assume things like permission checks have already been done before they're called. This separates the business logic from the permissions logic. If instead you implemented everything in the remote services, this separation wouldn't exist.

You may see code from other developers, however, who didn't implement the local service, and instead elected to place all their business and permission logic in the remote service. This works, but makes the code less readable. With the concerns separated, a business logic bug is contained in the local service, and a permissions bug is contained in the remote service.

To expose remote services, you'll implement methods in the `-ServiceImpl` classes instead of the `-LocalServiceImpl` classes. Since the primary concern is permissions, however, first create a helper class to hold the permissions:

1. In the `src/main/java` folder, create the new package `com.liferay.docs.guestbook.util`. In this new package, create this `ActionKeys` class:

   ```
   package com.liferay.docs.guestbook.util;

   public class ActionKeys extends
                   com.liferay.portal.kernel.security.permission.ActionKeys {

           public static final String ADD_ENTRY = "ADD_ENTRY";
           public static final String ADD_GUESTBOOK = "ADD_GUESTBOOK";
   }
   ```

The ADD_ENTRY and ADD_GUESTBOOK strings reference the permissions defined in the guestbook-service module's docroot/WEB-INF/src/resource-actions/default.xml file earlier in this Learning Path. It's a best practice to create strings to refer to permissions in a class called ActionKeys that extends com.liferay.portal.kernel.security.permission.ActionKeys. The parent ActionKeys contains strings that are used to refer to portal permissions. These include strings for common permissions such as VIEW, UPDATE, DELETE, and so on.

2. Add the following methods to the GuestbookServiceImpl class; then organize the imports by selecting *Source → Organize Imports*:

```
public Guestbook addGuestbook(long userId, String name,
    ServiceContext serviceContext) throws SystemException,
    PortalException {

    return guestbookLocalService.addGuestbook(userId, name, serviceContext);
}

public Guestbook deleteGuestbook(long guestbookId,
    ServiceContext serviceContext) throws PortalException,
    SystemException {

    return guestbookLocalService.deleteGuestbook(guestbookId, serviceContext);
}

public List<Guestbook> getGuestbooks(long groupId) throws SystemException {
        return guestbookLocalService.getGuestbooks(groupId);
}

public List<Guestbook> getGuestbooks(long groupId, int start, int end)
                throws SystemException {
        return guestbookLocalService.getGuestbooks(groupId, start, end);
}

public int getGuestbooksCount(long groupId) throws SystemException {
        return guestbookLocalService.getGuestbooksCount();
}

public Guestbook updateGuestbook(long userId, long guestbookId,
    String name, ServiceContext serviceContext) throws PortalException,
    SystemException {

    return guestbookLocalService.updateGuestbook(userId, guestbookId,
        name, serviceContext);
}
```

These are stub remote service methods that expose each guestbook local service method. For now, the remote service method implementations call the local service implementations. Later, you'll add permission checks to these methods, to wrap them in the same permissions you created in the UI. Service calls have no UI, so you must check for permission to access them. For now, you're exposing the services to confirm they work and are accessible.

3. Add the following methods to the EntryServiceImpl class, then organize the imports as you did in step 2:

```
public Entry addEntry(long userId, long guestbookId, String name,
        String email, String message, ServiceContext serviceContext)
        throws PortalException, SystemException {

    return entryLocalService.addEntry(userId, guestbookId, name, email,
             message, serviceContext);
}

public Entry deleteEntry(long entryId, ServiceContext serviceContext)
                throws PortalException, SystemException {

    return entryLocalService.deleteEntry(entryId, serviceContext);
}

public List<Entry> getEntries(long groupId, long guestbookId)
                throws SystemException {

    return entryLocalService.getEntries(groupId, guestbookId);
}

public List<Entry> getEntries(long groupId, long guestbookId, int start,
                int end) throws SystemException {

    return entryLocalService.getEntries(groupId, guestbookId, start, end);
}

public int getEntriesCount(long groupId, long guestbookId)
                throws SystemException {

    return entryLocalService.getEntriesCount(groupId, guestbookId);
}

public Entry updateEntry(long userId, long guestbookId, long entryId,
                String name, String email, String message,
                ServiceContext serviceContext) throws PortalException,
                SystemException {

    return entryLocalService.updateEntry(userId, guestbookId, entryId,
                        name, email, message, serviceContext);
}
```

Like you did for guestbooks, you've now created method stubs for guestbook entries. Each method implemented here exposes a service to the web. You'll add permission checks in the next section.

4. Run Service Builder and refresh the API and service modules. Then redeploy the `guestbook-*` modules.

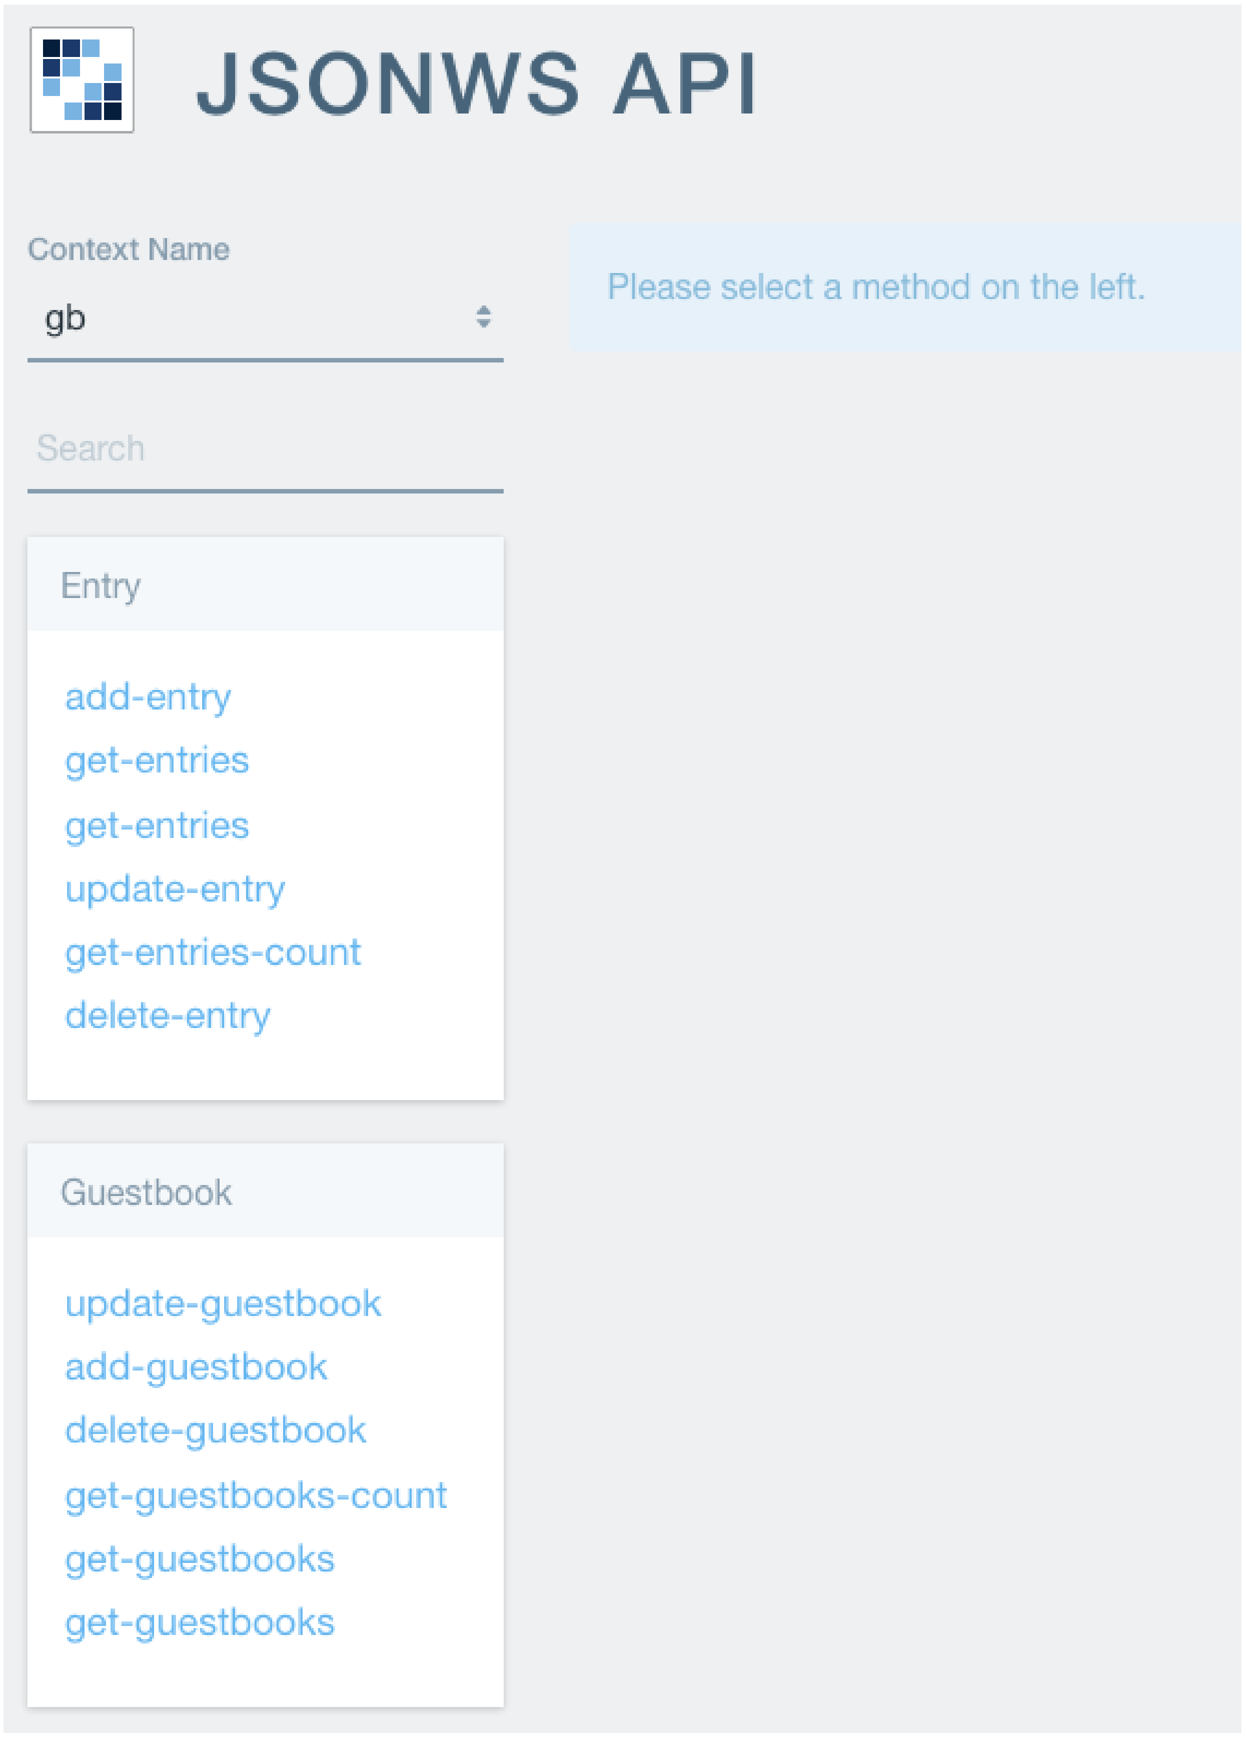
First, make sure you're logged in as a user that can read guestbooks. Navigate to Liferay DXP's JSONWS page (`http://[host name]:[port number]/api/jsonws`) and click the *Context Name* selector. The Guestbook app's context, `gb`, appears as an option. Select it and confirm that your remote service methods appear in the list.

To test that your remote services work, choose a method to invoke. Pick a simple method that doesn't require a Service Context parameter, like `getGuestbooksCount(long groupId)`. To find the appropriate `groupId` (the ID of the site containing the Guestbook app), navigate to that site in your browser and select *Configuration → Site Settings* from the Site Menu on the left. The site ID is listed at the top of the Site Settings page. Now return to the JSONWS page and enter the site ID into the group ID field and click *Invoke*. Confirm that the correct number of guestbooks is returned. Great! Your remote services work.

Next, you'll build a WSDD (Web Service Deployment Descriptor) document for your remote services to make them available via SOAP (Simple Object Access Protocol).

Follow these steps to do so:

1. In your Liferay workspace's `settings.gradle` file, add imports for `ServiceBuilderPlugin` and `WSDDBuilderPlugin` before the buildscript block. Then add the `gradle.beforeProject` closure at the bottom of the file:



JSONWS API

Context Name

gb

Search

Please select a method on the left.

Entry

add-entry
get-entries
get-entries
update-entry
get-entries-count
delete-entry

Guestbook

update-guestbook
add-guestbook
delete-guestbook
get-guestbooks-count
get-guestbooks
get-guestbooks

Figure 34.2: After you've added remote service methods to your project's *`ServiceImpl` classes, run Service Builder and redeploy your modules. Then check that your remote services are accessible.

```
import com.liferay.gradle.plugins.service.builder.ServiceBuilderPlugin
import com.liferay.gradle.plugins.wsdd.builder.WSDDBuilderPlugin

...

gradle.beforeProject {
    project ->

    project.plugins.withType(ServiceBuilderPlugin) {
        project.apply plugin: WSDDBuilderPlugin
    }
}
```

   Refresh your workspace's Gradle files: right click `settings.gradle` in the Project Explorer and select *Gradle → Refresh Gradle Project*.

2. In the *Gradle Tasks* window on the right-hand side of Liferay @ide@, expand the service module's *build* folder. Build the WSDD by double-clicking *buildWSDD*. If `buildWSDD` is missing, shut down your server and then restart Liferay @ide@. The `buildWSDD` command appears as described.

   The WSDD builder generates a WSDD JAR file in the `guestbook-service` module's `build/libs` folder. Because this folder isn't visible in @ide@, you must access it from the file system. The project's modules are in the Eclipse workspace on the file system. Here's the full file path to the WSDD JAR in your Eclipse workspace:

```
com-liferay-docs-guestbook/modules/guestbook/guestbook-service/build/libs/com.liferay.docs.guestbook.service-wsdd-1.0.0.jar
```

   If this file is missing, run `buildWSDD` again to generate it.

3. Deploy the WSDD JAR file to Liferay DXP, which is in the Liferay Workspace's `bundles` folder. To do this, copy and paste the WSDD JAR file into this folder in your Eclipse workspace on your file system:

```
com-liferay-docs-guestbook/bundles/deploy
```

   Return to Liferay @ide@ and check the console to make sure deployment completes successfully.

4. Go to `http://[host name]:[port number]/o/com.liferay.docs.guestbook.service/api/axis` in your browser to view the Guestbook app's SOAP web services. If you're running Liferay DXP locally on port 8080, this is http://localhost:8080/o/com.liferay.docs.guestbook.service/api/axis.

   This page contains links to the WSDL (Web Services Description Language) documents for the Guestbook and Entry remote service methods. WSDL files describe details about the remote service methods, including the type of data these methods require.

If you want to make your app's services available for remote invocation via SOAP, generating WSDD and WSDL files is required. For example, the Liferay Mobile SDK relies on the WSDD and WSDL to discover your Liferay DXP app's remote services. For the Liferay Mobile SDK to create a mobile client that can access your Liferay DXP app's web services, you must therefore generate a WSDD and WSDL for your app.

Next, you'll learn how to secure your web services. Unless you secure your web services by implementing permission checks, any user can add, update, or delete guestbooks or guestbook entries, and you certainly don't want that.

Chapter 35

Implementing Permission Checks

Now that your guestbook and guestbook entry web services exist, you must implement permission checks for them. Implementing permission checks for a web service ensures that only users with the correct permissions can invoke the web service. To implement permission checks in your remote services, you'll use the `GuestbookModelPermission`, `GuestbookPermission`, and `EntryPermission` helper classes that you created earlier. These classes provide helper methods for checking permissions. The helper methods in `GuestbookModelPermission` check top-level model permissions. For example, you can use `GuestbookModelPermission`'s helper methods to check if a user can add a new guestbook or guestbook entry. If, on the other hand, you must check if a user can update or delete an existing guestbook or guestbook entry, you'll use `GuestbookPermission` or `EntryPermission`.

Once you've secured your remote services with permission checks, you'll update your portlet classes to call remote services instead of local services. This prevents attackers from trying to bypass your app's UI by playing with URL parameters to access sensitive portions of your app.

Let's Go!

35.1 Implementing Permission Checks at the Service Layer

```
<p>Implementing Permission Checks<br>Step 1 of 2</p>
```

First, you'll add permission checks to `GuestbookServiceImpl`:

1. In `GuestbookServiceImpl`, replace the `addGuestbook`, `deleteGuestbook`, and `updateGuestbook` methods with these versions that contain the permission checks:

```
public Guestbook addGuestbook(long userId, String name,
            ServiceContext serviceContext) throws SystemException,
            PortalException {

        GuestbookModelPermission.check(getPermissionChecker(),
                    serviceContext.getScopeGroupId(), ActionKeys.ADD_GUESTBOOK);

        return guestbookLocalService.addGuestbook(userId, name, serviceContext);
}

public Guestbook deleteGuestbook(long guestbookId,
            ServiceContext serviceContext) throws PortalException,
            SystemException {
```

```
        GuestbookPermission.check(getPermissionChecker(), guestbookId,
                        ActionKeys.DELETE);

        return guestbookLocalService.deleteGuestbook(guestbookId, serviceContext);
}

public Guestbook updateGuestbook(long userId, long guestbookId,
                String name, ServiceContext serviceContext) throws PortalException,
                SystemException {

        GuestbookPermission.check(getPermissionChecker(), guestbookId,
                        ActionKeys.UPDATE);

        return guestbookLocalService.updateGuestbook(userId, guestbookId, name,
                        serviceContext);
}
```

Organize imports to add the imports for the *Permissions and ActionKeys classes.

These methods add permission checks to the remote service methods by calling the check helper methods in GuestbookModelPermission and GuestbookPermission. Remember that these methods throw exceptions, so if the user doesn't have permission, processing stops at the permission check. The GuestbookModelPermission.check method takes three parameters:

- a PermissionChecker object
- a groupId
- an actionId string

The GuestbookModelPermission.check and EntryModelPermission.check methods take three parameters:

- a PermissionChecker object
- an entity ID (either guestbookId or entryId)
- an actionId string

BaseServiceImpl contains a getPermissionChecker method that returns a PermissionChecker object. This is accessible since GuestbookServiceImpl extends GuestbookServiceBaseImpl, which extends BaseServiceImpl. The serviceContext method getScopeGroupId returns a groupId. The actionId string comes from your ActionKeys class. Using an ActionKeys field is less error prone than than manually typing the string's name every time you want to check a permission. Using an ActionKeys string also avoids creating a duplicate string.

2. Open EntryServiceImpl and replace the addEntry, deleteEntry, and updateEntry methods with ones that contain permission checks:

```
public Entry addEntry(long userId, long guestbookId, String name,
                String email, String message, ServiceContext serviceContext)
                throws PortalException, SystemException {

        GuestbookModelPermission.check(getPermissionChecker(),
                        serviceContext.getScopeGroupId(), ActionKeys.ADD_ENTRY);

        return entryLocalService.addEntry(userId, guestbookId, name, email,
                        message, serviceContext);
}
```

```
public Entry deleteEntry(long entryId, ServiceContext serviceContext)
                throws PortalException, SystemException {

        EntryPermission.check(getPermissionChecker(), entryId, ActionKeys.DELETE);

        return entryLocalService.deleteEntry(entryId, serviceContext);
}

public Entry updateEntry(long userId, long guestbookId, long entryId,
                String name, String email, String message,
                ServiceContext serviceContext) throws PortalException,
                SystemException {

        EntryPermission.check(getPermissionChecker(), entryId, ActionKeys.UPDATE);

        return entryLocalService.updateEntry(userId, guestbookId, entryId,
                        name, email, message, serviceContext);
}
```

As in step 1, organize imports to add the imports for the *Permissions and ActionKeys classes.

The permission checks in these methods work the same as those in GuestbookServiceImpl. For addEntry, you use GuestbookModelPermission.check for the permission check, since adding a guestbook entry is a top level model action. For deleteEntry and updateEntry, you use EntryPermission.check since these operations each require a specific permission on a specific entity.

3. Open GuestbookServiceImpl and replace both getGuestbooks methods (this method is overloaded) and the getGuestbookCount method with these:

```
public List<Guestbook> getGuestbooks(long groupId) throws SystemException {
        return guestbookPersistence.filterFindByGroupId(groupId);
}

public List<Guestbook> getGuestbooks(long groupId, int start, int end)
                throws SystemException {

        return guestbookPersistence.filterFindByGroupId(groupId, start, end);
}

public int getGuestbooksCount(long groupId) throws SystemException {
        return guestbookPersistence.filterCountByGroupId(groupId);
}
```

4. Open EntryServiceImpl and replace the getEntries methods (this method is overloaded) and the getGuestbookCount method with these:

```
public List<Entry> getEntries(long groupId, long guestbookId)
                throws SystemException {

        return entryPersistence.filterFindByG_G(groupId, guestbookId);
}

public List<Entry> getEntries(long groupId, long guestbookId, int start,
                int end) throws SystemException {

        return entryPersistence.filterFindByG_G(groupId, guestbookId, start,
                        end);
}

public int getEntriesCount(long groupId, long guestbookId)
                throws SystemException {

        return entryPersistence.filterCountByG_G(groupId, guestbookId);
}
```

5. Run Service Builder and refresh the API and service modules.

All remote service methods should include permission checks. In steps 1 and 2, you directly invoked permission checks for the remote service methods addGuestbook, deleteGuestbook, updateGuestbook, addEntry, deleteEntry, and updateEntry by using the check methods of the permissions utility classes: GuestbookModelPermission, GuestbookPermission, and EntryPermission. In steps 3 and 4, you indirectly invoked permission checks for the remote service methods getGuestbooks, getGuestbooksCount, getEntries, and getEntriesCount by calling the filterFindBy* and *filterCountBy* methods of GuestbookPersistenceImpl and EntryPersistenceImpl. The filterFindBy* and *filterCountBy* methods are generated by Service Builder if the following conditions are met:

- The entity has a simple primitive primary key
- The entity has permission checks registered in an XML file in your project's docroot/WEB-INF/src/resource-actions directory
- The entity has userId and groupId fields
- The finder method has a groupId argument in its method signature

Since it would be a very expensive operation to retrieve a large list of guestbook or guestbook entry entities and run permission checks on each one, Service Builder generates the filterFindBy* and filterCountBy* helper methods in the persistence layer to handle permission checks. The permission checking of these helper methods is done in the database, resulting in a less expensive operation. The filterFindBy* and filterCountBy* methods work just like the ordinary findBy* and countBy* methods in the *PersistenceImpl classes, except that the filterFindBy* and filterCountBy* methods include permission checks. Instances of the *PersistenceImpl classes are made available as Spring beans in the *ServiceImpl classes. These beans are named guestbookPersistence and entryPersistence in GuestbookServiceImpl and EntryServiceImpl, respectively.

Awesome! You're almost done. The only thing left is to secure the service calls you make in the web client.

35.2 Securing Service Calls at the Portlet Layer

<p>Implementing Permission Checks<br>Step 2 of 2</p>

Your remote services are now secure for direct use. Your web application, however, is another story–it's still calling local services. In a perfect world, that would be fine, but this isn't a perfect world.

Previously, you implemented portlet action methods such as addGuestbook, addEntry, deleteEntry, and so on in GuestbookPortlet and GuestbookAdminPortlet classes. These methods call local services. For example, in the addEntry method of GuestbookPortlet, you used the following call to add a new guestbook entry:

```
_entryLocalService.addEntry(serviceContext.getUserId(), guestbookId, userName,
    email, message, serviceContext);
```

Calling local services from an app's portlet layer isn't recommended because they don't contain permission checks. Nefarious individuals messing with URL parameters might be able to access protected areas of your app. To secure your app, only call *remote* services from the portlet layer, because that's the layer that has permission checking. Thus, to secure service calls at the portlet layer, all you have to do is replace the local service calls with remote service calls.

Note: An alternative approach to securing service calls at the portlet layer is to check permissions at the portlet layer manually. To do this, get a ThemeDisplay from the ActionRequest (ThemeDisplay themeDisplay

= (ThemeDisplay) request.getAttribute(WebKeys.THEME_DISPLAY);) and get a PermissionChecker from the ThemeDisplay (PermissionChecker permissionChecker = themeDisplay.getPermissionChecker();). If the user passes the permission check, then call the local service method. However, it's best to avoid rewriting permission checks whenever possible. For this reason, if you must wrap a service call in a permission check, implement that service method as a remote service and add the permission check to the remote service. This is the pattern Liferay DXP uses and that you have followed in this Learning Path.

Use the following steps to secure the service calls in the GuestbookPortlet class:

1. Replace the _guestbookLocalService and _entryLocalService variable declarations with these:

   ```
   private GuestbookService _guestbookService;
   private EntryService _entryService;
   ```

2. Replace the GuestbookLocalService and EntryLocalService imports with the these:

   ```
   import com.liferay.docs.guestbook.service.GuestbookService;
   import com.liferay.docs.guestbook.service.EntryService;
   ```

3. Replace all instances of _guestbookLocalService and _entryLocalService with _guestbookService and _entryService, respectively. Also make sure to replace any GuestbookLocalService and EntryLocalService method arguments with GuestbookService and EntryService, respectively.

Now follow the same steps to change guestbook services in GuestbookAdminPortlet. Note that service calls and variables for guestbook entries aren't necessary in GuestbookAdminPortlet.

To check that you haven't made a mistake in your GuestbookPortlet class, refer to the following complete class:

```
package com.liferay.docs.guestbook.portlet;

import java.io.IOException;
import java.util.List;
import java.util.logging.Level;
import java.util.logging.Logger;

import javax.portlet.ActionRequest;
import javax.portlet.ActionResponse;
import javax.portlet.Portlet;
import javax.portlet.PortletException;
import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

import com.liferay.docs.guestbook.model.Entry;
import com.liferay.docs.guestbook.model.Guestbook;
import com.liferay.docs.guestbook.portlet.constants.GuestbookPortletKeys;
import com.liferay.docs.guestbook.service.GuestbookService;
import com.liferay.docs.guestbook.service.EntryService;

import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet;
import com.liferay.portal.kernel.service.ServiceContext;
import com.liferay.portal.kernel.service.ServiceContextFactory;
import com.liferay.portal.kernel.servlet.SessionErrors;
import com.liferay.portal.kernel.servlet.SessionMessages;
import com.liferay.portal.kernel.util.ParamUtil;
```

```
import com.liferay.portal.kernel.util.PortalUtil;

/**
 * @author sezovr
 */
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.social",
        "com.liferay.portlet.instanceable=false",
        "com.liferay.portlet.scopeable=true",
        "javax.portlet.display-name=Guestbook",
        "javax.portlet.expiration-cache=0",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/guestbookwebportlet/view.jsp",
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=power-user,user",
        "javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK,
        "javax.portlet.supports.mime-type=text/html"
    },
    service = Portlet.class
)
public class GuestbookPortlet extends MVCPortlet {

    public void addEntry(ActionRequest request, ActionResponse response)
                    throws PortalException {

                ServiceContext serviceContext = ServiceContextFactory.getInstance(
                    Entry.class.getName(), request);

                String userName = ParamUtil.getString(request, "name");
                String email = ParamUtil.getString(request, "email");
                String message = ParamUtil.getString(request, "message");
                long guestbookId = ParamUtil.getLong(request, "guestbookId");
                long entryId = ParamUtil.getLong(request, "entryId");

            if (entryId > 0) {

                try {

                    _entryService.updateEntry(
                        serviceContext.getUserId(), guestbookId, entryId, userName,
                        email, message, serviceContext);

                    SessionMessages.add(request, "entryAdded");

                    response.setRenderParameter(
                        "guestbookId", Long.toString(guestbookId));

                }
                catch (Exception e) {
                    System.out.println(e);

                    SessionErrors.add(request, e.getClass().getName());

                    PortalUtil.copyRequestParameters(request, response);

                    response.setRenderParameter(
                        "mvcPath", "/guestbookwebportlet/edit_entry.jsp");
                }

            }
            else {

                try {
                    _entryService.addEntry(
                        serviceContext.getUserId(), guestbookId, userName, email,
                        message, serviceContext);
                    SessionMessages.add(request, "entryAdded");

                    response.setRenderParameter(
                        "guestbookId", Long.toString(guestbookId));

                }
                catch (Exception e) {
                    SessionErrors.add(request, e.getClass().getName());

                    PortalUtil.copyRequestParameters(request, response);

                    response.setRenderParameter(
                        "mvcPath", "/guestbookwebportlet/edit_entry.jsp");
                }
            }
        }

    public void deleteEntry(ActionRequest request, ActionResponse response) throws PortalException {
        long entryId = ParamUtil.getLong(request, "entryId");
        long guestbookId = ParamUtil.getLong(request, "guestbookId");

        ServiceContext serviceContext = ServiceContextFactory.getInstance(
            Entry.class.getName(), request);

        try {

            response.setRenderParameter(
                "guestbookId", Long.toString(guestbookId));

            _entryService.deleteEntry(entryId, serviceContext);
            SessionMessages.add(request, "entryDeleted");

        }

        catch (Exception e) {
            Logger.getLogger(GuestbookPortlet.class.getName()).log(
                Level.SEVERE, null, e);
            SessionErrors.add(request, e.getClass().getName());

        }
    }

    @Override
    public void render(
            RenderRequest renderRequest, RenderResponse renderResponse)
        throws IOException, PortletException {

        try {
            ServiceContext serviceContext = ServiceContextFactory.getInstance(
                Guestbook.class.getName(), renderRequest);

            long groupId = serviceContext.getScopeGroupId();

            long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");

            List<Guestbook> guestbooks = _guestbookService.getGuestbooks(
                groupId);

            if (guestbooks.isEmpty()) {
                Guestbook guestbook = _guestbookService.addGuestbook(
                    serviceContext.getUserId(), "Main", serviceContext);

                guestbookId = guestbook.getGuestbookId();
            }
```

```
            if (guestbookId == 0) {
                guestbookId = guestbooks.get(0).getGuestbookId();
            }

            renderRequest.setAttribute("guestbookId", guestbookId);
        }
        catch (Exception e) {
            throw new PortletException(e);
        }

        super.render(renderRequest, renderResponse);
    }

    @Reference(unbind = "-")
    protected void setEntryService(EntryService entryService) {
        _entryService = entryService;
    }

    @Reference(unbind = "-")
    protected void setGuestbookService(GuestbookService guestbookService) {
        _guestbookService = guestbookService;
    }

    private GuestbookService _guestbookService;
    private EntryService _entryService;

}
```

To check that you haven't made a mistake in your `GuestbookAdminPortlet` class, refer to the following complete class:

```

    },
    service = Portlet.class
)
public class GuestbookAdminPortlet extends MVCPortlet {

    public void addGuestbook(ActionRequest request, ActionResponse response)
            throws PortalException {

            ServiceContext serviceContext = ServiceContextFactory.getInstance(
              Guestbook.class.getName(), request);

            String name = ParamUtil.getString(request, "name");

            try {
              _guestbookService.addGuestbook(
                serviceContext.getUserId(), name, serviceContext);
              SessionMessages.add(request, "guestbookAdded");

            }
            catch (PortalException e) {

            Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
              Level.SEVERE, null, e);
            SessionErrors.add(request, e.getClass().getName());

              response.setRenderParameter(
                "mvcPath", "/guestbookadminportlet/edit_guestbook.jsp");
            }
          }

    public void updateGuestbook(ActionRequest request, ActionResponse response)
            throws PortalException {

            ServiceContext serviceContext = ServiceContextFactory.getInstance(
              Guestbook.class.getName(), request);

            String name = ParamUtil.getString(request, "name");
            long guestbookId = ParamUtil.getLong(request, "guestbookId");

            try {
              _guestbookService.updateGuestbook(
                serviceContext.getUserId(), guestbookId, name, serviceContext);
              SessionMessages.add(request, "guestbookUpdated");

            } catch (PortalException e) {

              Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
              Level.SEVERE, null, e);
              SessionErrors.add(request, e.getClass().getName());

              response.setRenderParameter(
                "mvcPath", "/guestbookadminportlet/edit_guestbook.jsp");
            }
          }

    public void deleteGuestbook(ActionRequest request, ActionResponse response)
            throws PortalException {

            ServiceContext serviceContext = ServiceContextFactory.getInstance(
              Guestbook.class.getName(), request);
            long guestbookId = ParamUtil.getLong(request, "guestbookId");

            try {
              _guestbookService.deleteGuestbook(guestbookId, serviceContext);
              SessionMessages.add(request, "guestbookDeleted");

            }
            catch (PortalException e) {

              Logger.getLogger(GuestbookAdminPortlet.class.getName()).log(
                  Level.SEVERE, null, e);
              SessionErrors.add(request, e.getClass().getName());

            }
          }

          private GuestbookService _guestbookService;

          @Reference(unbind = "-")
          protected void setGuestbookService(GuestbookService guestbookService) {
          _guestbookService = guestbookService;

          }

}
```

Now that you've implemented permission checks at the portlet layer, users without the proper permissions can't add, update, or delete a guestbook or guestbook entry entity. Even if a user manually entered a URL pointing to one of your portlet action methods, the portlet action now calls a remote service. The permission check in the remote service aborts the unauthorized user's request. Excellent work on securing your application's services!

From here, you can diverge. The later steps of this Learning Path (some still in progress) introduce you to other parts of Liferay DXP's development framework: workflow, the Recycle Bin, Lexicon, Friendly URLs, Staging and import/export, the Message Bus, and distributing your application on Marketplace. If you're interested in these topics, continue. But there's also another option.

Now that you've implemented web services, you can create a mobile Guestbook app with Liferay Screens. That Learning Path is available from the navigation on the left.

Chapter 36

Using Workflow

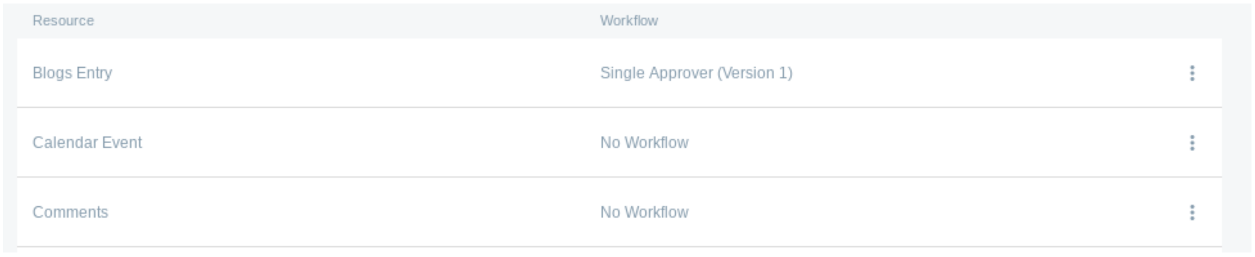
The Guestbook application accepts submissions from any logged in user, so there's no telling what people could post. Illegal data, objectionable content, the entire contents of Don Quixote: all of these and more are possibilities. You can make sure user posts don't run afoul of the law or policy by enabling *workflow* in your application.

Workflow is a review process that ensures a submitted entity isn't published before it's reviewed. To prevent posting objectionable content, an initially submitted Guestbook entry should be marked as a *draft* and sent through the workflow framework. It comes back to the application code ready to have any relevant fields updated in the database based on its status. The view layer must filter entities by status to display only reviewed entities.

Note: The exact review process is defined separately from the code that enables workflow. An XML file provides the definition of a workflow in Liferay DXP. If you're a Liferay Digital Enterprise subscriber, you have access to the Kaleo Workflow Designer, which offers a convenient drag-and-drop user interface for designing workflow definition files. You can read more about this in Liferay DXP's documentation. Liferay DXP comes with a workflow definition called the *Single Approver* definition, but you can write your own workflow definitions according to your organization's requirements.

A few additional definitions are included in Liferay DXP's source code, which you can use to see how workflow definitions are defined. To discover how to access these files, see here.

This section instructs the reader in workflow-enabling the Guestbook App's `Guestbook` and `Entry` entities to ensure that only approved content is published after review.



Resource	Workflow
Blogs Entry	Single Approver (Version 1)
Calendar Event	No Workflow
Comments	No Workflow

Figure 36.1: Enable workflow in your assets, just like Liferay DXP's own assets.

There are five steps to enabling workflow:

1. Update the service layer to set each entity's status fields.
2. Send the entity to Liferay DXP's workflow framework.
3. Add *getter* methods that account for an entity's workflow status.
4. Handle the entity as it returns from the workflow framework.
5. Update the user interface to account for workflow status.

The first three steps happen in the service layer, so that's a good place to start. Let's Go!

Chapter 37

Supporting Workflow at the Service Layer

When you asset enabled the Guestbook Application, you added four database columns in the Guestbook entities (e.g., GB_Entry) that keep track of workflow status (they're already added; celebrate!). The necessary fields are status, statusByUserName, statusByUserId, and statusDate. The columns are defined in the guestbook-service module's service.xml file.

```
<column name="status" type="int" />
<column name="statusByUserId" type="long" />
<column name="statusByUserName" type="String" />
<column name="statusDate" type="Date" />
```

The status field tells you the current status of the entity (it defaults to 0, which evaluates to *approved*). The other status fields store the date of the last change (statusDate) along with the ID and name of the user (statusByUserId and statusByUserName) who made the update.

Although the status columns are in the Guestbook application's entity tables, you must update the local service implementation's add methods to set them, and while you're there, send the entity to the workflow framework. You'll also write a method to update the status fields when the entity returns from the workflow framework, along with getters that take workflow status as a parameter. That sounds like a lot of work, but thanks to Service Builder, you must change only three files: service.xml, GuestbookLocalServiceImpl, and EntryLocalServiceImpl.

Let's Go!

37.1 Setting the Guestbook Status

```
<p>Supporting Workflow at the Service Layer<br>Step 1 of 3</p>
```

Before now, you set the status of all added guestbooks to approved in the service layer. Now you'll set it to draft and pass it to the workflow framework.

1. From guestbook-service, open GuestbookLocalServiceImpl and add the status fields below the existing setter methods in the addGuestbook method:

    ```
    guestbook.setStatus(WorkflowConstants.STATUS_DRAFT);
    guestbook.setStatusByUserId(userId);
    guestbook.setStatusByUserName(user.getFullName());
    guestbook.setStatusDate(serviceContext.getModifiedDate(null));
    ```

This manually populates the status fields and sets the workflow status as a draft in the GB_Entry database table. At this point they're identical to the similarly named non-status counterparts (like setUserId and setStatusByUserId), but they'll be updated independently in the updateStatus method you write later.

2. Still in the addGuestbook method, place the following code right before the return statement:

```
WorkflowHandlerRegistryUtil.startWorkflowInstance(guestbook.getCompanyId(),
            guestbook.getGroupId(), guestbook.getUserId(), Guestbook.class.getName(),
            guestbook.getPrimaryKey(), guestbook, serviceContext);
```

   The call to startWorkflowInstance detects whether workflow is installed and enabled. If it isn't, the added entity is automatically marked as approved. The startWorkflowInstance call also calls your GuestbookWorkflowHandler class, which you'll create later.

3. Organize imports (*[CTRL]+[SHIFT]+O*), and save your work.

The startWorkflowInstance method is where your entity enters the workflow framework, but you're not finished yet. Just like you wouldn't drop your child off at college and then change your number and move to a new address, you're not going to abandon your Guestbook entity (yet).

Exert control over how the status fields are updated in the database. Create an updateStatus method in GuestbookLocalServiceImpl, immediately following the deleteGuestbook method. Here's the first half of it:

```
public Guestbook updateStatus(long userId, long guestbookId, int status,
       ServiceContext serviceContext) throws PortalException,
       SystemException {

    User user = userLocalService.getUser(userId);
    Guestbook guestbook = getGuestbook(guestbookId);

    guestbook.setStatus(status);
    guestbook.setStatusByUserId(userId);
    guestbook.setStatusByUserName(user.getFullName());
    guestbook.setStatusDate(new Date());

    guestbookPersistence.update(guestbook);
```

If this method is called, it's because your entity is returning from the workflow framework, and it's time to update the status values in the database. Set the status fields, then persist the updated entity to the database. Before saving, finish the method:

```
    if (status == WorkflowConstants.STATUS_APPROVED) {

        assetEntryLocalService.updateVisible(Guestbook.class.getName(),
                guestbookId, true);

    } else {

        assetEntryLocalService.updateVisible(Guestbook.class.getName(),
                guestbookId, false);
    }

    return guestbook;
}
```

This if statement determines the visibility of the asset based on its workflow status. If it's approved, the assetEntryLocalService.updateVisible method sets the guestbook in question to true so it can be displayed in the Asset Publisher and in the search results. Otherwise (else) it sets the visibility to false to ensure that unapproved guestbooks aren't displayed to users in the Asset Publisher or the Search portlet.

Organize imports (*[CTRL]+[SHIFT]+O*) and save your work. Then run the buildService Gradle task.

There's one more update to make in the deleteGuestbook method. When deleting, you must clean up the workflow system's database tables to avoid leaving orphaned entries when the backing entity is deleted. Before making the method call, open service.xml and add the following tag below the existing <reference> tags:

```
<reference entity="WorkflowInstanceLink" package-path="com.liferay.portal" />
```

Save and run Service Builder. It injects the WorkflowInstanceLinkLocalService service into a protected variable in GuesbookLocalServiceBaseImpl. Since GuestbookLocalServiceImpl extends the base class, you can use it directly. Back in GuesbookLocalServiceImpl, find the deleteGuestbook method and put this method call right before the return statement:

```
workflowInstanceLinkLocalService.deleteWorkflowInstanceLinks(
    guestbook.getCompanyId(), guestbook.getGroupId(),
    Guestbook.class.getName(), guestbook.getGuestbookId());
```

Save the file and run *Refresh Gradle Project*. Now the guestbook entity's service layer populates the status fields in the database, sends the entity into the workflow framework, and cleans up when it's deleted. You'll do the same thing for guestbook entries next.

37.2 Setting the Entry Workflow Status

```
<p>Supporting Workflow at the Service Layer<br>Step 2 of 3</p>
```

Now you'll set the status fields, introduce entries to the workflow framework, and add the updateStatus method to EntryLocalServiceImpl. It works the same as it did for guestbooks.

Add the following lines in the addEntry method, immediately after the current setter methods (e.g., entry.setMessage(message)):

```
entry.setStatus(WorkflowConstants.STATUS_DRAFT);
entry.setStatusByUserId(userId);
entry.setStatusByUserName(user.getFullName());
entry.setStatusDate(serviceContext.getModifiedDate(null));
```

Still in the addEntry method, place the following code right before the return statement:

```
WorkflowHandlerRegistryUtil.startWorkflowInstance(entry.getCompanyId(),
            entry.getGroupId(), entry.getUserId(), Entry.class.getName(),
            entry.getPrimaryKey(), entry, serviceContext);
```

The startWorkflowInstance call eventually directs the workflow processing to your EntryWorkflowHandler class, which you'll create later. That class is responsible for making sure the entity is updated in the database (via an updateStatus method), but it's best practice to make persistence calls in the service layer. Thus you'll need a corresponding updateStatus method here in EntryLocalServiceImpl. Add this method to the bottom of the class:

```
 public Entry updateStatus(long userId, long guestbookId, long entryId, int status,
        ServiceContext serviceContext) throws PortalException,
        SystemException {

    User user = userLocalService.getUser(userId);
    Entry entry = getEntry(entryId);

    entry.setStatus(status);
    entry.setStatusByUserId(userId);
    entry.setStatusByUserName(user.getFullName());
    entry.setStatusDate(new Date());

    entryPersistence.update(entry);

    if (status == WorkflowConstants.STATUS_APPROVED) {

        assetEntryLocalService.updateVisible(Entry.class.getName(),
                entryId, true);

    } else {

        assetEntryLocalService.updateVisible(Entry.class.getName(),
                entryId, false);
    }

    return entry;
}
```

Organize imports (*[CTRL]+[SHIFT]+O*), save your work, and run Service Builder.

As with Guestbooks, you must add a call to `deleteWorkflowInstanceLinks` in the entry's delete method to avoid leaving orphaned database entries in the `workflowinstancelinks` table. First add the following `<reference>` tag to `service.xml`, this time in the entry entity section, below the existing reference tags:

```
<reference entity="WorkflowInstanceLink" package-path="com.liferay.portal" />
```

Save, run Service Builder, and then add the following method call to the `deleteEntry` method in `EntryLocalServiceImpl`, right before the `return` statement:

```
workflowInstanceLinkLocalService.deleteWorkflowInstanceLinks(
    entry.getCompanyId(), entry.getGroupId(),
    Entry.class.getName(), entry.getEntryId());
```

Now both entities support the status of the entity and can handle it as it enters the workflow framework and as it returns from the workflow framework. There's one more update to make in the local service implementation classes: adding getter methods that take the status as a parameter. Later you'll use these methods in the view layer so you can display only approved guestbooks and entries.

37.3 Retrieving Guestbooks and Entries by Status

```
<p>Supporting Workflow at the Service Layer<br>Step 3 of 3</p>
```

The service implementation for both entities now supports adding the status fields to the database tables. There's one more update to make in the service layer, but to understand why, you must think about the view layer. When the Guestbook portlet displays entries, you must make sure it doesn't show entries that haven't been approved. Currently, the entry's view layer shows all guestbooks:

```
    List<Guestbook> guestbooks = GuestbookLocalServiceUtil
            .getGuestbooks(scopeGroupId);
```

There's a problem: the getter only takes the `scopeGroupId` as a parameter, so there's no way to get guestbooks by their status.

Likewise, unapproved entries must not be displayed, but the view layer currently gets all entries:

```
<liferay-ui:search-container total="<%=EntryLocalServiceUtil.getEntriesCount()%>">
<liferay-ui:search-container-results
    results="<%=EntryLocalServiceUtil.getEntries(scopeGroupId.longValue(),
                guestbookId, searchContainer.getStart(),
                searchContainer.getEnd())%>" />
```

The solution is to implement for guestbooks and entries a getter that takes the `status` field as a parameter. Thankfully, Service Builder makes it easy.

Open the `guestbook-service` module's `service.xml` file.

1. For the entry entity, remove the following finder:

   ```
   <finder name="G_S" return-type="Collection">
     <finder-column name="groupId" />
     <finder-column name="status" />
   </finder>
   ```

2. Add this finder in its place:

   ```
   <finder name="G_G_S" return-type="Collection">
     <finder-column name="groupId" />
     <finder-column name="guestbookId" />
     <finder-column name="status" />
   </finder>
   ```

Run service builder (double-click `guestbook-service/build/buildService` in the Gradle Tasks pane of IDE). Service Builder generates finder methods in the persistence layer that take the specified fields (for example, `status`) as parameters.

Don't call the persistence layer directly in the application code. Instead expose the new persistence methods in the service layer.

Open `GuesbookLocalServiceImpl` and add this getter:

```
public List<Guestbook> getGuestbooks(long groupId, int status)
    throws SystemException {

    return guestbookPersistence.findByG_S(
        groupId, WorkflowConstants.STATUS_APPROVED);
}
```

This getter gets only approved guestbooks. That's why you hard code the workflow constant `STATUS_APPROVED` into the status parameter when calling the persistence method. Now open `EntryLocalServiceImpl` and add these two getters:

```
public List<Entry> getEntries(
    long groupId, long guestbookId, int status, int start, int end)
    throws SystemException {

    return entryPersistence.findByG_G_S(
        groupId, guestbookId, WorkflowConstants.STATUS_APPROVED);
}

public int getEntriesCount(
    long groupId, long guestbookId, int status)
```

```
    throws SystemException {

    return entryPersistence.countByG_G_S(
        groupId, guestbookId, WorkflowConstants.STATUS_APPROVED);
}
```

You'll replace the existing methods with these `getEntries` and `getEntriesCount` methods in the view layer, ensuring that only approved entries are displayed.

The work here relates to the UI updates you'll make later. Next, implement workflow handlers so that you can call the `updateStatus` service method when the entity returns from the workflow framework.

Chapter 38

Handling Workflow

The guestbook project's service layer is now updated to handle workflow. It now properly sets the status fields for guestbooks and guestbook entries, gets entities by their statuses, and sends entities to Liferay DXP's workflow framework whenever the `addGuestbook` or `addEntry` methods are called. Recall that you still have an uncalled service method, `updateStatus`, for both entities. In this section you'll implement workflow handlers, classes that interact with Liferay DXP's workflow framework and your service layer (by calling `updateStatus` on the appropriate entity).

There's a handy abstract class you can extend to make the job easier, called `BaseWorkflowHandler`. You'll do this next for both entities of the guestbook project, starting with guestbooks.

Let's Go!

38.1 Creating a Workflow Handler for Guestbooks

<p>Handling Workflow<br>Step 1 of 2</p>

Each workflow enabled entity needs a `WorkflowHandler`. Create a new package in the `guestboook-service` module called `com.liferay.docs.guestbook.workflow`, then create the `GuestbokWorkflowHandler` class in it. Extend `BaseWorkflowHandler` and pass in `Guestbook` as the type parameter:

```
public class GuestbookWorkflowHandler extends BaseWorkflowHandler<Guestbook> {
```

Make it a Component class:

```
@Component(immediate = true, service = WorkflowHandler.class)
```

There are three abstract methods to implement: `getClassName`, `getType`, and `updateStatus`.

```
    @Override
    public String getClassName() {
        return Guestbook.class.getName();
    }
```

`getClassName` returns the guestbook entity's fully qualified class name (`com.liferay.docs.guestbook.model.Guestbook`).

```
    @Override
    public String getType(Locale locale) {
        return _resourceActions.getModelResource(locale, getClassName());
    }
```

getType returns the model resource name (model.resource.com.liferay.docs.guestbook.model.Guestbook). The meat of the workflow handler is in the updateStatus method:

```
@Override
public Guestbook updateStatus(
        int status, Map<String, Serializable> workflowContext)
    throws PortalException {

    long userId = GetterUtil.getLong(
        (String)workflowContext.get(WorkflowConstants.CONTEXT_USER_ID));
    long resourcePrimKey = GetterUtil.getLong(
        (String)workflowContext.get(
            WorkflowConstants.CONTEXT_ENTRY_CLASS_PK));

    ServiceContext serviceContext = (ServiceContext)workflowContext.get(
        "serviceContext");

    return _guestbookLocalService.updateStatus(
        userId, resourcePrimKey, status, serviceContext);
}
```

When you crafted the service layer's updateStatus method (see the last section for more details), you specified parameters that must be passed to the method. Here you're making sure that those parameters are available to pass to the service call. Get the userId and resourcePrimKey from GetterUtil. Its getLong method takes a String, which you can get from the workflowContext Map using WorkflowConstants for the context user ID and the context entry class PK.

Make sure you inject the ResourceActions service into a private variable at the end of the class, using the @Reference annotation:

```
@Reference(unbind = "-")
protected void setResourceActions(ResourceActions resourceActions) {

    _resourceActions = resourceActions;
}

private ResourceActions _resourceActions;
```

Inject a GuestbookLocalService into a private variable using the @Reference annotation.

```
    @Reference(unbind = "-")
    protected void setGuestbookLocalService(
        GuestbookLocalService guestbookLocalService) {

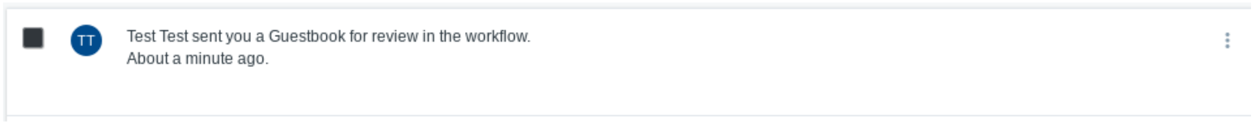
        _guestbookLocalService = guestbookLocalService;
    }

    private GuestbookLocalService _guestbookLocalService;

}
```

Organize imports (*[CTRL]+[SHIFT]+O*) and save your work.

Now the Guestbook Application updates the database with the necessary status information, interacting with Liferay's workflow classes to make sure each entity is properly handled by Liferay DXP. At this point you can enable workflow for the Guestbook inside Liferay DXP and see how it works. Navigate to *Control Panel → Workflow Configuration*. The Guestbook entity appears among Liferay DXP's native entities. Enable the Single Approver Workflow for Guestbooks; then go to the Guestbook Admin portlet and add a new Guestbook. A notification appears next to your user name in the product menu. You receive a notification from the workflow that a task is ready for review. Click it, and you're taken to the My Workflow Tasks portlet, where you can complete the review task.



Test Test sent you a Guestbook for review in the workflow.
About a minute ago.

Figure 38.1: Click the workflow notification in the Notifications portlet to review the guestbook submitted to the workflow.

To complete the review, click the actions button (⋮) from My Workflow Tasks and select *Assign to Me*. Click the actions button again and select *Approve*.

Right now the workflow process for guestbooks is functional, but the UI isn't adapted for it. You'll write the workflow handler for guestbook entries next, and then update the UI to account for each entity's workflow status.

38.2 Creating a Workflow Handler for Guestbook Entries

`<p>Handling Workflow<br>Step 2 of 2</p>`

The entry's workflow handler is almost identical to the guestbook's. Create a new class in the `com.liferay.docs.guestbook.workflow` package of the `guestbook-service` module. Name it `EntryWorkflowHandler` and extend `BaseWorkflowHandler`. Decorate it with a Component annotation and implement the same three methods you implemented in the `GuestbookWorkflowHandler`. Paste this in as the class body:

```
@Component(immediate = true, service = WorkflowHandler.class)
public class EntryWorkflowHandler extends BaseWorkflowHandler<Entry> {

    @Override
    public String getClassName() {

        return Entry.class.getName();

    }

    @Override
    public String getType(Locale locale) {

        return _resourceActions.getModelResource(locale, getClassName());
    }

    @Override
    public Entry updateStatus(
        int status, Map<String, Serializable> workflowContext)
        throws PortalException {

        long userId = GetterUtil.getLong(
            (String) workflowContext.get(WorkflowConstants.CONTEXT_USER_ID));
        long resourcePrimKey = GetterUtil.getLong(
            (String) workflowContext.get(
                WorkflowConstants.CONTEXT_ENTRY_CLASS_PK));

        ServiceContext serviceContext =
            (ServiceContext) workflowContext.get("serviceContext");

        long guestbookId =
            _entryLocalService.getEntry(resourcePrimKey).getGuestbookId();

        return _entryLocalService.updateStatus(
            userId, guestbookId, resourcePrimKey, status, serviceContext);
    }

    @Reference(unbind = "-")
    protected void setEntryLocalService(EntryLocalService entryLocalService) {

        _entryLocalService = entryLocalService;
    }

    @Reference(unbind = "-")
    protected void setResourceActions(ResourceActions resourceActions) {

        _resourceActions = resourceActions;
    }

    private EntryLocalService _entryLocalService;
    private ResourceActions _resourceActions;
}
```

There is nothing unique about this code as compared with the guestbook's workflow handler, except that we need the `gustbookId` for the entry. That's easily obtained by getting the `Entry` object with `entryLocalService`, then getting its `guestbookId`. See the last article for the rest of the handler's implementation details.

Organize imports with *CTRL+SHIFT+O* and save the file.

The back-end of the guestbook project is fully workflow enabled. All that's left is to update the Guestbook Application's UI to handle workflow status.

Chapter 39

Displaying Approved Workflow Items

There's not much left to do. Both entities in the guestbook project's back-end are workflow enabled, so it's time to update the UI. The Guestbook Admin portlet and the Guestbook portlet each requires its own display strategy.

The Guestbook Admin application is accessed by administrators, so it can display all guestbooks that have been submitted, even if they're not marked as approved. However, adding a *Status* field to the search container makes sense. That way admins can see which guestbooks are already approved, which are drafts, which are pending, etc.

The Guestbook application is meant to be viewed by site members and even guests (unauthenticated users of your site). Here it's smart to display only approved guestbooks and approved entries.

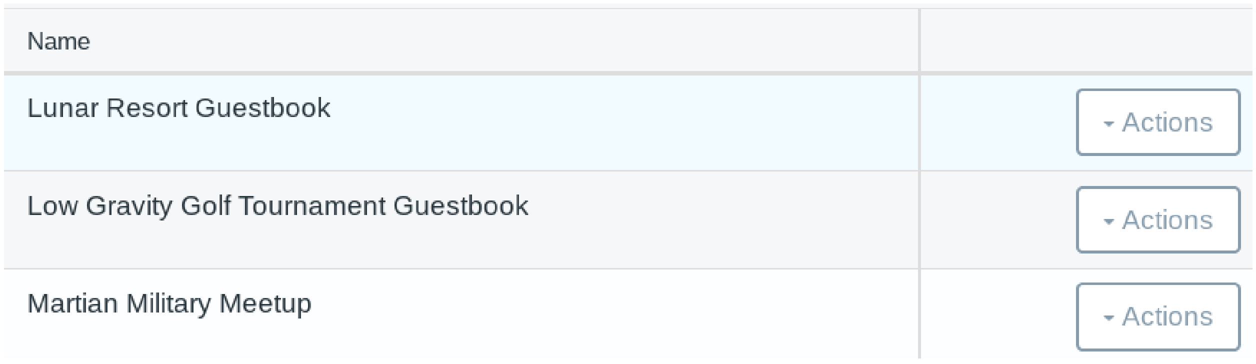
Start by updating the Guestbook Admin UI.

Let's Go!

39.1 Displaying Guestbook Status

<p>Displaying Approved Workflow Items<br>Step 1 of 2</p>

The Guestbook Admin application's main view currently has a search container with two columns: the guestbook name and the guestbook actions button.



Name	
Lunar Resort Guestbook	Actions
Low Gravity Golf Tournament Guestbook	Actions
Martian Military Meetup	Actions

Figure 39.1: The Guestbook Admin's main view currently shows the name of the guestbook and its actions button.

1. Add a third column between the two existing ones: call it *Status*. Open

   ```
   guestbook-web/src/main/reosurces/META-INF/resources/guestbookadminportlet/view.jsp
   ```

2. Find the existing search-container-column definitions:

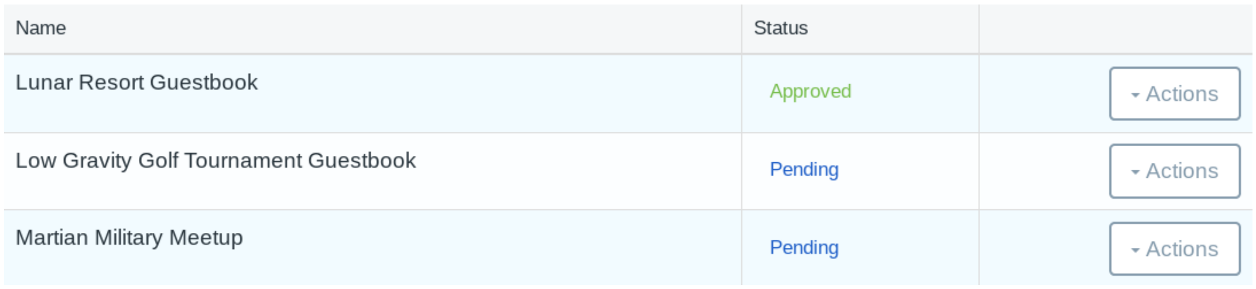
   ```
   <liferay-ui:search-container-column-text property="name" />

   <liferay-ui:search-container-column-jsp align="right"
       path="/guestbookadminportlet/guestbook_actions.jsp" />
   ```

3. Put the following new column between the existing columns:

   ```
   <liferay-ui:search-container-column-status property="status" />
   ```

Save the file and wait for the web module to redeploy. With the addition of one line in the JSP, the Guestbook Admin application now displays the guestbook's workflow status.



Name	Status	
Lunar Resort Guestbook	Approved	Actions
Low Gravity Golf Tournament Guestbook	Pending	Actions
Martian Military Meetup	Pending	Actions

Figure 39.2: The Guestbook Admin's main view, displaying the status of each guestbook.

Now move on to the Guestbook application's view layer.

39.2 Displaying Approved Entries

```
<p>Displaying Approved Workflow Items<br>Step 2 of 2</p>
```

The Guestbook application needs to be updated so that only guestbooks and entries with a status of *approved* appear in the UI.
Change the getters used to retrieve both entities in the view layer.

1. You need a new import, so first open

   ```
   guestbook-web/src/main/resources/META-INF/resources/init.jsp
   ```

   and add this line:

   ```
   <%@ page import="com.liferay.portal.kernel.workflow.WorkflowConstants"%>
   ```

2. Now open

```
guestbook-web/src/main/resources/META-INF/resources/guestbookwebportlet/view.jsp
```

Find the scriptlet that retrieves guestbooks:

```
<%
    List<Guestbook> guestbooks = GuestbookLocalServiceUtil
                .getGuestbooks(scopeGroupId);
        for (int i = 0; i < guestbooks.size(); i++) {
            Guestbook curGuestbook = (Guestbook) guestbooks.get(i);
            String cssClass = StringPool.BLANK;
            if (curGuestbook.getGuestbookId() == guestbookId) {
                cssClass = "active";
            }
            if (GuestbookPermission.contains(
                permissionChecker, curGuestbook.getGuestbookId(), "VIEW")) {

%>
```

Change it so it calls the getter you added that takes workflow status into account. All you need to do is change this method call

```
List<Guestbook> guestbooks = GuestbookLocalServiceUtil
            .getGuestbooks(scopeGroupId);
```

to

```
List<Guestbook> guestbooks = GuestbookLocalServiceUtil
            .getGuestbooks(scopeGroupId, WorkflowConstants.STATUS_APPROVED);
```

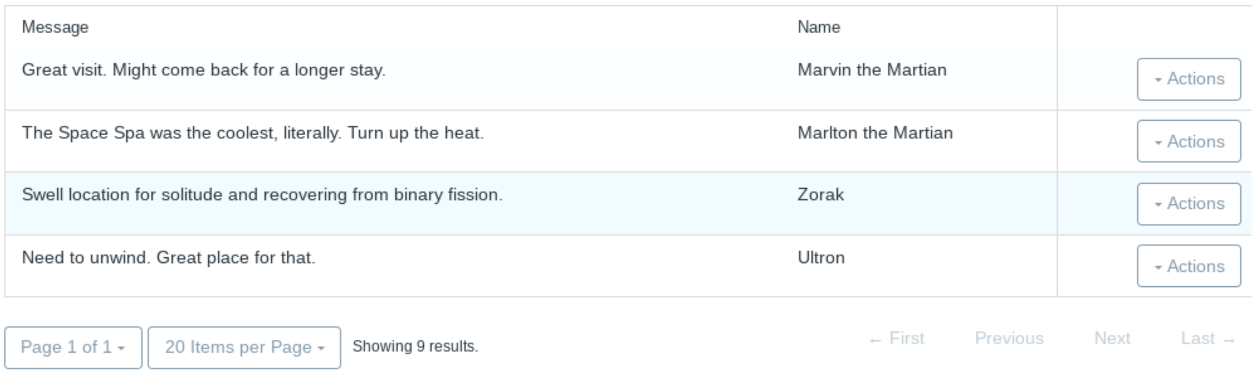
Save the file, and now only approved guestbooks are displayed in the Guestbook application.

3. Next, update the entry's UI in the same `view.jsp`. Find the tags that set the search container's total and its results:

```
<liferay-ui:search-container total="<%=EntryLocalServiceUtil.
                getEntriesCount()%>">
<liferay-ui:search-container-results results=
                "<%=EntryLocalServiceUtil.getEntries
                (scopeGroupId.longValue(),
                guestbookId, searchContainer.getStart(),
                searchContainer.getEnd())%>" />
```

Replace the getters to use the ones that take workflow status as a parameter, and pass `WorkflowConstants.STATUS_APPROVED` as the status. Here's what it looks like when you're finished:

```
<liferay-ui:search-container total="<%=EntryLocalServiceUtil.
                getEntriesCount(scopeGroupId.longValue(),
                guestbookId, WorkflowConstants.STATUS_APPROVED)%>">
<liferay-ui:search-container-results results=
                "<%=EntryLocalServiceUtil.getEntries(
                scopeGroupId.longValue(), guestbookId,
                WorkflowConstants.STATUS_APPROVED,
                searchContainer.getStart(), searchContainer.getEnd())%>" />
```



Message	Name

Page 1 of 1 · 20 Items per Page · Showing 9 results.

Figure 39.3: If you don't update the counter method to account for workflow status, it displays an incorrect count in the search container.

Now only approved entries are displayed, and the search container's counter only counts the approved entries. If you update the `getEntries` call but not the `getEntriesCount` call, the count that's displayed includes approved entries and entries with any other workflow status, and it won't match the total that's displayed at the bottom of the search container.

Now Guestbooks and Entries are now fully workflow enabled, to the great relief of the Lunar Resort's site administrators. You've saved them a lot of headaches dealing with inappropriate content, primarily submitted by visitors from Mars. Those Martians really need some lessons in netiquette.

Chapter 40

Enabling Staging and Export/Import

Your Guestbook application creates guestbooks and entries that are immediately published when they're saved. Sites constantly change, however, so it's crucial to have an area where updates can be planned and tested before publishing to your audience. Staging enables changing your Site behind the scenes without affecting the live Site. When you're done, you can publish all the changes at once.

Next, you'll implement Staging support in your Guestbook app so its entries can be tracked during the Staging phase of your publishing process.

Export/Import facilitates extracting data so it can be imported into another Liferay DXP installation. Behind the scenes, Export/Import is used during the Staging process. When publishing your staged content to the live Site, you're essentially importing content from the staged Site and exporting it to the live Site. Since the Export/Import framework is programmatically similar to Staging, you can implement it with Staging.

Ready to support Staging in your Guestbook app?

Let's Go!

40.1 Creating Staged Models

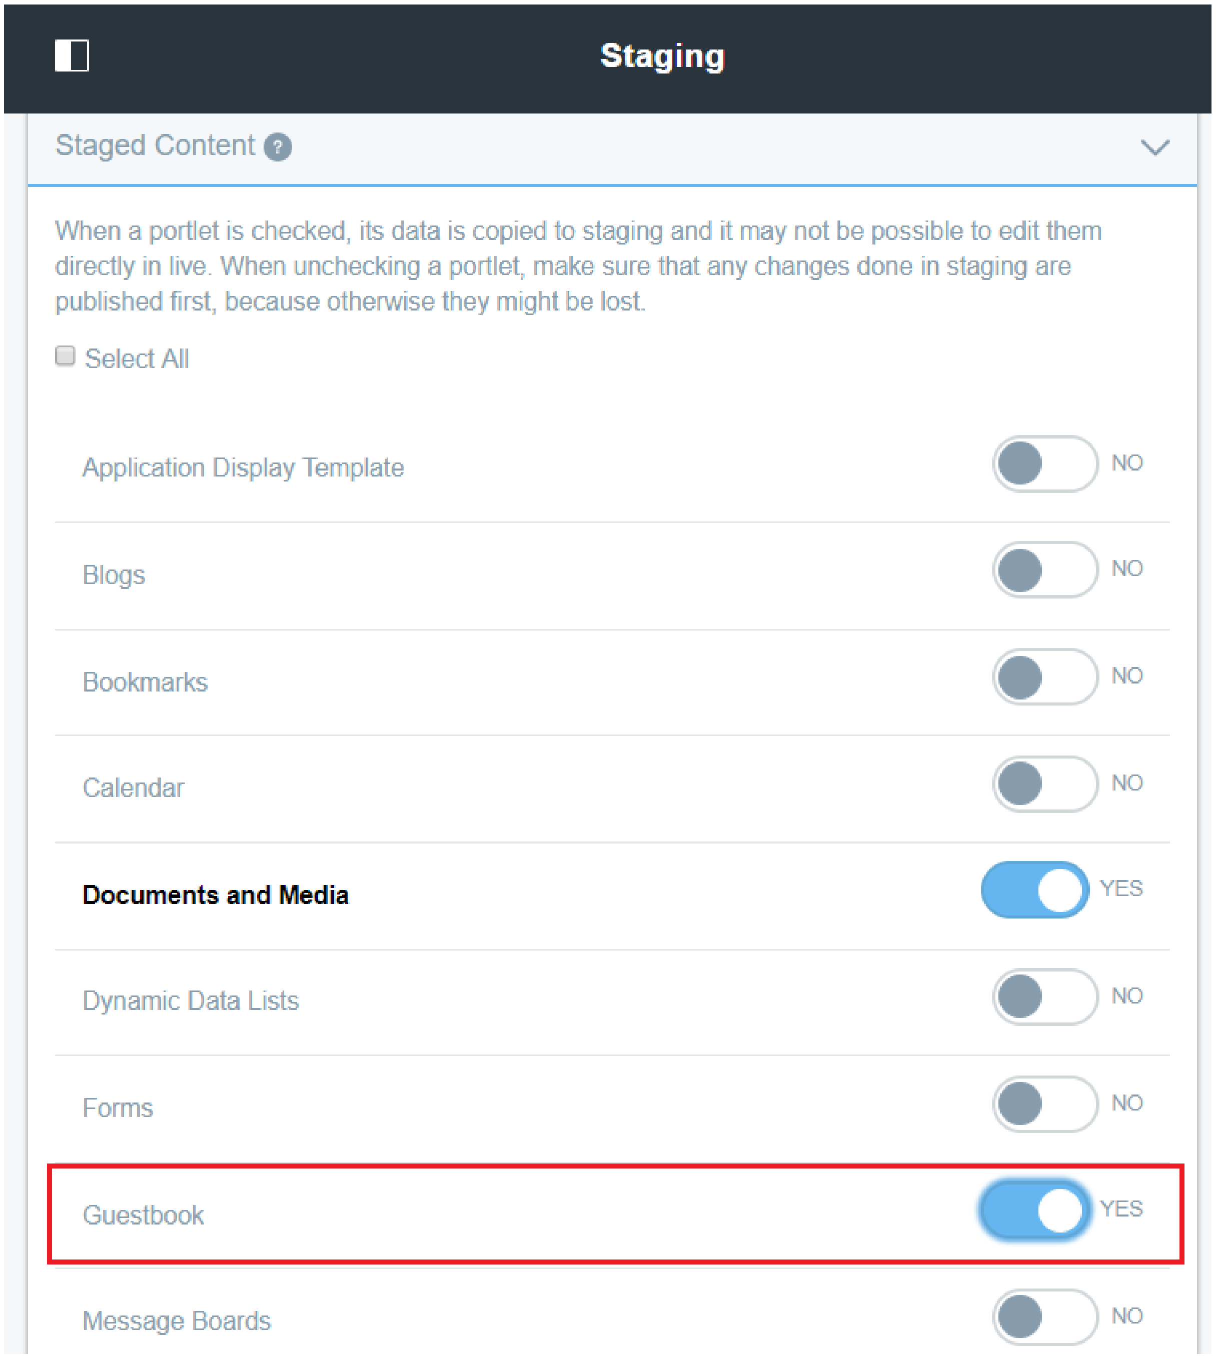
`<p>Enabling Staging and Export/Import<br>Step 1 of 7</p>`

To implement the Staging framework, you must first specify the entities you want to track. For the Guestbook application, there are two: `Guestbooks` and `Entrys`. You can register these entities so they're recognizable to the Staging framework by implementing the `StagedModel` interface in your Guestbook's model classes.

Service Builder generates an app's models as staged models when certain attributes are specified in the app's `service.xml` file. The Guestbook app already defines many of the necessary attributes in its `service.xml` file, so both your `GuestbookModel` and `EntryModel` interfaces already extend the `StagedModel` interface! For example, your Guestbook app's `EntryModel` interface's declaration looks like this:

```
public interface EntryModel extends BaseModel<Entry>, GroupedModel, ShardedModel,
    StagedAuditedModel, WorkflowedModel {
```

The `StagedModel` interface is implemented by the extension of the `StagedAuditedModel` interface. Service Builder chose the `StagedAuditedModel` interface based on the columns you declared. You'll update this later.



Staging

Staged Content

When a portlet is checked, its data is copied to staging and it may not be possible to edit them directly in live. When unchecking a portlet, make sure that any changes done in staging are published first, because otherwise they might be lost.

Liferay is staged. You are viewing the staged version of *Liferay*. You can make changes here an

Message	Name	
Best Wishes!	Joe Bloggs	Actions
Congratulations!	Tommy Johnson	Actions

Figure 40.2: A Staging-enabled Guestbook app can be modified on the staged site first without any users seeing it on the live Site.

The following Staging-specific attributes/columns are currently defined in the Guestbook app's `service.xml` file:

- `uuid` (required)
- `groupId`
- `companyId` (required)
- `userId`
- `userName`
- `createDate` (required)
- `modifiedDate` (required)

One of the most important attributes used by the Staging framework is the UUID (Universally Unique Identifier). This attribute must be set to true in `service.xml` for Service Builder to recognize your model as an eligible staged model. The UUID can differentiate entities between environments, because it's unique across multiple systems.

The `companyId`, `createDate`, and `modifiedDate` columns track the current entity's instance and creation/modification dates.

The others leverage features of the Staging framework like automatic group mapping or entity level Last Publish Date handling. See the Understanding Staged Models tutorial for more information.

Before adding Staging features to your Guestbook app, you must declare some necessary dependencies.

Declaring Staging Dependencies

There are two Staging-specific dependencies used by the Guestbook's Staging functionality.

1. Open the `guestbook-service` module's `build.gradle` file.

2. Add the following dependencies within the `dependencies` block:

   ```
   compileOnly group: "com.liferay", name: "com.liferay.exportimport.api", version: "2.1.0"
   compileOnly group: "com.liferay", name: "com.liferay.xstream.configurator.api", version: "2.0.0"
   ```

3. Save the file, right-click the Guestbook project, and run *Gradle → Refresh Gradle Project*.

Now you're ready to begin implementing staging in your app.

Updating the Extended Staged Model Interface

Staged models that extend the `StagedAuditedModel` interface function independently from the group concept (sometimes referred to as company models). This means that, for example, your guestbook and entry's scope would not be tracked by the Staging framework. You must add one more column to your `service.xml` file to convert your models to `StagedGroupedModels`, so your entities' scope is tracked correctly.

1. Open your `guestbook-service` module's `service.xml` file and add the `lastPublishDate` column for both Guestbook and Entry entities:

   ```
   <column name="lastPublishDate" type="Date" />
   ```

2. Run Service Builder. Do this by navigating to the Gradle Tasks pane on the right side of IDE and selecting your project's *build → buildService* task.

3. Run *Gradle → Refresh Gradle Project* to resolve any remaining errors.

Service Builder has updated your models to extend the `StagedGroupedModel`. For example, your `EntryModel` interface's declaration now looks like this:

```
public interface EntryModel extends BaseModel<Entry>, ShardedModel,
    StagedGroupedModel, WorkflowedModel {
```

For more information on the available staged model interfaces, see this tutorial.

Excellent! Now it's time to create your staged model data handlers.

40.2 Creating the Entry Staged Model Data Handler

```
<p>Enabling Staging and Export/Import<br>Step 2 of 7</p>
```

A Staged Model Data Handler supplies information about a staged model (entity) to the Staging and Export/Import framework. Data handlers replace the need to access the database directly and run queries to export/import data.

You must create a staged model data handler for every entity you want Staging to track. This means you must create a data handler for both your guestbook and entry entities.

First, you'll create a staged model data handler for guestbook entries.

1. In your `guestbook-service` module, create a package named `com.liferay.docs.guestbook.exportimport.data.handler`.

2. In that package, create the `EntryStagedModelDataHandler` class and have it extend the `BaseStagedModelDataHandler<STAGEI` class:

    ```
    public class EntryStagedModelDataHandler
        extends BaseStagedModelDataHandler<Entry> {
    ```

3. Add an `@Component` annotation above the class declaration to declare that the `EntryStagedModelDataHandler` class provides an implementation of the `StagedModelDataHandler` service:

    ```
    @Component(
        immediate = true,
        service = StagedModelDataHandler.class
    )
    ```

4. Set the staged model's local services you need in your data handler:

    ```
    @Reference(unbind = "-")
    protected void setEntryLocalService(EntryLocalService entryLocalService) {

        _entryLocalService = entryLocalService;
    }

    @Reference(unbind = "-")
    protected void setGuestbookLocalService(
        GuestbookLocalService guestbookLocalService) {

        _guestbookLocalService = guestbookLocalService;
    }

    private EntryLocalService _entryLocalService;
    private GuestbookLocalService _guestbookLocalService;
    ```

    This injects the entry and guestbook's local services.

5. You must provide the class names of the models the data handler tracks. You can do this by overriding the `StagedModelDataHandler`'s `getClassNames()` method:

    ```
    public static final String[] CLASS_NAMES = {Entry.class.getName()};

    @Override
    public String[] getClassNames() {
            return CLASS_NAMES;
    }
    ```

As a best practice, you should have one staged model data handler per staged model. It's possible to use multiple class types, but this is not recommended.

6. Add a method that retrieves the staged model's display name:

```
@Override
public String getDisplayName(Entry entry) {
    return entry.getName();
}
```

The display name is presented with the progress bar during the export/import and publication processes.

Test Test, modified 2 Seconds ago.
Untitled
40%
Exporting... Guestbook Landon's Birthday Party
In Progress

Figure 40.3: Your staged model data handler provides the display name in the Publish to Live UI.

7. A staged model data handler should ensure everything required for its operation is also imported/exported. For example, an entry requires a guestbook. Therefore, the guestbook should be exported first followed by the entry.

   Add methods that import and export your staged model and its references.

```
@Override
protected void doExportStagedModel(
        PortletDataContext portletDataContext, Entry entry)
    throws Exception {

    Guestbook guestbook =
        _guestbookLocalService.getGuestbook(entry.getGuestbookId());

    StagedModelDataHandlerUtil.exportReferenceStagedModel(
        portletDataContext, entry, guestbook,
        PortletDataContext.REFERENCE_TYPE_PARENT);

    Element entryElement = portletDataContext.getExportDataElement(entry);

    portletDataContext.addClassedModel(
        entryElement, ExportImportPathUtil.getModelPath(entry), entry);
}

@Override
protected void doImportStagedModel(
        PortletDataContext portletDataContext, Entry entry)
    throws Exception {

    long userId = portletDataContext.getUserId(entry.getUserUuid());

    Map<Long, Long> guestbookIds =
        (Map<Long, Long>) portletDataContext.getNewPrimaryKeysMap(
            Guestbook.class);

    long guestbookId = MapUtil.getLong(
        guestbookIds, entry.getGuestbookId(), entry.getGuestbookId());

    Entry importedEntry = null;

    ServiceContext serviceContext =
        portletDataContext.createServiceContext(entry);

    if (portletDataContext.isDataStrategyMirror()) {
        Entry existingEntry = fetchStagedModelByUuidAndGroupId(
            entry.getUuid(), portletDataContext.getScopeGroupId());

        if (existingEntry == null) {
            serviceContext.setUuid(entry.getUuid());

            importedEntry = _entryLocalService.addEntry(
                userId, guestbookId, entry.getName(), entry.getEmail(),
                entry.getMessage(), serviceContext);
        }
        else {
            importedEntry = _entryLocalService.updateEntry(
                userId, guestbookId, existingEntry.getEntryId(),
                entry.getName(), entry.getEmail(), entry.getMessage(),
                serviceContext);
        }
    }
    else {
        importedEntry = _entryLocalService.addEntry(
            userId, guestbookId, entry.getName(), entry.getEmail(),
            entry.getMessage(), serviceContext);
    }

    portletDataContext.importClassedModel(entry, importedEntry);
}
```

The `doExportStagedModel` method retrieves the entry's data element from the `PortletDataContext` and then adds the class model characterized by that data element to the `PortletDataContext`. The `PortletDataContext` populates the LAR file with your application's data during the export process. Note that once an entity has been exported, subsequent calls to the export method don't repeat the export process multiple times, ensuring optimal performance.

An important feature of the import process is that all exported reference elements are automatically imported when needed. The `doImportStagedModel` method does not need to import the reference elements manually; it must only find the new assigned ID for the guestbook before importing the entry.

The `PortletDataContext` keeps this information and a slew of other data up-to-date during the import process. The code snippet shows how to access the old ID and new ID mapping, by using the `portletDataContext.getNewPrimaryKeysMap()` method. The method proceeds with checking the import mode (e.g., Copy As New or Mirror) and depending on the process configuration and existing environment, the entry is either added or updated.

8. When importing a LAR (i.e., publishing to the live Site), the import process expects all of an entity's references to be available and validates their existence.

   For example, if you republish an updated guestbook to the live Site and did not include some of its existing entries in the publication, these entries are considered missing references. A more practical example of this would be an image included in a web content article. If the image included in the web content lives on a different Site (i.e., the image is contained in a different group) or was not included in the publication process, it's considered a missing reference of the web content article.

Since you're dealing with references on two separate Sites that have differing IDs, the system can't easily match them during publication. Consider this scenario for the Guestbook app; suppose you export a guestbook entry as a missing reference with a primary key (ID) of 1. When importing that information, the LAR only provides the ID but not the entry itself. Therefore, during the import process, the Data Handler framework searches for the entry to replace by its UUID, but the entry to replace has a different ID (primary key) of 2. You must provide a way to handle these missing references.

To do this, you must add a method that maps the missing reference's primary key from the export to the existing primary key during import. Since the reference's UUID is constant across systems, it's used to complete the mapping of differing primary keys. Note that a reference can only be missing on the live Site if it has already been published previously. Therefore, when publishing a guestbook for the first time, the system doesn't check for missing references.

Add this method to your class:

```
@Override
protected void doImportMissingReference(
    PortletDataContext portletDataContext, String uuid, long groupId,
    long entryId)
throws Exception {

    Entry existingEntry = fetchMissingReference(uuid, groupId);

    if (existingEntry == null) {
        return;
    }

    Map<Long, Long> entryIds =
        (Map<Long, Long>) portletDataContext.getNewPrimaryKeysMap(
        Entry.class);

    entryIds.put(entryId, existingEntry.getEntryId());
}
```

This method maps the existing staged model to the old ID in the reference element. When a reference is exported as missing, the Data Handler framework calls this method during the import process and updates the new primary key map in the portlet data context.

9. Provide a way for the staged model data handler to fetch your staged models:

```
@Override
public Entry fetchStagedModelByUuidAndGroupId(String uuid, long groupId) {

    return _entryLocalService.fetchEntryByUuidAndGroupId(uuid, groupId);
}

@Override
public List<Entry> fetchStagedModelsByUuidAndCompanyId(
    String uuid, long companyId) {

    return _entryLocalService.getEntriesByUuidAndCompanyId(
        uuid, companyId, QueryUtil.ALL_POS, QueryUtil.ALL_POS,
        new StagedModelModifiedDateComparator<Entry>());
}
```

These methods use the entry's local service to get the entries by UUID and company ID (i.e., portal instance's primary key) or group ID (i.e., Site, Organization, or User Group's primary key).

10. Override the BaseStagedModelDataHandler's delete methods to leverage your newly created fetch method and custom local service:

```
@Override
public void deleteStagedModel(
        String uuid, long groupId, String className, String extraData)
    throws PortalException {

    Entry entry = fetchStagedModelByUuidAndGroupId(uuid, groupId);

    if (entry ≠ null) {
        deleteStagedModel(entry);
    }

}

@Override
public void deleteStagedModel(Entry entry)
    throws PortalException {

    _entryLocalService.deleteEntry(entry);
}
```

    These methods are necessary for the Staging framework to properly delete your entry staged models.

11. Organize your imports (*[CTRL]+[SHIFT]+O*), and save the file.

The entry's staged model data handler is complete! Next you can create the guestbook's staged model data handler.

40.3 Creating the Guestbook Staged Model Data Handler

```
<p>Enabling Staging and Export/Import<br>Step 3 of 7</p>
```

The guestbook's staged model data handler is similar to the entry's data handler. Refer to the previous article for how this works.

1. In the `guestbook-service` module's `com.liferay.docs.guestbook.exportimport.data.handler` package, create the `GuestbookStagedModelDataHandler` class.

2. Declare `BaseStagedModelDataHandler<STAGED_MODEL>` as your extension class and add the `@Component` declaration to declare `StagedModelDataHandler` as your implemented service:

```
@Component(
    immediate = true,
    service = StagedModelDataHandler.class
)
public class GuestbookStagedModelDataHandler
    extends BaseStagedModelDataHandler<Guestbook> {
```

3. Set the staged model's local service you want to leverage in your data handler:

```
@Reference(unbind = "-")
protected void setGuestbookLocalService(
    GuestbookLocalService guestbookLocalService) {

    _guestbookLocalService = guestbookLocalService;
}

private GuestbookLocalService _guestbookLocalService;
```

4. Add the methods to retrieve the guestbook staged model's classes to track and display names:

```
public static final String[] CLASS_NAMES = {
    Guestbook.class.getName()
};

@Override
public String[] getClassNames() {

    return CLASS_NAMES;
}

@Override
public String getDisplayName(Guestbook guestbook) {

    return guestbook.getName();
}
```

5. Add methods to ensure all import/export information is provided to the Staging framework for your guestbook entity:

```
@Override
protected void doExportStagedModel(
        PortletDataContext portletDataContext, Guestbook guestbook)
    throws Exception {

    Element guestbookElement =
        portletDataContext.getExportDataElement(guestbook);

    portletDataContext.addClassedModel(
        guestbookElement, ExportImportPathUtil.getModelPath(guestbook),
        guestbook);
}

@Override
protected void doImportStagedModel(
        PortletDataContext portletDataContext, Guestbook guestbook)
    throws Exception {

    long userId = portletDataContext.getUserId(guestbook.getUserUuid());

    Map<Long, Long> guestbookIds =
        (Map<Long, Long>) portletDataContext.getNewPrimaryKeysMap(
        Guestbook.class);

    long guestbookId = MapUtil.getLong(
        guestbookIds, guestbook.getGuestbookId(),
        guestbook.getGuestbookId());

    Guestbook importedGuestbook = null;

    ServiceContext serviceContext =
        portletDataContext.createServiceContext(guestbook);

    if (portletDataContext.isDataStrategyMirror()) {
        Guestbook existingGuestbook = fetchStagedModelByUuidAndGroupId(
            guestbook.getUuid(), portletDataContext.getScopeGroupId());

        if (existingGuestbook == null) {
            serviceContext.setUuid(guestbook.getUuid());

            importedGuestbook = _guestbookLocalService.addGuestbook(
                userId, guestbook.getName(), serviceContext);
        }
        else {
            importedGuestbook = _guestbookLocalService.updateGuestbook(
                userId, existingGuestbook.getGuestbookId(), guestbook.getName(), serviceContext);

        }
    }
    else {
        importedGuestbook = _guestbookLocalService.addGuestbook(
            userId, guestbook.getName(), serviceContext);
    }

    portletDataContext.importClassedModel(guestbook, importedGuestbook);
}
```

Similar to the guestbook entry, these methods add export/import information to the `PortletDataContext`.

6. Add a method that maps the missing reference ID from the export to the existing ID during import:

```
@Override
protected void doImportMissingReference(
        PortletDataContext portletDataContext, String uuid, long groupId,
        long guestbookId)
    throws Exception {

    Guestbook existingGuestbook = fetchMissingReference(uuid, groupId);

    if (existingGuestbook == null) {
        return;
    }

    Map<Long, Long> guestbookIds =
        (Map<Long, Long>) portletDataContext.getNewPrimaryKeysMap(
        Guestbook.class);

    guestbookIds.put(guestbookId, existingGuestbook.getGuestbookId());
}
```

Remember, this is not called for new entities being published/imported since all of an entity's references are new to the live Site.

7. Provide a way for the staged model data handler to fetch your staged models:

```
@Override
public Guestbook fetchStagedModelByUuidAndGroupId(
    String uuid, long groupId) {

    return _guestbookLocalService.fetchGuestbookByUuidAndGroupId(
        uuid, groupId);
}

@Override
public List<Guestbook> fetchStagedModelsByUuidAndCompanyId(
    String uuid, long companyId) {
        return _guestbookLocalService.getGuestbooksByUuidAndCompanyId(
            uuid, companyId, QueryUtil.ALL_POS, QueryUtil.ALL_POS,
            new StagedModelModifiedDateComparator<Guestbook>());
    }
```

8. Override the `BaseStagedModelDataHandler`'s delete methods to leverage your newly created fetch method and custom local service:

```
@Override
public void deleteStagedModel(
        String uuid, long groupId, String className, String extraData)
    throws PortalException {

    Guestbook guestbook = fetchStagedModelByUuidAndGroupId(uuid, groupId);

    if (guestbook ≠ null) {
        deleteStagedModel(guestbook);
    }
}

@Override
public void deleteStagedModel(Guestbook guestbook)
    throws PortalException {

    _guestbookLocalService.deleteGuestbook(guestbook);
}
```

9. Organize your imports (*[CTRL]+[SHIFT]+O*), and save the file.

Your guestbook staged model data handler is ready to go! Next, you'll begin updating your guestbook's permissions to account for Staging.

40.4 Updating Permissions to Support Staging

```
<p>Enabling Staging and Export/Import<br>Step 4 of 7</p>
```

The guestbook's current permission handlers do not account for Staging. For example, the current configuration would display the *Add Guestbook* and *Add Entry* buttons on the live Site while Staging was enabled. These options should only be available on the staged Site when Staging is enabled.

First, edit the Guestbook app's permissions helper classes to provide permission checks to leverage when Staging is enabled.

1. Open the `GuestbookModelPermission` class residing in the `guestbook-service`'s `com.liferay.docs.guestbook.service.perm` package. Replace the `contains(...)` methods with those below:

```
public static boolean contains(
    PermissionChecker permissionChecker, long groupId, String actionId) {

    return contains(
        permissionChecker, RESOURCE_NAME, GuestbookPortletKeys.GUESTBOOK,
        groupId, actionId);
}

public static boolean contains(
    PermissionChecker permissionChecker, String name, long classPK,
    String actionId) {
```

```
    Group group = GroupLocalServiceUtil.fetchGroup(classPK);

    if ((group != null) && group.isStagingGroup()) {
        classPK = group.getLiveGroupId();
    }

    return permissionChecker.hasPermission(
        classPK, name, classPK, actionId);
}

public static boolean contains(
    PermissionChecker permissionChecker, String name, String portletId,
    long classPK, String actionId) {

    Boolean hasPermission = StagingPermissionUtil.hasPermission(
        permissionChecker, classPK, name, classPK, portletId, actionId);

    if (hasPermission != null) {
        return hasPermission.booleanValue();
    }

    return contains(permissionChecker, name, classPK, actionId);
}
```

This adds two additional contains methods. The original contains method now redirects to a new method that instantiates a `hasPermission` field using the staging permission checker. If it returns as a non-null value (i.e., the app is rendered on the staged Site), the appropriate boolean value is returned based on the user's permissions. If the `hasPermission` field is null (i.e., the app is rendered on the live Site), the third contains method is invoked, which calls the permission checker with group info from the live Site.

Now you'll edit the permissions helper classes for your two entities. These are for the model/resource permissions, so you supply the primary key of the entity you're checking permissions for (e.g., `guestbookId`).

2. Open the `EntryPermission` class residing in the `guestbook-service`'s `com.liferay.docs.guestbook.service.permission` package. In the `contains(PermissionChecker, Entry, String)` method, add this logic:

```
Boolean hasPermission = StagingPermissionUtil.hasPermission(
    permissionChecker, entry.getGroupId(), Entry.class.getName(),
    entry.getEntryId(), GuestbookPortletKeys.GUESTBOOK, actionId);

    if (hasPermission != null) {
        return hasPermission.booleanValue();
    }
```

If the new `hasPermission` field is returned as a non-null value (i.e., the app is rendered on the staged Site), the appropriate boolean value is returned based on the staging context.

3. Open the `GuestbookPermission` class and add the following code in the `contains(PermissionChecker, Guestbook, String)` method:

```
Boolean hasPermission = StagingPermissionUtil.hasPermission(
    permissionChecker, guestbook.getGroupId(),
    Guestbook.class.getName(), guestbook.getGuestbookId(),
    GuestbookPortletKeys.GUESTBOOK, actionId);

if (hasPermission != null) {
    return hasPermission.booleanValue();
}
```

This is similar to the logic added for the entry's permissions.

4. Organize your imports (*[CTRL]+[SHIFT]+O*) for all three classes, and then save them.

Your Guestbook app can now display the proper functionality depending on its staging context (i.e., staged Site or live Site).

The Guestbook's admin portlet requires additional modifications in its JSPs to display options correctly based on staging context.

1. In your `guestbook-web` module, open the `src/main/resources/META-INF/resources/guestbookadminportlet/guestbook_ac` file. Directly after the opening `<liferay-ui:icon-menu>` tag, add the following `if` statement:

```
<c:if test='<%= GuestbookPermission.contains(permissionChecker, guestbook.getGuestbookId(), ActionKeys.UPDATE) %>'>
```

   Close the `if` statement directly after the `<liferay-ui:icon />` tag. When completed, the `if` statement should look like this:

```
<c:if test='<%= GuestbookPermission.contains(permissionChecker, guestbook.getGuestbookId(), ActionKeys.UPDATE) %>'>
    <portlet:renderURL var="editURL">
        <portlet:param name="guestbookId"
            value="<%=String.valueOf(guestbook.getGuestbookId())%>" />
        <portlet:param name="mvcPath"
            value="/guestbookadminportlet/edit_guestbook.jsp" />
    </portlet:renderURL>

    <liferay-ui:icon image="edit" message="Edit"
        url="<%=editURL.toString()%>" />
</c:if>
```

   The new `if` statement hides the Guestbook's editing functionality if the user does not have the permissions to edit a guestbook. Since you added new staging permissions, those are verified too.

2. Below the `</c:if>` statement, add another `if` statement:

```
<c:if test='<%= GuestbookPermission.contains(permissionChecker, guestbook.getGuestbookId(), ActionKeys.DELETE) %>'>
```

   Close the `if` statement directly after the `<liferay-ui:icon-delete />` tag. When completed, the `if` statement should look like this:

```
<c:if test='<%= GuestbookPermission.contains(permissionChecker, guestbook.getGuestbookId(), ActionKeys.DELETE) %>'>
    <portlet:actionURL name="deleteGuestbook" var="deleteURL">
        <portlet:param name="guestbookId"
            value="<%=String.valueOf(guestbook.getGuestbookId())%>" />
    </portlet:actionURL>

    <liferay-ui:icon-delete url="<%=deleteURL.toString()%>" />
</c:if>
```

   Similar to the previous `if` statement, this one hides the Guestbook's delete functionality if the user does not have the permissions to delete a guestbook.

3. Open the `src/main/resources/META-INF/resources/guestbookadminportlet/view.jsp` file and wrap the `<aui:button-row />` tag with the following `if` statement:

```
<c:if test='<%= GuestbookModelPermission.contains(permissionChecker, scopeGroupId, "ADD_GUESTBOOK") %>'>
    ...
</c:if>
```

When finished, it should look like this:

```
<c:if test='<%= GuestbookModelPermission.contains(permissionChecker, scopeGroupId, "ADD_GUESTBOOK") %>'>
    <aui:button-row cssClass="guestbook-admin-buttons">
        <portlet:renderURL var="addGuestbookURL">
            <portlet:param name="mvcPath"
                value="/guestbookadminportlet/edit_guestbook.jsp" />
            <portlet:param name="redirect" value="<%="currentURL"%>" />
        </portlet:renderURL>

        <aui:button onClick="<%= addGuestbookURL.toString() %>"
            value="Add Guestbook" />
    </aui:button-row>
</c:if>
```

This `if` statement hides the Guestbook's *Add Guestbook* button if the user does not have the permissions to create a new guestbook.

Great! You've updated your Guestbook app's permissions to support Staging!

40.5 Configuring XStream

<p>Enabling Staging and Export/Import<br>Step 5 of 7</p>

Configuring XStream for your Guestbook app provides an easy way to customize how entities are serialized to XML and back again. You can use it to enhance the Guestbook's Staging implementation; however, it's not required. There are three ways to leverage Liferay's offering of XStream via the XStreamConfigurator:

- *Allowed Types:* whitelists entities so everything is forbidden except a certain set of items. All staged models are allowed by default; this would be in addition to the default functionality. Liferay DXP defines a default list of allowed types, which are available in the portlet data context.
- *Aliases:* helps with the readability and char length of LAR files by creating an alias for an otherwise long winded entity name.
- *Converters:* converts configured objects to and from XML. This is primarily used to protect sensitive data; when serialized this way, sensitive data cannot be extracted from the generated LAR.

Since Allowed Types don't make sense in this context (there are no additional entities to allow), you don't need them for Guestbook. Converters let you re-write the serialization process from scratch—for example, to add encryption. This is a tutorial on Staging, not serialization, so the default serialization implementation is fine. That leaves aliases.

In the Guestbook, you'll leverage XStream by creating an alias that modifies the XML in the LAR file produced by your app during the staging and export processes.

For example, by default your generated data has this structure:

```
<com.liferay.docs.guestbook.model.impl.GuestBookImpl>
    <field1>...</field1>
    ...
</com.liferay.docs.guestbook.model.impl.GuestBookImpl>
```

With an XStream alias configured in your app, that same LAR content has this structure:

```
<GuestBook>
    <field1>...</field1>
    ...
</GuestBook>
```

Follow the instructions below to create an XStream alias:

1. In the `guestbook-service` module, create a package named `com.liferay.docs.guestbook.xstream.configurator`. In that package, create a class named `GuestbookXStreamConfigurator`.

2. Modify the class to implement the `XStreamConfigurator` interface and create an `@Component` annotation declaring that same class as the implementation service:

   ```
   @Component(
       immediate = true,
       service = XStreamConfigurator.class
   )
   public class GuestbookXStreamConfigurator implements XStreamConfigurator {
   ```

3. Since the Guestbook won't leverage the *Allowed Types* and *Converters* XStream options, override their associated methods and have them return `null`:

   ```
   @Override
   public List<XStreamType> getAllowedXStreamTypes() {

       return null;
   }

   @Override
   public List<XStreamConverter> getXStreamConverters() {

       return null;
   }
   ```

4. Override the `getXStreamAliases()` method to return a list of aliases you want to define. Also, define the list field.

   ```
   @Override
   public List<XStreamAlias> getXStreamAliases() {
       return ListUtil.toList(_xStreamAliases);
   }

   private XStreamAlias[] _xStreamAliases;
   ```

   Next, you'll define the list.

5. Create an `activate()` method that defines the aliases to use for Guestbook's generated LAR file. You'll define an alias for the `GuestbookImpl` and `EntryImpl` classes to convert them from their full package names to simple entity names:

   ```
   @Activate
   protected void activate() {

       _xStreamAliases = new XStreamAlias[] {
           new XStreamAlias(GuestbookImpl.class, "Guestbook"),
           new XStreamAlias(EntryImpl.class, "Entry"),
       };
   }
   ```

6. Organize your imports (*[CTRL]+[SHIFT]+O*), and save the file.

Awesome! You implemented an XStream Configurator for the Guestbook and created an alias for your guestbook and entry entity declarations.

40.6 Defining System Events for Deletions

<p>Enabling Staging and Export/Import<br>Step 6 of 7</p>

The Staging framework tracks entity modifications in a few different ways. Actions like *adding* a guestbook or *editing* an entry are tracked automatically by the framework with the configuration of staged models and their data handlers. Entity deletions are handled slightly differently using system events.

For the Guestbook app, you must define system events for entity deletions so they're appropriately tracked by the Staging framework. If Staging can't track your entity deletions, they can't be managed on the staged Site, which means you can only delete entities from the live Site.

You must define your system events in your local services.

1. Open the `guestbook-service` module's `com.liferay.docs.guestbook.service.impl.GuestbookLocalServiceImpl` class and add the following `deleteGuestbook` methods. These override the default Service Builder generated methods the application has been using:

```
@Indexable(type = IndexableType.DELETE)
@Override
public Guestbook deleteGuestbook(long guestbookId)
    throws PortalException {

    Guestbook guestbook =
        guestbookPersistence.findByPrimaryKey(guestbookId);

    return guestbookLocalService.deleteGuestbook(guestbook);
}

@Indexable(type = IndexableType.DELETE)
@Override
@SystemEvent(type = SystemEventConstants.TYPE_DELETE)
public Guestbook deleteGuestbook(Guestbook guestbook) {

    return guestbookPersistence.remove(guestbook);
}
```

   These methods override the `GuestbookLocalServiceBaseImpl`'s `deleteGuestbook` methods. The major addition is the `@SystemEvent` annotation added to the `deleteGuestbook(Guestbook)` method. This notifies the Staging framework that a deletion system event occurs when the method is called.

   The `deleteGuestbook(long)` method is rerouted to call the `SystemEvent` tracked method, so all deletions are accounted for.

2. Ensure that the remaining `deleteGuestbook` method triggers the system event. Within the `deleteGuestbook(long, ServiceContext)` method, change

```
guestbook = deleteGuestbook(guestbook);
```

   to this

```
guestbook = guestbookLocalService.deleteGuestbook(guestbook);
```

Now all guestbook deletions are tracked via `SystemEvent`.

3. Add the import packages for the new `SystemEvent` annotation (*[CTRL]+[SHIFT]+O*) and then save the file.

4. You must apply the deletion system event to both entities. Open the `com.liferay.docs.guestbook.service.impl.EntryLoc` class and add similar delete methods:

```
@Indexable(type = IndexableType.DELETE)
@Override
public Entry deleteEntry(long entryId)
    throws PortalException {

    Entry entry = entryPersistence.findByPrimaryKey(entryId);

    return entryLocalService.deleteEntry(entry);
}

@Indexable(type = IndexableType.DELETE)
@Override
@SystemEvent(type = SystemEventConstants.TYPE_DELETE)
public Entry deleteEntry(Entry entry) {

    return entryPersistence.remove(entry);
}
```

This is the same logic as before, except the delete system event is now applied for the entry.

5. Make sure the remaining `deleteEntry` method triggers the system event. Within the `deleteEntry(long, ServiceContext)` method, change

```
entry = deleteEntry(entryId);
```

to this

```
entry = entryLocalService.deleteEntry(entry);
```

Now all entry deletions are tracked via `SystemEvent`.

6. Add the import packages for the new `SystemEvent` annotation (*[CTRL]+[SHIFT]+O*) and then save the file.

7. Run Service Builder by navigating to the Gradle Tasks pane on the right side of @ide@ and selecting your project's *build* → *buildService* task.

Your Guestbook app's deletions are now properly tracked by the Staging framework.

40.7 Creating the Portlet Data Handler

<p>Enabling Staging and Export/Import<br>Step 7 of 7</p>

A Portlet Data Handler imports/exports portlet-specific data to a LAR file. Its primary role is to query and coordinate between staged model data handlers. It also configures the Export/Import UI options for the application. For example, the Guestbook application's portlet data handler should

- import/export portlet-specific data pertaining to the Guestbook app
- track actions dealing with guestbook and entry entities (staged models)
- configure export/import UI options for the Guestbook app

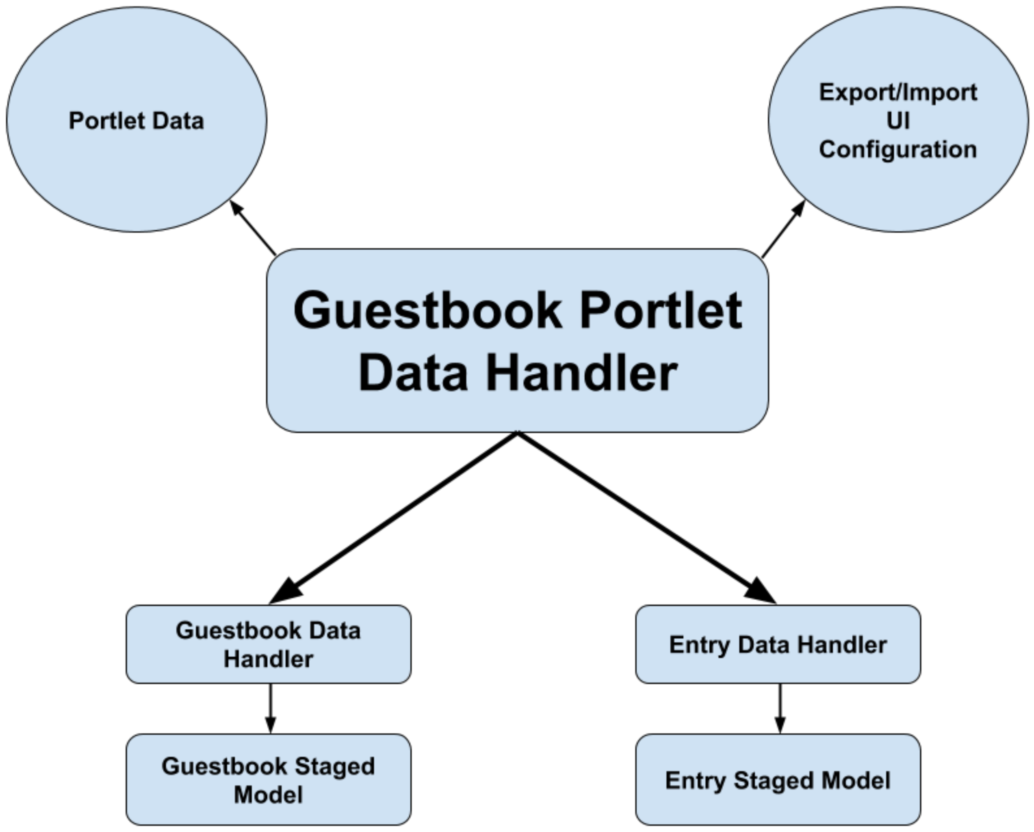

Figure 40.4: The Guestbook's portlet data handler must manage the portlet data, staged model data handlers, and UI configuration.

Follow the instructions below to create the Guestbook's portlet data handler.

1. In your `guestbook-service` module's `com.liferay.docs.guestbook.exportimport.data.handler` package, create the `GuestbookPortletDataHandler` class.

2. Extend the `BasePortletDataHandler` class and add the `@Component` annotation to the class declaration with several configured properties like this:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK,
        "javax.portlet.name=" + GuestbookPortletKeys.GUESTBOOK_ADMIN
    },
    service = PortletDataHandler.class
)
public class GuestbookPortletDataHandler extends BasePortletDataHandler {
```

The three set annotation attributes are described below:

- The `immediate` element tells the container to activate the component immediately once its provided module has started.
- The `property` element sets various properties for the component service. You must associate the portlets you wish to handle with this service so they function properly in the export/import environment. For example, since the Guestbook data handler is used for two portlets, they're both configured using the `javax.portlet.name` property.
- The `service` element should point to the `PortletDataHandler.class` interface.

3. Set what the portlet data handler controls and the portlet's Export/Import UI by adding an activate method:

```
@Activate
protected void activate() {

    setDeletionSystemEventStagedModelTypes(
        new StagedModelType(Entry.class),
        new StagedModelType(Guestbook.class));

    setExportControls(
        new PortletDataHandlerBoolean(
            NAMESPACE, "entries", true, false, null,
            Entry.class.getName()));

    setImportControls(getExportControls());
}
```

This method is called during initialization of the component by using the `@Activate` annotation. It's invoked after dependencies are set and before services are registered.

The three set methods called in the `GuestbookPortletDataHandler`'s `activate` method are described below:

- `setDeletionSystemEventStagedModelTypes`: sets the staged model deletions that the portlet data handler should track. For the Guestbook application, guestbooks and entries are tracked.
- `setExportControls`: adds fine grained controls over export behavior that are rendered in the Export UI. For the Guestbook application, a checkbox is added to select Guestbook content (entries) to export.
- `setImportControls`: adds fine grained controls over import behavior that are rendered in the Import UI. For the Guestbook application, a checkbox is added to select Guestbook content (entries) to import.

4. Set the entity local services you want to leverage in your portlet data handler:

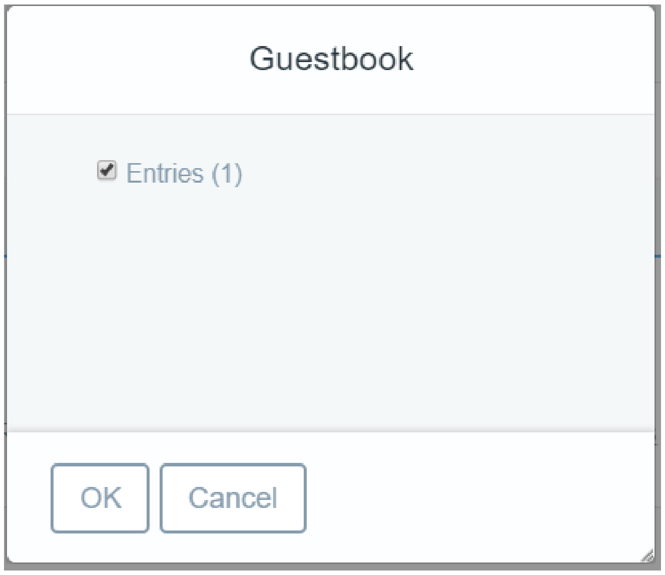

Figure 40.5: You can select the content types you'd like to export/import in the UI.

```
@Reference(unbind = "-")
protected void setGuestbookLocalService(
    GuestbookLocalService guestbookLocalService) {

    _guestbookLocalService = guestbookLocalService;
}

@Reference(unbind = "-")
protected void setEntryLocalService(EntryLocalService entryLocalService) {

    _entryLocalService = entryLocalService;
}

private GuestbookLocalService _guestbookLocalService;
private EntryLocalService _entryLocalService;
```

This provides access to the entry and guestbook's local services.

5. Create a namespace for your entities so the Export/Import framework can tell your application's entities from other entities in Liferay DXP.

```
public static final String NAMESPACE = "guestbook";
```

6. Your portlet data handler should retrieve the data related to its staged model entities so it can properly export/import them. Add this functionality by inserting the following methods:

```
@Override
protected String doExportData(
        final PortletDataContext portletDataContext, String portletId,
        PortletPreferences portletPreferences)
    throws Exception {

    Element rootElement = addExportDataRootElement(portletDataContext);

    if (!portletDataContext.getBooleanParameter(NAMESPACE, "entries")) {
        return getExportDataRootElementString(rootElement);
    }

    portletDataContext.addPortletPermissions(
        GuestbookModelPermission.RESOURCE_NAME);

    rootElement.addAttribute(
        "group-id", String.valueOf(portletDataContext.getScopeGroupId()));

    ActionableDynamicQuery guestbookActionableDynamicQuery =
        _guestbookLocalService.getExportActionableDynamicQuery(
            portletDataContext);
    guestbookActionableDynamicQuery.performActions();

    ActionableDynamicQuery entryActionableDynamicQuery =
        _entryLocalService.getExportActionableDynamicQuery(
            portletDataContext);
        entryActionableDynamicQuery.performActions();

    return getExportDataRootElementString(rootElement);
}

@Override
protected PortletPreferences doImportData(
        PortletDataContext portletDataContext, String portletId,
        PortletPreferences portletPreferences, String data)
    throws Exception {

    if (!portletDataContext.getBooleanParameter(NAMESPACE, "entries")) {
        return null;
    }

    portletDataContext.importPortletPermissions(
        GuestbookModelPermission.RESOURCE_NAME);

    Element guestbooksElement =
        portletDataContext.getImportDataGroupElement(Guestbook.class);

    List<Element> guestbookElements = guestbooksElement.elements();

    for (Element guestbookElement : guestbookElements) {
        StagedModelDataHandlerUtil.importStagedModel(
            portletDataContext, guestbookElement);
    }

    Element entriesElement =
        portletDataContext.getImportDataGroupElement(Entry.class);

    List<Element> entryElements = entriesElement.elements();

    for (Element entryElement : entryElements) {
        StagedModelDataHandlerUtil.importStagedModel(
            portletDataContext, entryElement);
    }

    return null;
}
```

The `doExportData` method first checks if anything should be exported. The `portletDataContext.getBooleanParameter(...`
method checks if the user selected Guestbook entries for export. Later, the `ActionableDynamicQuery` framework runs a query against guestbooks and entries to find ones which should be exported to the LAR file.

The `-ActionableDynamicQuery` classes are automatically generated by Service Builder and are available in your application's local service. It queries the database searching for certain Staging-specific parameters (e.g., `createDate` and `modifiedDate`), and based on those parameters, finds a list of exportable records from the staged model data handler.

The `doImportData` method queries for guestbook and entry data in the imported LAR file that should be added to the database. This is done by extracting XML elements from the LAR file by using utility methods from the `StagedModelDataHandlerUtil` class. The extracted elements tell Liferay DXP what data to import from the LAR file.

7. Add a method that counts the number of affected entities based on the current export or staging process:

```
@Override
protected void doPrepareManifestSummary(
        PortletDataContext portletDataContext,
        PortletPreferences portletPreferences)
    throws Exception {

    ActionableDynamicQuery entryExportActionableDynamicQuery =
        _entryLocalService.getExportActionableDynamicQuery(
            portletDataContext);
    entryExportActionableDynamicQuery.performCount();

    ActionableDynamicQuery guestbookExportActionableDynamicQuery =
        _guestbookLocalService.getExportActionableDynamicQuery(
            portletDataContext);
    guestbookExportActionableDynamicQuery.performCount();
}
```

   This number is displayed in the Export and Staging UI. Note that since the Staging framework traverses the entity graph during export, the built-in components provide an approximate value in some cases.

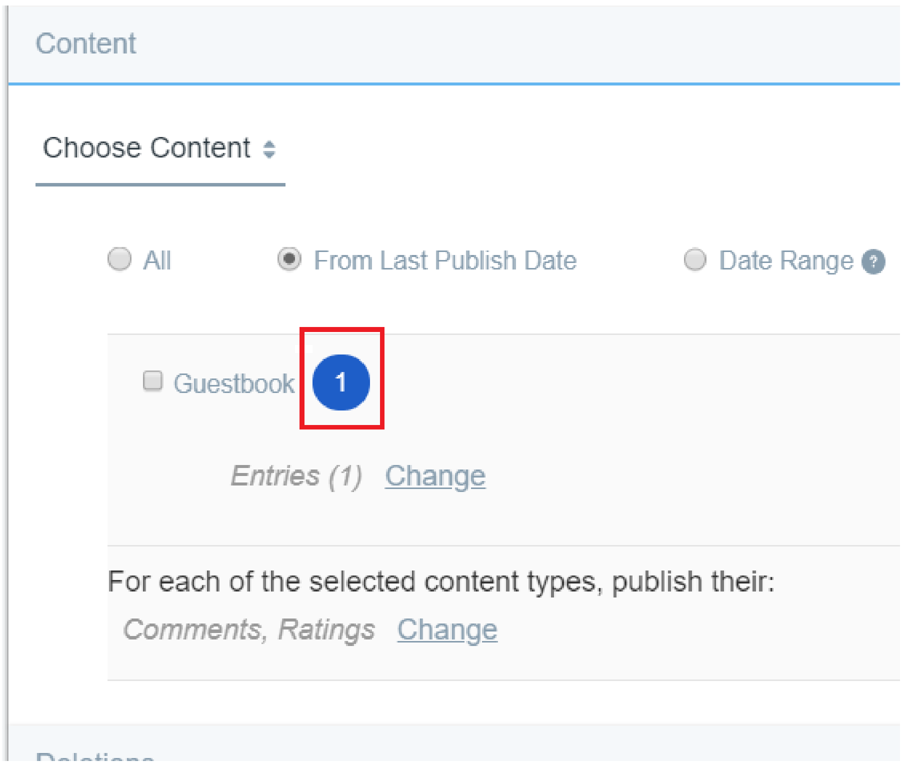
8. Organize your imports (*[CTRL]+[SHIFT]+O*), and save the file. **Hint:** Be sure to choose the `javax.portlet.PortletPreferences` import package.

Excellent! You've set up your Guestbook's portlet data handler and can now handle your portlet's data and control its staged model data handlers.

Your Guestbook app is now leveraging the Staging and Export/Import frameworks! To verify this, when you go to enable Staging, you can now enable it for your Guestbook app.

You can also navigate to the Guestbook Admin portlet and manage Staging from the Options menu. This menu also offers a way to export and import Guestbook LAR files manually.

The Guestbook is ready for the staging process!



For each of the selected content types, publish their:

Comments, Ratings Change

Chapter 41

Writing an Android App for Liferay DXP

Users expect to access Liferay DXP content from their mobile devices. As an intrepid developer, you naturally want to turn these expectations into reality. Thankfully, Liferay provides a way for your mobile apps to access Liferay DXP content and applications with Liferay Screens! Screens contains native components called *Screenlets* that can call Liferay DXP's remote services and display the results in your app. Each Screenlet comes complete with its own fully pluggable UI that you can customize to your liking. Although the Screenlets included with Screens only work with Liferay DXP's built-in remote services, you can write your own Screenlets that work with your custom portlets' remote services.

If you're an experienced Android developer but need a start-to-finish guide on how to integrate Android apps with Liferay DXP, you're in the right place. This Learning Path walks you through the creation of an Android app that interacts with the Guestbook portlet developed in the Developing a Web Application Learning Path. Since this is a custom portlet, you'll write your own Screenlets that let your app retrieve and display guestbooks and their entries.

You should note that although this Learning Path provides complete code snippets of the app, not every aspect of Android development is explained in detail. Focus is instead placed on the code that leverages Liferay Screens. Therefore, you **must** have significant Android development experience before attempting this Learning Path. Otherwise, you'll likely be confused. Google provides extensive documentation of the Android APIs as well as some basic tutorials on developer.android.com.

Experience in Android development is all you need to start working. You needn't have completed the Liferay MVC Learning Path to obtain a working Guestbook portlet. The complete Guestbook portlet's modules are provided for installation into your local Liferay DXP instance.

Now that you know what you'll be doing here, it's time to move on to the first series of articles: Beginning Android Development for Liferay DXP. These articles walk you through the steps required to get started developing an Android app that interacts with Liferay DXP.

Chapter 42

Beginning Android Development for Your Liferay DXP Instance

Getting started with Liferay Screens for Android is a straightforward process. This series of Learning Path articles walks you through creating an Android app and preparing it to work with the Guestbook portlet developed in the Developing a Web Application Learning Path.

Since Liferay Screens uses the Liferay Mobile SDK to make remote service calls, you'll build a Mobile SDK capable of calling the Guestbook portlet's remote services (the Guestbook Mobile SDK). You'll then install this Mobile SDK and Screens into your Android project. You'll also learn about the Android app's design and implement authentication with Login Screenlet.

This section of the Learning Path covers these topics:

1. Setting up the Guestbook portlet
2. Building the Guestbook Mobile SDK
3. Creating the Android project
4. Installing the Guestbook Mobile SDK and Liferay Screens in the Android project
5. Designing Your App
6. Using Login Screenlet for Authentication

When you finish, you'll be ready to start developing your first Screenlet.

42.1 Setting up the Guestbook Portlet

Before you begin developing the Guestbook app for Android, you must set up the Guestbook portlet in a Liferay DXP instance. To do this, follow these steps:

1. Install JDK 8
2. Install and Configure a Local Liferay DXP bundle
3. Deploy the Guestbook Portlet to the Local Liferay DXP Instance

Installing the JDK

To get started, you must have JDK 8 installed. You can download and install the Java SE JDK from the Java downloads page. This page also has links to the JDK installation instructions.

Installing and Configuring a Local Liferay DXP Bundle

First, download a Liferay DXP Tomcat bundle from liferay.com. Then click here and follow the instructions to install the bundle. To follow Liferay DXP best practices, you should create a `bundles` folder and unzip it there. The bundle's root folder is referred to as *Liferay Home* and is named according to the version, edition, and specific Liferay DXP release. For example, if you downloaded Liferay Portal 7.0 CE GA4 and unzipped it to a `bundles` folder on your machine, that bundle's Liferay Home folder path is:

```
bundles/liferay-ce-portal-7.0-ga4
```

Now you're ready to start Liferay DXP! Start the bundle as described in the link above. If you're on Mac or Linux you should also run `tail -f ../logs/catalina.out` immediately after the `./startup.sh` command executes. This ensures that the server log prints to the terminal. This step isn't necessary on Windows because the server log automatically opens in another window.

After a minute or two, Liferay DXP starts up and automatically takes you to its initial setup page at http://localhost:8080. On this page, you need to provide some basic information about how to set up your Liferay DXP instance. Enter a name for your instance, select the default language, and then uncheck the *Add Sample Data* box. Then enter the first name, last name, and email address of the default administrative user. For the purposes of this Learning Path, these don't have to be real. If you want to connect Liferay DXP to a separate database such as MySQL or PostgreSQL, you can configure that connection here. Note that although the default embedded database is fine for development on your local machine, it isn't optimized for production. Click *Finish Configuration* when you're done. Then accept the terms of use and set a password and a password reminder query for your administrative user. Your Liferay DXP instance then takes you to its default site.

Great! Next, you'll deploy the Guestbook portlet to your Liferay DXP instance.

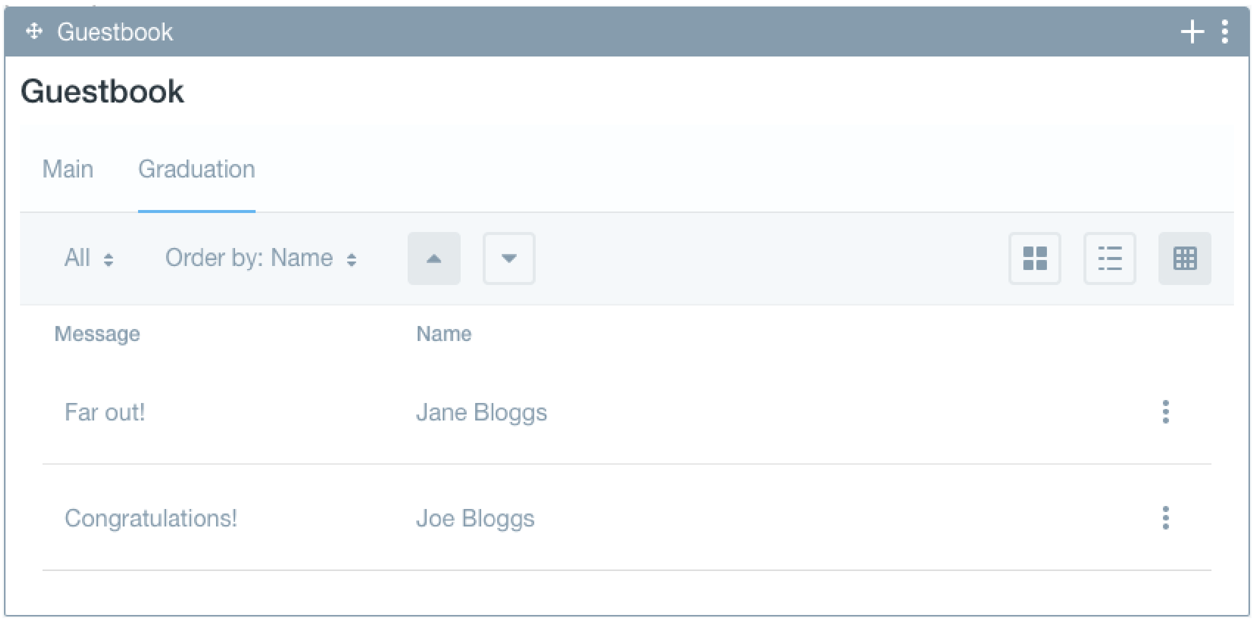
Deploying the Guestbook Portlet

Now that your Liferay DXP instance is set up, you can deploy the Guestbook portlet to it. First, click here to download the Guestbook portlet's modules:

- `com.liferay.docs.guestbook.api-1.0.0.jar`
- `com.liferay.docs.guestbook.portlet-1.0.0.jar`
- `com.liferay.docs.guestbook.service-1.0.0.jar`
- `com.liferay.docs.guestbook.service-wsdd-1.0.0.jar`

Place these modules in your Liferay DXP instance's `[Liferay Home]/deploy` folder. You should then see console messages indicating that the modules have successfully deployed and started. On your Liferay DXP instance's default site, click the *Add* button (➕) on the upper-right corner of the screen. Then click the *Applications → Sample* category and drag *Guestbook* onto the page. The Guestbook portlet should now appear with the default guestbook (Main). In the portlet, add a new guestbook and an entry or two each from the *Add* menu (⊕) that appears in the top right of the portlet's border when you mouse over the portlet. When you create the Guestbook Android app, this ensures there's some content to display in it. The Guestbook portlet on your site should now look like this:

Stupendous! You've successfully set up a Liferay DXP instance and added the Guestbook portlet to it. Now you're ready to get started with the Liferay Mobile SDK.



Message	Name
Far out!	Jane Bloggs
Congratulations!	Joe Bloggs

Figure 42.1: The Guestbook portlet, with a new guestbook and some entries.

42.2 Building the Guestbook Mobile SDK

Once you've deployed the Guestbook portlet, you're ready to build the Guestbook Mobile SDK. You might be asking yourself, "Why do I have to build a separate Mobile SDK? Can't I just use the pre-built Mobile SDK that Liferay already provides?" Fantastic question! The reason is that Liferay's pre-built Mobile SDK doesn't have the classes it needs to call the Guestbook portlet's remote services. The pre-built Mobile SDK includes only the framework necessary to make server calls to the remote services of Liferay DXP's *core* apps. Core apps (also referred to as *out-of-the-box* apps) are those included with every Liferay DXP instance. Since you're calling services of an app the default Mobile SDK doesn't know about (the Guestbook portlet), you must build a Mobile SDK that can call its services. Now put on your hard hat, because it's time to get building!

Building the Mobile SDK

In the Mobile SDK source code, Liferay provides a Mobile SDK Builder that you can use to build your own Mobile SDKs. For the builder to generate the classes that can call a non-core app's remote services, those services must be available and accompanied by a Web Service Deployment Descriptor (WSDD). To learn how the Guestbook portlet's remote services and WSDD were generated, see the section Generating Web Services in the web application Learning Path. Since the Guestbook portlet's web services already exist, you don't need to generate them. Just remember that you must generate web services when developing your own portlets.

To build the Guestbook Mobile SDK, first download the Mobile SDK's source code by clicking here. Unzip the file to a location on your machine where you want the Mobile SDK to reside. This location is purely personal preference; the builder works the same no matter where you put the Mobile SDK's source code. Once unzipped, the Mobile SDK's source code is in the `liferay-mobile-sdk-android-7.0.6` folder.

Now you're ready to build the Guestbook Mobile SDK. The builder contains a convenient command line wizard to assist you in building Mobile SDKs. To start it, navigate to the `liferay-mobile-sdk-android-7.0.6` folder and run the following command:

```
./gradlew createModule
```

The wizard launches and asks you to enter your project's properties. You must first provide the `Context` property. This is the context path of the remote services the builder will generate classes and methods for. To view your Liferay DXP instance's remote service context paths, go to http://localhost:8080/api/jsonws. On the page's upper left, there's a menu for selecting the context path. Select *gb*, which is the Guestbook portlet's context path. The UI updates to show only the remote services available in the selected context path. Return to the terminal and enter `gb` for the `Context` property.

Next, the wizard needs the `Package Name` property. This is the package path for the classes the builder generates. Accept the default value of `com.liferay.mobile.android`. The wizard then asks for the `POM Description` property. Technically, you only need this if you want to publish your Mobile SDK to Maven. Since the builder requires it, however, enter `Guestbook SDK`. The following screenshot shows these properties entered in the wizard:

Once you enter the final property, the builder runs and generates a `BUILD SUCCESSFUL` message. Now that the builder contains a `gb` module, you must generate that module's remote services. To do this, first navigate to the following folder:

```
liferay-mobile-sdk-android-7.0.6/modules/gb
```

Then run the following command:

```
../../gradlew generate
```

As before, the builder runs and generates a `BUILD SUCCESSFUL` message. Great! You're probably wondering what just happened, though. The builder generated the source classes you'll use in your Android app to interact with the Guestbook portlet. You can find these source classes in the following folder of the Mobile SDK's source code:

```
modules/gb/android/src/gen/java
```

Also note that the source classes are in the package path you specified when generating the module, with an additional folder that denotes the Liferay DXP version they work with. The full path to the generated source classes is therefore:

```
modules/gb/android/src/gen/java/com/liferay/mobile/android/v7
```

This folder has two subfolders that correspond to each entity in the Guestbook portlet: `guestbook` and `entry`. Each subfolder contains that entity's source class, `GuestbookService` and `EntryService`, respectively.

There's one last thing to do before you can use these classes in your Android app: put them in a JAR file. To do this, make sure you're still in the `modules/gb` folder on the command line and run `../../gradlew jar`. This command does two things:

1. Generates a JAR file in `modules/gb/build/libs` that contains the Guestbook portlet's service classes. This JAR file is the Guestbook Mobile SDK.

2. Generates a custom-built version of Liferay's pre-built Mobile SDK in `liferay-mobile-sdk-android-7.0.6/android/build/libs`.

Congratulations! You just built the Guestbook Mobile SDK. Now that's an accomplishment worth writing in a guestbook. All you need now is an Android app in which to install this Mobile SDK. The next article shows you how to create this.

POM Description: Guestbook SDK
```

Figure 42.3: To build your Mobile SDK, you must enter values for the `Context`, `Package Name`, and `POM Description` properties. The blue values in square brackets are defaults.

42.3 Creating the Android Project

Now that you've built the Guestbook Mobile SDK, you're ready to create the Guestbook Android app. This article walks you through the steps required to create the app's project in Android Studio. After this, you'll be ready to install the Guestbook Mobile SDK and Liferay Screens. First though, you should make sure you've installed Android's development tools.

Installing Android Studio

This Learning Path uses Android Studio–Android's official IDE–to develop the Guestbook app. As an Android developer, you're likely very familiar with Android Studio. If you need help setting up and using Android Studio, see the following topics in Android Studio's documentation:

- Android Studio Installation Instructions
- Meet Android Studio

Once Android Studio is up and running, you're ready to create the Guestbook app!

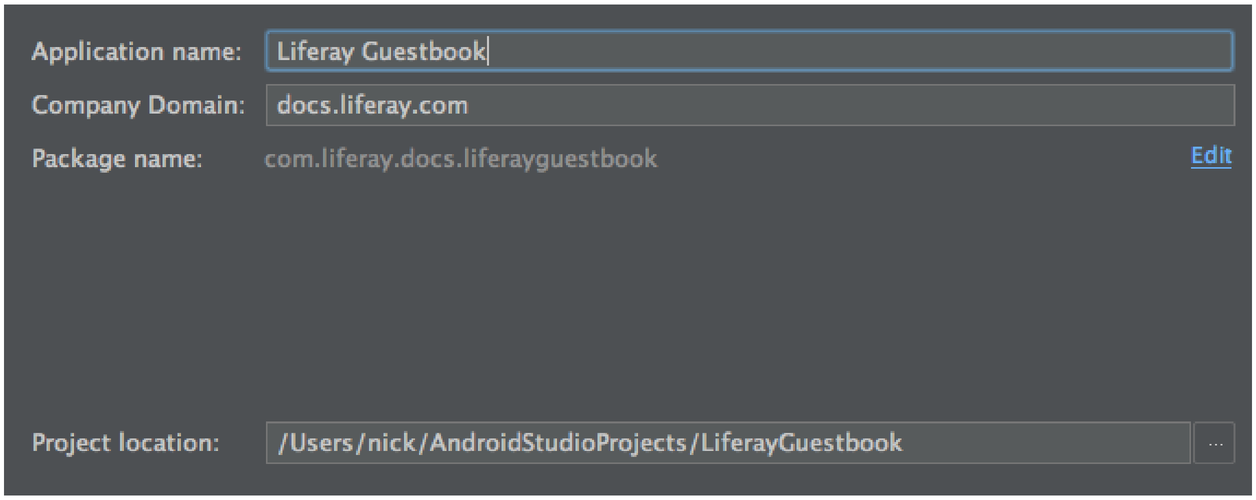
Creating the Guestbook App

When you start Android Studio, it presents a welcome screen containing a Quick Start menu. Click *Start a new Android Studio project* in this menu. This launches the *Create New Project* wizard, which asks you to enter the app name, company domain, and project location. Enter *Liferay Guestbook* as the app name and *docs.liferay.com* as the company domain. Android Studio uses these values to autofill your app's package name and project location. Accept the package name `com.liferay.docs.liferayguestbook`, and choose a project location that's convenient. Click *Next*.

The next screen asks you to specify your app's supported form factors and minimum Android SDK. Make sure that only the *Phone and Tablet* checkbox is selected. In the *Minimum SDK* menu, select *API 15: Android 4.0.3 (IceCreamSandwich)*. Android Studio gives you an estimate of the percentage of devices active on the Google Play store that can run the selected API level. You can view a graphical representation of these estimates by clicking the *Help me choose* link in the text below the Minimum SDK menu. Click *Next* when you're finished.

You must now specify your app's first activity. Although you'll use this activity to authenticate users to your Liferay DXP instance, don't select Login Activity. Select *Empty Activity* instead. Later, you'll insert Login Screenlet in this activity. Login Screenlet contains everything your users need to authenticate to a Liferay DXP instance, including the UI. Click *Next*.

The final screen of the New Project Wizard asks you to enter the activity's name and the name of its layout file. Accept the defaults and click *Finish*.



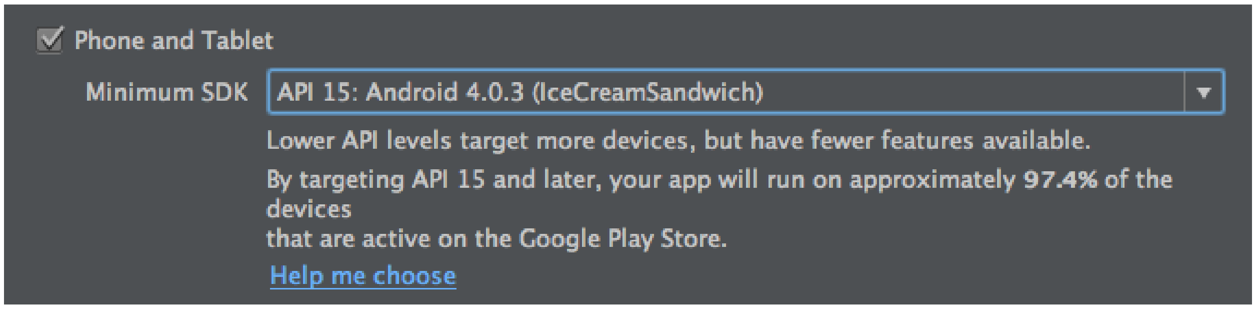
Application name: Liferay Guestbook

Company Domain: docs.liferay.com

Package name: com.liferay.docs.liferayguestbook

Project location: /Users/nick/AndroidStudioProjects/LiferayGuestbook

Figure 42.4: The first screen of Android Studio's Create New Project wizard asks you to enter your app's name and company domain.



☑ Phone and Tablet

Minimum SDK: API 15: Android 4.0.3 (IceCreamSandwich)

Lower API levels target more devices, but have fewer features available.

By targeting API 15 and later, your app will run on approximately **97.4%** of the devices that are active on the Google Play Store.

Figure 42.5: The second screen of Android Studio's Create New Project wizard lets you select your app's form factors and minimum Android API level.

A progress indicator appears that indicates your project is building. Android Studio then opens the project with the activity's class and layout ready to edit. The project's structure appears on the left side of the screen.

Well done! You successfully created the Guestbook app's project. Now it's time to put the Guestbook Mobile SDK and Liferay Screens to work!

42.4 Installing the Guestbook Mobile SDK and Liferay Screens for Android

For your Android app to interact with the Guestbook portlet, you must install the following libraries in your Android project:

- **Liferay's pre-built Mobile SDK:** This Mobile SDK contains the classes that call Liferay DXP's core remotes services. It also contains the framework necessary for any Mobile SDK to make server calls.
- **The Guestbook Mobile SDK:** This Mobile SDK contains only the classes that call the Guestbook portlet's remote services.

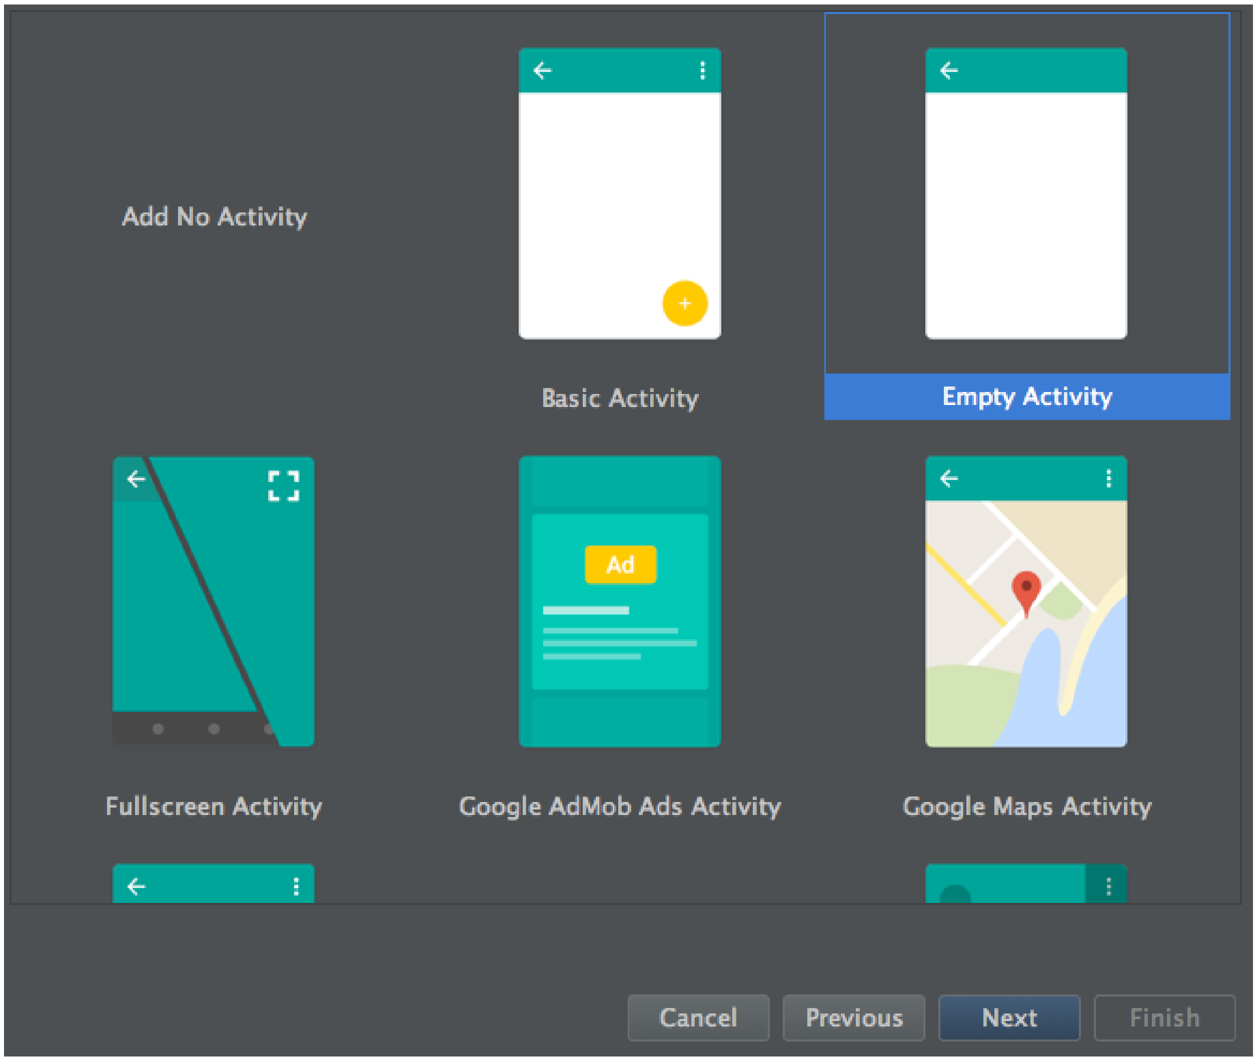


Figure 42.6: The third screen of Android Studio's Create New Project wizard lets you specify an activity for your app.

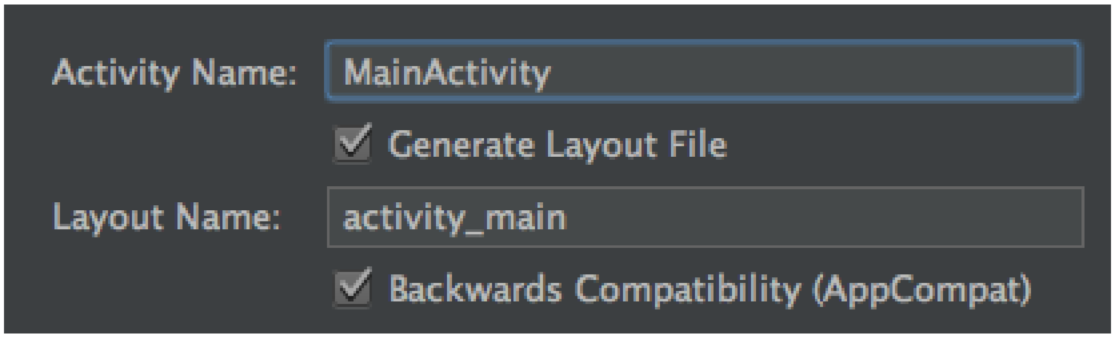


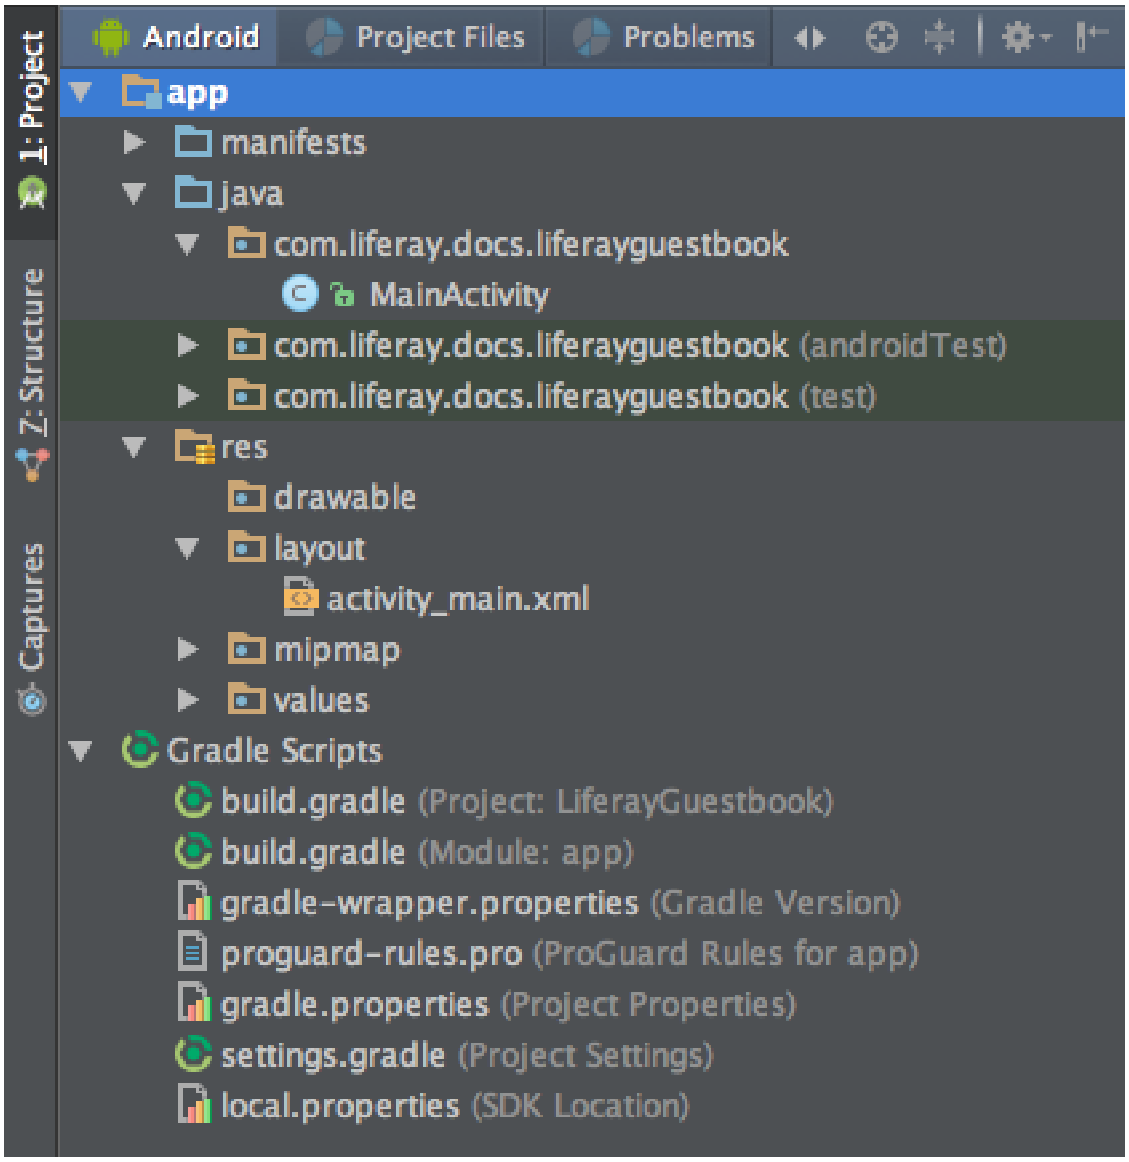
Activity Name: MainActivity

☑ Generate Layout File

Layout Name: activity_main

☑ Backwards Compatibility (AppCompat)

Figure 42.7: In the final screen of Android Studio's Create New Project wizard, accept the default values for the activity and layout name.



```
app
    manifests
    java
        com.liferay.docs.liferayguestbook
            MainActivity
        com.liferay.docs.liferayguestbook (androidTest)
        com.liferay.docs.liferayguestbook (test)
    res
        drawable
        layout
            activity_main.xml
        mipmap
        values
Gradle Scripts
    build.gradle (Project: LiferayGuestbook)
    build.gradle (Module: app)
    gradle-wrapper.properties (Gradle Version)
    proguard-rules.pro (ProGuard Rules for app)
    gradle.properties (Project Properties)
    settings.gradle (Project Settings)
    local.properties (SDK Location)
```

Figure 42.8: Android Studio shows your project's structure.

- **Liferay Screens:** Screens contains the Screenlet framework and several built-in Screenlets like Login Screenlet. Because these built-in Screenlets interact with Liferay DXP's core apps, they make their server calls with Liferay's pre-built Mobile SDK. Note that all Screenlets, including those that make server calls with a custom-built Mobile SDK, must use the framework in Liferay's pre-built Mobile SDK to issue their calls.

Since Liferay's pre-built Mobile SDK is a dependency of Liferay Screens, installing Screens automatically installs this Mobile SDK. You must, however, install the Guestbook Mobile SDK manually.

This article walks you through the installation of the Guestbook Mobile SDK and Liferay Screens. When you finish, you'll be ready to start developing the app.

Installing the Guestbook Mobile SDK

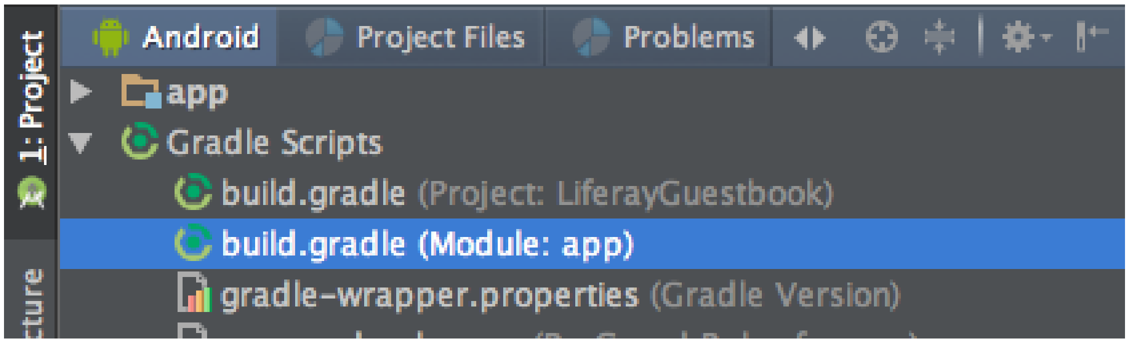
The Mobile SDK Builder generated two separate JAR files in your `liferay-mobile-sdk-android-7.0.6` folder:

1. `modules/gb/build/libs/liferay-gb-android-sdk-1.0.jar`
2. `android/build/libs/liferay-android-sdk-7.0.6.jar`

The first JAR file is the Guestbook Mobile SDK. The second JAR file is a custom built version of Liferay's pre-built Mobile SDK. Because Screens includes the pre-built Mobile SDK, you don't need to install the second JAR file. You must, however, install the first JAR file. To do so, copy `liferay-gb-android-sdk-1.0.jar` into your app's `app/libs` folder (the default location for your Android app is `AndroidStudioProjects/LiferayGuestbook`). That's it! Next, you'll install Liferay Screens.

Installing Liferay Screens

To install Liferay Screens, you must edit your app's `build.gradle` file. Note that your project has two `build.gradle` files: one for the project, and another for the app module. You can find them under *Gradle Scripts* in your Android Studio project. This screenshot highlights the app module's `build.gradle` file:



1: Project
Android
Project Files
Problems
app
Gradle Scripts
build.gradle (Project: LiferayGuestbook)
build.gradle (Module: app)
gradle-wrapper.properties (Gradle Version)

Figure 42.9: The app module's `build.gradle` file.

In the app module's `build.gradle` file, add the following lines of code inside the `dependencies` element:

```
compile 'com.liferay.mobile:liferay-screens:2.1.1'
compile 'com.liferay.mobile:liferay-material-viewset:2.1.1'
```

This adds the `liferay-screens` and `liferay-material-viewset` dependencies. Although only the `liferay-screens` dependency is necessary to install Screens, adding other View Sets, like the Material View Set, gives you flexibility when designing your app's look and feel. Click here for more information on Views in Liferay Screens.

Once you edit build.gradle, a message appears at the top of the file that asks you to sync your app with its Gradle files. Syncing with the Gradle files is required to incorporate any changes you make to them. Syncing also downloads and installs any new dependencies, like those you just added. Sync the Gradle files now by clicking the *Sync Now* link in the message.

Note that after syncing, your build.gradle may show an error similar to this:

```
All com.android.support libraries must use the exact same version specification...
```

If this occurs, you must manually add the correct version of the com.android.support dependencies. For example, the app in this Learning Path currently uses version 25.3.1 of the com.android.support libraries. This requires that you manually add the following dependencies to the app's build.gradle:

```
compile 'com.android.support:support-v4:25.3.1'
compile 'com.android.support:recyclerview-v7:25.3.1'
compile 'com.android.support:transition:25.3.1'
compile 'com.android.support:design:25.3.1'
compile 'com.android.support:exifinterface:25.3.1'
```

After adding these inside the dependencies element, click *Sync Now* again. The error message should be gone once the sync completes.

Great! Now you're ready to test your Screens and Mobile SDK installations.

Verifying the Installations

To check your Screens and Mobile SDK installations, first open your project's MainActivity class in Android Studio. It's in the java folder's com.liferay.docs.liferayguestbook package. Then add the following imports to this file:

```
import com.liferay.mobile.android.service.Session;
import com.liferay.mobile.android.v7.entry.EntryService;
import com.liferay.mobile.android.v7.guestbook.GuestbookService;
import com.liferay.mobile.screens.auth.login.LoginScreenlet;
```

If Android Studio recognizes these imports, then you're good to go! Remove them once you've verified that they're valid. Next, there's one final small but important task to complete: point your app at the correct Liferay DXP instance.

Configuring Communication with Liferay DXP

For Screens to work properly with your app, you must point it to your Liferay DXP instance. You do this by adding a server_context.xml file in your project's res/values directory. Create this file and add the following code to it:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

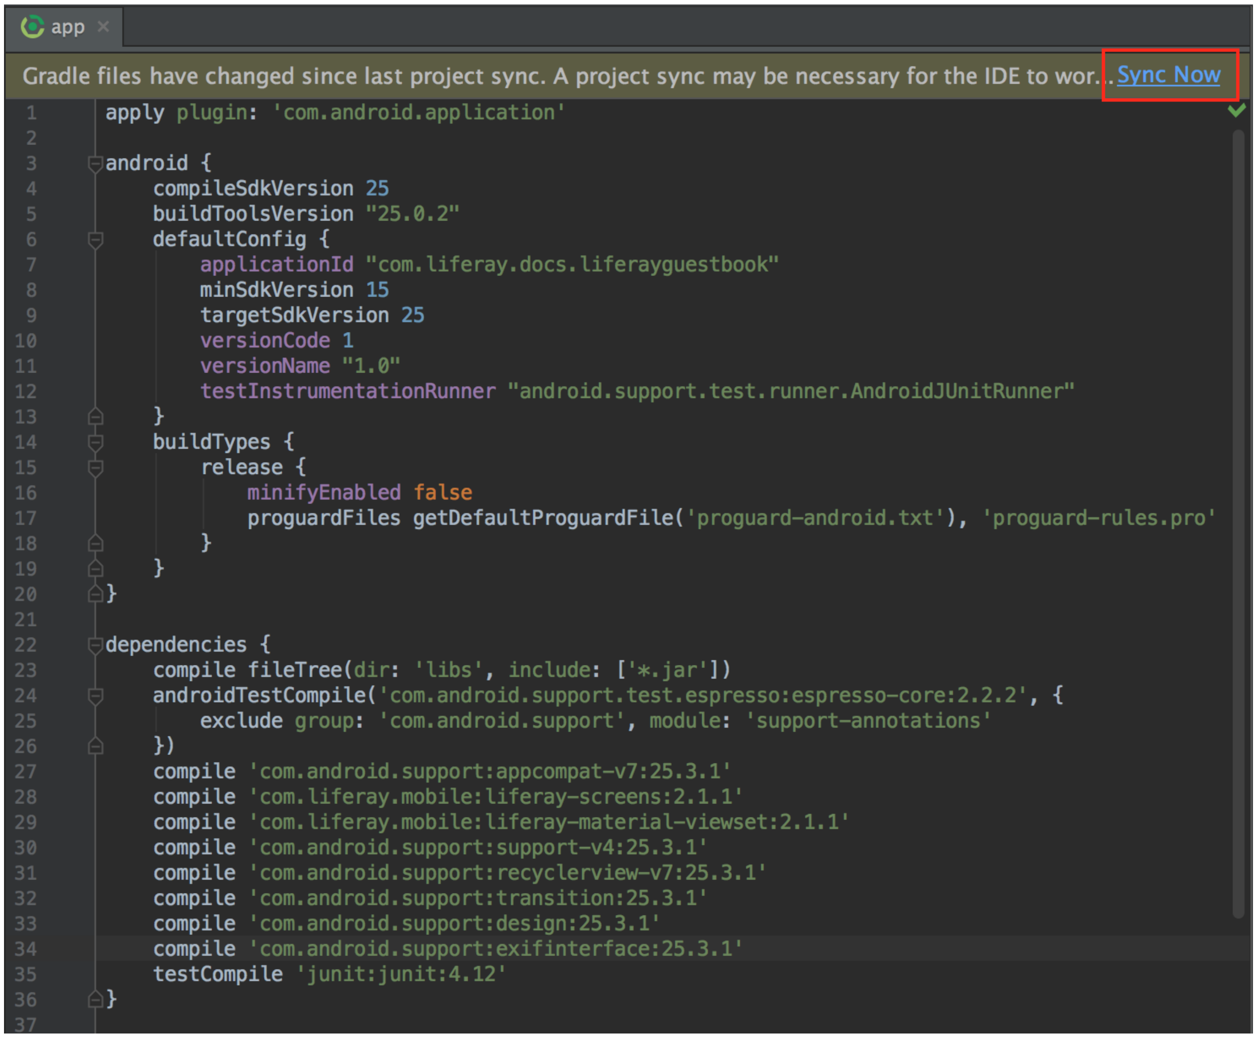
    <!-- Change these values for your portal instance -->

    <string name="liferay_server">http://10.0.2.2:8080</string>

    <integer name="liferay_company_id">20116</integer>
    <integer name="liferay_group_id">20147</integer>

    <integer name="liferay_portal_version">70</integer>

</resources>
```



app
Gradle files have changed since last project sync. A project sync may be necessary for the IDE to wor...
Sync Now

```
apply plugin: 'com.android.application'

android {
    compileSdkVersion 25
    buildToolsVersion "25.0.2"
    defaultConfig {
        applicationId "com.liferay.docs.liferayguestbook"
        minSdkVersion 15
        targetSdkVersion 25
        versionCode 1
        versionName "1.0"
        testInstrumentationRunner "android.support.test.runner.AndroidJUnitRunner"
    }
    buildTypes {
        release {
            minifyEnabled false
            proguardFiles getDefaultProguardFile('proguard-android.txt'), 'proguard-rules.pro'
        }
    }
}

dependencies {
    compile fileTree(dir: 'libs', include: ['*.jar'])
    androidTestCompile('com.android.support.test.espresso:espresso-core:2.2.2', {
        exclude group: 'com.android.support', module: 'support-annotations'
    })
    compile 'com.android.support:appcompat-v7:25.3.1'
    compile 'com.liferay.mobile:liferay-screens:2.1.1'
    compile 'com.liferay.mobile:liferay-material-viewset:2.1.1'
    compile 'com.android.support:support-v4:25.3.1'
    compile 'com.android.support:recyclerview-v7:25.3.1'
    compile 'com.android.support:transition:25.3.1'
    compile 'com.android.support:design:25.3.1'
    compile 'com.android.support:exifinterface:25.3.1'
    testCompile 'junit:junit:4.12'
}

```

Figure 42.10: After editing the app module's `build.gradle` file, click *Sync Now* to incorporate the changes in your app.

As the comment indicates, change the values to match those of your Liferay DXP instance. The server address `http://10.0.2.2:8080` is suitable for testing with Android Studio's emulator, because it corresponds to `localhost:8080` through the emulator. The Liferay DXP instance you set up earlier should be running on `localhost:8080`.

The `liferay_company_id` value is your Liferay DXP instance's ID. You can find it in your Liferay DXP instance at *Control Panel* → *Configuration* → *Virtual Instances*. The instance's ID is in the *Instance ID* column. Copy and paste this value into the `liferay_company_id` value in `server_context.xml`.

The `liferay_group_id` value is the ID of the site your app needs to communicate with. Since the app needs to communicate with the Guestbook portlet, navigate to the site you put the Guestbook portlet on. In the *Site Administration* menu, select *Configuration* → *Site Settings*. The site ID is listed at the top of the *General* tab. Copy and paste this value from your portal to the `liferay_group_id` value in `server_context.xml`.

Awesome! Next, you'll learn the app's basic design.

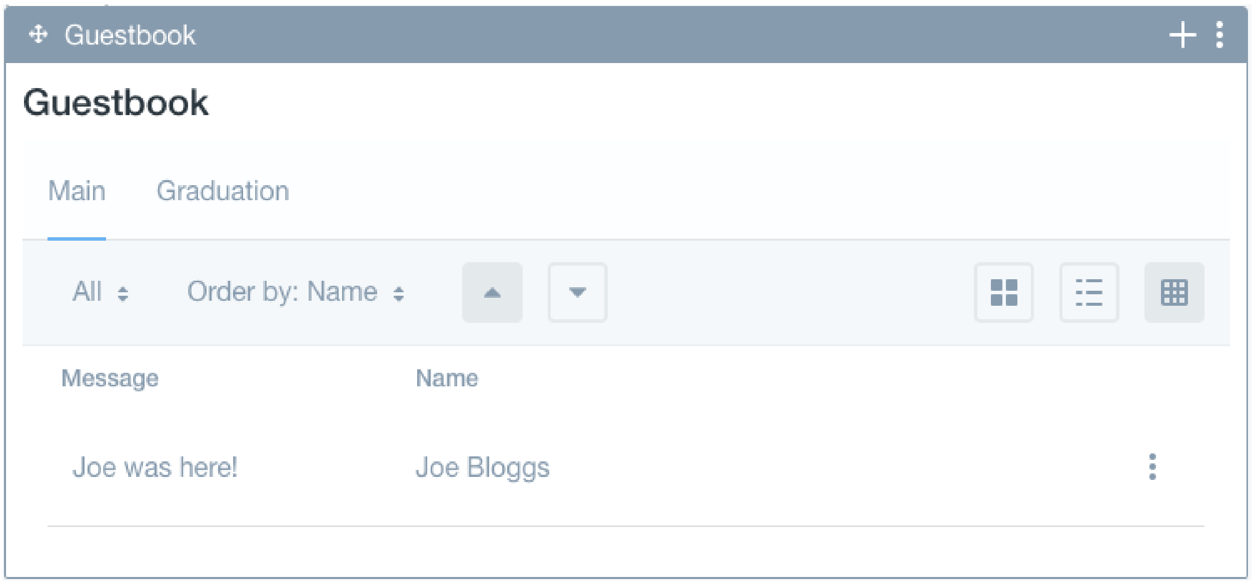
42.5 Designing Your App

As a developer, you know that developing any kind of app without an overall design goal and plan to implement it is a recipe for disaster. To avoid this, you need to decide some things upfront. The Liferay Guestbook app needs a straightforward way to do three things:

1. Authenticate users
2. Display guestbooks
3. Display entries

To authenticate users, all you need to do is insert and configure Login Screenlet in your app. Login Screenlet comes complete with its own UI. The design for authentication, therefore, like with Liferay DXP itself, is done for you.

You must, however, create the UI for displaying guestbooks and entries. What sort of UI would be best for this? Although the *best* UI for any purpose is a matter of opinion, displaying guestbooks and entries in a list is a good choice. Lists are common, compact design elements familiar to mobile users. Since most mobile devices don't have room to display a list of guestbooks and a list of entries at the same time, you also need a user-friendly way to display and manage these lists. It makes sense to show the first guestbook's entries automatically after the user authenticates. This is similar to the Guestbook portlet's design: it shows a list of the first guestbook's entries by default. When the user selects a different guestbook, you can then use the same UI to show the selected guestbook's entries instead.



Message	Name
Joe was here!	Joe Bloggs

Figure 42.11: By default, the first guestbook in the portlet is selected.

You must also decide how the users can select different guestbooks. Showing the list of guestbooks in a navigation drawer that slides out from the left side of the screen is a good choice. A navigation drawer is easily hidden and is a common Android UI element.

To display these lists of guestbooks and entries, you'll create your own Screenlets: Guestbook List Screenlet and Entry List Screenlet. Guestbook List Screenlet needs to retrieve guestbooks from the portlet and display them in a simple list. Once written, using this Screenlet is a simple matter of inserting it in the navigation drawer. Entry List Screenlet needs to retrieve and display a guestbook's entries in a similar list. You'll display the entries by inserting Entry List Screenlet in the UI element where you want it.

Also note that these Screenlets are *list Screenlets*. You develop list Screenlets by using the list Screenlet framework, which sits on top of the core Screenlet framework. The list Screenlet framework makes it easy for developers to write Screenlets that display lists of entities from a Liferay DXP instance.

Awesome! Now you have a basic UI design and know the Screenlets you'll create to implement it. But where in the app can you use these Screenlets? The app only contains one empty activity, `MainActivity`, which you'll use for authentication with Login Screenlet. To use your custom list Screenlets, you'll need to create an additional activity and a fragment: `GuestbooksActivity` and `EntriesFragment`. You'll create the activity in a moment.

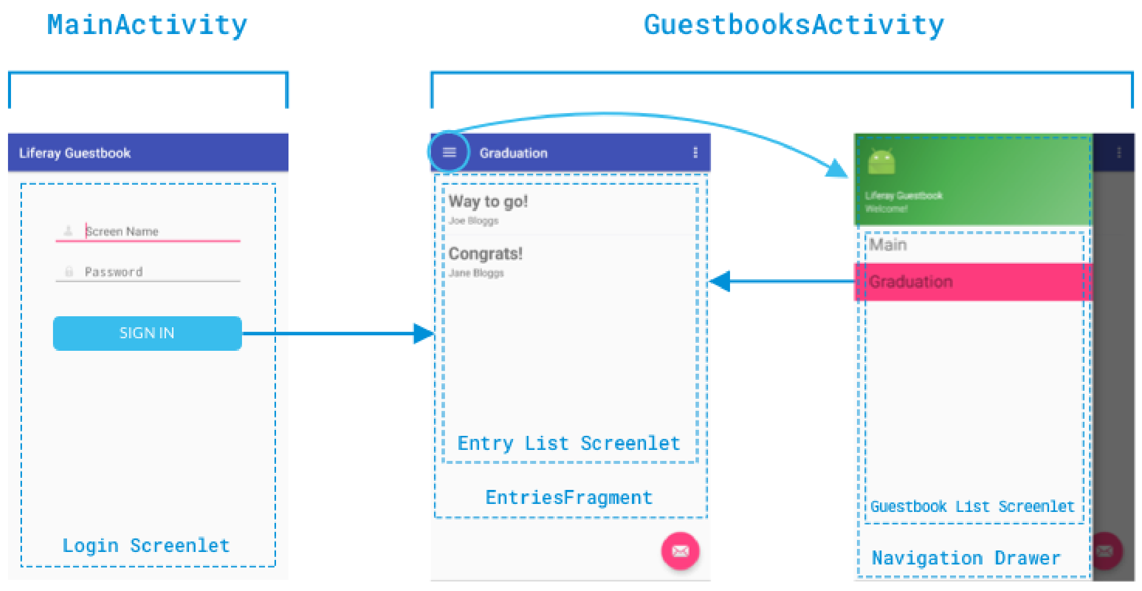


Figure 42.12: The Liferay Guestbook app's design uses two activities and a fragment. In this diagram, each activity and fragment is labeled, along with the Screenlets and the navigation drawer.

In addition to showing the app's components, this diagram shows how the user navigates through the app. After sign in, the user transitions to `GuestbooksActivity`. This activity uses Entry List Screenlet in `EntriesFragment` to display the selected guestbook's entries (the first guestbook is selected by default). Pressing the hamburger button at the top-left of this screen opens the navigation drawer, where Guestbook List Screenlet displays the list of guestbooks. Selecting a guestbook closes the drawer to reveal that guestbook's entries. Note that you only need one activity, `GuestbooksActivity`, to display guestbooks and entries. The navigation drawer and `EntriesFragment` are part of this activity.

Now you're ready to create `GuestbooksActivity`. Fortunately, Android Studio has a template for creating an activity that contains a navigation drawer. Follow these steps to create `GuestbooksActivity` with the navigation drawer template:

1. Right click the package `com.liferay.docs.liferayguestbook` and select *New* → *Activity* → *Navigation Drawer Activity* to launch the New Android Activity wizard.

2. Name the activity `GuestbooksActivity`, accept the defaults for the remaining fields, and click *Finish*.

3. After Android Studio creates the activity, the GuestbooksActivity class and content_guestbooks.xml layout open in the editor. Close them. You don't need to edit these files yet.

Great! Now you understand the Liferay Guestbook app's design. You also have the app structure in place. Next, you'll authenticate users by adding Login Screenlet to MainActivity.

42.6 Using Login Screenlet for Authentication

For the app to retrieve data from the Guestbook portlet, the user must first authenticate to the Liferay DXP instance. You can implement authentication using the Liferay Mobile SDK, but it takes time to write. Using Liferay Screens to authenticate takes about ten minutes. In this article, you'll use Login Screenlet to implement authentication in your app.

Adding Login Screenlet to the App

To use any Screenlet, you must follow two steps:

1. Insert the Screenlet's XML in the layout of the activity or fragment where you want the Screenlet to appear.

2. Implement the Screenlet's listener in the activity or fragment class.

In this app, you'll use Login Screenlet in MainActivity. This means you must insert the Screenlet's XML in MainActivity's layout, activity_main.xml. You'll then implement Login Screenlet's listener, LoginListener, in the MainActivity class.

Insert the Screenlet's XML

Follow these steps to insert Login Screenlet's XML in activity_main.xml:

1. Open activity_main.xml from the res/layout folder and delete the TextView generated by Android Studio when you created the project. Insert Login Screenlet's XML in its place:

   ```
   <com.liferay.mobile.screens.auth.login.LoginScreenlet
       android:id="@+id/login_screenlet"
       android:layout_width="match_parent"
       android:layout_height="match_parent"
       app:basicAuthMethod="screen_name"
       app:layoutId="@layout/login_default"
       />
   ```

   Note the two app attributes in the Login Screenlet's XML. The app:basicAuthMethod attribute tells the Screenlet to use basic authentication instead of OAuth. The screen_name value tells the Screenlet to authenticate with the user's screen name. You can alternatively set this to email or userId. This Learning Path uses screen_name only because it's much faster to type a screen name than a full email address in the emulator. Also, this value must match the authentication setting in the Liferay DXP instance. By default, Liferay DXP instances use email address for authentication. For this Learning Path, you need to set your Liferay DXP instance to authenticate by screen name instead. Click here for instructions on changing your Liferay DXP instance's authentication setting.

   The second app attribute in Login Screenlet's XML is app:layoutId. This attribute sets the *View* to display the Screenlet with. Views in Liferay Screens set a Screenlet's look and feel independent of the Screenlet's core functionality. You can think of them as a sort of skin or theme for a Screenlet. The value `@layout/login_default` specifies Login Screenlet's Default View, which is part of the Default *View Set*. A View Set is a collection of Views for several Screenlets. Using a View Set lets you apply a consistent look and feel across multiple Screenlets. To use a View that is part of a View Set, like Login Screenlet's Default View, the theme of the app or activity must inherit the theme that sets the View Set's styles. For the Default View Set, this is `default_theme`.

2. To set the app's theme to inherit from `default_theme`, open `res/values/styles.xml` and set the base app theme's parent to `default_theme`. In this app, the base app theme is `AppTheme`. The theme declaration should now look like this:

```
<style name="AppTheme" parent="default_theme">
    ...
```

Click here for more information on using Views in Liferay Screens. For more information on Login Screenlet's available attributes, click here.

Next, you'll implement `LoginListener` in the `MainActivity` class.

Implement the Screenlet's Listener

To use a Screenlet in an activity or fragment, you must also implement the Screenlet's listener in that activity or fragment's class. You'll do this now to use Login Screenlet in `MainActivity`:

1. Open `MainActivity` and change its declaration to implement `LoginListener`. The class declaration should now look like this:

```
public class MainActivity extends AppCompatActivity implements LoginListener {...
```

   You must also import `com.liferay.mobile.screens.auth.login.LoginListener`.

2. Implementing `LoginListener` requires you to implement the `onLoginSuccess` and `onLoginFailure` methods. Add them to the class as follows:

```
@Override
public void onLoginSuccess(User user) {
    Toast.makeText(this, "Login successful!", Toast.LENGTH_SHORT).show();
}

@Override
public void onLoginFailure(Exception e) {
    Toast.makeText(this, "Couldn't log in " + e.getMessage(), Toast.LENGTH_LONG).show();
}
```

   When you add these methods, you must import `android.widget.Toast` and `com.liferay.mobile.screens.context.User`.

   These are listener methods called when login succeeds or fails, respectively. Using them lets your app respond the Screenlet's actions. For the moment, they each only do one thing: display a success or failure message to the user. You'll change this shortly. Note that each Screenlet has different listener methods; they're listed in the Screenlet reference documentation.

3. Now you must get a reference to the Screenlet and set the `MainActivity` class as its listener. To do so, add the following code to the end of the `onCreate` method:

```
LoginScreenlet loginScreenlet = (LoginScreenlet) findViewById(R.id.login_screenlet);
loginScreenlet.setListener(this);
```

This requires you to import `com.liferay.mobile.screens.auth.login.LoginScreenlet`.

The `findViewById` method uses the Screenlet's ID from the layout to create the reference. The `setListener` method then sets `MainActivity` as Login Screenlet's listener.

Now run the app by clicking the green *play* button in the toolbar, or by selecting *Run 'app'* from the *Run* menu. If you've never run the emulator, you must first create and choose an Android Virtual Device (AVD) to run your app. For more information on this and running the emulator in general, click here. Once the emulator launches, unlock it if necessary. Your app automatically opens to Login Screenlet. Enter your credentials and click *SIGN IN*. The toast message pops up saying that the login succeeded.

The toast message goes away and you remain on the login screen. Nothing else happens. Don't worry, this is supposed to happen; you haven't added any other functionality yet. You'll fix this next.

Navigating from Login Screenlet

When login succeeds, the app should open `GuestbooksActivity`. You'll do this by using an Android intent in `MainActivity`'s `onLoginSuccess` method:

1. Replace the contents of `onLoginSuccess` with this code:

   ```
   Intent intent = new Intent(this, GuestbooksActivity.class);
   startActivity(intent);
   ```

   When login succeeds, this code creates an `Intent` and uses it to start `GuestbooksActivity`. If you haven't already, make sure to import `android.content.Intent` in `MainActivity`.

2. Now you're ready to see the intent in action! Run the app in the emulator and log in when prompted. When login succeeds, `GuestbooksActivity` opens.

Nice work! You successfully implemented Liferay DXP authentication in your Android app. It didn't take you that long, either. So far, however, that's all your app does; it doesn't display any content. Next, you'll rectify this by developing Guestbook List Screenlet.

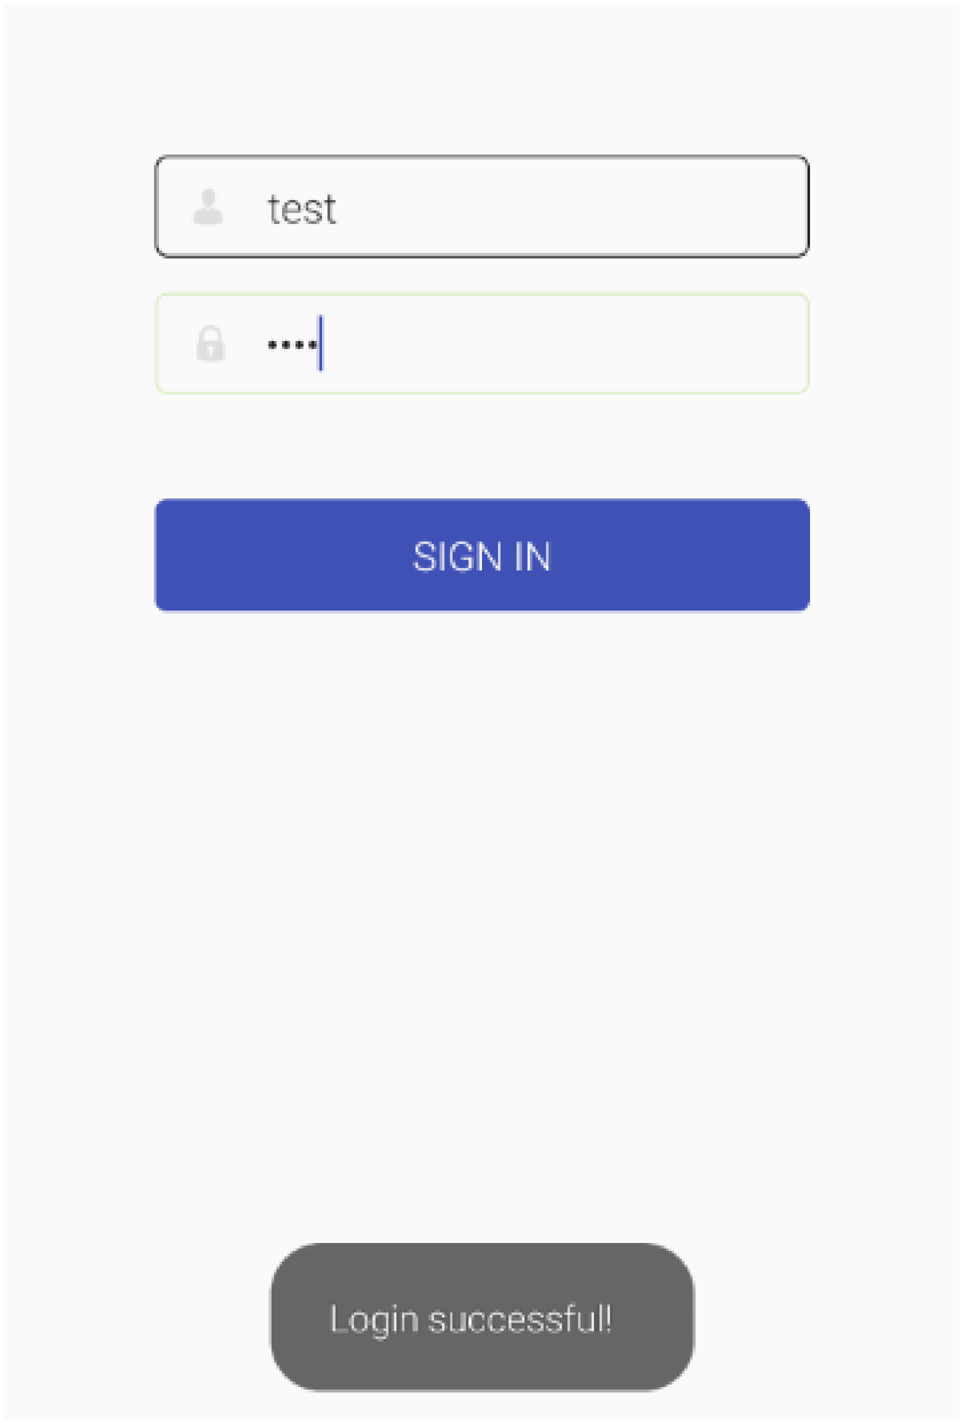

Figure 42.13: Login Screenlet successfully authenticated you with the Liferay DXP instance.

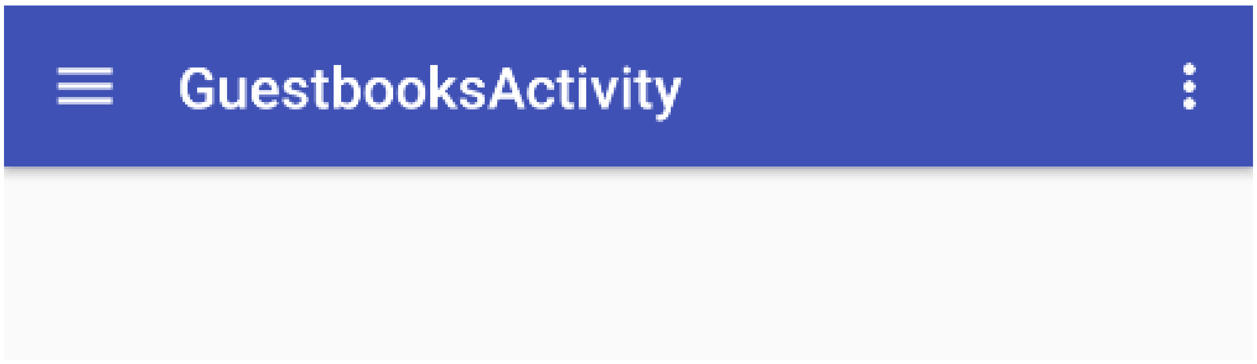

Figure 42.14: Upon login, the app takes you to the new activity.

Chapter 43

Creating Guestbook List Screenlet

In the previous section, you created an Android app that contains the Guestbook Mobile SDK and Liferay Screens. You also used Login Screenlet to implement authentication to Liferay DXP. That's all your app does though. It doesn't display any Guestbook portlet content. In this section of the Learning Path, you'll create Guestbook List Screenlet to retrieve and display the portlet's guestbooks in your app's navigation drawer.

Creating your own Screenlets brings additional benefits. Since you use a consistent, repeatable development model to create them, you can often reuse code when creating other Screenlets. You can also package and reuse Screenlets in other apps. What's more, Screenlet UIs are fully pluggable. This lets you change a Screenlet's appearance quickly without affecting its functionality. In summary, Screenlets are pretty much the greatest thing since sliced bread. Now it's time to make a sandwich.

As background material, the following materials are helpful:

1. Getting started: creating the Screenlet's package, and model class.

2. Creating the Screenlet's UI (its View).

3. Creating the Screenlet's Interactor. Interactors are Screenlet components that make server calls.

4. Creating the Screenlet class. The Screenlet class governs the Screenlet's behavior.

Before beginning, you should read the following tutorials:

- Architecture of Liferay Screens for Android: Explains the components that constitute a Screenlet, and how they relate to one another.

- Creating Android Screenlets: Explains the general steps for creating a Screenlet.

- Creating Android List Screenlets: Explains the general steps for creating a list Screenlet. This section of the Learning Path follows this tutorial.

Note that these tutorials explain Screenlet and list Screenlet concepts that this Learning Path doesn't cover in depth. Although it's possible to complete this Learning Path without reading these tutorials, they explain how Screenlets work in more detail. By reading them you'll be better able to apply the Learning Path material to your own Screenlets.

If you get confused or stuck while creating Guestbook List Screenlet, refer to the finished app that contains the Screenlet code here in GitHub.

43.1 Getting Started with Guestbook List Screenlet

Before creating a Screenlet, you should know how you'll use it. If you plan to use it in only one app, then you can create it in that app's project. If you need to use it in several apps, however, then it's best to create it in a separate project for redistribution. For information on creating Screenlets for redistribution, see the tutorial Packaging Your Android Screenlets. Since you'll use Guestbook List Screenlet in only this app, you can create it in a new package inside the app's project. Create this package now:

1. In Android Studio, right click the *java* folder and select *New → Package*.
2. Select *.../app/src/main/java* as the destination directory, and click *OK*.
3. Enter `com.liferay.docs.guestbooklistscreenlet` as the package's name and click *OK*. Android Studio lists the new package alongside the package that contains the app's activity and fragment (`liferayguestbook`). If it doesn't appear at first, you may need to collapse and reopen the *java* folder.

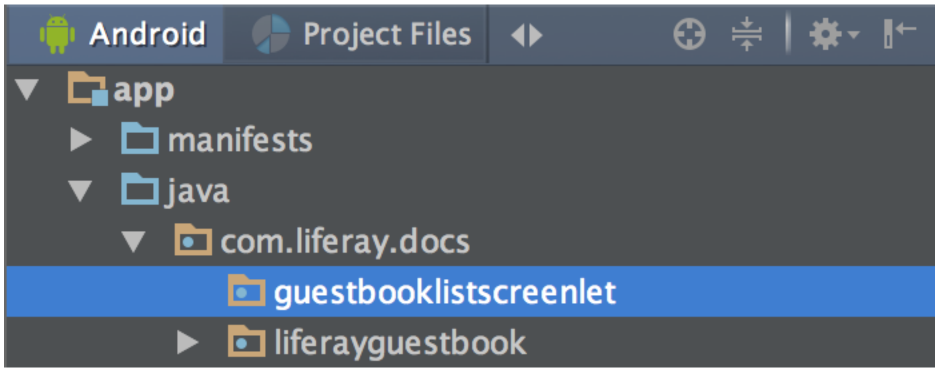

Figure 43.1: Guestbook List Screenlet's new package is highlighted.

Before getting started, you should understand how pagination works in list Screenlets.

Pagination

To ensure that users can scroll smoothly through large lists of items, list Screenlets support fluent pagination. Support for this is built into the list Screenlet framework. You'll see this as you construct your list Screenlet. For example, several methods have parameters for the start row and end row of a page in the list.

Now you're ready to begin!

Creating the Model Class for Guestbooks

Entities come back from Liferay Portal in JSON. To work with these results efficiently in your app, you must convert them to model objects that represent the entity in the portal. Although Screens's `BaseListInteractor` transforms the JSON entities into `Map` objects for you, you still must convert these into proper entity objects for use in your app. You'll do this via a model class.

The model class you'll create for Guestbook List Screenlet, `GuestbookModel`, creates `GuestbookModel` objects that represent guestbooks retrieved from the Guestbook portlet. You'll create this model class in a separate package outside of the `guestbooklistscreenlet` package. In this case, it makes sense to organize your code this way because other Screenlets may also use the model class. For example, if a Screenlet that edits guestbooks existed, it would also need `GuestbookModel` objects. Putting the model class in a separate package makes it clear that this class doesn't belong exclusively to a single Screenlet.

Follow these steps to create `GuestbookModel`:

1. Create a new package called `model` inside the `com.liferay.docs` package.

2. Inside this new `model` package, create a new class called `GuestbookModel`.

3. Replace `GuestbookModel`'s contents with this code:

```
package com.liferay.docs.model;

import android.os.Parcel;
import android.os.Parcelable;

import java.util.Date;
import java.util.Map;

public class GuestbookModel implements Parcelable {

    private Map values;
    private long guestbookId;
    private long groupId;
    private long companyId;
    private long userId;
    private String userName;
    private long createDate;
    private long modifiedDate;
    private String name;

    public static final Creator<GuestbookModel> CREATOR = new Creator<GuestbookModel>() {
        @Override
        public GuestbookModel createFromParcel(Parcel in) {
            return new GuestbookModel(in);
        }

        @Override
        public GuestbookModel[] newArray(int size) {
            return new GuestbookModel[size];
        }
    };

    public GuestbookModel() {
        super();
    }

    protected GuestbookModel(Parcel in) {
        guestbookId = in.readLong();
        groupId = in.readLong();
        companyId = in.readLong();
        userId = in.readLong();
        userName = in.readString();
        createDate = in.readLong();
        modifiedDate = in.readLong();
        name = in.readString();
    }

    public GuestbookModel(Map<String, Object> stringObjectMap) {
        values = stringObjectMap;
        guestbookId = Long.parseLong((String) stringObjectMap.get("guestbookId"));
        groupId = Long.parseLong((String) stringObjectMap.get("groupId"));
        companyId = Long.parseLong((String) stringObjectMap.get("companyId"));
        userId = Long.parseLong((String) stringObjectMap.get("userId"));
        userName = (String) stringObjectMap.get("userName");
        createDate = (long) stringObjectMap.get("createDate");
```

```
            modifiedDate = (long) stringObjectMap.get("modifiedDate");
            name = (String) stringObjectMap.get("name");
        }

        @Override
        public void writeToParcel(Parcel dest, int flags) {
            dest.writeLong(guestbookId);
            dest.writeLong(groupId);
            dest.writeLong(companyId);
            dest.writeLong(userId);
            dest.writeString(userName);
            dest.writeLong(createDate);
            dest.writeLong(modifiedDate);
            dest.writeString(name);
        }

        @Override
        public int describeContents() {
            return 0;
        }

        public long getGuestbookId() {
            return guestbookId;
        }

        public long getGroupId() {
            return groupId;
        }

        public long getCompanyId() {
            return companyId;
        }

        public long getUserId() {
            return userId;
        }

        public String getUserName() {
            return userName;
        }

        public Date getCreateDate() {
            return new Date(createDate);
        }

        public Date getModifiedDate() {
            return new Date(modifiedDate);
        }

        public String getName() {
            return name;
        }

        public Map getValues() {
            return values;
        }

        public void setValues(Map values) {
            this.values = values;
        }
    }
```

This class creates `GuestbookModel` objects that represent the Guestbook portlet's `Guestbook` objects. The constructor with the `Map<String, Object>` argument does the heavy lifting. Following a successful Mobile SDK call, the list Screenlet framework's `BaseListInteractor` class returns this `Map`, which contains the data of a guestbook retrieved from the portlet. To get the guestbook's data from the `Map`, the constructor uses the `get` method with each parameter of the portlet's `Guestbook` entity. To see how the portlet defines these parameters, see the Liferay MVC Learning Path article on Service Builder. For now, the only parameters you really need in `GuestbookModel` are `guestbookId` and `name`. Because you might need the rest later, however, it's best to add all of them now.

Besides the getters and setter, the remaining code in `GuestbookModel` implements Android's `Parcelable` interface. For more information on this, see Android's documentation on `Parcelable`.

Great! Now you have a model class for guestbooks. Next, you'll create the Screenlet's UI.

43.2 Creating Guestbook List Screenlet's UI

Recall that in Liferay Screens for Android, Screenlet UIs are called Views, and every Screenlet must have at least one View. In this article, you'll use the following steps to create a View for Guestbook List Screenlet:

1. Create the row layout. This layout defines the UI for each row instance in the list.

2. Create the adapter class. This is an Android adapter that fills a row layout instance with the data for one list item. This repeats for each list item until the list is full.

3. Create the View class. This class renders the UI, handles user interactions, and communicates with the Screenlet class.

4. Create the View's layout. This layout defines the Screenlet's UI as a whole. For a list Screenlet, this is a scrollable list.

Note that these are the same steps for creating a View as those in the list Screenlet tutorial.

You'll create Guestbook List Screenlet's View in its own package inside the `guestbooklistscreenlet` package. Create a new package named `view` inside the `guestbooklistscreenlet` package. Now you're ready to create the row layout.

Creating the Row Layout

First, you must create the layout that defines the UI for each row instance in the list. Since each row in Guestbook List Screenlet displays only a single guestbook's name, the row layout only needs a single `TextView`. Create the layout file `res/layout/guestbook_row.xml` and paste in this content:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/guestbook_name"
        android:textSize="25sp"
        android:padding="10dp"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```

Note that the `textSize` and `padding` values result in clean, readable text for this example. When you develop your own list Screenlets, you can style your row layouts however you like.

Creating the Adapter Class

Android adapters fill a layout with content. In Guestbook List Screenlet, the layout is `guestbook_row.xml` (the row layout) and the content is a guestbook's name. To make list scrolling smooth, the adapter class should use an Android view holder. To make this easier, you can extend the list Screenlet framework's `BaseListAdapter` class with your model class and view holder as type arguments. By extending `BaseListAdapter`, your adapter needs only two methods:

- `createViewHolder`: instantiates the view holder
- `fillHolder`: fills in the view holder for each row

Your view holder should also contain variables for any data each row needs to display. The view holder must assign these variables to the corresponding row layout elements, and set the appropriate data to them.

Inside the Screenlet's `view` package, create the following `GuestbookAdapter` class:

```
package com.liferay.docs.guestbooklistscreenlet.view;

import android.support.annotation.NonNull;
import android.view.View;
import android.widget.TextView;

import com.liferay.docs.liferayguestbook.R;
import com.liferay.docs.model.GuestbookModel;
import com.liferay.mobile.screens.base.list.BaseListAdapter;
import com.liferay.mobile.screens.base.list.BaseListAdapterListener;

public class GuestbookAdapter extends
    BaseListAdapter<GuestbookModel, GuestbookAdapter.GuestbookViewHolder> {

    public GuestbookAdapter(int layoutId, int progressLayoutId, BaseListAdapterListener listener) {
        super(layoutId, progressLayoutId, listener);
    }

    @NonNull
    @Override
    public GuestbookViewHolder createViewHolder(View view, BaseListAdapterListener listener) {
        return new GuestbookAdapter.GuestbookViewHolder(view, listener);
    }

    @Override
    protected void fillHolder(GuestbookModel entry, GuestbookViewHolder holder) {
        holder.bind(entry);
    }

    public class GuestbookViewHolder extends BaseListAdapter.ViewHolder {

        private final TextView name;

        public GuestbookViewHolder(View view, BaseListAdapterListener listener) {
            super(view, listener);

            name = (TextView) view.findViewById(R.id.guestbook_name);
        }

        public void bind(GuestbookModel entry) {
            name.setText(entry.getName());
        }

    }
}
```

This adapter class extends `BaseListAdapter` with `GuestbookModel` and `GuestbookAdapter.GuestbookViewHolder` as type arguments. The view holder is an inner class that extends `BaseListAdapter`'s view holder. Since

Guestbook List Screenlet only needs to display a guestbook's name in each row, the view holder only needs one variable: `name`. The view holder's constructor assigns the `TextView` from `guestbook_row.xml` to this variable. The `bind` method then sets the guestbook's name as the `TextView`'s text. The other methods in `GuestbookAdapter` leverage the view holder. The `createViewHolder` method instantiates `GuestbookViewHolder`. The `fillHolder` method calls the view holder's `bind` method to set the guestbook's name as the `name` variable's text.

Next, you'll create the View class.

Creating the View Class

Recall that the View class controls a Screenlet's UI. It renders the UI, handles user interactions, and communicates with the Screenlet class. The list Screenlet framework provides most of this functionality for you via the `BaseListScreenletView` class. Your View class must extend this class to provide your row layout ID and an instance of your adapter. You'll do this by overriding `BaseListScreenletView`'s `getItemLayoutId` and `createListAdapter` methods. Also, when you extend `BaseListScreenletView` you must do so with your model class, view holder, and adapter as type arguments. This is required for your View class to represent your model objects in a view holder, inside an adapter.

Create the `GuestbookListView` class inside the `view` package, and replace its contents with this code:

```
package com.liferay.docs.guestbooklistscreenlet.view;

import android.content.Context;
import android.util.AttributeSet;

import com.liferay.docs.liferayguestbook.R;
import com.liferay.docs.model.GuestbookModel;
import com.liferay.mobile.screens.base.list.BaseListScreenletView;

public class GuestbookListView extends BaseListScreenletView<GuestbookModel,
    GuestbookAdapter.GuestbookViewHolder, GuestbookAdapter> {

    public GuestbookListView(Context context) {
        super(context);
    }

    public GuestbookListView(Context context, AttributeSet attributes) {
        super(context, attributes);
    }

    public GuestbookListView(Context context, AttributeSet attributes, int defaultStyle) {
        super(context, attributes, defaultStyle);
    }

    @Override
    protected GuestbookAdapter createListAdapter(int itemLayoutId, int itemProgressLayoutId) {
        return new GuestbookAdapter(itemLayoutId, itemProgressLayoutId, this);
    }

    @Override
    protected int getItemLayoutId() {
        return R.layout.guestbook_row;
    }
}
```

This View class represents `GuestbookModel` instances in a `GuestbookViewHolder` inside a `GuestbookAdapter`. This class therefore extends `BaseListScreenletView` parameterized with `GuestbookModel`, `GuestbookAdapter.GuestbookViewHold` and `GuestbookAdapter`. Besides overriding `createListAdapter` to return a `GuestbookAdapter` instance, the only other functionality that this View class needs to support is to get the layout for each row in the list. The overridden `getItemLayoutId` method does this by returning the row layout `guestbook_row`.

Now you're ready to create your View's main layout.

Creating the View's Layout

Although you already created a layout for your list rows, you must still create a layout to define the list as a whole. This layout must contain:

- The View class's fully qualified name as the layout's first element.
- An Android `RecyclerView` to let your app efficiently scroll through a potentially large list of items.
- An Android `ProgressBar` to indicate progress when loading the list.

Apart from the View class and styling, this layout's code is the same for all list Screenlets.

Create the layout file `res/layout/list_guestbooks.xml` and replace its contents with this code:

```
<com.liferay.docs.guestbooklistscreenlet.view.GuestbookListView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/liferay_list_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ProgressBar
        android:id="@+id/liferay_progress"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:visibility="gone"/>

    <android.support.v7.widget.RecyclerView
        android:id="@+id/liferay_recycler_list"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:visibility="gone"/>
</com.liferay.docs.guestbooklistscreenlet.view.GuestbookListView>
```

Note that the `android:id` values in this layout XML are hardcoded into the Screens framework and changing them will cause your app to crash.

Great! You're done with Guestbook List Screenlet's View. Next, you'll create the Screenlet's Interactor.

43.3 Creating Guestbook List Screenlet's Interactor

Interactors are Screenlet components that make server calls and process the results. Interactors themselves are made up of several components:

1. **The event class:** creates event objects that contain the server call's results. Liferay Screens uses these event objects via the EventBus library to communicate the results between the Screenlet's components.

2. **The listener interface:** defines the methods the app developer needs to respond to the Screenlet's behavior. For example, Login Screenlet's listener defines the `onLoginSuccess` and `onLoginFailure` methods. Screens calls these methods when login succeeds or fails, respectively. By implementing these methods in the activity or fragment class that contains the Screenlet, the app developer can respond to login success and failure.

3. **The Interactor class:** makes the server calls, processes the results in the event objects, and notifies the listener of those results.

Since the list Screenlet framework already contains two listener interfaces, you only need to create the event and Interactor classes. You'll create the event class first.

Creating the Event Class

1. First, create a new package called `interactor` in the `com.liferay.docs.guestbooklistscreenlet` package. You'll create your Interactor's components in this new package.

2. A list Screenlet's event class must extend the `ListEvent` class with the Screenlet's model class as a type argument. This lets the event class contain the server call's results as model objects. Guestbook List Screenlet's event class, `GuestbookEvent`, must therefore extend `ListEvent` with `GuestbookModel` as a type argument. Create this class now in the `interactor` package. The class declaration should look like this:

   ```
   public class GuestbookEvent extends ListEvent<GuestbookModel> {...
   ```

   This requires you to import `com.liferay.docs.model.GuestbookModel` and `com.liferay.mobile.screens.base.list.intera`

3. The event class should also contain a private instance variable for the model class, a constructor that sets this variable, and a no-argument constructor that calls the superclass constructor. Add this code now:

   ```
   private GuestbookModel guestbook;

   public GuestbookEvent() {
       super();
   }

   public GuestbookEvent(GuestbookModel guestbook) {
       this.guestbook = guestbook;
   }
   ```

4. You must also implement `ListEvent`'s abstract methods in your event class. Note that these methods support offline mode. Even though Guestbook List Screenlet doesn't support offline mode, you must still implement these methods. Add these methods to `GuestbookEvent` now:

   - `getListKey`: returns the ID for the cache. This ID is typically the data each list row displays. For example, the `getListKey` method in `GuestbookEvent` returns the guestbook's name:

     ```
     @Override
     public String getListKey() {
         return guestbook.getName();
     }
     ```

   - `getModel`: unwraps the model entity to the cache by returning the model class instance. For example, the `getModel` method in `GuestbookEvent` method returns the guestbook:

     ```
     @Override
     public GuestbookModel getModel() {
         return guestbook;
     }
     ```

Note that this code is almost identical to the example event class in the list Screenlet tutorial. The only difference is that `GuestbookEvent` handles `GuestbookModel` objects.

Nice work! Your event class is done. You're almost ready to write the Screenlet's server call. First, however, you should understand the basics of how server calls work in Interactors.

Understanding Screenlet Server Calls

Recall that Interactor classes use the Liferay Mobile SDK to make server calls and process the results. An Interactor class does this with the following sequence:

1. Get the Mobile SDK session and use it to create the Mobile SDK service you want to call.
2. Invoke the Mobile SDK service method that makes the server call.
3. Create an event object from the JSON that the server call returns. If your Screenlet has a model class, create a model object from this JSON, then use the model object to create the event object.

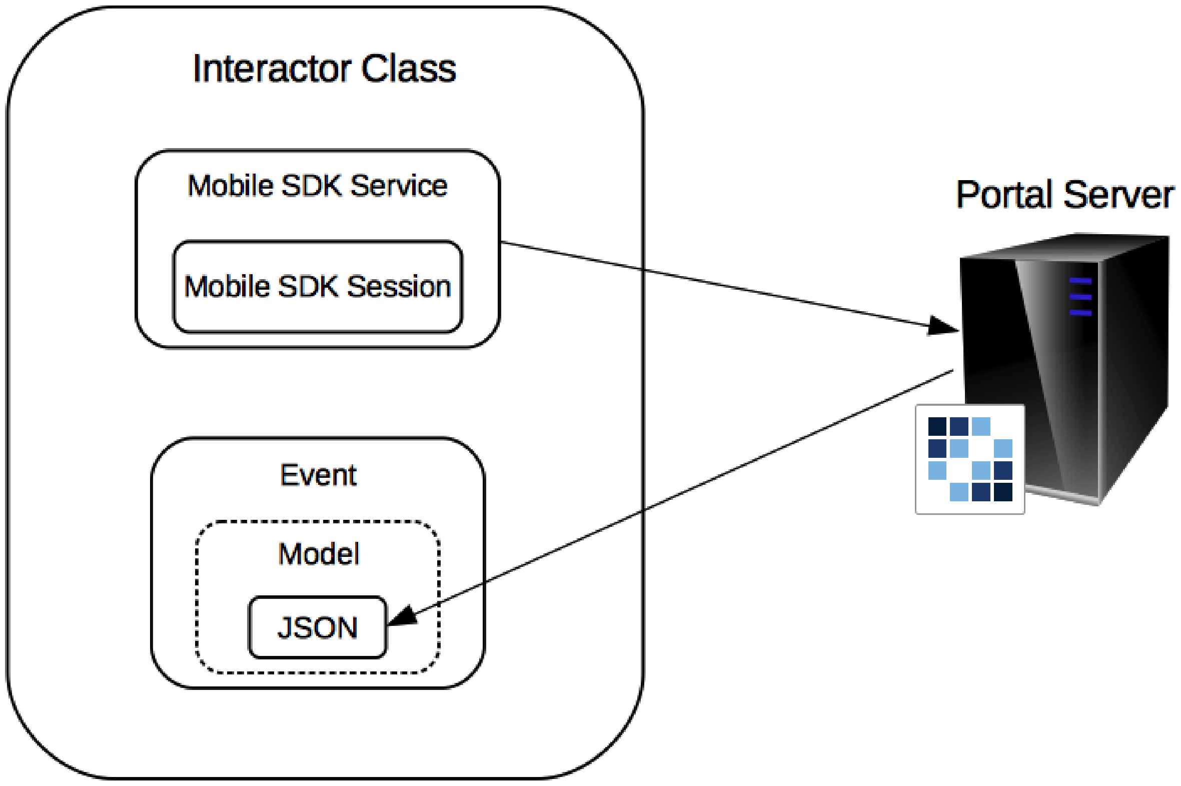

Figure 43.2: This diagram shows a typical server call made by a Screenlet's Interactor. The dashed line around the model class indicates that it's optional. Although list Screenlets require model classes, non-list Screenlets don't.

To call the Guestbook portlet's remote services, you'll use the Guestbook Mobile SDK you built and installed earlier. This Mobile SDK contains the services required to call the Guestbook portlet's remote services. Next, you'll create Guestbook List Screenlet's Interactor class.

Creating the Interactor Class

A Screenlet's Interactor class is the central component of the Interactor. It makes the server calls, processes the results in the event objects, and notifies the listener of those results. The list Screenlet framework's `BaseListInteractor` class provides most of the functionality that Interactor classes in list Screenlets require.

You must, however, extend `BaseListInteractor` to make your service calls and handle their results via your model and event classes.

Follow these steps to create Guestbook List Screenlet's Interactor class, `GuestbookListInteractor`:

1. Create the `GuestbookListInteractor` class in the package `com.liferay.docs.guestbooklistscreenlet.interactor`. A list Screenlet's Interactor class must extend `BaseListInteractor` with `BaseListInteractorListener<YourModelClass>` and your event class as type arguments. You must therefore change `GuestbookListInteractor` to extend `BaseListInteractor` with `BaseListInteractorListener<GuestbookModel>` and `GuestbookEvent` as type arguments:

   ```
   public class GuestbookListInteractor extends
       BaseListInteractor<BaseListInteractorListener<GuestbookModel>, GuestbookEvent> {...
   ```

   This requires that you add the following imports:

   ```
   import com.liferay.docs.model.GuestbookModel;
   import com.liferay.mobile.screens.base.list.interactor.BaseListInteractor;
   import com.liferay.mobile.screens.base.list.interactor.BaseListInteractorListener;
   ```

2. Override the `getPageRowsRequest` method to retrieve a page of entities. In this method, you can use the `getSession()` method to retrieve the session created by authentication with Login Screenlet. Then make the server call by creating a service instance from the session and calling the service method that retrieves the entities. Guestbook List Screenlet must retrieve a page of guestbooks, so you must create a `GuestbookService` instance from the session. Then call the service's `getGuestbooks` method with the `groupId`, start row, and end row. The `groupId` specifies the site to retrieve guestbooks from, while the start row and end row define the list rows that mark the start and end of the page of guestbooks, respectively. Add this `getPageRowsRequest` method to `GuestbookListInteractor`:

   ```
   @Override
   protected JSONArray getPageRowsRequest(Query query, Object... args) throws Exception {

       return new GuestbookService(getSession()).getGuestbooks(groupId, query.getStartRow(),
           query.getEndRow());
   }
   ```

   Note that the `groupId` variable isn't set anywhere. Interactors that extend `BaseListInteractor`, like `GuestbookListInteractor`, inherit this variable via the Screens framework. You'll set it when you create the Screenlet class.

   This `getPageRowsRequest` method requires that you add the following imports:

   ```
   import com.liferay.mobile.android.v7.guestbook.GuestbookService;
   import com.liferay.mobile.screens.base.list.interactor.Query;
   import org.json.JSONArray;
   ```

3. Override the `getPageRowCountRequest` method to retrieve the total number of entities. This enables pagination. In `GuestbookListInteractor`, you retrieve the total number of guestbooks from a site by creating a `GuestbookService` instance from the session and then calling the service's `getGuestbooksCount` method with the `groupId`. Add this `getPageRowCountRequest` method to `GuestbookListInteractor`:

```
@Override
protected Integer getPageRowCountRequest(Object... args) throws Exception {

    return new GuestbookService(getSession()).getGuestbooksCount(groupId);
}
```

4. Override the `createEntity` method to create and return a new event object containing the server call's results. The `BaseListInteractor` class converts the JSON that results from a successful server call into a `Map<String, Object>`. The `createEntity` method's only argument is this `Map`, which you use to create a `GuestbookModel` object. Then use the model object to create and return a new `GuestbookEvent` object. Add this `createEntity` method to `GuestbookListInteractor`:

   ```
   @Override
   protected GuestbookEvent createEntity(Map<String, Object> stringObjectMap) {
       GuestbookModel guestbook = new GuestbookModel(stringObjectMap);
       return new GuestbookEvent(guestbook);
   }
   ```

   This requires you to import `java.util.Map`.

5. Override the `getIdFromArgs` method to return the value of the first object argument as a string. Add this method to `GuestbookListInteractor`:

   ```
   @Override
   protected String getIdFromArgs(Object... args) {
       return String.valueOf(args[0]);
   }
   ```

   This is a boilerplate method that returns a cache key for offline mode. Even though you won't add offline mode support to Guestbook List Screenlet, this method makes it easier if you decide to do so later.

Nice work! Your Interactor class is finished. Note that this class is very similar to the Interactor class in the list Screenlet creation tutorial.

Your Interactor is finished too. Next, you'll create the Screenlet class.

43.4 Creating Guestbook List Screenlet's Screenlet Class

When using a Screenlet, app developers primarily interact with its Screenlet class. The Screenlet class contains attributes for configuring the Screenlet's behavior, a reference to the Screenlet's View, methods for invoking Interactor operations, and more.

You'll use these steps to create the Screenlet class:

1. Define the Screenlet's attributes. These are the XML attributes the app developer can set when inserting the Screenlet's XML. These attributes control aspects of the Screenlet's behavior.

2. Create the Screenlet class. This class implements the Screenlet's functionality defined in the View and Interactor. It also reads the attribute values and configures the Screenlet accordingly.

First, you'll define Guestbook List Screenlet's attributes.

Defining Screenlet Attributes

Before creating the Screenlet class, you should define its attributes. These are the attributes the app developer can set when inserting the Screenlet's XML in an activity or fragment layout. For example, to use Login Screenlet, the app developer could insert the following Login Screenlet XML in an activity or fragment layout:

```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:basicAuthMethod="email"
    app:layoutId="@layout/login_default"
    />
```

The app developer can set the app attributes `basicAuthMethod` and `layoutId` to set Login Screenlet's authentication method and View, respectively. The Screenlet class reads these settings to enable the appropriate functionality.

When creating a Screenlet, you can define the attributes you want to make available to app developers. You do this in an XML file inside your Android project's `res/values` directory. Guestbook List Screenlet only needs one attribute. You'll define it now. Create the file `guestbook_attrs.xml` in your app's `res/values` directory. Replace the file's contents with the following code:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <declare-styleable name="GuestbookListScreenlet">
        <attr name="groupId"/>
    </declare-styleable>
</resources>
```

This defines the `groupId` attribute, which the app developer can use to set the portal site to communicate with if they don't want to use the default `groupId` setting in `server_context.xml`. You'll account for this attribute's functionality in the Screenlet class.

Now that you've defined this attribute and know what it needs to do, you're ready to write the Screenlet class.

Extending BaseListScreenlet

Because the `BaseListScreenlet` class provides the basic functionality for all Screenlet classes in list Screenlets, including methods for pagination and other default behavior, your Screenlet class must extend `BaseListScreenlet` with your model class and Interactor as type arguments.

Use the following steps to create the Screenlet class for Guestbook List Screenlet, `GuestbookListScreenlet`:

1. Create the `GuestbookListScreenlet` class in the package `com.liferay.docs.guestbooklistscreenlet`. This class must extend `BaseListScreenlet` with the model and Interactor as type arguments:

   ```
   public class GuestbookListScreenlet extends
       BaseListScreenlet<GuestbookModel, GuestbookListInteractor> {...
   ```

   This requires you to add the following imports:

   ```
   import com.liferay.docs.guestbooklistscreenlet.interactor.GuestbookListInteractor;
   import com.liferay.docs.model.GuestbookModel;
   import com.liferay.mobile.screens.base.list.BaseListScreenlet;
   ```

2. For constructors, leverage the superclass constructors:

   ```
   public GuestbookListScreenlet(Context context) {
       super(context);
   }

   public GuestbookListScreenlet(Context context, AttributeSet attrs) {
       super(context, attrs);
   }

   public GuestbookListScreenlet(Context context, AttributeSet attrs, int defStyleAttr) {
       super(context, attrs, defStyleAttr);
   }

   public GuestbookListScreenlet(Context context, AttributeSet attrs, int defStyleAttr,
       int defStyleRes) {
           super(context, attrs, defStyleAttr, defStyleRes);
   }
   ```

   This requires you to add the following imports:

   ```
   import android.content.Context;
   import android.util.AttributeSet;
   ```

3. Implement the error method. This is a boilerplate method that uses a listener in the Screenlet framework to propagate any exception, and the user action that produced it, that occurs during the service call. This method does this by checking for a listener and then calling its error method with the Exception and userAction:

   ```
   @Override
   public void error(Exception e, String userAction) {
       if (getListener() != null) {
           getListener().error(e, userAction);
       }
   }
   ```

4. Override the createScreenletView method. This method reads the Screenlet's attribute values via an Android TypedArray, and instantiates the View. In Guestbook List Screenlet, you only need to read the value of the groupId attribute and set it to the groupId variable. Recall that the Screens framework propagates this variable to your Interactor. Finish the createScreenletView method by calling the superclass's createScreenletView method. This instantiates the View for you:

   ```
   @Override
   protected View createScreenletView(Context context, AttributeSet attributes) {
       TypedArray typedArray = context.getTheme().obtainStyledAttributes(attributes,
           R.styleable.GuestbookListScreenlet, 0, 0);
       groupId = typedArray.getInt(R.styleable.GuestbookListScreenlet_groupId,
           (int) LiferayServerContext.getGroupId());
       typedArray.recycle();

       return super.createScreenletView(context, attributes);
   }
   ```

   Note that if the app developer doesn't set the groupId attribute, LiferayServerContext.getGroupId() is called to retrieve the app's default liferay_group_id setting from res/values/server_context.xml.

   This createScreenletView method requires you to add the following imports:

```
import android.content.res.TypedArray;
import android.view.View;
import com.liferay.docs.liferayguestbook.R;
import com.liferay.mobile.screens.context.LiferayServerContext;
```

5. Override the `loadRows` method to start your Interactor and thereby retrieve the list rows from the server. This method takes an instance of your Interactor as an argument, which you use to call the Interactor's `start` method. The `loadRows` method in `GuestbookListScreenlet` therefore starts a `GuestbookListInteractor` instance. Note that the Interactor inherits `start` from `BaseListInteractor`. Also, because you don't need to pass any data to `GuestbookListInteractor`, you can call the `start` method with `0` as an argument:

   ```
   @Override
   protected void loadRows(GuestbookListInteractor interactor) {
       interactor.start(0);
   }
   ```

6. Override the `createInteractor` method to instantiate your Interactor. Since that's all this method needs to do, call your Interactor's constructor and return the new instance:

   ```
   @Override
   protected GuestbookListInteractor createInteractor(String actionName) {
       return new GuestbookListInteractor();
   }
   ```

Awesome! Your Screenlet class is finished. Note that this Screenlet class is very similar to the one in the list Screenlet creation tutorial.

Your Screenlet is finished, too! Before using Guestbook List Screenlet, however, you'll create Entry List Screenlet to show a list of each guestbook's entries. After all, viewing guestbooks without their entries doesn't make much sense. It isn't very exciting either. What's really exciting is that you can create Entry List Screenlet with the same set of steps you used to create Guestbook List Screenlet. The next series of articles in this Learning Path walks you through this.

Chapter 44

Creating Entry List Screenlet

In the previous section, you created Guestbook List Screenlet to retrieve and display guestbooks from the Guestbook portlet. You still need a way to retrieve and display each guestbook's entries, though. You'll do this by creating another list Screenlet: Entry List Screenlet. This section walks you through the steps required to create it.

Because you use a consistent development model to create Screenlets, similar Screenlets have similar code. As with guestbooks, it makes sense to display entries in a list using a list Screenlet. This means you can reuse most of Guestbook List Screenlet's code in Entry List Screenlet. You'll therefore create Entry List Screenlet using the same sequence of steps you used to create Guestbook List Screenlet:

1. Getting started: creating the Screenlet's package and model class.
2. Creating the Screenlet's UI (its View).
3. Creating the Screenlet's Interactor.
4. Creating the Screenlet class.

Although this Learning Path section presents complete code snippets, it only discusses the code unique to Entry List Screenlet. Refer back to the previous section for detailed explanations of the code shared with Guestbook List Screenlet. If you get confused or stuck, refer to the finished app that contains the Screenlet code here in GitHub.

44.1 Getting Started with Entry List Screenlet

Like Guestbook List Screenlet, you'll create Entry List Screenlet in a new package inside your app's project. Get started by creating the package `com.liferay.docs.entrylistscreenlet`. Once you have this package, you're ready to start writing the Screenlet.

Creating the Model Class for Entries

Recall that you need a model class to represent entities retrieved from Liferay DXP. The model class you'll create for guestbook entries, `EntryModel`, creates `EntryModel` objects that serve as guestbook entries retrieved from the Guestbook portlet.

Create the following `EntryModel` class alongside the `GuestbookModel` class in the `com.liferay.docs.model` package:

```
package com.liferay.docs.model;

import android.os.Parcel;
import android.os.Parcelable;

import java.util.Date;
import java.util.Map;

public class EntryModel implements Parcelable {

    private Map values;
    private long entryId;
    private long groupId;
    private long companyId;
    private long userId;
    private String userName;
    private long createDate;
    private long modifiedDate;
    private String name;
    private String email;
    private String message;
    private long guestbookId;

    public static final Creator<EntryModel> CREATOR = new Creator<EntryModel>() {
        @Override
        public EntryModel createFromParcel(Parcel in) {
            return new EntryModel(in);
        }

        @Override
        public EntryModel[] newArray(int size) {
            return new EntryModel[size];
        }
    };

    public EntryModel() {
        super();
    }

    protected EntryModel(Parcel in) {
        entryId = in.readLong();
        groupId = in.readLong();
        companyId = in.readLong();
        userId = in.readLong();
        userName = in.readString();
        createDate = in.readLong();
        modifiedDate = in.readLong();
        name = in.readString();
        email = in.readString();
        message = in.readString();
        guestbookId = in.readLong();
    }

    public EntryModel(Map<String, Object> stringObjectMap) {
        values = stringObjectMap;
        entryId = Long.parseLong((String) stringObjectMap.get("entryId"));
        groupId = Long.parseLong((String) stringObjectMap.get("groupId"));
        companyId = Long.parseLong((String) stringObjectMap.get("companyId"));
        userId = Long.parseLong((String) stringObjectMap.get("userId"));
        userName = (String) stringObjectMap.get("userName");
        createDate = (long) stringObjectMap.get("createDate");
        modifiedDate = (long) stringObjectMap.get("modifiedDate");
        name = (String) stringObjectMap.get("name");
        email = (String) stringObjectMap.get("email");
        message = (String) stringObjectMap.get("message");
        guestbookId = Long.parseLong((String) stringObjectMap.get("guestbookId"));
    }
```

```
@Override
public void writeToParcel(Parcel dest, int flags) {
    dest.writeLong(entryId);
    dest.writeLong(groupId);
    dest.writeLong(companyId);
    dest.writeLong(userId);
    dest.writeString(userName);
    dest.writeLong(createDate);
    dest.writeLong(modifiedDate);
    dest.writeString(name);
    dest.writeString(email);
    dest.writeString(message);
    dest.writeLong(guestbookId);
}

@Override
public int describeContents() {
    return 0;
}

public Map getValues() {
    return values;
}

public void setValues(Map values) {
    this.values = values;
}

public long getEntryId() {
    return entryId;
}

public long getGroupId() {
    return groupId;
}

public long getCompanyId() {
    return companyId;
}

public long getUserId() {
    return userId;
}

public String getUserName() {
    return userName;
}

public Date getCreateDate() {
    return new Date(createDate);
}

public Date getModifiedDate() {
    return new Date(modifiedDate);
}

public String getName() {
    return name;
}

public String getEmail() {
    return email;
}

public String getMessage() {
    return message;
}
```

```
    public long getGuestbookId() {
        return guestbookId;
    }

}
```

Besides working with entries instead of guestbooks, this class works the same as `GuestbookModel`. For an explanation of the code, see the article on getting started with Guestbook List Screenlet.

Next, you'll create the Screenlet's UI.

44.2 Creating Entry List Screenlet's UI

Once you have the model class for entries, you can create the Screenlet's UI. Recall that in Liferay Screens for Android, you create a Screenlet's UI by implementing a View. In this article, you'll create Entry List Screenlet's View by using the same sequence of steps you used to create Guestbook List Screenlet's View:

1. Create the row layout. This layout defines the UI for each row in the list.
2. Create the adapter class. The adapter fills a row layout instance with the data for one list item. This repeats for each list item.
3. Create the View class. This class renders the UI, handles user interactions, and communicates with the Screenlet class.
4. Create the View's layout. This layout defines the Screenlet's UI as a whole. For a list Screenlet, this is a scrollable list.

As you follow these steps, you'll see that Entry List Screenlet's View shares a great deal of code with Guestbook List Screenlet's View. The biggest difference between these Views is that one displays guestbooks and the other displays entries. The mechanisms they use to display data, however, are almost identical.

To get started, create a new package named `view` inside the `entrylistscreenlet` package. You'll create the row layout first.

Creating the Row Layout

You must create the layout that defines the Screenlet's UI for each list row instance. Recall that in Guestbook List Screenlet, `guestbook_row.xml` serves this purpose with a single `TextView` it uses to display a guestbook's name. You'll create a similar layout here for Entry List Screenlet, but you'll use two `TextView` elements: one for the entry and one for the name of the person that left it. Create `entry_row.xml` in your app's `res/layout` directory and replace its contents with this code:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/entry_message"
        android:textSize="25sp"
        android:textStyle="bold"
        android:paddingLeft="10dp"
        android:paddingRight="10dp"
        android:paddingBottom="1dp"
        android:paddingTop="10dp"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

    <TextView
        android:id="@+id/entry_name"
        android:textSize="15sp"
        android:paddingLeft="10dp"
        android:paddingRight="10dp"
        android:paddingBottom="10dp"
        android:paddingTop="1dp"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```

You'll use the first `TextView` (`entry_message`) to display the entry, and the second `TextView` (`entry_name`) to display the name of the person that left it. The `padding` settings in each `TextView` element group the text closer together and create extra space at the top and bottom of the row. This makes it clear that the text in each row belongs together as a single list item. Of course, this is only one of many possible representations. You can style each row as you wish.

Next, you'll create your Screenlet's adapter class.

Creating the Adapter Class

Recall that an adapter class is required to fill each row with data. Entry List Screenlet's adapter class is almost identical to that of Guestbook List Screenlet. The only difference, besides working with `EntryModel` instead of `GuestbookModel`, is that it needs two variables: one for the entry and one for the name of the person who left it. In contrast, Guestbook List Screenlet's adapter class needed only one variable for the guestbook's name.

Inside the Entry List Screenlet's `view` package, create the following `EntryAdapter` class:

```
package com.liferay.docs.entrylistscreenlet.view;

import android.support.annotation.NonNull;
import android.view.View;
import android.widget.TextView;

import com.liferay.docs.liferayguestbook.R;
import com.liferay.docs.model.EntryModel;
import com.liferay.mobile.screens.base.list.BaseListAdapter;
import com.liferay.mobile.screens.base.list.BaseListAdapterListener;

public class EntryAdapter extends BaseListAdapter<EntryModel, EntryAdapter.EntryViewHolder> {

    public EntryAdapter(int layoutId, int progressLayoutId, BaseListAdapterListener listener) {
        super(layoutId, progressLayoutId, listener);
    }

    @NonNull
    @Override
    public EntryViewHolder createViewHolder(View view, BaseListAdapterListener listener) {
        return new EntryAdapter.EntryViewHolder(view, listener);
    }

    @Override
    protected void fillHolder(EntryModel entry, EntryViewHolder holder) {
        holder.bind(entry);
    }

    public class EntryViewHolder extends BaseListAdapter.ViewHolder {

        private final TextView message;
        private final TextView name;

        public EntryViewHolder(View view, BaseListAdapterListener listener) {
            super(view, listener);

            message = (TextView) view.findViewById(R.id.entry_message);
            name = (TextView) view.findViewById(R.id.entry_name);
        }

        public void bind(EntryModel entry) {
            message.setText(entry.getMessage());
            name.setText(entry.getName());
        }

    }
}
```

For an explanation of how this code works, see the section on the adapter class in the article on Creating Guestbook List Screenlet's UI.

Now you're ready to create the View class.

Creating the View Class

Recall that the View class controls a Screenlet's UI. Because Entry List Screenlet is so similar to Guestbook List Screenlet, their View classes are almost identical. The only difference is–you guessed it–one uses entries and the other uses guestbooks. For a full explanation of the View class, see the section on the View class in the article on Creating Guestbook List Screenlet's UI.

Create the `EntryListView` class inside Entry List Screenlet's `view` package, and replace its contents with this code:

```
package com.liferay.docs.entrylistscreenlet.view;

import android.content.Context;
import android.util.AttributeSet;

import com.liferay.docs.liferayguestbook.R;
import com.liferay.docs.model.EntryModel;
import com.liferay.mobile.screens.base.list.BaseListScreenletView;

public class EntryListView extends BaseListScreenletView<EntryModel,
    EntryAdapter.EntryViewHolder, EntryAdapter> {

    public EntryListView(Context context) {
        super(context);
    }

    public EntryListView(Context context, AttributeSet attributes) {
        super(context, attributes);
    }

    public EntryListView(Context context, AttributeSet attributes, int defaultStyle) {
        super(context, attributes, defaultStyle);
    }

    @Override
    protected EntryAdapter createListAdapter(int itemLayoutId, int itemProgressLayoutId) {
        return new EntryAdapter(itemLayoutId, itemProgressLayoutId, this);
    }

    @Override
    protected int getItemLayoutId() {
        return R.layout.entry_row;
    }
}
```

Fabulous work! Next, you'll create your View's main layout.

Creating the View's Layout

In the first step, you created a layout for each list row. Recall that you must also create a layout for the list as a whole. Although you may be getting tired of hearing this, it's saving you a great deal of work: Entry List Screenlet's layout is almost identical to that of Guestbook List Screenlet. The only difference is that Entry List Screenlet's layout uses `EntryListView` instead of `GuestbookListView`.

Create the file `list_entries.xml` in the `res/layout` directory, and replace its contents with this code:

```
<com.liferay.docs.entrylistscreenlet.view.EntryListView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/liferay_list_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ProgressBar
        android:id="@+id/liferay_progress"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:visibility="gone"/>

    <android.support.v7.widget.RecyclerView
        android:id="@+id/liferay_recycler_list"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:visibility="gone"/>
</com.liferay.docs.entrylistscreenlet.view.EntryListView>
```

For a full explanation of this layout, see the section on creating the layout in the article on creating Guestbook List Screenlet's UI. You must also be sure not to change the layout's `android:id` values. They're hard-coded into the list Screenlet framework and changing them will cause your app to crash.

Nice job! You're done creating Entry List Screenlet's View. Next, you'll create the Screenlet's Interactor.

44.3 Creating Entry List Screenlet's Interactor

Recall that Interactors are Screenlet components that make server calls and process the results. Also recall that Interactors themselves are made up of several components:

1. The event class
2. The listener interface
3. The Interactor class

Since the list Screenlet framework already contains two listeners, you only need to create the event and Interactor classes. This article walks you through the steps required do this. Because Entry List Screenlet's Interactor is so similar to that of Guestbook List Screenlet, these steps aren't explained in detail. Focus is instead placed on the few places in the code where the Interactors diverge. For a full explanation of the code, see the article on creating Guestbook List Screenlet's Interactor.

You'll create the event class first.

Creating the Event Class

Recall that you must create an event class to communicate the server call's results via EventBus. First, create a new package called `interactor` in the `com.liferay.docs.entrylistscreenlet` package. Then create the `EntryEvent` class in the `interactor` package. Replace this class's contents with this code:

```
package com.liferay.docs.entrylistscreenlet.interactor;

import com.liferay.docs.model.EntryModel;
import com.liferay.mobile.screens.base.list.interactor.ListEvent;

public class EntryEvent extends ListEvent<EntryModel> {

    private EntryModel entry;

    public EntryEvent() {
        super();
    }

    public EntryEvent(EntryModel entry) {
        this.entry = entry;
    }

    @Override
    public String getListKey() {
        return entry.getMessage();
    }

    @Override
    public EntryModel getModel() {
        return entry;
    }
}
```

This code is almost identical to `GuestbookEvent`. The only difference is that it works with entries instead of guestbooks.

Next, you'll create the Interactor class.

Creating the Interactor Class

Recall that an Interactor class issues the server call and processes the results via the event. In the `interactor` package, create a new class called `EntryListInteractor`. Replace this class's content with this code:

```
package com.liferay.docs.entrylistscreenlet.interactor;

import com.liferay.docs.model.EntryModel;
import com.liferay.mobile.android.v7.entry.EntryService;
import com.liferay.mobile.screens.base.list.interactor.BaseListInteractor;
import com.liferay.mobile.screens.base.list.interactor.BaseListInteractorListener;
import com.liferay.mobile.screens.base.list.interactor.Query;

import org.json.JSONArray;
import java.util.Map;

public class EntryListInteractor extends
    BaseListInteractor<BaseListInteractorListener<EntryModel>, EntryEvent> {

    @Override
    protected JSONArray getPageRowsRequest(Query query, Object... args) throws Exception {

        long guestbookId = (long) args[0];
        return new EntryService(getSession()).getEntries(groupId, guestbookId,
            query.getStartRow(), query.getEndRow());
    }

    @Override
    protected Integer getPageRowCountRequest(Object... args) throws Exception {

        long guestbookId = (long) args[0];
        return new EntryService(getSession()).getEntriesCount(groupId, guestbookId);
    }

    @Override
    protected EntryEvent createEntity(Map<String, Object> stringObjectMap) {
        EntryModel entry = new EntryModel(stringObjectMap);
        return new EntryEvent(entry);
    }

    @Override
    protected String getIdFromArgs(Object... args) {
        return String.valueOf(args[0]);
    }
}
```

Besides getting entries instead of guestbooks, this class is almost identical to `GuestbookListInteractor`. The only other differences are due to the service calls that retrieve the entries and number of entries from a guestbook in the Guestbook portlet. These service calls, made in `getPageRowsRequest` and `getPageRowCountRequest`, require an `EntryService` instance. The `getEntries` method retrieves a guestbook's entries, and the `getEntriesCount` method retrieves the number of entries in a guestbook. Note that these calls require a guestbook ID (`guestbookId`) in addition to the group ID (`groupId`). The `getPageRowsRequest` and `getPageRowCountRequest` methods get the `guestbookId` from the args argument, and then use it along with `groupId` make their service calls. You'll see how the `guestbookId` gets into the args argument when you create the Screenlet class.

Nicely done! Now that Entry List Screenlet has an Interactor, you must create the Screenlet class. The next article shows you how to do this.

44.4 Creating Entry List Screenlet's Screenlet Class

Recall that when using a Screenlet, the app developer primarily interacts with its Screenlet class. The Screenlet class contains attributes for configuring the Screenlet's behavior, a reference to the Screenlet's View, methods for invoking Interactor operations, and more. This article shows you how to create Entry List Screenlet's Screenlet class.

As with most of Entry List Screenlet, its Screenlet class is almost identical to that of Guestbook List Screenlet. Besides working with entries instead of guestbooks, the only difference is that it must know its entries' guestbook ID. Even the Screenlets' attributes are the same.

Therefore, this article doesn't explain all the code in detail. Focus is instead placed on the few parts that differ from Guestbook List Screenlet. For a full explanation of the code, click here to see the article on creating Guestbook List Screenlet's Screenlet class.

You'll create Entry List Screenlet's class with the same steps you used to create Guestbook List Screenlet's class:

1. Define the Screenlet's attributes. These are the XML attributes the app developer can set when inserting the Screenlet's XML. These attributes control aspects of the Screenlet's behavior.

2. Create the Screenlet class. This class implements the Screenlet's functionality defined in the View and Interactor. It also reads the attribute values and configures the Screenlet accordingly.

First, you'll define Entry List Screenlet's attributes.

Defining Screenlet Attributes

Recall that before creating the Screenlet class, you must define the attributes the app developer needs to control the Screenlet's behavior. Entry List Screenlet, like Guestbook List Screenlet, only needs a `groupId` attribute. In your app's `res/values` directory, create `entry_attrs.xml` and replace its contents with this code:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <declare-styleable name="EntryListScreenlet">
        <attr name="groupId"/>
    </declare-styleable>
</resources>
```

Next, you'll create the Screenlet class.

Creating the Screenlet Class

Entry List Screenlet's class must contain an instance variable for the ID of the guestbook the Screenlet retrieves entries from. This is required to start the Interactor. This is the only significant difference between the Screenlet classes of Entry List Screenlet and Guestbook List Screenlet. The remaining differences exist only because they handle different entities.

Create the `EntryListScreenlet` class in the `entrylistscreenlet` package. Replace the class's content with this code:

```
package com.liferay.docs.entrylistscreenlet;

import android.content.Context;
import android.content.res.TypedArray;
import android.util.AttributeSet;
import android.view.View;

import com.liferay.docs.entrylistscreenlet.interactor.EntryListInteractor;
import com.liferay.docs.liferayguestbook.R;
import com.liferay.docs.model.EntryModel;
import com.liferay.mobile.screens.base.list.BaseListScreenlet;
import com.liferay.mobile.screens.context.LiferayServerContext;

public class EntryListScreenlet extends BaseListScreenlet<EntryModel, EntryListInteractor> {

    private long guestbookId;

    public EntryListScreenlet(Context context) {
        super(context);
    }

    public EntryListScreenlet(Context context, AttributeSet attrs) {
        super(context, attrs);
    }

    public EntryListScreenlet(Context context, AttributeSet attrs, int defStyleAttr) {
        super(context, attrs, defStyleAttr);
    }

    public EntryListScreenlet(Context context, AttributeSet attrs, int defStyleAttr, int defStyleRes) {
        super(context, attrs, defStyleAttr, defStyleRes);
    }

    @Override
    public void error(Exception e, String userAction) {
        if (getListener() != null) {
            getListener().error(e, userAction);
        }
    }
    @Override
    protected View createScreenletView(Context context, AttributeSet attributes) {
        TypedArray typedArray = context.getTheme().obtainStyledAttributes(attributes,
            R.styleable.GuestbookListScreenlet, 0, 0);
        groupId = typedArray.getInt(R.styleable.GuestbookListScreenlet_groupId,
            (int) LiferayServerContext.getGroupId());
        typedArray.recycle();

        return super.createScreenletView(context, attributes);
    }

    @Override
    protected void loadRows(EntryListInteractor interactor) {
        interactor.start(guestbookId);
    }

    @Override
    protected EntryListInteractor createInteractor(String actionName) {
        return new EntryListInteractor();
    }

    public long getGuestbookId() {
        return guestbookId;
    }

    public void setGuestbookId(long guestbookId) {
        this.guestbookId = guestbookId;
    }
}
```

The instance variable for the guestbook ID is `guestbookId`. The getter and setter methods `getGuestbookId` and `setGuestbookId` let the app developer get and set this variable, respectively. The `loadRows` method starts the Interactor by calling the `start` method with `guestbookId` as an argument. Behind the scenes, the list Screenlet framework passes `guestbookId` to the Interactor's `getPageRowsRequest` and `getPageRowCountRequest` methods via the args argument. This is why you were able to extract `guestbookId` from the args argument in these methods. For an explanation of how the rest of this Screenlet class works, click here to see the article on creating Guestbook List Screenlet's Screenlet class.

That's it! Now you're ready to use Entry List Screenlet alongside Guestbook List Screenlet. The following section of this Learning Path concludes with both Screenlets working together in harmony.

Chapter 45

Using the Guestbook List and Entry List Screenlets

Now that you have the Guestbook List and Entry List Screenlets, you're ready to put them to work. As you'll see, using these Screenlets isn't much more difficult than using Login Screenlet. This is an advantage of Screenlets; it typically takes only a few minutes to get them up and running. They also integrate with the rest of your app's UI.

To add your Screenlets to the app, you'll follow these steps:

1. Understand how `GuestbooksActivity`'s UI works. Since your Screenlets augment this UI instead of replacing it, you should first understand how it works.

2. Prepare `GuestbooksActivity` for Guestbook List Screenlet.

3. Use Guestbook List Screenlet by inserting it in `GuestbooksActivity`.

4. Create `EntriesFragment` for Entry List Screenlet. You'll also set `GuestbooksActivity` to display this fragment when a guestbook is selected in Guestbook List Screenlet.

5. Use Entry List Screenlet by inserting it in `EntriesFragment`.

If you get confused or stuck at any point in this section of the Learning Path, refer to the finished app's code here in GitHub.

First, you'll see how `GuestbooksActivity`'s UI works.

45.1 Understanding GuestbooksActivity's UI

Recall that you used Android Studio's Navigation Drawer Activity template to create `GuestbooksActivity`. Any activity this template creates contains a navigation drawer and all the components the activity needs. This includes layout files that display content. Currently, these files contain simple placeholder content. You'll replace this content shortly with content from your Guestbook portlet. Before doing so, however, you should know where the placeholder content exists in the project's structure and how the app displays it.

The app's UI is defined by three layout files that combine to display the app's content:

1. activity_guestbooks.xml: The activity's main layout file. This layout defines the navigation drawer and includes the app_bar_guestbooks layout. The latter appears when the navigation drawer is closed.

2. app_bar_guestbooks.xml: Defines the action bar (app bar) and includes the content_guestbooks layout.

3. content_guestbooks.xml: Defines the activity's main content, which appears below the action bar.

First, you'll learn how activity_guestbooks.xml works.

Understanding the Activity's Main Layout File

First, open GuestbooksActivity's main layout file, activity_guestbooks.xml. This file should look similar to this one:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.v4.widget.DrawerLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    xmlns:tools="http://schemas.android.com/tools"
    android:id="@+id/drawer_layout"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:fitsSystemWindows="true"
    tools:openDrawer="start">

    <include layout="@layout/app_bar_guestbooks"
        android:layout_width="match_parent"
        android:layout_height="match_parent" />

    <android.support.design.widget.NavigationView
        android:id="@+id/nav_view"
        android:layout_width="wrap_content"
        android:layout_height="match_parent"
        android:layout_gravity="start"
        android:fitsSystemWindows="true"
        app:headerLayout="@layout/nav_header_guestbooks"
        app:menu="@menu/activity_guestbooks_drawer" />

</android.support.v4.widget.DrawerLayout>
```

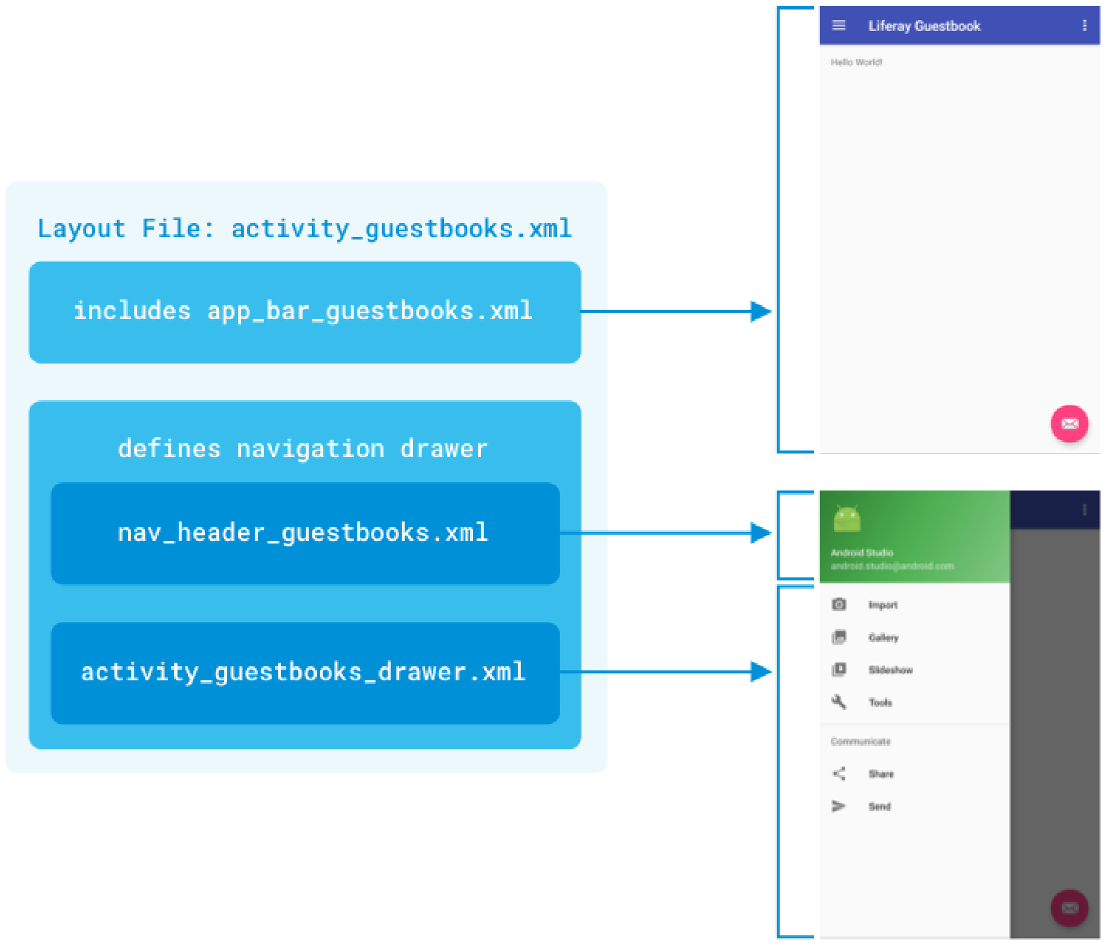
This isn't much code considering everything that's in GuestbooksActivity. The NavigationView and its parent DrawerLayout define the navigation drawer. Two attributes in NavigationView define the drawer's contents: app:headerLayout and app:menu. The app:headerLayout value "@layout/nav_header_guestbooks" specifies that the layout res/layout/nav_header_guestbooks.xml renders the drawer's header section. The app:menu value "@menu/activity_guestbooks_drawer" specifies that the menu in res/menu/activity_guestbooks_drawer.xml creates the drawer's items. Above the NavigationView, the include statement adds the layout app_bar_guestbooks.xml as the content shown when the navigation drawer is closed. The following diagram illustrates how activity_guestbooks.xml maps to the UI.

The activity's main content also contains a toolbar (the action bar), some text, and a floating action button. Next, you'll see how these are defined.

Understanding the app_bar_guestbooks and content_guestbooks Layouts

Open app_bar_guestbooks.xml. It should look similar to this:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.design.widget.CoordinatorLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
```



Layout File: activity_guestbooks.xml
includes app_bar_guestbooks.xml
defines navigation drawer
nav_header_guestbooks.xml
activity_guestbooks_drawer.xml
Liferay Guestbook
Hello World!
Android Studio
android.studio@android.com
Import
Gallery
Slideshow
Tools
Communicate
Share
Send

Figure 45.1: The `activity_guestbooks.xml` layout defines the app's main UI components.

```
xmlns:app="http://schemas.android.com/apk/res-auto"
xmlns:tools="http://schemas.android.com/tools"
android:layout_width="match_parent"
android:layout_height="match_parent"
android:fitsSystemWindows="true"
tools:context="com.liferay.docs.liferayguestbook.GuestbooksActivity">

<android.support.design.widget.AppBarLayout
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:theme="@style/AppTheme.AppBarOverlay">

    <android.support.v7.widget.Toolbar
        android:id="@+id/toolbar"
        android:layout_width="match_parent"
        android:layout_height="?attr/actionBarSize"
        android:background="?attr/colorPrimary"
        app:popupTheme="@style/AppTheme.PopupOverlay" />
    </android.support.design.widget.AppBarLayout>

    <include layout="@layout/content_guestbooks" />

    <android.support.design.widget.FloatingActionButton
        android:id="@+id/fab"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="bottom|end"
        android:layout_margin="@dimen/fab_margin"
        android:src="@android:drawable/ic_dialog_email" />

</android.support.design.widget.CoordinatorLayout>
```

The AppBarLayout and Toolbar elements define the toolbar at the top of the activity. Following the toolbar definition, the include statement adds the content_guestbooks layout to app_bar_guestbooks. The content_guestbooks layout defines the content displayed in the activity's body (below the toolbar). Right now, this layout only contains an empty ConstraintLayout element. Now open content_guestbooks.xml. Its contents should look similar to this:

```
<?xml version="1.0" encoding="utf-8"?>
<android.support.constraint.ConstraintLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    xmlns:tools="http://schemas.android.com/tools"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:layout_behavior="@string/appbar_scrolling_view_behavior"
    tools:context="com.liferay.docs.liferayguestbook.GuestbooksActivity"
    tools:showIn="@layout/app_bar_guestbooks">

</android.support.constraint.ConstraintLayout>
```

Anything you define in this layout becomes the activity's main body content. Later, you'll return to content_guestbooks.xml to display the guestbook entries retrieved from the Guestbook portlet.

Now return to app_bar_guestbooks.xml. This layout concludes by using FloatingActionButton to define the floating action button. Pressing this button in the app slides a snackbar containing placeholder content up from the bottom of the screen. Although you won't do anything with the floating action button in this Learning Path, you'll leave it in place. When you finish this Learning Path, you may want to test your Liferay mobile development chops by adding functionality to this button.

The following figure illustrates how the app_bar_guestbooks layout maps to the activity's UI. On the left, this figure lists each UI component in app_bar_guestbooks. Each arrow points to the component's rendering on the right.

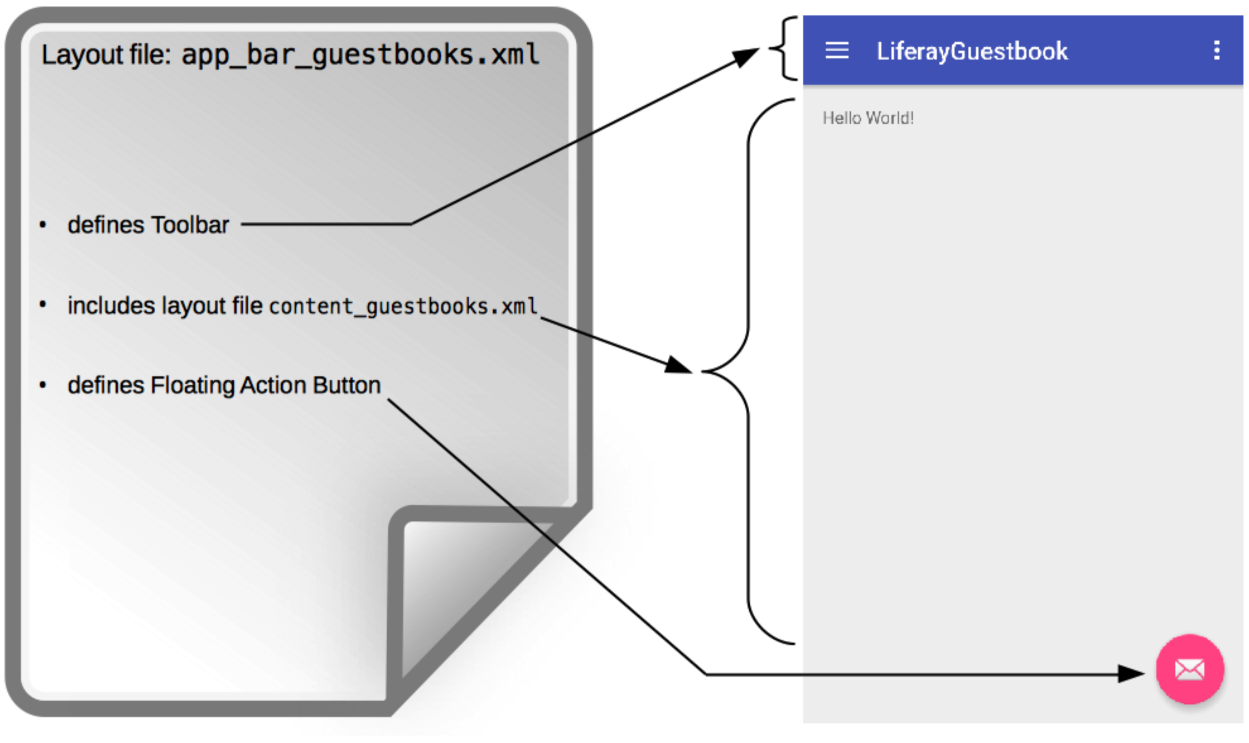
Awesome! Now you know which layout files in the project define the app's UI. You also know the exact UI components these files define. Next, you'll prepare GuestbooksActivity for Guestbook List Screenlet.

45.2 Preparing GuestbooksActivity for Guestbook List Screenlet

Recall that you want GuestbooksActivity to display Guestbook List Screenlet and Entry List Screenlet. Before using these Screenlets, however, you must prepare GuestbooksActivity as follows:

1. Refactor the action bar so you can later set its title to the selected guestbook's name.

2. Refactor the navigation drawer so you can later close it when a guestbook is selected in Guestbook List Screenlet.



Layout file: app_bar_guestbooks.xml
defines Toolbar
includes layout file content_guestbooks.xml
defines Floating Action Button
LiferayGuestbook
Hello World!

Figure 45.2: The layout `app_bar_guestbooks.xml` defines the activity's main content.

3. Delete the `NavigationView.OnNavigationItemSelectedListener` implementation. Since Guestbook List Screenlet handles guestbook selections, you don't need `NavigationView`.

When you finish, you'll be ready to use Guestbook List Screenlet. Note that you won't always have to take steps like these before using Screenlets. You only do so here to fit this particular app's design.

First, you'll refactor the action bar.

Refactoring the Action Bar

By default, the action bar displays the activity's name. When you use Guestbook List Screenlet, you want the action bar to display the selected guestbook's name instead. You'll enable this by modifying the code that creates the action bar. Android Studio created this code for you in the `GuestbooksActivity` class's `onCreate` method:

```
Toolbar toolbar = (Toolbar) findViewById(R.id.toolbar);
setSupportActionBar(toolbar);
```

1. Remove this code. Although you could edit it, you'll instead create a separate method that creates the action bar. Note that you don't need to worry about the now missing `toolbar` variable in `onCreate`; you'll fix it shortly.

2. Create `ActionBar` and `Toolbar` instance variables. This lets you refer to them anywhere in the activity. Add these variables to the `GuestbooksActivity` class:

```
Toolbar toolbar = (Toolbar) findViewById(R.id.toolbar);
setSupportActionBar(toolbar);
```

This requires that you import `android.support.v7.app.ActionBar`.

3. Add the following `initActionBar()` method to `GuestbooksActivity`:

```
private void initActionBar() {
    toolbar = (Toolbar) findViewById(R.id.toolbar);
    setSupportActionBar(toolbar);
    actionBar = getSupportActionBar();
    actionBar.setTitle("");
}
```

   Like the code you removed from `onCreate`, this method also creates a `Toolbar` and sets it as the action bar. It also sets the action bar's title to an empty string. This prevents the activity's title from showing in the action bar before the app can retrieve guestbooks from the portlet.

4. Call `initActionBar()` in `onCreate`. Place the call immediately below the `setContentView` call. The first few lines of `onCreate` should now look like this:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_guestbooks);

    initActionBar();

    ...
}
```

Next, you'll modify the code that controls the navigation drawer.

Refactoring the Navigation Drawer

Before you can use Guestbook List Screenlet in the navigation drawer, you must refactor the drawer's existing code. Do so now by following these steps:

1. Currently, the navigation drawer initialization code is in the `onCreate` method. Android Studio created this code for you when you used the Navigation Drawer Activity template to create `GuestbooksActivity`. Delete this code from `onCreate`:

```
DrawerLayout drawer = (DrawerLayout) findViewById(R.id.drawer_layout);
ActionBarDrawerToggle toggle = new ActionBarDrawerToggle(
    this, drawer, toolbar, R.string.navigation_drawer_open, R.string.navigation_drawer_close);
drawer.setDrawerListener(toggle);
toggle.syncState();
```

   Instead, you'll initialize the navigation drawer in a separate method that you'll call in `onCreate`. You'll create this method shortly.

2. You'll also change the `drawer` variable to be an instance variable that you can refer to throughout the class. This lets you use this variable to close the drawer when a guestbook is selected in Guestbook List Screenlet. Add this variable to `GuestbooksActivity`:

```
private DrawerLayout drawer;
```

3. Add the following `initDrawer` method. This method's contents match the drawer initialization code you deleted in `onCreate`, except that `drawer` is now an instance variable:

```
private void initDrawer() {
    // drawer initialization
    drawer = (DrawerLayout) findViewById(R.id.drawer_layout);
    ActionBarDrawerToggle toggle = new ActionBarDrawerToggle(
        this, drawer, toolbar, R.string.navigation_drawer_open,
        R.string.navigation_drawer_close);
    drawer.setDrawerListener(toggle);
    toggle.syncState();
}
```

4. In the `onCreate` method, place the call to `initDrawer()` immediately below the `initActionBar` call. The first few lines of `onCreate` should now look like this:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_guestbooks);

    initActionBar();
    initDrawer();

    ...
}
```

5. Also, because you want to use the same `DrawerLayout` instance throughout the class, delete the line of code that creates a new `DrawerLayout` in the `onBackPressed` method. Your `onBackPressed` method should now look like this:

```
@Override
public void onBackPressed() {
    if (drawer.isDrawerOpen(GravityCompat.START)) {
        drawer.closeDrawer(GravityCompat.START);
    } else {
        super.onBackPressed();
    }
}
```

Now you're ready to delete the `NavigationView.OnNavigationItemSelectedListener` implementation. The next section walks you through this.

Deleting the NavigationView.OnNavigationItemSelectedListener Implementation

Since Guestbook List Screenlet handles navigation drawer item selections, you don't need to implement `NavigationView.OnNavigationItemSelectedListener` in `GuestbooksActivity`. Follow these steps to remove this implementation:

1. Delete the implementation from the class declaration. The class declaration should now look like this:

```
public class GuestbooksActivity extends AppCompatActivity {...
```

2. Remove the code in `GuestbooksActivity` that implements `NavigationView.OnNavigationItemSelectedListener`. To do this, first delete the following code at the end of the `onCreate` method:

```
NavigationView navigationView = (NavigationView) findViewById(R.id.nav_view);
navigationView.setNavigationItemSelectedListener(this);
```

Your onCreate method should now look like this:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_guestbooks);

    initActionBar();
    initDrawer();

    FloatingActionButton fab = (FloatingActionButton) findViewById(R.id.fab);
    fab.setOnClickListener(new View.OnClickListener() {
        @Override
        public void onClick(View view) {
            Snackbar.make(view, "Replace with your own action", Snackbar.LENGTH_LONG)
                .setAction("Action", null).show();
        }
    });
}
```

3. Delete the `onNavigationItemSelected` method, along with its `@Override` and `@SuppressWarnings("StatementWithEmptyBody`
   statements.

4. Finally, remove the `android.support.design.widget.NavigationView` import.

Great job! Now you're ready to insert Guestbook List Screenlet in `GuestbooksActivity`.

45.3 Using Guestbook List Screenlet

The steps for using Guestbook List Screenlet are the same as those for using any Screenlet:

1. Insert the Screenlet's XML in the activity or fragment layout you want the Screenlet to appear in.

2. Implement the Screenlet's listener in the activity or fragment class.

Recall that you used these steps to insert Login Screenlet in `MainActivity`. First, you'll insert Guestbook List Screenlet's XML in `GuestbooksActivity`'s layout.

Inserting the Screenlet XML in the Layout

Recall that `activity_guestbooks.xml` defines `GuestbooksActivity`'s UI. Also recall that the `NavigationView` in `activity_guestbooks.xml` defines the navigation drawer.

To put Guestbook List Screenlet in the drawer, you must insert the Screenlet's XML in the `NavigationView`. You must also remove the placeholder content from the `NavigationView`. To do these things, replace the `NavigationView` in `activity_guestbooks.xml` with this code:

```
<android.support.design.widget.NavigationView
    android:id="@+id/nav_view"
    android:layout_width="wrap_content"
    android:layout_height="match_parent"
    android:layout_gravity="start"
    android:fitsSystemWindows="true"
    app:headerLayout="@layout/nav_header_guestbooks">
    <com.liferay.docs.guestbooklistscreenlet.GuestbookListScreenlet
        android:id="@+id/guestbooklist_screenlet"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        android:paddingTop="@dimen/nav_header_height"
        app:layoutId="@layout/list_guestbooks"/>

</android.support.design.widget.NavigationView>
```

Compared to the `NavigationView` it replaced, this `NavigationView` contains Guestbook List Screenlet's XML and lacks the `app:menu` attribute. Recall that this attribute pointed to the menu resource file that creates the drawer's items. Since the Screenlet now handles the drawer's items (the guestbooks), you don't need `app:menu` or the menu resource file. Delete the menu resource file `res/menu/activity_guestbooks_drawer.xml`. You also don't need the drawable resources that Android Studio created for the navigation drawer's placeholder content. Delete `res/values/drawables.xml`, and each of the `ic_menu_*.xml` files in `res/drawable`.

Returning your attention to `activity_guestbooks.xml`, note that Guestbook List Screenlet's XML strongly resembles Login Screenlet's XML. Both contain an `android:id` value that you can use in the activity to get a reference to the Screenlet. Both also use a `layoutId` attribute to specify the Screenlet's View. Guestbook List Screenlet's XML, however, differs by using the `android:paddingTop` attribute. This attribute's value, `@dimen/nav_header_height`, pads the top of the Screenlet by the height of the navigation drawer's header section. This prevents the Screenlet and drawer header from overlapping.

Great! Next, you'll implement the Screenlet's listener interface in `GuestbooksActivity`.

Implementing the Screenlet's Listener

To use a Screenlet, you must implement its listener methods in the class of the activity or fragment where you want the Screenlet to appear. How you implement these methods depends on how you want the Screenlet to function in your app. For example, when you used Login Screenlet you implemented `LoginListener` in `MainActivity`. You implemented this listener's `onLoginSuccess` and `onLoginFailure` methods to display a message to the user. You then changed the `onLoginSuccess` implementation to navigate from `MainActivity` to `GuestbooksActivity`. Since these methods are `void`, however, you could have left them empty. Obviously this wouldn't have made for a very useful app, but it highlights an important point: Screenlet listener methods let the app developer choose how to respond to the Screenlet's events. By implementing these methods, app developers can therefore control how the Screenlet functions with their app.

Before implementing Guestbook List Screenlet's listener, however, you should add a method that the listener methods can use to help display a guestbook and its entries. You might now be thinking, "I thought you said Screenlets contain their own UIs? Why does the activity need special methods for displaying the Screenlets' entities?" Although a list Screenlet's UI displays the list of entities, the rest of the app's UI must still account for that list. Consider the action bar, for example. List Screenlets don't include an action bar, but you should still change the action bar's contents to reflect what's on the screen. When a guestbook is selected in Guestbook List Screenlet, the action bar should display that guestbook's name. You can accomplish this by calling a method that takes a `GuestbookModel` and sets that guestbook's name as the action bar's title.

Follow these steps to add this method and implement the listener:

1. Add this `showEntries` method to `GuestbooksActivity`:

```
    public void showEntries(GuestbookModel guestbook) {

        actionBar.setTitle(guestbook.getName());
    }
```

This requires you to import `com.liferay.docs.model.GuestbookModel`. This method is called `showEntries` because you'll also use it to display the guestbook's entries via Entry List Screenlet (you'll add this code later). You'll call this method in the listener methods you'll implement to process a guestbook selection.

2. Recall that Guestbook List Screenlet doesn't need any custom listener methods. It can use the listener methods defined in the list Screenlet framework's `BaseListListener` interface. Change `GuestbooksActivity`'s class declaration to implement `BaseListListener<GuestbookModel>`. The class declaration should now look like this:

```
public class GuestbooksActivity extends AppCompatActivity implements
    BaseListListener<GuestbookModel> {...
```

   This requires you to import `com.liferay.mobile.screens.base.list.BaseListListener`.

3. To implement `BaseListListener`, you must implement the following methods:

   - `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call failed. Implement this method to show the user a toast message containing an error:

```
@Override
public void onListPageFailed(int startRow, Exception e) {

    Toast.makeText(this, "Page request failed", Toast.LENGTH_LONG).show();
}
```

     This requires you to import `android.widget.Toast`.

   - `onListPageReceived(int startRow, int endRow, List<E> entries, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method's arguments include the list of objects retrieved from the server (`entries`), and the page's start row (`startRow`), and end row (`endRow`). Recall that by default, you want the activity to display the first guestbook's entries. You'll use this method to do so because it receives the guestbooks from the server. Note that because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first guestbook on the first page. Use an `if` statement to select this guestbook, and then call `showEntries`:

```
@Override
public void onListPageReceived(int startRow, int endRow, List<GuestbookModel> guestbooks,
    int rowCount) {

    if (startRow == 0) {
        showEntries(guestbooks.get(0));
    }
}
```

     This requires you to import `java.util.List`.

   - `onListItemSelected(E element, View view)`: Called when the user selects an item in the list. This method's arguments include the selected list item (`element`). To process the guestbook's selection, call `showEntries` in this method. Also, close the navigation drawer following the `showEntries` call:

```
    @Override
    public void onListItemSelected(GuestbookModel guestbook, View view) {

        showEntries(guestbook);
        drawer.closeDrawers();
    }
```

4. Because BaseListListener extends the BaseCacheListener interface, the activity must also implement BaseCacheListener's error method. This method lets you respond to an error alongside the user action that caused it. In this app, you don't need to do anything in this method, so you can leave its contents empty:

```
@Override
public void error(Exception e, String userAction) {

}
```

5. Now that you've implemented the listener methods, you must set GuestbooksActivity as the listener. This is where the guestbooklist_screenlet ID that you set in the Screenlet's XML comes in handy. Add the following code to the end of the activity's onCreate method:

```
GuestbookListScreenlet screenlet =
    (GuestbookListScreenlet) findViewById(R.id.guestbooklist_screenlet);
screenlet.setListener(this);
```

   This requires you to import com.liferay.docs.guestbooklistscreenlet.GuestbookListScreenlet.

   This code first uses the ID guestbooklist_screenlet to get a reference to GuestbookListScreenlet. It then sets this GuestbooksActivity instance as the Screenlet's listener.

Great! That's it! Your app's GuestbooksActivity now contains Guestbook List Screenlet. You're almost ready to use Entry List Screenlet. Before you do so, however, you must create a fragment to put it in. You'll do this next.

45.4 Creating a Fragment for Entry List Screenlet

Using a fragment for Entry List Screenlet lets you swap out part of GuestbookActivity's contents without recreating the entire activity from scratch each time a guestbook is selected. Your app doesn't currently have any fragments, though. In this step, you'll create a fragment and then add it to GuestbooksActivity. When you finish, you'll be ready to use Entry List Screenlet in this fragment.

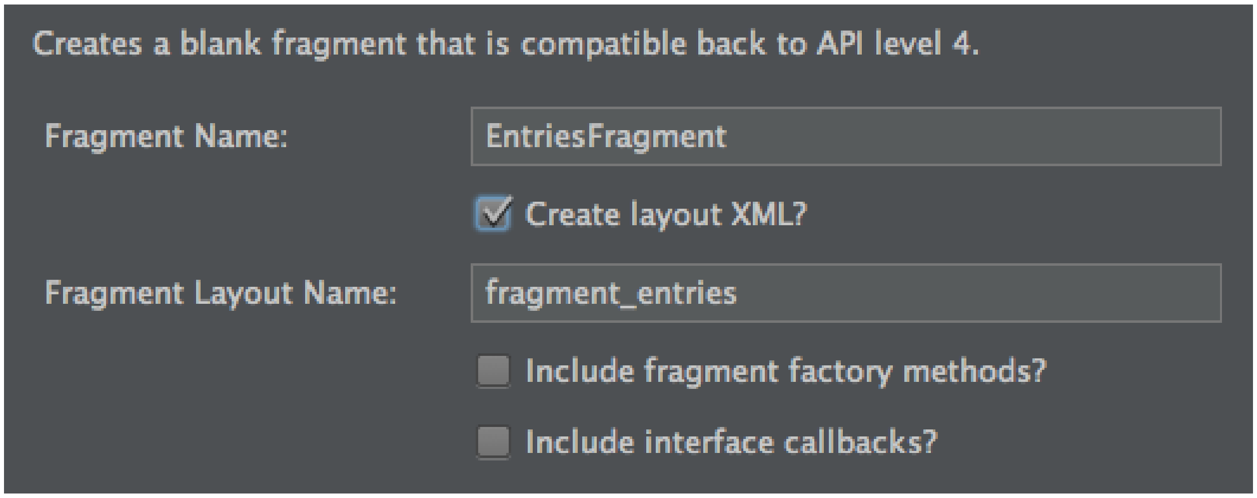
Creating the Fragment

Follow these steps to create the fragment:

1. To create the fragment, right click the com.liferay.docs.liferayguestbook package and select *New → Fragment → Fragment (Blank)*. In the wizard, check only the box to create the layout XML, name the fragment EntriesFragment, and then click *Finish*. The following screenshot illustrates this:

   This creates the EntriesFragment class and its layout file fragment_entries.xml.

2. Replace the class's contents with this code:



Creates a blank fragment that is compatible back to API level 4.

Fragment Name: EntriesFragment

☑ Create layout XML?

Fragment Layout Name: fragment_entries

☐ Include fragment factory methods?

☐ Include interface callbacks?

Figure 45.3: Create a new blank fragment for the entries.

```
package com.liferay.docs.liferayguestbook;

import android.os.Bundle;
import android.support.v4.app.Fragment;
import android.view.LayoutInflater;
import android.view.View;
import android.view.ViewGroup;

public class EntriesFragment extends Fragment {

    public static EntriesFragment newInstance(long guestbookId) {
        EntriesFragment entriesFragment = new EntriesFragment();
        Bundle args = new Bundle();
        args.putLong("guestbookId", guestbookId);
        entriesFragment.setArguments(args);

        return entriesFragment;
    }

    @Override
    public View onCreateView(LayoutInflater inflater, ViewGroup container,
                     Bundle savedInstanceState) {
        // Inflate the layout for this fragment
        View view = inflater.inflate(R.layout.fragment_entries, container, false);
        long guestbookId = getArguments().getLong("guestbookId");

        return view;
    }

}
```

If you have experience with Android fragments, then you're likely familiar with the static `newInstance` method. In short, using such a method instead of an empty constructor lets you create the fragment and initialize its data in one step. This makes it easier to create and restore the fragment. Click here for more information.

Since this fragment will contain Entry List Screenlet, its data must include the guestbook ID the Screenlet retrieves entries from (`guestbookId`). Also, the `onCreateView` method uses the bundle arguments set in newInstance to retrieve the guestbookId. For now, you don't have to do anything with the guestbookId in onCreateView. You'll use this variable when you add the Screenlet to the fragment.

Next, you'll add this fragment to GuestbooksActivity.

Adding the Fragment to GuestbooksActivity

Now that EntriesFragment exists, you can add it to GuestbooksActivity. To do this, you must put an Android fragment container in the layout where you want the fragment. For more information, see Android's documentation on adding fragments at runtime. Since you want Entry List Screenlet to appear in GuestbooksActivity, your first thought might be to put the fragment container directly in activity_guestbooks.xml. Don't do this. Recall that Android Studio's Navigation Drawer Activity template created the layout content_guestbooks.xml to hold the activity's main body content. You'll add the fragment container to this layout, then write the code in GuestbooksActivity that displays the fragment.

Follow these steps to add the fragment to GuestbooksActivity:

1. Open content_guestbooks.xml and place the following fragment container inside the ConstraintLayout. This fragment container should be the only other element inside the ConstraintLayout:

```
<FrameLayout
    android:id="@+id/fragment_container"
    android:layout_width="match_parent"
    android:layout_height="match_parent" />
```

2. Next, you must write the GuestbooksActivity code that displays the fragment when a guestbook is selected in Guestbook List Screenlet. You'll do this with an Android fragment transaction. Recall that you created GuestbooksActivity's showEntries method to process a list item selection in Guestbook List Screenlet. All showEntries does right now is set the action bar's title to the selected guestbook's name. You'll add the fragment transaction to showEntries, so a guestbook selection also shows that guestbook's entries. Replace the showEntries method in GuestbooksActivity with this code:

```
public void showEntries(GuestbookModel guestbook) {
    actionBar.setTitle(guestbook.getName());

    EntriesFragment entriesFragment = EntriesFragment.newInstance(guestbook.getGuestbookId());
    FragmentTransaction transaction = getSupportFragmentManager().beginTransaction();
    transaction.replace(R.id.fragment_container, entriesFragment);
    transaction.commit();
}
```

This requires that you import android.support.v4.app.FragmentTransaction.

This method's actionBar.setTitle call is the same as before. Only the fragment code is new. In it, you first use newInstance to create a new EntriesFragment instance with the selected guestbook's ID. A fragment transaction then adds this fragment to the fragment container.

Fantastic! Now you have a fragment to put Entry List Screenlet in, and the code that displays this fragment in GuestbooksActivity. Next, you'll put Entry List Screenlet in the fragment.

45.5 Using Entry List Screenlet

You'll use Entry List Screenlet by following the same steps to use any Screenlet: insert the Screenlet's XML in an activity or fragment layout, and then implement the Screenlet's listener in the activity or fragment class. You'll follow these steps here to insert Entry List Screenlet in `EntriesFragment`.

First, you'll insert Entry List Screenlet's XML in `EntriesFragment`'s layout, `fragment_entries.xml`.

Inserting the Screenlet in the Layout

Inserting Entry List Screenlet's XML is very simple. Since all you want `fragment_entries.xml` to do is display the Screenlet, it must only contain the Screenlet's XML. Replace the contents of `fragment_entries.xml` with the following markup:

```
<com.liferay.docs.entrylistscreenlet.EntryListScreenlet
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:id="@+id/entrylist_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:layoutId="@layout/list_entries"/>
```

As with Guestbook List Screenlet, you'll use the `android:id` value to get a Screenlet reference. Next, you must implement the Screenlet's listener.

Implementing the Screenlet's Listener

Recall that to use a Screenlet, you must implement its listener. The listener methods let the app developer respond to the Screenlet's behavior in the activity or fragment class that contains the Screenlet. Also recall that because Guestbook List Screenlet didn't need extra listener methods, you used it in `GuestbooksActivity` by implementing the `BaseListListener` interface with `GuestbookModel` as a type argument. Entry List Screenlet also doesn't need extra listener methods. Like Guestbook List Screenlet, you can use it by implementing `BaseListListener` with its model class as a type argument.

Follow these steps to implement Entry List Screenlet's listener in `EntriesFragment`:

1. Change `EntriesFragment`'s class declaration to implement `BaseListListener<EntryModel>`. The class declaration should now look like this:

   ```
   public class EntriesFragment extends Fragment implements BaseListListener<EntryModel> {...
   ```

   This requires that you add the following imports:

   ```
   import com.liferay.docs.model.EntryModel;
   import com.liferay.mobile.screens.base.list.BaseListListener;
   ```

2. Now you must implement the listener's methods. Recall that this includes the `BaseCacheListener` interface's, `error` method, since `BaseListListener` extends `BaseCacheListener`. For a full explanation of the methods in both listeners, see using Guestbook List Screenlet. Note that in `EntriesFragment`, you don't need to take any action in these methods. There are no UI elements or other parts of the fragment that must be updated or processed in response to the Screenlet's behavior. All this Screenlet must do is display its content, which it does regardless of anything you do in the listener methods. The only thing you may want to add is a toast message in `onListPageFailed` to notify the user if the server call fails, but this isn't required. Implement these methods now:

```
@Override
public void onListPageFailed(int startRow, Exception e) {
    Toast.makeText(getActivity(), "Page request failed", Toast.LENGTH_LONG).show();
}

@Override
public void onListPageReceived(int startRow, int endRow, List<EntryModel> entries, int rowCount) {

}

@Override
public void onListItemSelected(EntryModel entry, View view) {

}

@Override
public void error(Exception e, String userAction) {

}
```

This requires you to add the following imports:

```
import android.widget.Toast;
import java.util.List;
```

3. Now you're ready to register `EntriesFragment` as the Screenlet's listener. You'll do this the same way you registered `GuestbooksActivity` as Guestbook List Screenlet's listener: get a reference to the Screenlet and call its `setListener` method. After doing this, you'll use the Entry List Screenlet reference's `setGuestbookId` method to set its guestbook ID. This sets the guestbook where the Screenlet gets its entries. You'll do these things in the `onCreateView` method. Replace the `onCreateView` method with this updated version:

```
@Override
public View onCreateView(LayoutInflater inflater, ViewGroup container,
                     Bundle savedInstanceState) {
    // Inflate the layout for this fragment
    View view = inflater.inflate(R.layout.fragment_entries, container, false);
    long guestbookId = getArguments().getLong("guestbookId");

    EntryListScreenlet screenlet = (EntryListScreenlet) view.findViewById(R.id.entrylist_screenlet);
    screenlet.setListener(this);
    screenlet.setGuestbookId(guestbookId);

    return view;
}
```

This requires you to import `com.liferay.docs.entrylistscreenlet.EntryListScreenlet`.

As you can see, `onCreateView` now registers `EntriesFragment` as the Screenlet's listener and sets the Screenlet's guestbook ID. The rest of `onCreateView` is unchanged.

Now run the app in the emulator and log in with your credentials when prompted. The app then presents you with the first guestbook's entries. Open the navigation drawer by pressing the hamburger button, then select a different guestbook. The drawer then closes to show the selected guestbook's entries. Nice work! Your app now uses Guestbook List Screenlet and Entry List Screenlet to show the same guestbooks and entries as the Guestbook portlet. The following screenshots show these Screenlets in action.

Although your Screenlets work, you may have noticed something odd about the navigation drawer's header–it's hideous. The action bar is somewhere on the purple-blue spectrum, while the drawer header is

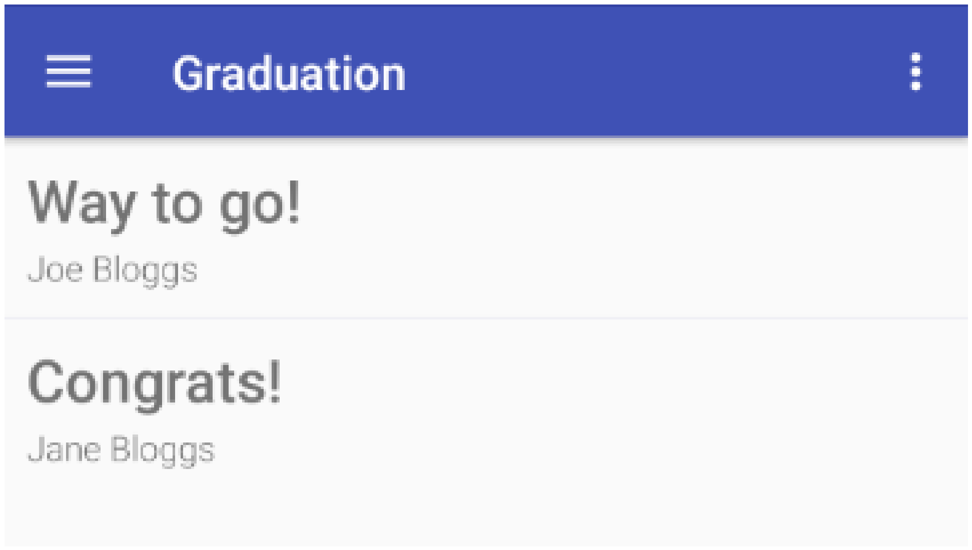


Figure 45.4: Entry List Screenlet displays guestbook entries in your app.

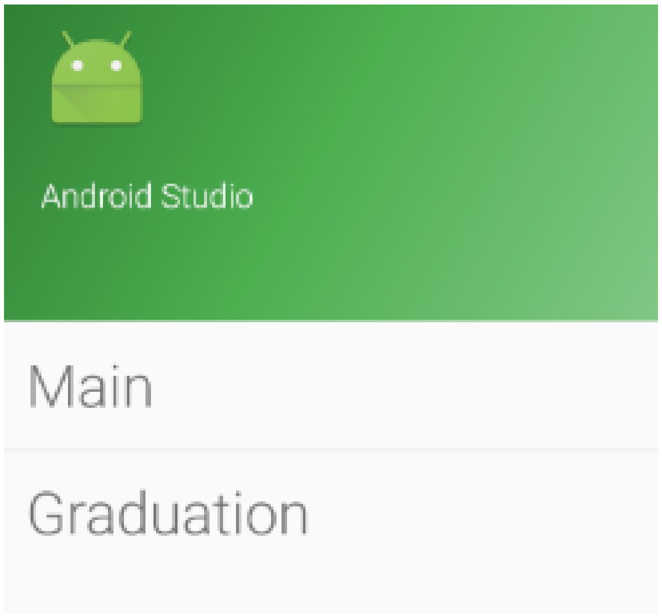

Figure 45.5: Guestbook List Screenlet displays guestbooks in the navigation drawer.

green. You've probably seen more attractive finger paintings. Fortunately, it's simple to change the drawer header's color. Also, the drawer header contains the generic text *Android Studio*. You should change this to something more suitable for your app, like *Liferay Guestbook*.

Follow these steps to apply these changes to the drawer header:

1. In `res/drawable/side_nav_bar.xml`, replace `android:centerColor`, `android:endColor`, and `android:startColor` with the following settings:

   ```
   android:centerColor="@color/colorPrimary"
   android:endColor="@color/colorPrimaryDark"
   android:startColor="@color/colorPrimary"
   ```

   This sets the drawer header's colors to match the colors used in the rest of the app.

2. Define the following string resource in `res/values/strings.xml`:

   ```
   <string name="liferay_guestbook">Liferay Guestbook</string>
   ```

3. In `nav_header_guestbooks.xml`, find the `TextView` element that contains `android:text="Android Studio"`, and replace `Android Studio` with `@string/liferay_guestbook`. You can delete any other `TextView` elements in this file. Run the app again, and open the drawer after signing in. The drawer header now shows your greeting. It's a lot prettier too.

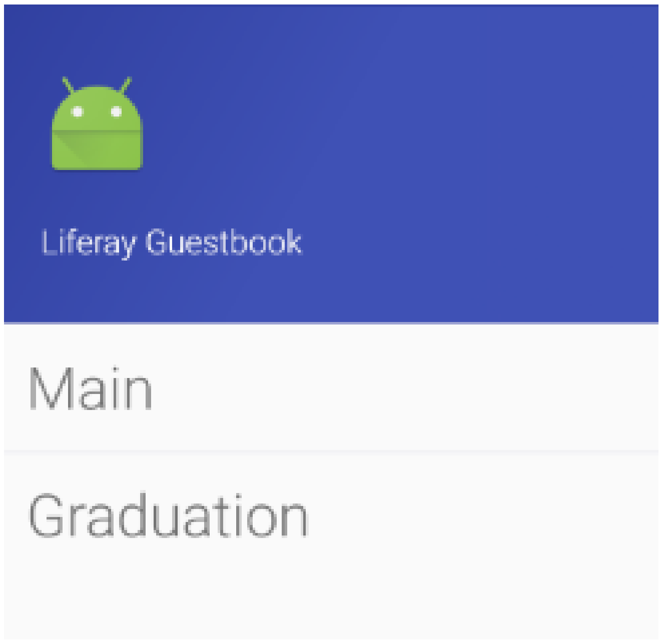

Figure 45.6: The drawer header looks a lot better after some light customization.

Congratulations! Now you know how to use Liferay Screens and create your own Screenlets. This opens up a world of possibilities for developing apps that leverage Liferay DXP. Although you learned a great deal in this Learning Path, there's still more. You can customize your Screenlet's appearance, package it for redistribution, and even configure it to receive push notifications. These topics, and more, are covered in the tutorials on Android apps with Liferay Screens.

Chapter 46

Writing an iOS App with Liferay Screens

Users expect to access portal content from their mobile devices. As an intrepid developer, you naturally want to turn these expectations into reality. Thankfully, Liferay provides a way for your mobile apps to access portal content and applications with Liferay Screens! Screens contains native components called *Screenlets* that can call Liferay DXP's remote services and display the results in your app. Each Screenlet comes complete with its own fully pluggable UI that you can customize to your liking. Although the Screenlets included with Screens only work with Liferay DXP's built-in remote services, you can write your own Screenlets that work with your custom portlets' remote services.

If you're an experienced iOS developer but need a start-to-finish guide on how to integrate iOS apps with Liferay DXP, you're in the right place. This Learning Path walks you through the creation of an iOS app that interacts with the Guestbook portlet developed in the Developing a Web Application Learning Path. Since this is a custom portlet, you'll write your own Screenlets that let your app retrieve and display guestbooks and their entries.

You should note that although this Learning Path provides complete code snippets of the app, not every aspect of iOS development is explained in detail. Focus is instead placed on the code that leverages Liferay Screens. Therefore, you **must** have significant iOS development experience before attempting this Learning Path. Otherwise, you'll likely be confused. Apple provides extensive documentation of the iOS APIs as well as some basic tutorials on developer.apple.com.

Experience in iOS development is all you need to start working. You needn't have completed the Developing a Web Application Learning Path to obtain a working Guestbook portlet. The complete Guestbook portlet's modules are provided for installation into your local Liferay DXP instance.

Now that you know what you'll be doing here, it's time to move on to the first series of articles: Beginning iOS Development for Your Portal. These articles walk you through the steps required to get started developing an iOS app that interacts with Liferay DXP.

Chapter 47

Beginning iOS Development for Your Portal

Getting started with Liferay Screens for iOS is straightforward. This series of Learning Path articles walks you through creating an iOS app and preparing it to work with the Guestbook portlet developed in the Developing a Web Application Learning Path. Since Liferay Screens uses the Liferay Mobile SDK to make remote service calls, you'll build a Mobile SDK capable of calling the Guestbook portlet's remote services (the Guestbook Mobile SDK). You'll then install this Mobile SDK and Screens into your iOS project. You'll also learn about the iOS app's design and implement authentication with Login Screenlet.

This section of the Learning Path covers these topics:

1. Setting up the Guestbook portlet
2. Building the Guestbook Mobile SDK
3. Creating the iOS project
4. Installing the Guestbook Mobile SDK and Liferay Screens in the iOS project
5. Designing Your App
6. Using Login Screenlet for Authentication
7. Creating the Guestbooks Scene

When you finish, you'll be ready to start developing your first Screenlet.

47.1 Setting up the Guestbook Portlet

Before you begin developing the Guestbook app for iOS, you must set up the Guestbook portlet in a Liferay DXP instance. To do this, follow these steps:

1. Install JDK 8
2. Install and Configure a Local Liferay DXP Bundle
3. Deploy the Guestbook Portlet to the Local Liferay DXP Instance

Installing the JDK

To get started, you must have JDK 8 installed. You can download and install the Java SE JDK from the Java downloads page. This page also has links to the JDK installation instructions.

Installing and Configuring a Local Liferay DXP Bundle

Follow these instructions to install and configure a local Liferay DXP instance:

1. Download a Liferay DXP Tomcat bundle from liferay.com.

2. Unzip the bundle to a new `bundles` folder. Note that the bundle's root folder is referred to as *Liferay Home* and is named according to the version, edition, and specific Liferay DXP release. For example, if you downloaded Liferay CE Portal 7.0 GA5 and unzipped it to a `bundles` folder on your machine, that bundle's Liferay Home folder is:

   ```
   bundles/liferay-ce-portal-7.0-ga5
   ```

3. Now you're ready to start Liferay DXP! Open a terminal and navigate to `[Liferay Home]/tomcat-[version]/bin`. Then run these commands:

   ```
   ./startup.sh
   tail -f ../logs/catalina.out
   ```

   The `tail` command ensures that the server log prints to the terminal.

4. After a minute or two, Liferay DXP starts up and automatically takes you to its initial setup page at http://localhost:8080. On this page, provide the following information to set up your Liferay DXP instance:

   - Enter a name for your instance.
   - Select the default language.
   - Uncheck the *Add Sample Data* box.
   - Enter the first name, last name, and email address of the default administrative user. For the purposes of this Learning Path, these don't have to be real.
   - If you want to connect Liferay DXP to a separate database such as MySQL or PostgreSQL, you can configure that connection here. Note that although the default embedded database is fine for development on your local machine, it isn't optimized for production.

   Click *Finish Configuration* when you're done.

5. Accept the terms of use.

6. Set a password and a password reminder query for your administrative user. Your Liferay DXP instance then takes you to its default site.

Great! Next, you'll deploy the Guestbook portlet to your Liferay DXP instance.

Deploying the Guestbook Portlet

Now that your portal is set up, you can deploy the Guestbook portlet to it. Follow these instructions to do so:

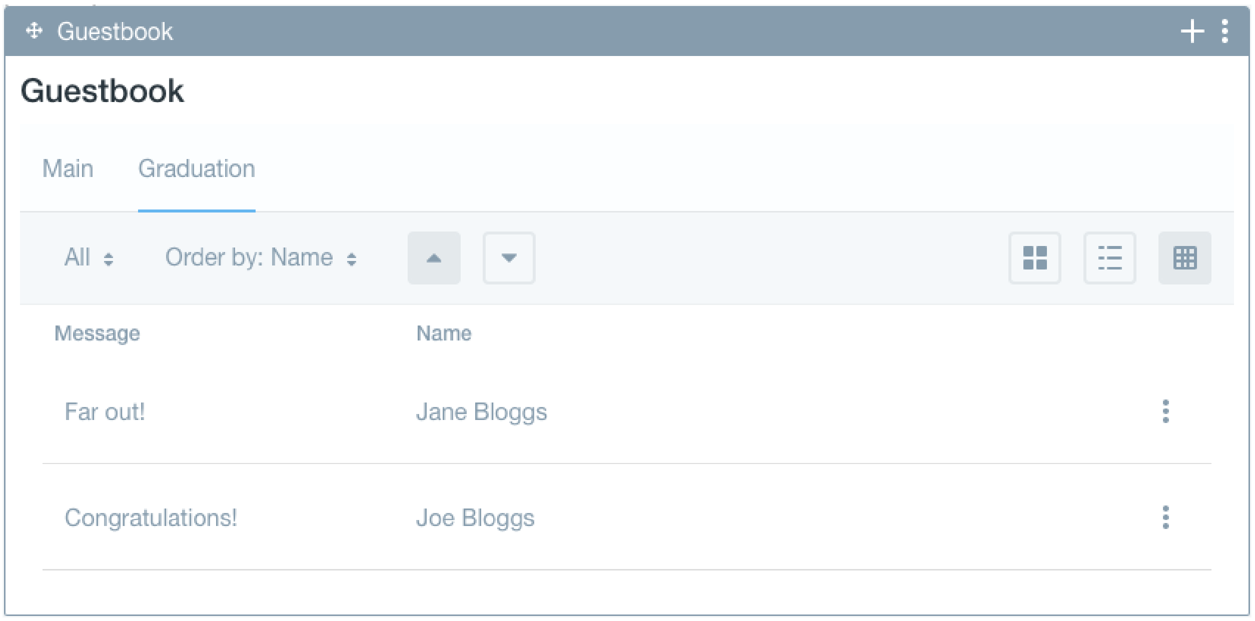
1. Download the Guestbook portlet's modules:

   - `com.liferay.docs.guestbook.api-1.0.0.jar`
   - `com.liferay.docs.guestbook.portlet-1.0.0.jar`
   - `com.liferay.docs.guestbook.service-1.0.0.jar`
   - `com.liferay.docs.guestbook.service-wsdd-1.0.0.jar`

2. Place these modules in your Liferay DXP instance's `[Liferay Home]/deploy` folder. You should then see console messages indicating that the modules have successfully deployed and started.

3. On your Liferay DXP instance's default site, click the *Add* button (+) on the upper-right corner of the screen. Then click the *Applications* → *Sample* category and drag *Guestbook* onto the page. The Guestbook portlet should now appear with the default guestbook (Main).

4. In the portlet, add a new guestbook and an entry or two each from the *Add* menu (+) that appears in the top right of the portlet's border when you mouse over the portlet. When you create the Guestbook iOS app, this ensures there's some content to display in it. The Guestbook portlet on your site should now look like this:



Message	Name
Far out!	Jane Bloggs
Congratulations!	Joe Bloggs

Figure 47.1: The Guestbook portlet, with a new guestbook and some entries.

Stupendous! You've successfully set up a Liferay DXP instance and added the Guestbook portlet to it. Now you're ready to get started with the Liferay Mobile SDK.

47.2 Building the Guestbook Mobile SDK

Once you've deployed the Guestbook portlet, you're ready to build the Guestbook Mobile SDK. You might be asking yourself, "Why do I have to build a separate Mobile SDK? Can't I just use the pre-built Mobile SDK that Liferay already provides?" Fantastic question! The reason is that Liferay's pre-built Mobile SDK doesn't have the classes it needs to call the Guestbook portlet's remote services. The pre-built Mobile SDK includes only the framework necessary to make server calls to the remote services of Liferay DXP's *core* apps. Core apps (also referred to as *out-of-the-box* apps) are those included with every Liferay DXP instance. Since you're calling services of an app the default Mobile SDK doesn't know about (the Guestbook portlet), you must build a Mobile SDK that can call its services. Now put on your hard hat, because it's time to get building!

Building the Mobile SDK

In the Mobile SDK source code, Liferay provides a Mobile SDK Builder that you can use to build your own Mobile SDKs. For the builder to generate the classes that can call a non-core app's remote services, those services must be available and accompanied by a Web Service Deployment Descriptor (WSDD). To learn how the Guestbook portlet's remote services and WSDD were generated, see the section Generating Web Services in the web application Learning Path. Since the Guestbook portlet's web services already exist, you don't need to generate them. Just remember that you must generate web services when developing your own portlets.

1. Download the Mobile SDK's source code and unzip the file to a location on your machine where you want the Mobile SDK to reside. This location is purely personal preference; the builder works the same no matter where you put the Mobile SDK's source code. Once unzipped, the Mobile SDK's source code is in the folder `liferay-mobile-sdk-ios-7.0.13`.

2. Now you're ready to build the Guestbook Mobile SDK. The builder contains a convenient command line wizard to assist you in building Mobile SDKs. To start it, navigate to the `liferay-mobile-sdk-ios-7.0.13` folder and run the following command:

   ```
   ./gradlew createModule
   ```

   The wizard launches and asks you to enter your project's properties. You'll do this next.

3. You must first provide the `Context` property. This is the context path of the remote services the builder will generate classes and methods for. To view your Liferay DXP instance's remote service context paths, go to http://localhost:8080/api/jsonws. On the page's upper left, there's a menu for selecting the context path. Select *gb*, which is the Guestbook portlet's context path. The UI updates to show only the remote services available in the selected context path. Return to the terminal and enter `gb` for the `Context` property.

4. Next, the wizard needs the `Package Name` property. Because the builder also builds an Android version of the Mobile SDK, this property defines the Java package path for the classes the builder generates. Accept the default value of `com.liferay.mobile.android`.

5. The wizard then asks for the `POM Description` property. This property also applies to the Android version of the Mobile SDK. Since the builder requires it, however, enter `Guestbook SDK`. The following screenshot shows these properties entered in the wizard:

   Once you enter the final property, the builder runs and generates a `BUILD SUCCESSFUL` message.

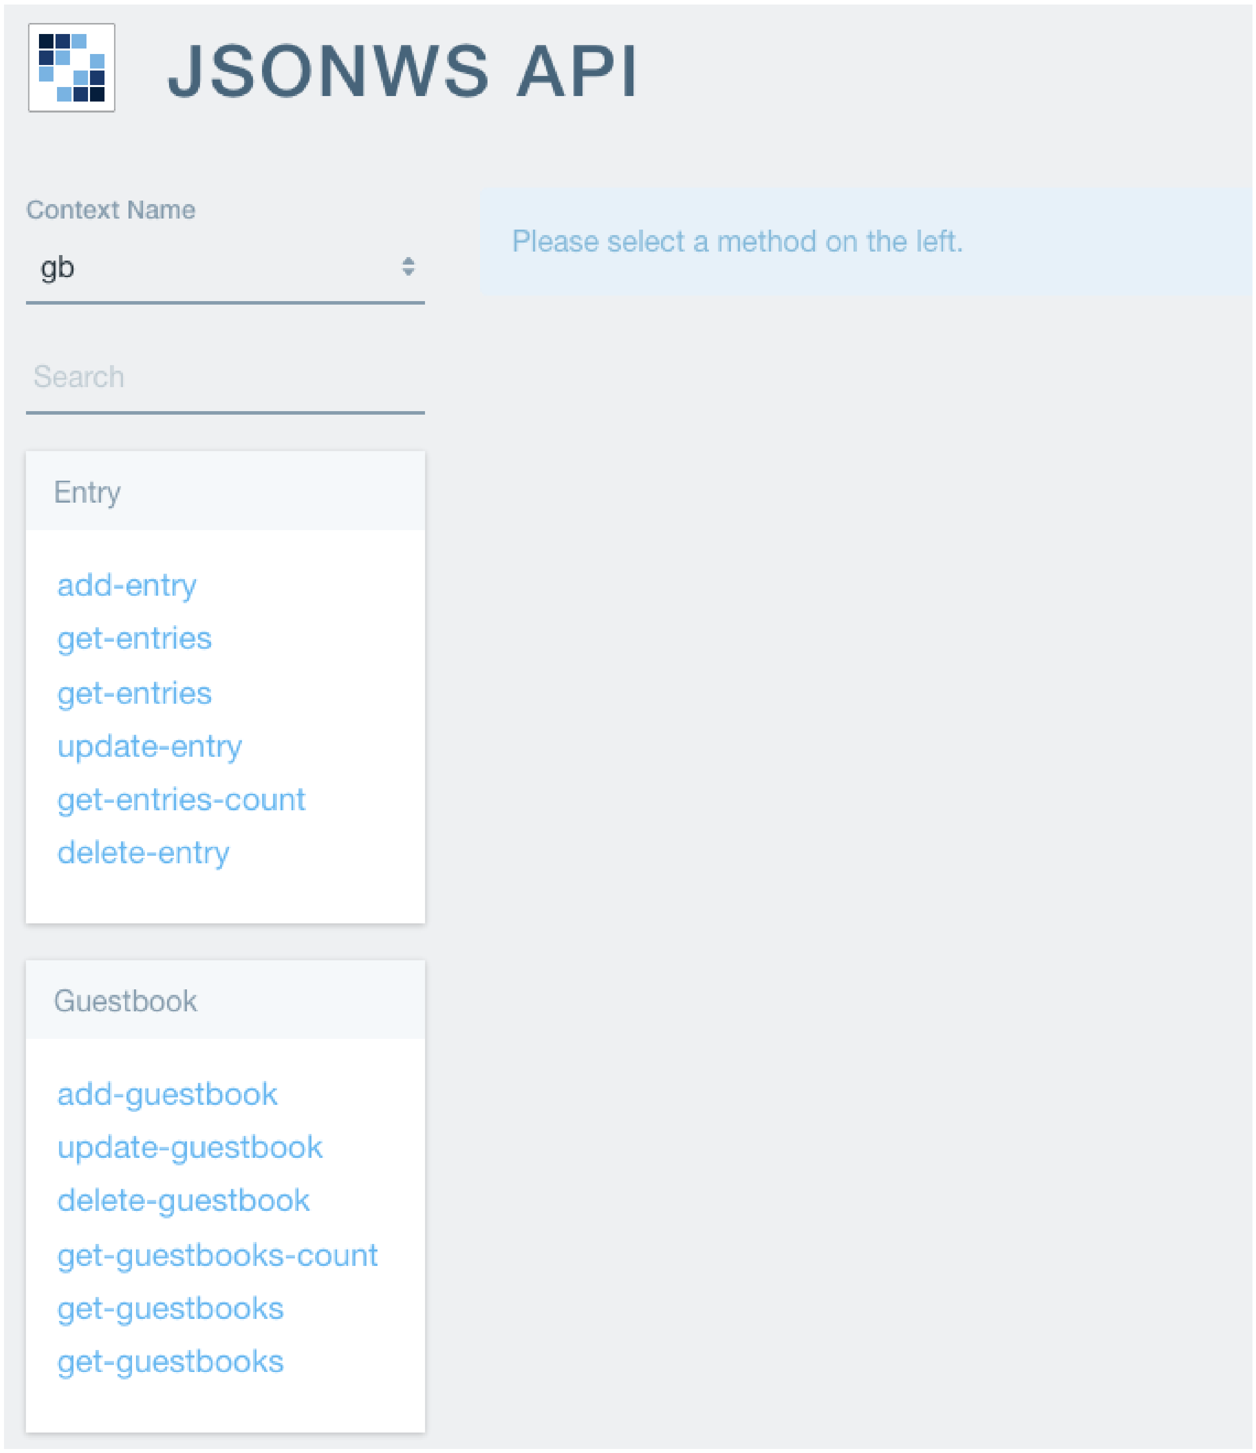


Figure 47.2: The Guestbook Portlet's context path (gb) on the server.

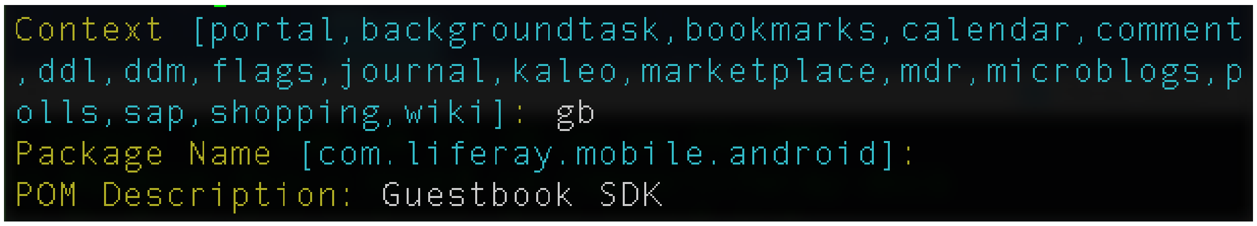

```
Context [portal,backgroundtask,bookmarks,calendar,comment
,ddl,ddm,flags,journal,kaleo,marketplace,mdr,microblogs,p
olls,sap,shopping,wiki]: gb
Package Name [com.liferay.mobile.android]:
POM Description: Guestbook SDK
```

Figure 47.3: To build your Mobile SDK, you must enter values for the Context, Package Name, and POM Description properties. The blue values in square brackets are defaults.

6. Now that the builder contains a gb module, you must generate that module's remote services. To do this, first navigate to this folder:

   ```
   liferay-mobile-sdk-ios-7.0.13/modules/gb
   ```

   Then run this command:

   ```
   ../../gradlew generate
   ```

   As before, the builder runs and generates a BUILD SUCCESSFUL message. Great! You're probably wondering what just happened, though. The builder generated the source classes you'll use in your iOS app to interact with the Guestbook portlet. You can find these source classes in the following folder of the Mobile SDK's source code:

   ```
   modules/gb/ios/Source/Service/v7
   ```

   The last folder in this path, v7, denotes the Liferay DXP version the classes work with. This folder has two subfolders that correspond to each entity in the Guestbook portlet: guestbook and entry. Each subfolder contains an Objective-C class header and implementation file for that entity's class (LRGuestbookService_v7 and LREntryService_v7, respectively).

7. There's one last thing to do before you can use these classes in your iOS app: put them in a JAR file. To do this, make sure you're still in the modules/gb folder on the command line and run this command:

   ```
   ../../gradlew zip
   ```

   This command generates this ZIP file:

   ```
   modules/gb/build/liferay-gb-ios-sdk-1.0.zip
   ```

   This ZIP file is the Guestbook Mobile SDK. It contains the service classes required to call the Guestbook portlet's remote services.

Congratulations! You just built the Guestbook Mobile SDK. Now that's an accomplishment worth writing in a guestbook. All you need now is an iOS app to install this Mobile SDK in. The next article shows you how to create it.

47.3 Creating the iOS Project

Now that you've built the Guestbook Mobile SDK, you're ready to create the Guestbook iOS app. This article walks you through the steps required to create the app's project in Xcode. After this, you'll be ready to install the Guestbook Mobile SDK and Liferay Screens.

Note: This learning path presumes that you've installed and know how to use Xcode. If you need assistance with Xcode, see Apple's developer site.

Follow these steps to create the Liferay Guestbook iOS project:

1. Open Xcode and click *Create a new Xcode project* on the welcome screen. Alternatively, you can select *File* → *New* → *Project*.
2. In the *Application* section of the *iOS* tab, select *Single View Application* and click *Next*.

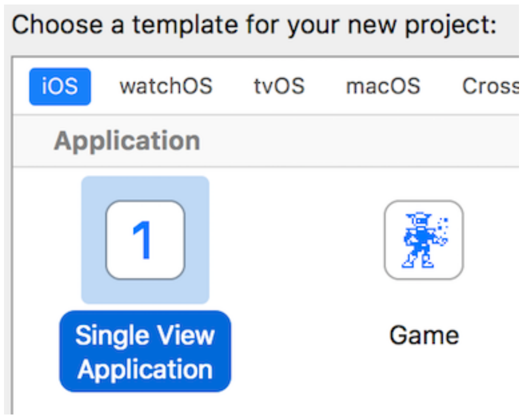

Figure 47.4: Use the Single View Application project template.

3. Enter the following fields as listed here:

    - **Product Name:** Liferay Guestbook
    - **Organization Name:** Your name
    - **Organization Identifier:** com.liferay.docs
    - **Language:** Swift

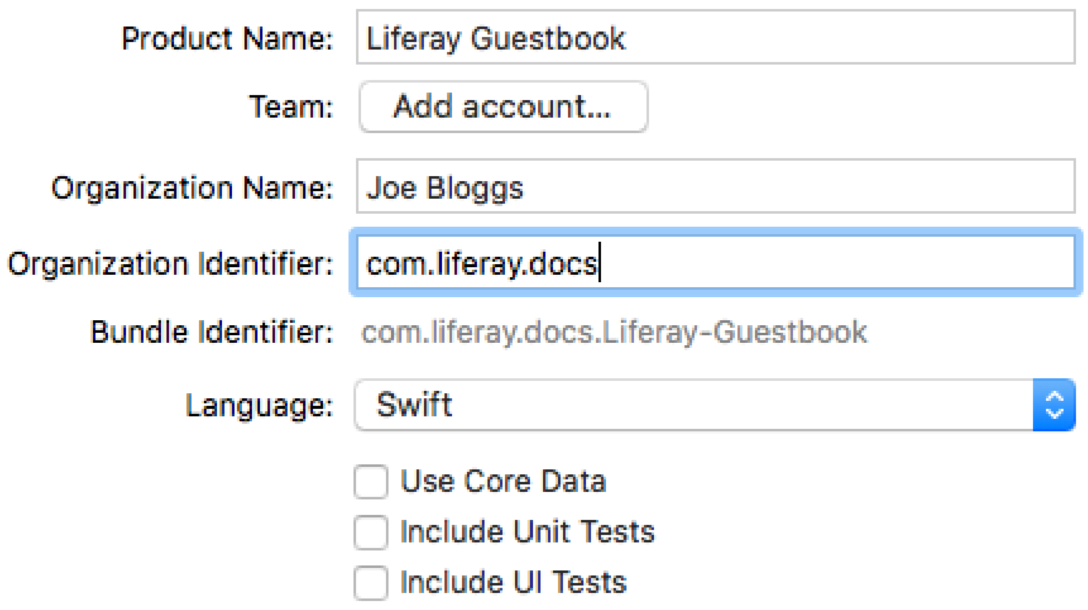
    Make sure the checkboxes below these fields are unchecked, and click *Next*.

4. Select a location for your project and click *Create*. Xcode creates and opens your new project.

Nice! You now have the iOS project in which you'll develop the Liferay Guestbook app. Before doing any development, however, you must install Liferay Screens and the Guestbook Mobile SDK. You'll do this next.

47.4 Installing Liferay Screens and the Guestbook Mobile SDK

For your iOS app to work with the Guestbook portlet, you must install the following in your iOS project:



Product Name:	Liferay Guestbook
Team:	Add account...
Organization Name:	Joe Bloggs
Organization Identifier:	com.liferay.docs
Bundle Identifier:	com.liferay.docs.Liferay-Guestbook
Language:	Swift
☐ Use Core Data	
☐ Include Unit Tests	
☐ Include UI Tests	

Figure 47.5: Fill out this form as shown.

- **Liferay's pre-built Mobile SDK:** This Mobile SDK contains the classes that call Liferay DXP's core remote services. It also contains the framework necessary for any Mobile SDK to make server calls.
- **The Guestbook Mobile SDK:** This Mobile SDK contains only the classes that call the Guestbook portlet's remote services.
- **Liferay Screens:** Screens contains the Screenlet framework and several built-in Screenlets like Login Screenlet. Because these built-in Screenlets work with Liferay DXP's core apps, they make their server calls with Liferay's pre-built Mobile SDK. Note that all Screenlets, including those that make server calls with a custom-built Mobile SDK, must use the framework in Liferay's pre-built Mobile SDK to issue their calls.

Since Liferay's pre-built Mobile SDK is a dependency of Liferay Screens, installing Screens automatically installs this Mobile SDK. You must, however, install the Guestbook Mobile SDK manually.

This article walks you through the installation of the Guestbook Mobile SDK and Liferay Screens. When you finish, you'll be ready to start developing the app.

Anatomy of the Liferay Guestbook iOS Project

Before getting started, you should learn a couple of terms this Learning Path uses when referring to the project's structure. Knowing these terms ensures that you know where to add folders and files in the project. In Xcode's Project navigator, there are two *Liferay Guestbook* items:

1. **The root project:** This is the first item in the Project navigator. It contains all other items in the project, and is labeled with a blue application document icon. The root project corresponds with a folder in

your file system that this Learning Path refers to as the *root project folder*. For example, the root project folder for the Liferay Guestbook project is `Liferay Guestbook`.

2. **The Liferay Guestbook folder:** This is immediately under the root project. It contains the app's files, and is labeled with a manila folder icon. Even though this folder shares a name with the root project folder on your file system, it **is not** the same thing. The root project folder contains this `Liferay Guestbook` folder.

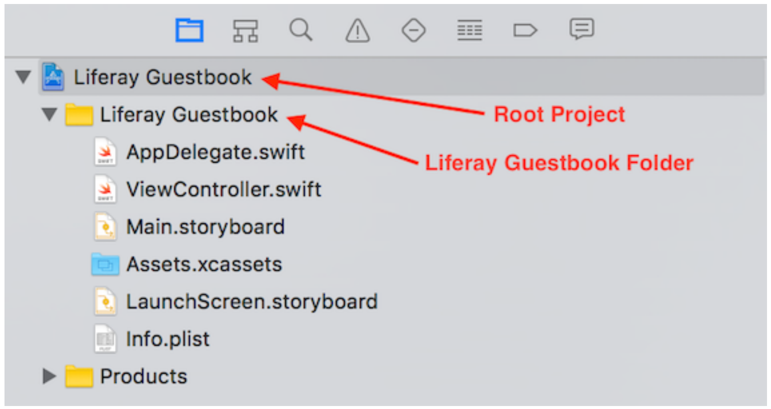


Figure 47.6: The root project and Liferay Guestbook folder are labeled in this screenshot.

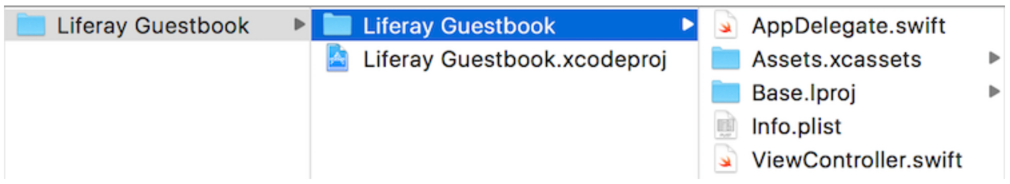

Figure 47.7: On your file system, the `Liferay Guestbook` root project folder contains the app's `Liferay Guestbook` folder. The latter is selected in this screenshot.

It's important not to confuse these two items. If you're ever confused about where things should go, click here to see the finished app in GitHub.

Now you're ready to install Liferay Screens!

Installing Liferay Screens

You'll use CocoaPods to install Liferay Screens. Click here for instructions on installing CocoaPods. After installing it, use these steps to install Screens:

1. In your root project's folder, create a file named `Podfile` that contains the following:

```
source 'https://github.com/CocoaPods/Specs.git'

platform :ios, '9.0'
use_frameworks!

target "Liferay Guestbook" do
    pod 'LiferayScreens', '3.0.2'
end

post_install do |installer|
  incompatiblePods = [
    'Cosmos',
    'CryptoSwift',
    'KeychainAccess',
    'Liferay-iOS-SDK',
    'Liferay-OAuth',
    'LiferayScreens',
    'Kingfisher'
  ]

  installer.pods_project.targets.each do |target|
    if incompatiblePods.include? target.name
      target.build_configurations.each do |config|
        config.build_settings['SWIFT_VERSION'] = '3.2'
      end
    end
    target.build_configurations.each do |config|
        config.build_settings['CONFIGURATION_BUILD_DIR'] = '$PODS_CONFIGURATION_BUILD_DIR'
    end
  end
end
```

This adds Liferay Screens 3.0.2 (the most recent version at the time this Learning Path was published) as a dependency. Since Screens 3.0.2 is incompatible with Swift 4, this `Podfile` also specifies that Screens and several of its dependencies (`incompatiblePods`) should be compiled by Swift 3.2. This lets you develop the app in Swift 4, while Screens itself is compiled in Swift 3.2.

Also note the setting for `CONFIGURATION_BUILD_DIR`. This is a workaround for a benign bug that causes Screenlet previews to fail in Interface Builder.

2. On the terminal, navigate to your root project's folder and run this command:

```
pod repo update
```

This ensures you have the latest version of the CocoaPods repository on your machine. Note that this command can take a while to run.

3. Still in your root project's folder in the terminal, run this command:

```
pod install
```

This installs the Liferay Screens as specified in your `Podfile`. Once this completes, quit Xcode and reopen your project by using the `LiferayGuestbook.xcworkspace` file in your root project's folder. From now on, you must use this file to open your project.

Great! You just installed Liferay Screens and the Liferay Mobile SDK! Next, you'll install the Guestbook Mobile SDK.

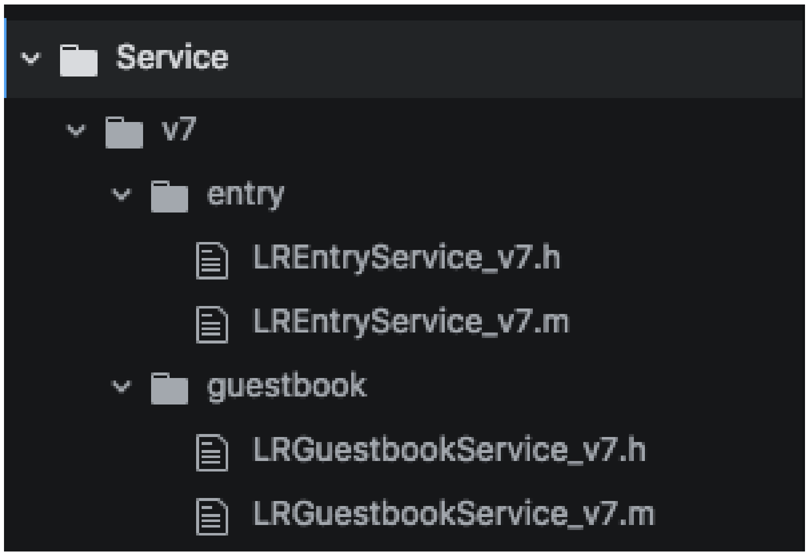
Installing the Guestbook Mobile SDK

To install the Guestbook Mobile SDK, you must add its service classes to your project. Recall that these service classes are Objective-C. To use them from your project's Swift code, you must also add and configure an Objective-C bridging header. You'll do these things now:

1. Recall that you created the following ZIP file containing the Guestbook Mobile SDK:

```
modules/gb/build/liferay-gb-ios-sdk-1.0.zip
```

Unzip this file to a location of your choosing on your machine. This creates the following directory hierarchy:

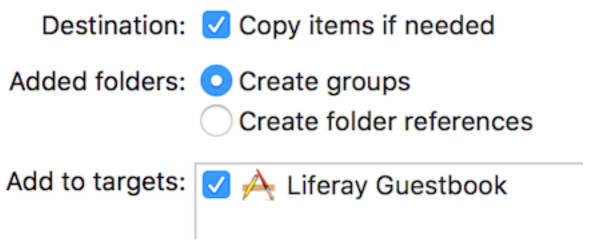


Service
v7
entry
LREntryService_v7.h
LREntryService_v7.m
guestbook
LRGuestbookService_v7.h
LRGuestbookService_v7.m

Figure 47.8: The Guestbook Mobile SDK's Objective-C classes unzip to this folder structure.

This should look familiar. It's the same `Service` folder, contents and all, from the Guestbook Mobile SDK you built earlier.

2. To install the service classes in your project, drag the v7 folder from your Finder into your Xcode project, directly under the root project. In the dialog that appears, make sure you select the following items, and then click *Finish*:



Destination: [✓ Copy items if needed]
Added folders: [✓ Create groups] Create folder references
Add to targets: [✓ Liferay Guestbook]

Figure 47.9: When adding the Guestbook Mobile SDK to your project, select these options and then click *Finish*.

3. The v7 folder and its contents are now inside your Xcode project. Now you must change each Objective-C class header file in the Guestbook Mobile SDK to always import the Liferay Mobile SDK framework. This is necessary because you used `use_frameworks!` in your `Podfile`.

   In `LREntryService_v7.h` and `LRGuestbookService_v7.h`, replace the `#if ... #endif` statement with `@import LRMobileSDK;`. Don't worry if Xcode doesn't recognize this import–you'll fix this shortly by adding and configuring an Objective-C bridging header in your project.

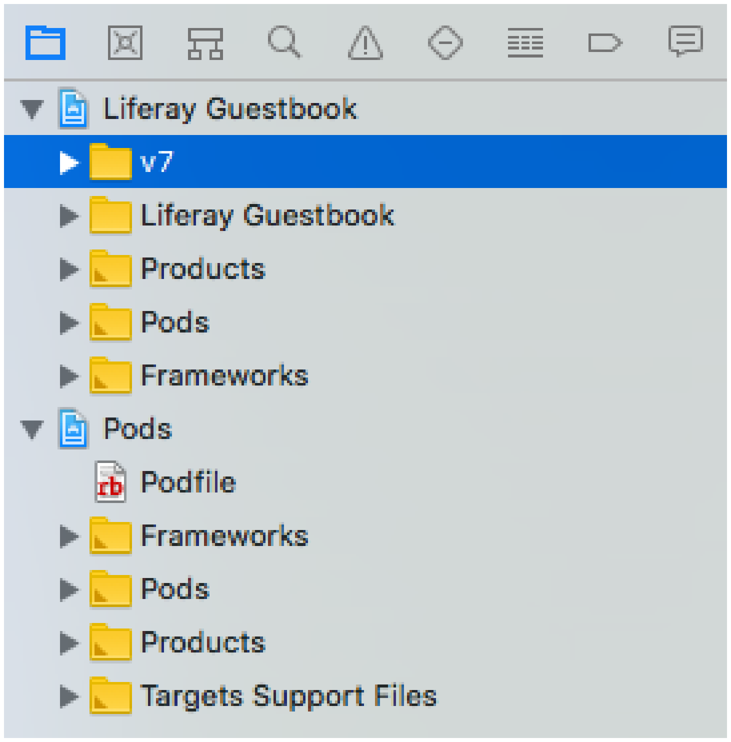


Figure 47.10: Your project structure should look like this after adding the Guestbook SDK.

4. In Xcode, for each `*.m` file in the Guestbook Mobile SDK (`LREntryService_v7.m` and `LRGuestbookService_v7.m`), make sure the checkbox for the *Liferay Guestbook* target is selected in the File inspector's *Target Membership* section.

To use the Guestbook Mobile SDK's Objective-C classes from Swift, you must add and configure an Objective-C bridging header in your project. Follow these instructions to do so:

1. In Xcode's project navigator, right-click the root project and select *New File*. In the window that appears, select *Header File* from the *Source* section of the *iOS* tab, and click *Next*.

2. Name the file `Liferay Guestbook-Bridging-Header.h` and make sure that *Liferay Guestbook* with the blue icon is selected in the *Group* menu. To finish creating the file, uncheck any items in *Targets* and click *Create*.

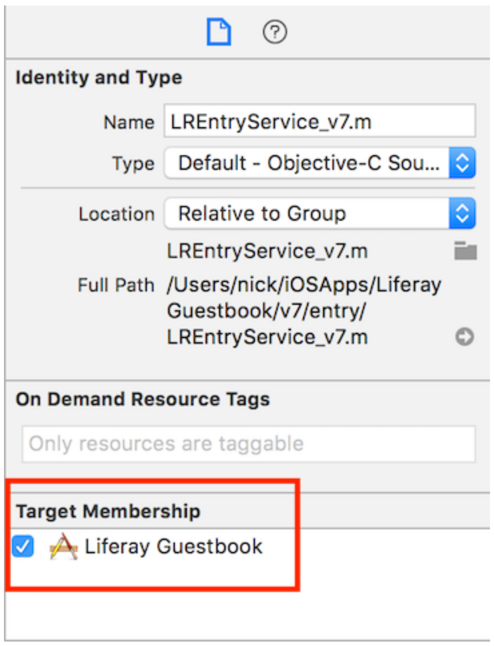
3. Upon creating the header file, Xcode opens it in the editor. In this file, you must import the Guestbook Mobile SDK's header files. Add these imports immediately below the comments at the top of the file:

```
#import "LRGuestbookService_v7.h"
#import "LREntryService_v7.h"
```

Your bridging header file should now look like this:

```
#import "LRGuestbookService_v7.h"
#import "LREntryService_v7.h"

#ifndef Liferay_Guestbook_Bridging_Header_h
#define Liferay_Guestbook_Bridging_Header_h
```



Identity and Type

Name LREntryService_v7.m

Type Default - Objective-C Sou...

Location Relative to Group

LREntryService_v7.m

Full Path /Users/nick/iOSApps/Liferay Guestbook/v7/entry/LREntryService_v7.m

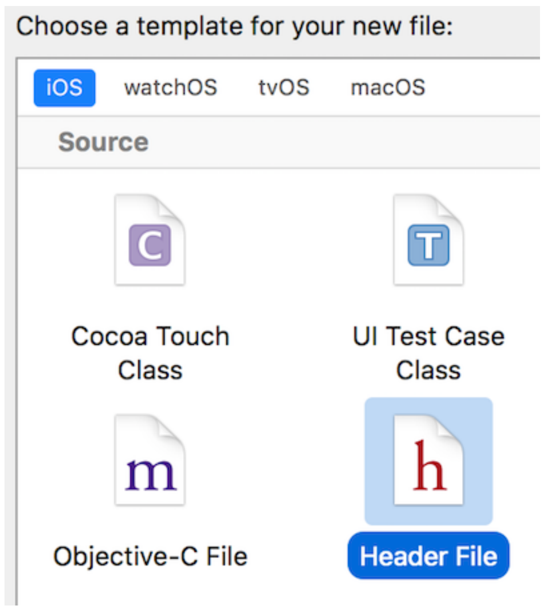
On Demand Resource Tags

Only resources are taggable

Target Membership

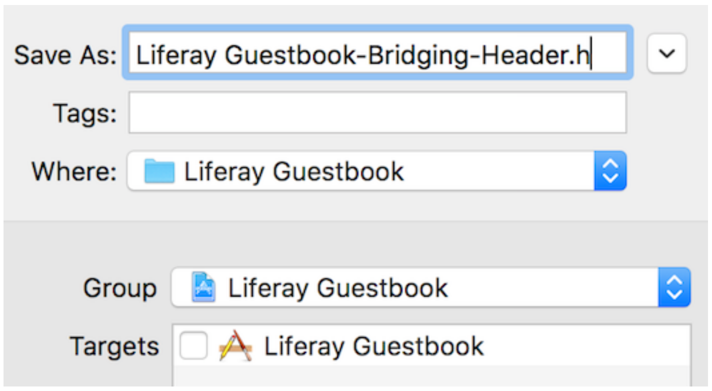
☑ Liferay Guestbook

Figure 47.11: Each `*.m` file in the Guestbook Mobile SDK must be part of the *Liferay Guestbook* target.



Choose a template for your new file:

Figure 47.12: Create a new iOS header file.

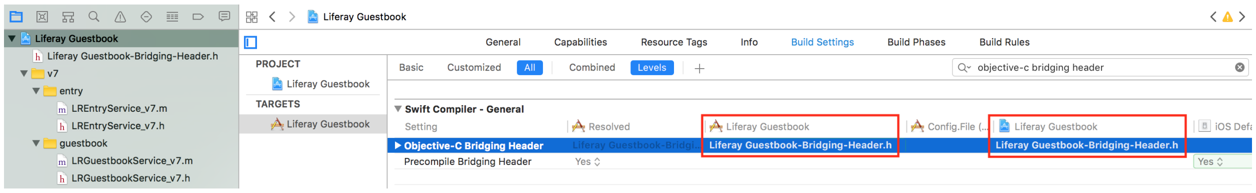


Save As: Liferay Guestbook-Bridging-Header.h
Tags:
Where: Liferay Guestbook
Group: Liferay Guestbook
Targets: Liferay Guestbook

Figure 47.13: Use these options to create the header file.

```
#endif
```

4. Now you must configure your project to use this file. Select the root project on the left and then click *Build Settings*. Enter for *Objective-C Bridging Header* in the search box. The matching build setting appears under the section *Swift Compiler - General*. In the two *Liferay Guestbook* fields for this build setting, enter the bridging header's file name.



Swift Compiler - General

Setting	Resolved	Liferay Guestbook	Config.File (...	Liferay Guestbook	iOS Defa
Objective-C Bridging Header	Liferay Guestbook-Bridgi...	Liferay Guestbook-Bridging-Header.h		Liferay Guestbook-Bridging-Header.h	
Precompile Bridging Header	Yes				Yes

Figure 47.14: The red boxes highlight the two Liferay Guestbook fields configured to use the bridging header file.

5. Build the project.

Awesome! You've successfully installed the Guestbook Mobile SDK. Next, you'll configure your app to communicate with your Liferay DXP installation.

Configuring Communication with Liferay Portal

For Liferay Screens to work with your app, you must configure it to communicate with your Liferay DXP installation. You'll do this by setting attributes in a `plist` file:

1. In Xcode's project navigator, right-click the *Liferay Guestbook* folder (**not** the root project) and select *New File*. In the dialog that appears, select the *iOS* tab then scroll down to the *Resource* section and select *Property List*. Click *Next*.

2. Name the file `liferay-server-context.plist` and make sure you're creating it in the *Liferay Guestbook* folder, which should be selected in the *Group* menu. Also make sure that *Liferay Guestbook* is selected in the *Targets* menu. Then click *Create*.

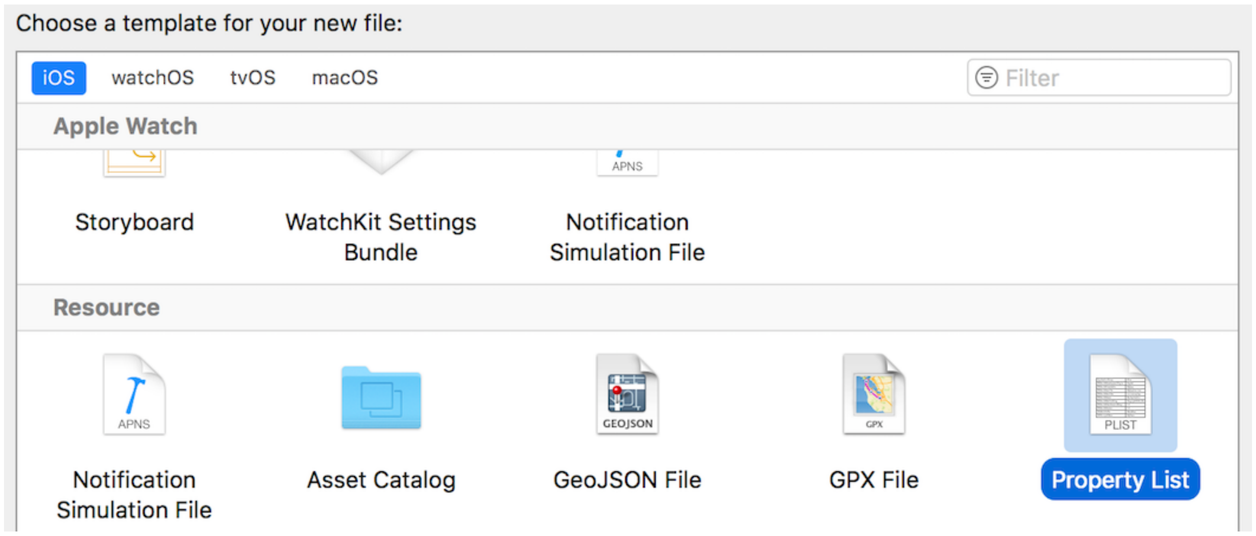


Figure 47.15: : Use the Property List template to create a new plist file.

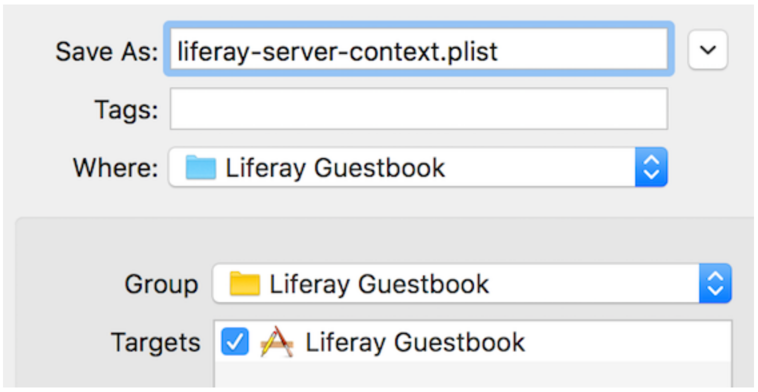


Save As: liferay-server-context.plist
Tags:
Where: Liferay Guestbook
Group Liferay Guestbook
Targets ✓ Liferay Guestbook

Figure 47.16: : Create the plist file as shown here.

3. The plist file now opens in the editor. Right-click the file in the Project navigator and select *Open As → Source Code*. Replace the file's contents with this code:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
    <key>server</key>
    <string>http://localhost:8080</string>
    <key>version</key>
    <integer>70</integer>
    <key>companyId</key>
    <integer>20116</integer>
    <key>groupId</key>
    <integer>20143</integer>
</dict>
</plist>
```

This plist file sets the server address (http://localhost:8080), Liferay DXP version (70 specifies Liferay CE Portal 7.0 and Liferay DXP 7.0), companyId (Liferay DXP instance ID), and groupId (site ID) the app retrieves data from.

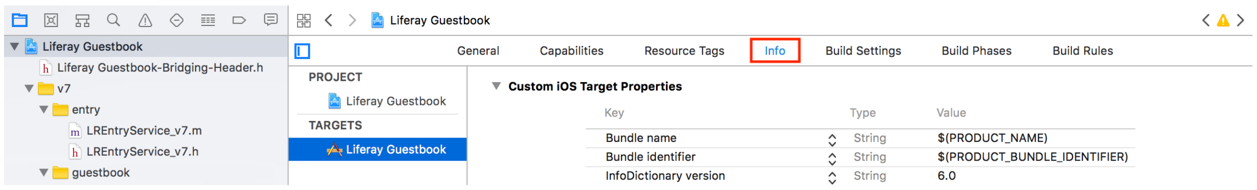
4. Change the `companyId` and `groupId` in the `plist` file to match those of your Liferay DXP instance. You can find your company ID in your portal at *Control Panel* → *Configuration* → *Virtual Instances*. The instance's ID is in the *Instance ID* column. You can find your site ID from the site you put the Guestbook portlet on. Navigate to this site, and in the *Site Administration* menu select *Configuration* → *Site Settings*. The site ID is listed at the top of the *General* tab.

Next, you'll configure iOS App Transport Security.

Disabling App Transport Security

App Transport Security is an iOS security feature that restricts all network activity to HTTPS. It isn't necessary for use in development and testing. Since your local Liferay DXP instance uses HTTP by default, App Transport Security prevents your app from communicating with the portal. You must therefore disable it:

1. Select your project in Xcode's Project navigator. With the *Liferay Guestbook* target selected in the outline, click the *Info* tab.



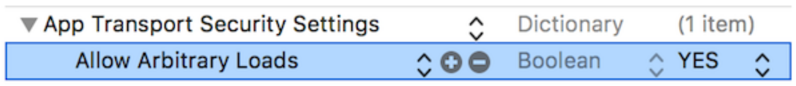
Custom iOS Target Properties

Key	Type	Value
Bundle name	String	$(PRODUCT_NAME)
Bundle identifier	String	$(PRODUCT_BUNDLE_IDENTIFIER)
InfoDictionary version	String	6.0

Figure 47.17: : You'll disable App Transport Security in the Info tab.

2. In *Custom iOS Target Properties*, right-click *Bundle OS Type Code* and select *Add Row*. In the new row's text field, enter *App Transport Security Settings*.

3. Even though it doesn't yet contain any items, ensure that the App Transport Security Settings category is open (click the triangle icon to its left to open/close it). Now click the + icon next to App Transport Security Settings and select *Allow Arbitrary Loads*. Then select *YES* for this field's value.



App Transport Security Settings	Dictionary	(1 item)
Allow Arbitrary Loads	Boolean	YES

Figure 47.18: : Your App Transport Security settings should look like this.

The Allow Arbitrary Loads setting should look like this when viewing your app's `Info.plist` file as code:

```
...
<key>NSAppTransportSecurity</key>
<dict>
    <key>NSAllowsArbitraryLoads</key>
    <true/>
</dict>
...
```

Stupendous! You've successfully installed Liferay Screens and the Guestbook Mobile SDK, and configured your app to communicate with your Liferay DXP instance. Before starting work on the app, however, you should learn the app's design. The next article walks you through this.

47.5 Designing Your App

As a developer, you know that developing any kind of app without an overall design goal and plan to implement it is a recipe for disaster. To avoid this, you need to decide some things upfront. The Liferay Guestbook app needs a straightforward way to do three things:

1. Authenticate users
2. Display guestbooks
3. Display entries

To authenticate users, all you need to do is insert and configure Login Screenlet in your app. Login Screenlet comes complete with its own UI. The design for authentication, therefore, like with Liferay DXP itself, is done for you.

You must, however, create the UI for displaying guestbooks and entries. What sort of UI would be best for this? Although the *best* UI for any purpose is a matter of opinion, displaying guestbooks and entries in lists is a good choice. Lists are common, compact design elements familiar to mobile users. Since most mobile devices don't have room to display a list of guestbooks and a list of entries at the same time, you also need a user-friendly way to display and manage these lists. It makes sense to show a list of guestbooks automatically after the user authenticates. The user can then select a guestbook to view a list of its entries. Users are familiar with this drill-down navigation style, as it's common throughout iOS.

To display these lists, you'll create your own Screenlets: Guestbook List Screenlet and Entry List Screenlet. Guestbook List Screenlet needs to retrieve guestbooks from the portlet and display them in a simple list. Once written, using this Screenlet is a simple matter of inserting it in a scene. Entry List Screenlet needs to retrieve and display a guestbook's entries in a similar list. You'll display the entries by inserting Entry List Screenlet in another scene.

Also note that these Screenlets are *list Screenlets*. You develop list Screenlets by using the list Screenlet framework, which sits on top of the core Screenlet framework. The list Screenlet framework makes it easy for developers to write Screenlets that display lists of entities from a Liferay DXP instance.

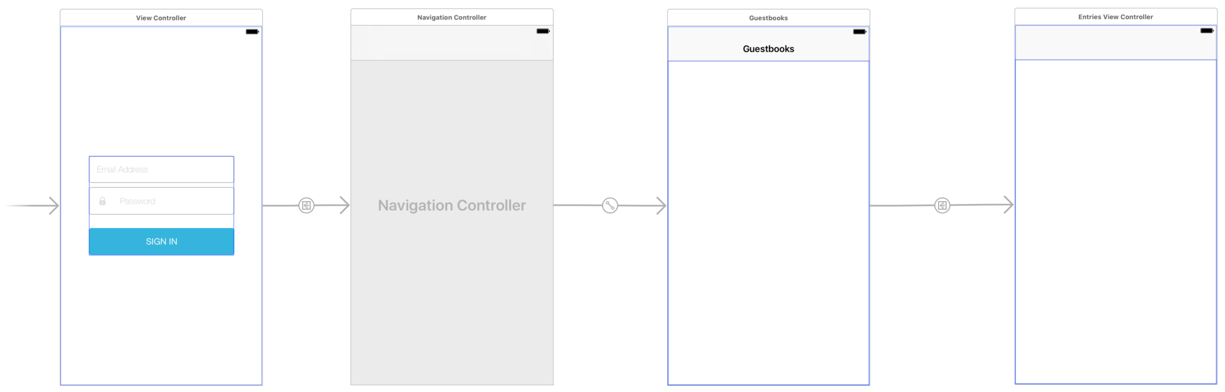


Figure 47.19: After login, the user transitions to the guestbooks scene where Guestbook List Screenlet displays a list of guestbooks. Upon selecting a guestbook, the entries scene displays a list of that guestbook's entries with Entry List Screenlet. Because the guestbooks and entries scenes are embedded in a navigation controller, the user can navigate back to the guestbooks scene via a back button in the navigation bar.

Awesome! Now you have a basic UI design and know the Screenlets you'll create to implement it. But the app currently contains only one empty scene, which you'll use for authentication with Login Screenlet. To use your custom list Screenlets, you'll need to create two additional scenes. You'll do this as you develop the app.

Great! Now you understand the Liferay Guestbook app's design. Next, you'll use Login Screenlet to implement authentication.

47.6 Using Login Screenlet for Authentication

For the app to retrieve data from the Guestbook portlet, the user must first authenticate to the Liferay DXP instance. You can implement authentication using the Liferay Mobile SDK, but it takes time to write. Using Liferay Screens to authenticate takes about ten minutes. In this article, you'll use Login Screenlet to implement authentication in your app.

Adding Login Screenlet to the App

To use any Screenlet, you must follow two steps:

1. Insert the Screenlet in the storyboard scene where you want it to appear. You do this by adding an empty view to the scene, and then setting the Screenlet class as the view's custom class.
2. Conform the scene's view controller's class to the Screenlet's delegate protocol. This lets the view controller respond to the Screenlet's events.

In this app, you'll use Login Screenlet in the app's first (and at this time, only) scene. After adding the Screenlet to this scene, you'll conform `ViewController` (the scene's view controller class) to the `LoginScreenletDelegate` protocol.

Adding Login Screenlet to the Scene

Follow these steps to add Login Screenlet to the scene:

1. In `Main.storyboard`, first select the scene's view controller. Then drag and drop a plain view (`UIView`) from the Object Library onto the view controller. In the outline view, this new view should be nested under the view controller's existing view.

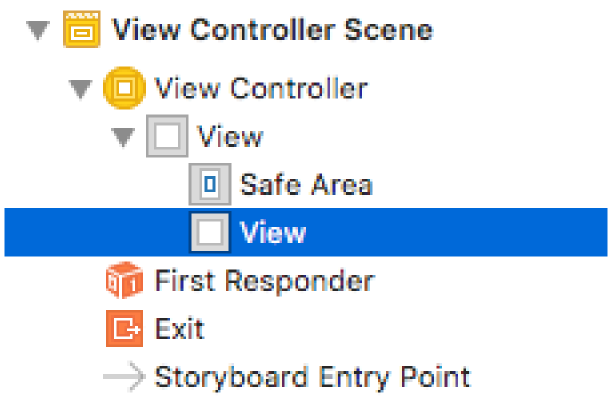

Figure 47.20: The new view is nested under the view controller's existing view.

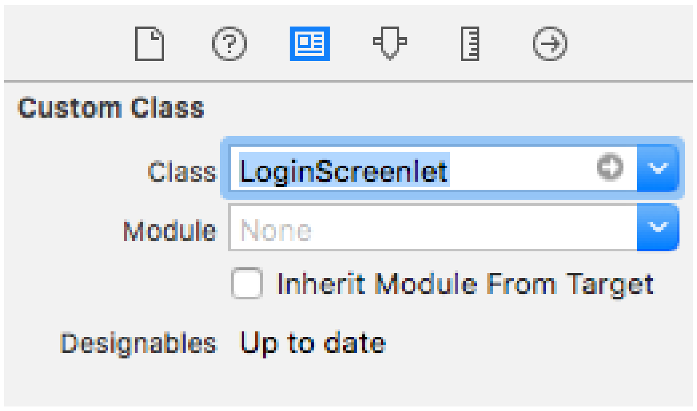
2. With the new view selected, open the Identity inspector and set the view's Custom Class as `LoginScreenlet`. Xcode now builds the project and renders Login Screenlet's preview in the view. Also note that the view now appears as Login Screenlet in the outline view.



Custom Class

Class LoginScreenlet

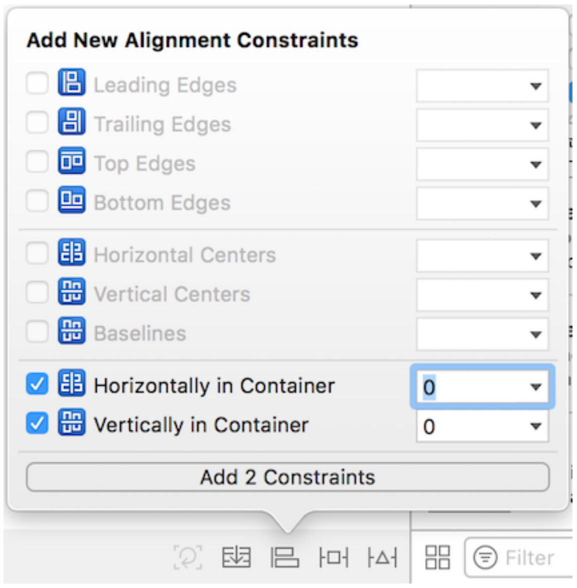
Module None

☐ Inherit Module From Target

Designables Up to date

Figure 47.21: You must set the view's Custom Class to `LoginScreenlet`.

3. Now you'll set the constraints to center Login Screenlet in the scene. Although this isn't required (you can technically position Login Screenlet anywhere you want), centering an authentication UI is common in mobile apps. Center Login Screenlet in the scene, and click the *Align* menu at the bottom-right of the canvas. In this menu, check the checkboxes for *Horizontally in Container* and *Vertically in Container*, and click the *Add 2 Constraints* button (don't worry about the Auto Layout errors that appear–you'll resolve these in the next step).



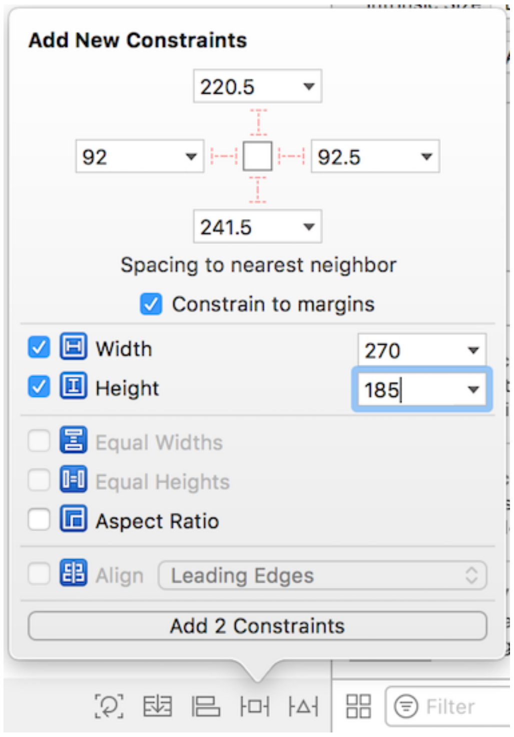
Add New Alignment Constraints

☐ Leading Edges	
☐ Trailing Edges	
☐ Top Edges	
☐ Bottom Edges	
☐ Horizontal Centers	
☐ Vertical Centers	
☐ Baselines	
✓ Horizontally in Container	0
✓ Vertically in Container	0

Add 2 Constraints

Figure 47.22: These alignment constraints center Login Screenlet in the scene.

4. By default, Login Screenlet stretches or compresses to fill the view. It's compressed at the moment because of the alignment constraints. To avoid any ill-effects caused by automatic resizing, you'll set the Screenlet to a fixed size. With the view selected, open the *Add New Constraints* menu at the bottom-right of the canvas. In this menu, set the *Width* to 270 and the *Height* to 185, and click the *Add 2 Constraints* button. The Screenlet looks better now and the Auto Layout errors are gone. Note that you don't have to use these exact width and height values when using Login Screenlet. You can size the Screenlet however you wish.



Add New Constraints

220.5

92

92.5

241.5

Spacing to nearest neighbor

✓ Constrain to margins

✓ Width 270

✓ Height 185

Equal Widths

Equal Heights

Aspect Ratio

Align Leading Edges

Add 2 Constraints

Figure 47.23: Setting these size constraints ensures that Login Screenlet isn't too stretched out or compressed.

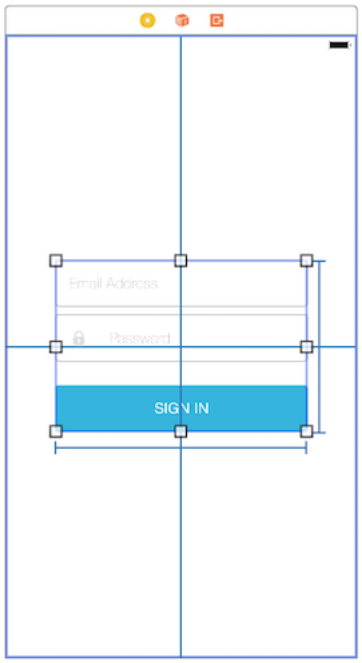


Figure 47.24: With the alignment and size constraints set, Login Screenlet appears in the center of the scene and its UI components aren't too compressed or stretched out.

Nicely done! The scene now contains Login Screenlet. Next, you'll conform `ViewController` (the scene's view controller class) to the `LoginScreenletDelegate` protocol.

Conforming to the Screenlet's Delegate Protocol

A view controller can respond to a Screenlet's events by conforming to the Screenlet's delegate protocol. This lets the app developer choose how their app behaves with the Screenlet. To respond to Login Screenlet's events, `ViewController` must conform to the `LoginScreenletDelegate` protocol. The Login Screenlet events that need a response are login success and failure. The delegate defines methods for both.

Follow these steps to conform `ViewController` to the `LoginScreenletDelegate` protocol:

1. Import `LiferayScreens` and set `ViewController` to adopt the `LoginScreenletDelegate` protocol. The first few lines of the class should look like this:

```
import UIKit
import LiferayScreens

class ViewController: UIViewController, LoginScreenletDelegate {...
```

2. Implement the `LoginScreenletDelegate` method `screenlet(_:onLoginResponseUserAttributes:)`. This method is called when authentication with Login Screenlet succeeds. Right now, you don't need to do anything in this method besides indicate that login succeeded:

```
func screenlet(_ screenlet: BaseScreenlet,
    onLoginResponseUserAttributes attributes: [String:AnyObject]) {
        print("Login Successful!")
}
```

3. Implement the `LoginScreenletDelegate` method `screenlet(_:onLoginError:)`. This method is called when authentication with Login Screenlet fails. All you need to do in this method is print a message indicating that login failed:

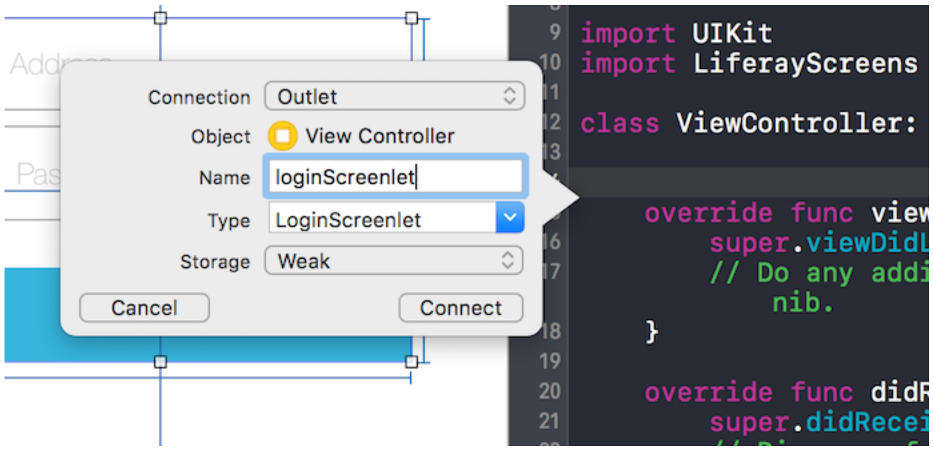
```
func screenlet(_ screenlet: BaseScreenlet, onLoginError error: NSError) {
    print("Login Failed!")
}
```

4. Now you must get a Login Screenlet reference in `ViewController`. You'll do this by creating an outlet to the Screenlet. Return to your storyboard and enter the Assistant editor to display `ViewController`'s code and the storyboard side by side. With Login Screenlet selected in the storyboard, Control-drag from the Screenlet to the `ViewController` class to create the outlet. In the dialog that appears upon releasing your mouse button, enter the following information and click *Connect*:

    - **Connection:** Outlet
    - **Name:** loginScreenlet
    - **Type:** LoginScreenlet
    - **Storage:** Weak

   Xcode then adds the following code inside the `ViewController` class:

```
@IBOutlet weak var loginScreenlet: LoginScreenlet!
```



Connection: Outlet
Object: View Controller
Name: loginScreenlet
Type: LoginScreenlet
Storage: Weak

```
import UIKit
import LiferayScreens

class ViewController:

    override func view
        super.viewDidL
        // Do any addi
            nib.
    }

    override func didR
        super.didRecei
```

Figure 47.25: Create an outlet from Login Screenlet to the `ViewController` class.

5. In the `ViewController` class, use the new `loginScreenlet` variable to set the view controller as the Screenlet's delegate. Do this in the `viewDidLoad()` method by deleting the placeholder comment and inserting this code below the call to `super.viewDidLoad()`:

   ```
   self.loginScreenlet?.delegate = self
   ```

Great, you're finished! Before running the app, make sure that your `ViewController` class looks like this:

```
import UIKit
import LiferayScreens

class ViewController: UIViewController, LoginScreenletDelegate {

    @IBOutlet weak var loginScreenlet: LoginScreenlet!

    override func viewDidLoad() {
        super.viewDidLoad()
        self.loginScreenlet?.delegate = self
    }

    override func didReceiveMemoryWarning() {
        super.didReceiveMemoryWarning()
    }

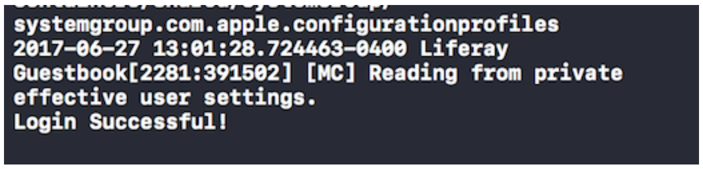
    func screenlet(_ screenlet: BaseScreenlet, onLoginResponseUserAttributes attributes: [String:AnyObject]) {
        print("Login Successful!")
    }

    func screenlet(_ screenlet: BaseScreenlet, onLoginError error: NSError) {
        print("Login Failed!")
    }

}
```

Now you're ready to test your work. With your Liferay DXP instance running, launch the app using the iPhone simulator (any iPhone version supported by Xcode will work). Enter your credentials when Login Screenlet appears and click *SIGN IN*. In Xcode, the `Login Successful!` message appears in the console.

Nice job! Nothing else happens, though. Your app still displays Login Screenlet. This is expected. There aren't any other scenes for your app to navigate to. In the next article, you'll create the scene for displaying guestbooks: the guestbooks scene.



```
systemgroup.com.apple.configurationprofiles
2017-06-27 13:01:28.724463-0400 Liferay
Guestbook[2281:391502] [MC] Reading from private
effective user settings.
Login Successful!
```

Figure 47.26: It worked!

47.7 Creating the Guestbooks Scene

In the previous article, you used Login Screenlet to implement authentication in the login scene. Now you must create the scene you want the user to see following login: the guestbooks scene. Later in this Learning Path, you'll display guestbooks in this scene via Guestbook List Screenlet. For now, though, all you need to do is create the scene and take the user to it after login. This article shows you how to do this with the following steps:

1. Add a view controller to your storyboard. You'll then embed the view controller in a navigation controller. The navigation controller gives the scene a navigation bar and automatically implements back-navigation in the entries scene you'll create later.
2. Create the guestbook scene's view controller class. This class controls the view controller's behavior.
3. Create a segue from the login scene to the guestbooks scene. Upon login, this segue takes the user to the guestbooks scene.

First, you'll add a view controller to the storyboard.

Adding a View Controller to the Storyboard

Follow these steps to add a view controller to the storyboard:

1. Open your storyboard and drag and drop a *View Controller* from the Object Library to the right of the login scene.
2. Now you must embed this view controller in a navigation controller. Navigation controllers in iOS implement a *navigation stack*. You can loosely think of a navigation stack as a deck of cards where each card is a view controller with a navigation bar. The navigation bar contains a back button that lets you navigate to the previous view controller in the stack. You can also change the navigation bar's title to reflect the scene's content.

   With the new view controller selected in the storyboard, select *Editor → Embed In → Navigation Controller*. Your storyboard now shows the navigation controller with a segue to the guestbooks scene. Also, the guestbooks scene now contains an empty navigation bar.
3. Select the Navigation Item in the guestbooks scene's navigation bar. In the Attributes inspector, enter *Guestbooks* in the *Title* field, then enter a single space in the *Back Button* field and press return. This labels the scene via the navigation bar, and ensures that the back button in the Navigation controller has no label. The back button's default left chevron indicates the button's purpose without the need for additional text.

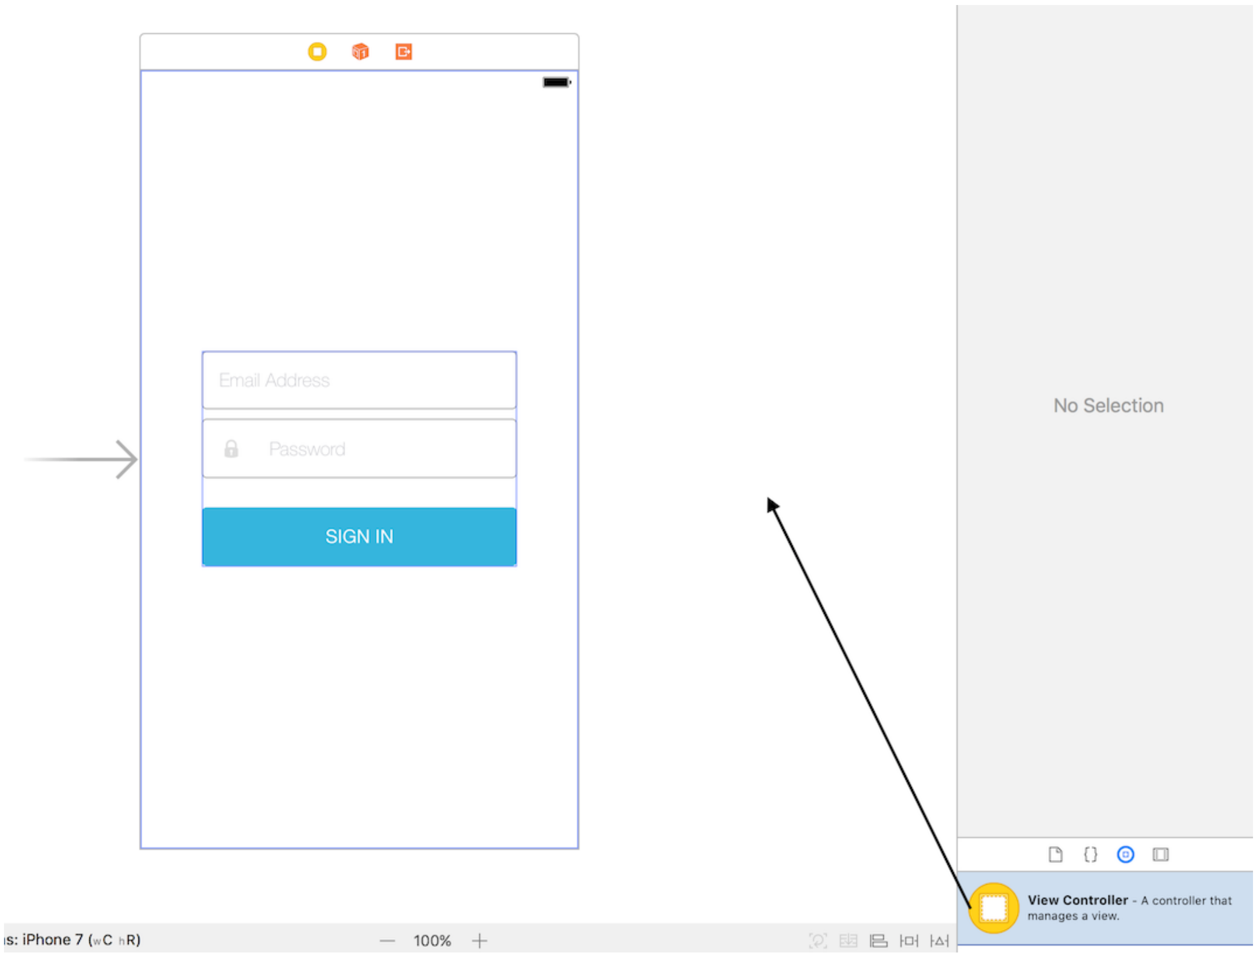


Figure 47.27: The arrow shows where to drag and drop the View Controller to create the new guestbooks scene.

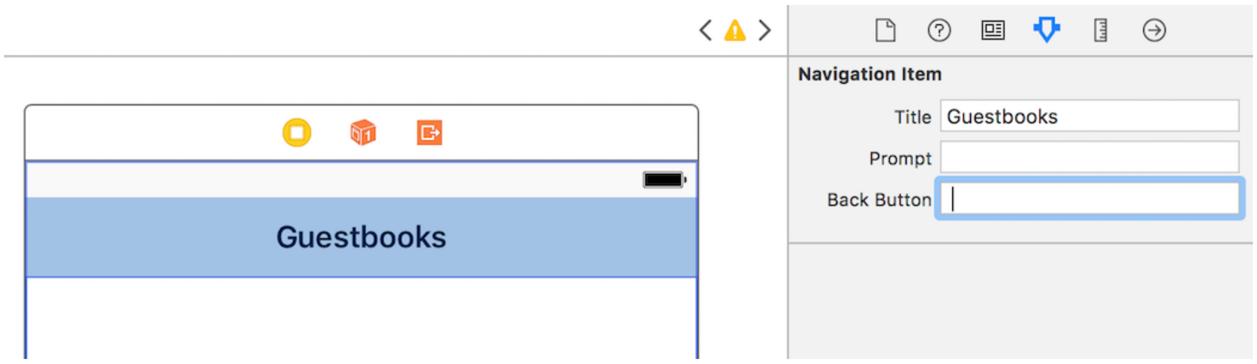
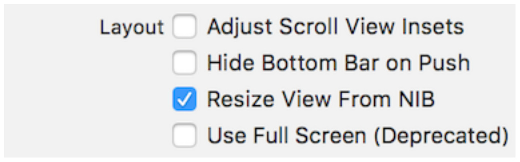


Title: Guestbooks
Prompt:
Back Button:

Figure 47.28: Label the scene in the navigation bar, and set the back button's label to an empty space.



Layout

☐ Adjust Scroll View Insets

☐ Hide Bottom Bar on Push

☑ Resize View From NIB

☐ Use Full Screen (Deprecated)

Figure 47.29: Make sure the view controller's *Adjust Scroll View Insets* option is unchecked in the Attributes inspector.

4. With the guestbooks scene's view controller selected in the storyboard, open the Attributes inspector and uncheck *Adjust Scroll View Insets*. This ensures that the scene's contents are flush with the navigation bar.

Great! You now have the guestbooks scene, embedded in a navigation controller. For this scene's view controller to work, it must have a class that controls its behavior. You'll create this class next.

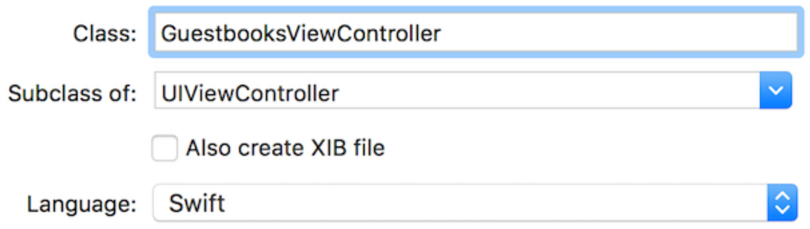
Creating the Guestbooks Scene's View Controller Class

Each view controller must have a class that controls its behavior. In this section, you'll create this class for the guestbooks scene's view controller. In the storyboard, you'll then set this class as the view controller's custom class.

1. Right-click the *Liferay Guestbook* folder in Xcode's project navigator and select *New File*. In the *iOS → Source* section of the dialog that appears, select *Cocoa Touch Class* and click *Next*.

2. The next screen in the dialog lets you set the class's name, subclass, and language. You can also choose whether to create an XIB file for the class. Enter the following information and click *Next*:

   - **Class:** `GuestbooksViewController`
   - **Subclass of:** `UIViewController`
   - **Also create XIB file:** Unchecked
   - **Language:** Swift



Class: GuestbooksViewController

Subclass of: UIViewController

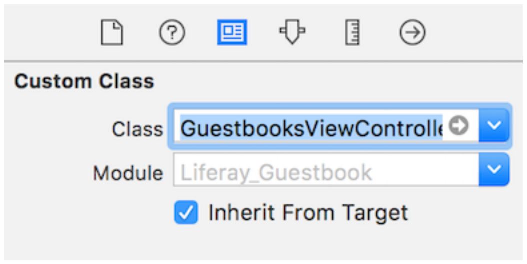
☐ Also create XIB file

Language: Swift

Figure 47.30: Set these options when creating the view controller's class.

3. The final screen in the dialog lets you set the class's location, group, and targets. Make sure *Liferay Guestbook* is selected for both the *Group* and *Targets* menus, and click *Create*.

4. In the storyboard, select the guestbooks scene's view controller. In the Identity inspector, set `GuestbooksViewController` as the Custom Class.



Custom Class

Class: GuestbooksViewControlle

Module: Liferay_Guestbook

☑ Inherit From Target

Figure 47.31: Set `GuestbooksViewController` as the custom class of the guestbooks scene's view controller.

Nice! The guestbooks scene's view controller now has a class that governs its behavior. You may have noticed a big problem, though. There's no way for the user to get from the login scene to the guestbooks scene. This is because there's no segue from the login scene to the navigation controller the guestbooks scene is embedded in. You'll fix this next.

Creating the Segue

Follow these steps to create and trigger the segue:

1. Control-drag from the login scene's view controller to the navigation controller. In the dialog that appears when you release your mouse button, select *show* for the segue type. The segue now connects the login scene's view controller and the navigation controller.

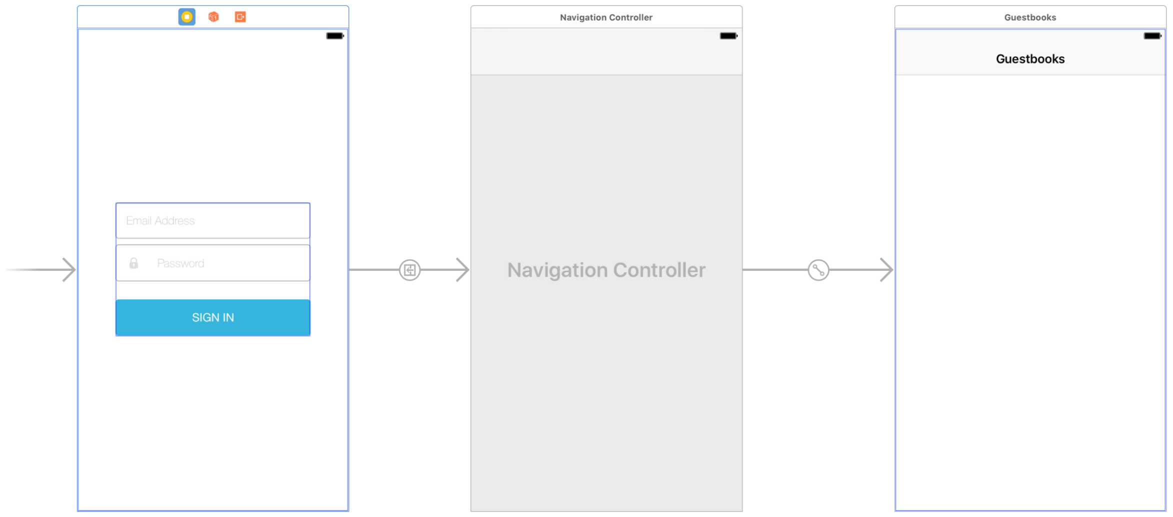


Figure 47.32: A segue now exists from the login scene to the navigation controller.

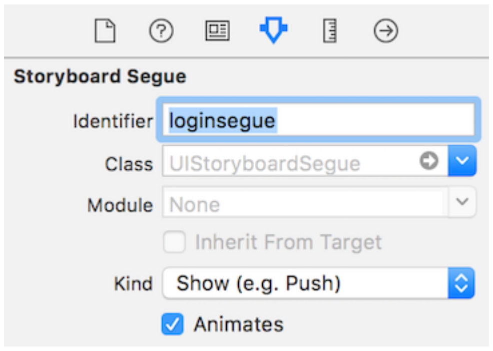
2. Now you must tell the login scene's view controller when to perform this segue. You'll do this programmatically in the `ViewController` class. To perform a segue programmatically, you must first give it an identifier in your storyboard. You'll then use this identifier in `ViewController` to perform the segue when a user logs in.

   In your storyboard, select the segue and then enter the Attributes inspector. Enter *loginsegue* in the *Identifier* field, and press *return*.



Storyboard Segue

Identifier loginsegue

Class UIStoryboardSegue

Module None

Inherit From Target

Kind Show (e.g. Push)

Animates

Figure 47.33: Set the segue's ID in the Attributes inspector.

3. Recall that the ViewController class's screenlet(_:onLoginResponseUserAttributes:) method is called upon successful login. You'll therefore trigger the segue in this method. Currently, this method only prints a success message. Below the line that prints this message, add the following code:

```
performSegue(withIdentifier: "loginsegue", sender: nil)
```

The performSegue(withIdentifier:sender:) method performs the segue with the specified identifier and includes any additional sender code. You send nil here since you don't need to send any information with the segue. Your screenlet(_:onLoginResponseUserAttributes:) method should now look like this:

```
func screenlet(_ screenlet: BaseScreenlet,
    onLoginResponseUserAttributes attributes: [String:AnyObject]) {
        print("Login Successful!")
        performSegue(withIdentifier: "loginsegue", sender: nil)
}
```

Great! Your app can now navigate to the guestbooks scene after login. To verify this, run the app and log in.

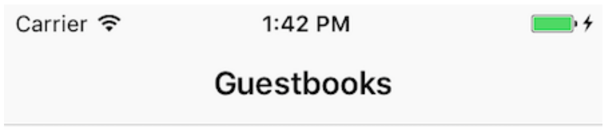


Figure 47.34: Following successful login, the app now navigates to the empty guestbooks scene.

Awesome! You've successfully added a scene for displaying guestbooks, and set the app to take the user there after login. Now you're ready to develop Guestbook List Screenlet. The next section in this Learning Path walks you through this.

Chapter 48

Creating Guestbook List Screenlet

In the previous section, you created an iOS app that contains the Guestbook Mobile SDK and Liferay Screens. You also used Login Screenlet to implement authentication to Liferay DXP. That's all your app does though. It doesn't display any Guestbook portlet content. In this section of the Learning Path, you'll create Guestbook List Screenlet to retrieve and display the portlet's guestbooks in your app's guestbooks scene.

Creating your own Screenlets brings additional benefits. Since you use a consistent, repeatable development model to create them, you can often reuse code when creating other Screenlets. You can also package and reuse Screenlets in other apps. What's more, Screenlet UIs are fully pluggable. This lets you change a Screenlet's appearance quickly without affecting its functionality. In summary, Screenlets are pretty much the greatest thing since sliced bread. Now it's time to make a sandwich.

You'll use these steps to create Guestbook List Screenlet:

1. Getting started: Create the Screenlet's folder, and the model class. The model class creates objects that represent guestbooks retrieved from the portlet, making it easier to work with guestbooks in your app.
2. Create the Screenlet's UI (its Theme).
3. Create the Connector. Connectors are Screenlet components that make server calls.
4. Create the Interactor. In list Screenlets, Interactors are Screenlet components that instantiate Connectors and receive their results.
5. Create the delegate. Delegates let other classes respond to the Screenlet's events.
6. Create the Screenlet class. The Screenlet class governs the Screenlet's behavior.

As background material, the following materials are helpful:

- Architecture of Liferay Screens for iOS: Explains the components that constitute a Screenlet, and how they relate to one another.
- Creating iOS Screenlets: Explains the general steps for creating a Screenlet.
- Creating iOS List Screenlets: Explains the general steps for creating a list Screenlet. This section of the Learning Path follows this tutorial.

Note that these tutorials explain Screenlet and list Screenlet concepts that this Learning Path doesn't cover in depth. Although it's possible to complete this Learning Path without reading these tutorials, they explain how Screenlets work in more detail. By reading them you'll be better able to apply the Learning Path material to your own Screenlets.

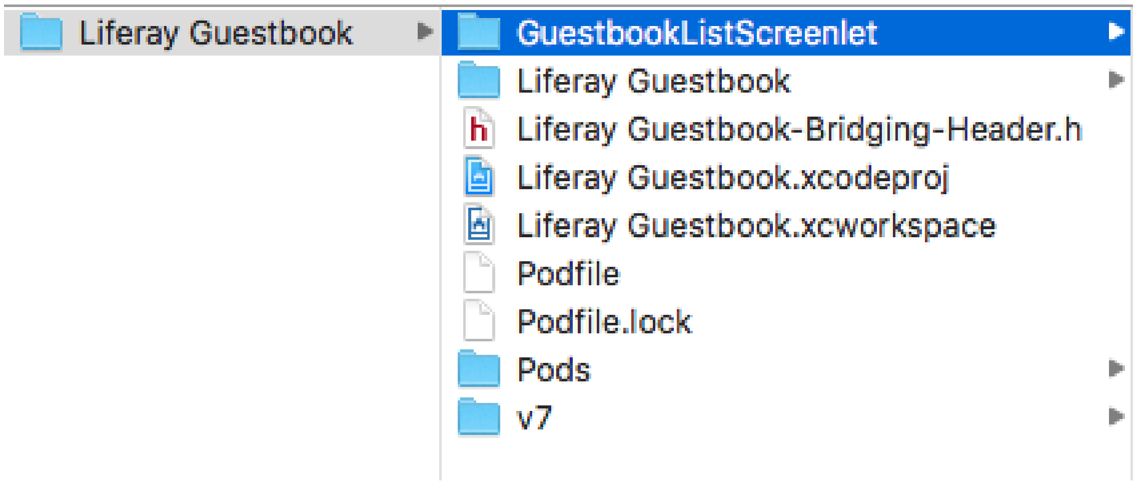
If you get confused or stuck while creating Guestbook List Screenlet, refer to the finished app that contains the Screenlet code here in GitHub.

48.1 Getting Started with Guestbook List Screenlet

Before creating a Screenlet, you should know how you'll use it. If you plan to use it in only one app, then you can create it in that app's project. If you need to use it in several apps, however, then it's best to create it in a separate project for redistribution. For information on creating Screenlets for redistribution, see the tutorial Packaging iOS Themes. Even though that tutorial is for packaging Themes, you can use the same steps to package Screenlets.

Since you'll use Guestbook List Screenlet in only this app, you can create it in a new folder inside the app's project. Create this folder now:

1. In the Finder, create the `GuestbookListScreenlet` folder inside the root project folder.



Liferay Guestbook
GuestbookListScreenlet
Liferay Guestbook
Liferay Guestbook-Bridging-Header.h
Liferay Guestbook.xcodeproj
Liferay Guestbook.xcworkspace
Podfile
Podfile.lock
Pods
v7

Figure 48.1: The new `GuestbookListScreenlet` folder should be inside your root project folder.

2. Drag and drop the `GuestbookListScreenlet` folder from the Finder into your Xcode project, under the root project. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `GuestbookListScreenlet` folder now appears in your project.

Great! Now you have a folder to create Guestbook List Screenlet in. Before getting started, you should understand how pagination works in in list Screenlets.

Pagination

To ensure that users can scroll smoothly through large lists of items, list Screenlets support fluent pagination. Support for this is built into the list Screenlet framework. You'll see this as you construct your list Screenlet. For example, several methods have parameters for the start row and end row of a page in the list.

Now you're ready to begin creating the Screenlet!

Creating the Model Class

Liferay Screens typically receives entities from a Liferay DXP instance as a `[String:AnyObject]` dictionary, where `String` is the entity's attribute and `AnyObject` is the attribute's value. Although your Screenlet can

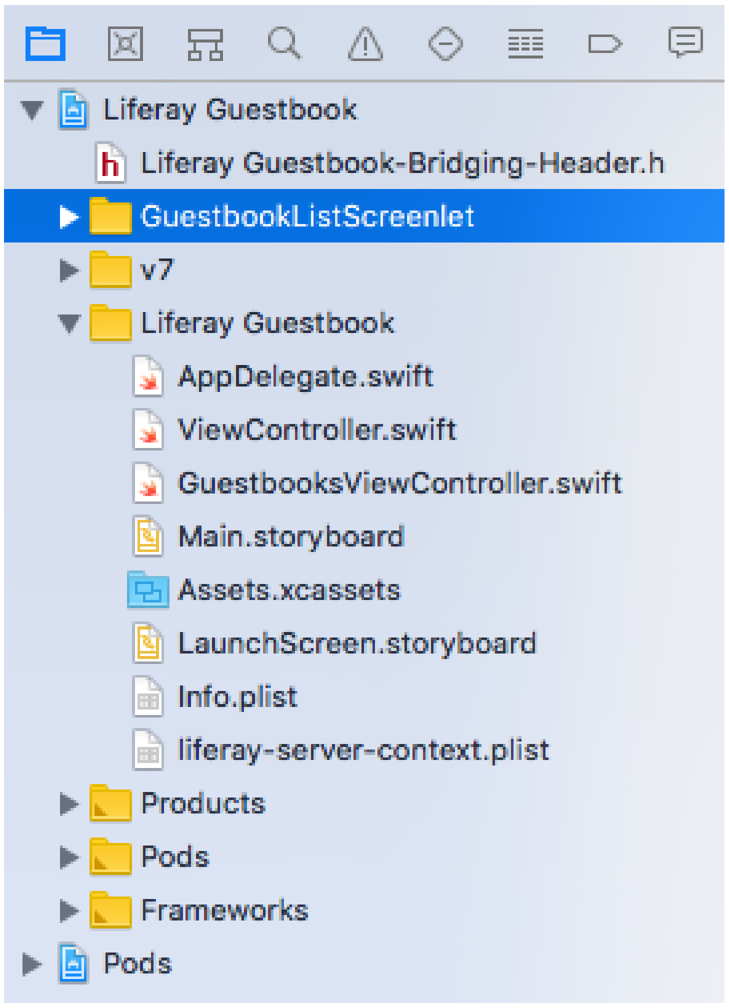


Figure 48.2: After adding the `GuestbookListScreenlet` folder, your project should look something like this.

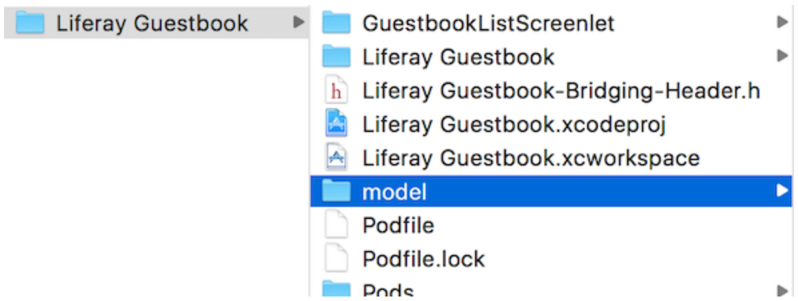
use these dictionary objects, it's often easier to create a *model class* that converts each into an object that represents the corresponding entity in the portal. Model classes are especially convenient for complex entities composed of many attribute-value pairs, like guestbooks in the Guestbook portlet.

Your model class must contain all the code necessary to transform each `[String:AnyObject]` dictionary that comes back from the server into a model object that represents a guestbook. This includes a public constant for holding each `[String:AnyObject]` dictionary, a public initializer that sets this constant, and a public property for each attribute value.

The model class you'll create for Guestbook List Screenlet, `GuestbookModel`, creates `GuestbookModel` objects that represent guestbooks retrieved from the Guestbook portlet. You'll create this model class in a separate folder outside of the `GuestbookListScreenlet` folder. In this case, it makes sense to organize your code this way because other Screenlets may also use the model class. For example, if a Screenlet that edits guestbooks existed, it would also need `GuestbookModel` objects. Putting the model class in a separate folder makes it clear that this class doesn't belong exclusively to a single Screenlet.

Follow these steps to create Guestbook List Screenlet's model class:

1. In the Finder, create the `model` folder inside your root project folder.



Liferay Guestbook
GuestbookListScreenlet
Liferay Guestbook
Liferay Guestbook-Bridging-Header.h
Liferay Guestbook.xcodeproj
Liferay Guestbook.xcworkspace
model
Podfile
Podfile.lock
Pods

Figure 48.3: The new `model` folder should be inside your root project folder.

2. Drag and drop the `model` folder from the Finder into your Xcode project, under the root project. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `model` folder now appears in your project.

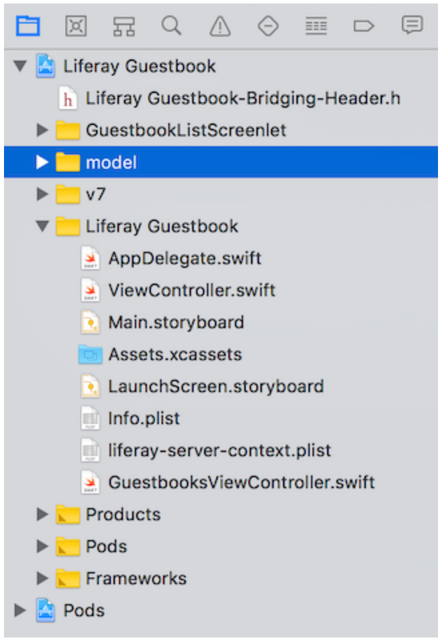


Figure 48.4: After adding the `model` folder, your project should look something like this.

3. In the Project navigator, right-click the `model` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

   - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
   - Name the class `GuestbookModel`, set it to extend `NSObject`, select *Swift* for the language, and click *Next*.
   - Make sure the `model` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

   The new class now opens in the editor.

4. Replace the class file's contents with this code:

```
import UIKit

@objc public class GuestbookModel: NSObject {

    public let attributes: [String:AnyObject]

    public var guestbookId: Int64 {
        return attributes["guestbookId"]?.int64Value ?? 0
    }

    public var groupId: Int64 {
        return attributes["groupId"]?.int64Value ?? 0
    }

    public var companyId: Int64 {
        return attributes["companyId"]?.int64Value ?? 0
    }

    public var userId: Int64 {
        return attributes["userId"]?.int64Value ?? 0
    }

    public var userName: String {
        return attributes["userName"] as? String ?? ""
    }

    public var createDate: Int64 {
        return attributes["createDate"]?.int64Value ?? 0
    }

    public var modifiedDate: Int64 {
        return attributes["modifiedDate"]?.int64Value ?? 0
    }

    public var name: String {
        return attributes["name"] as? String ?? ""
    }

    //MARK: Initializer

    public init(attributes: [String:AnyObject]) {
        self.attributes = attributes
    }

}
```

This class creates `GuestbookModel` objects that represent guestbooks from the Guestbook portlet. The `[String:AnyObject]` dictionary contains the data of a guestbook retrieved from the portlet. The initializer sets this dictionary to the `attributes` property. Each computed property returns the value of a guestbook parameter in `attributes`. For example, the `guestbookId` property returns the value of the `guestbookId` parameter, the `groupId` property returns the value of the `groupId` parameter, and so on. To see how the Guestbook portlet defines these parameters, see the section on generating the portlet's back end in the Liferay Web Application Learning Path.

Also note that each computed property defaults to an empty string or `0`, depending on the property's type, if the parameter contains a value that can't be represented as that type. This prevents the app from crashing if the parameter doesn't have an appropriate value. For example, if the `guestbookId` parameter contains `nil`, then the `guestbookId` property returns `0`.

Great! Now you have a model class for guestbooks. Next, you'll create the Screenlet's UI.

48.2 Creating Guestbook List Screenlet's UI

In Liferay Screens for iOS, Screenlet UIs are called *Themes*. Every Screenlet must have at least one Theme. You'll use the following steps to create a Theme for Guestbook List Screenlet:

1. Create your Theme's folder and add it to your Xcode project.
2. Create an XIB file and use it to construct the UI.
3. Create your Theme's View class and set it as the XIB file's custom class.

Creating Your Theme's Folder

Even if you only plan on creating one Theme, it's best practice to create it in its own folder inside a parent `Themes` folder. The parent `Themes` folder gives you a place to put any additional Themes you create. You'll create a single Theme for Guestbook List Screenlet: the Default Theme. You'll therefore create the `Themes/Default` folder path inside the `GuestbookListScreenlet` folder.

Follow these steps to create your Theme's folder:

1. In the Finder, create the `Themes` folder inside your project's `GuestbookListScreenlet` folder. Then create the `Default` folder inside the new `Themes` folder.

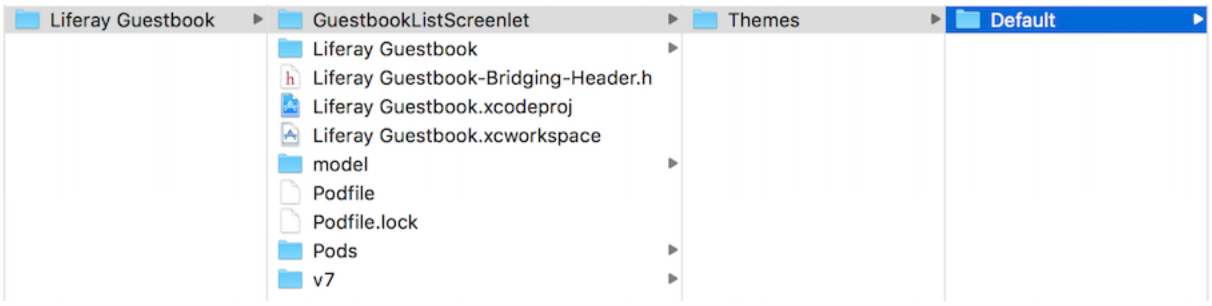

Figure 48.5: The new `Themes/Default` folder structure should be inside the Screenlet's folder.

2. Drag and drop the `Themes` folder from the Finder into your Xcode project, under the `GuestbookListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `Themes/Default` folder structure now appears in your project.

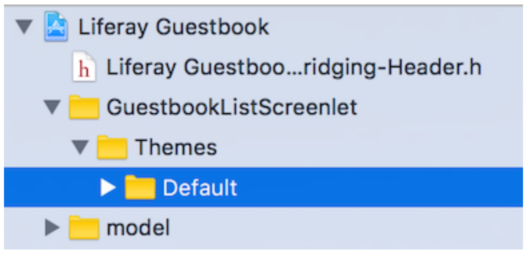

Figure 48.6: After adding the `Themes` folder to your project, the `Themes/Default` folder structure should appear in the Project navigator.

Now you're ready to start creating your Theme. First, you'll create its XIB file.

Creating the XIB File

A Theme requires an XIB file to define the UI's components and layout. Use these steps to create your Theme's XIB file:

1. In the Project navigator, right-click the `Default` folder and select *New File*. In the dialog that appears, select *iOS* → *User Interface* → *Empty*, and click *Next*. Name the file `GuestbookListView_default.xib`, and ensure that *Default* is selected for the save location and group. The *Liferay Guestbook* target should also be selected. Click *Create*. The file should then open in Interface Builder.

2. In Interface Builder, drag and drop a View from the Object Library to the canvas. Then add a Table View to the View. Set the Table View to take up the entire View.

3. With the Table View selected, open the *Add New Constraints* menu at the bottom-right of the canvas. In this menu, set *Spacing to nearest neighbor* to 0 on all sides, select *Constrain to margins*, and then click the *Add 4 Constraints* button.

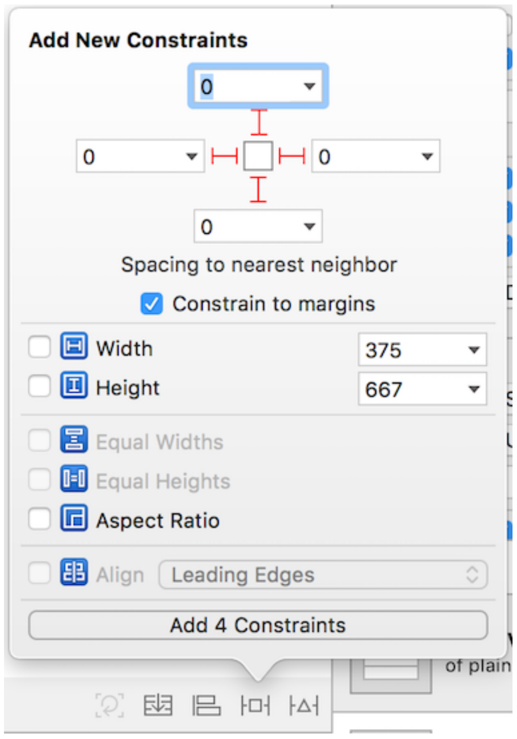

Figure 48.7: Add these constraints to the Table View in the XIB.

Your Theme's XIB is now finished. Next, you'll create your View class.

Creating the Theme's View Class

Every Theme needs a View class that controls its behavior. Since the XIB file uses a `UITableView` to show a list of guestbooks, your View class must extend the `BaseListTableView` class. Liferay Screens provides this class to serve as the base class for list Screenlets' View classes. Since `BaseListTableView` provides most of the required functionality, extending it lets you focus on the parts of your View class that are unique to your Screenlet.

Follow these steps to create your Screenlet's View class:

1. In the Project navigator, right-click the `Default` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS → Source → Cocoa Touch Class*, and click *Next*.
    - Name the class `GuestbookListView_default`, set it to extend `BaseListTableView`, select *Swift* for the language, and click *Next*.
    - Make sure the `Default` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. In `GuestbookListView_default`, add an import for `LiferayScreens` and delete any placeholder comments in the class body.

3. Now you must override the View class methods that fill the table cells' contents. There are two methods for this, depending on the cell type:

    - **Normal cells:** the cells that show the entities. These cells typically use `UILabel`, `UIImage`, or another UI component to show the entity. Override the `doFillLoadedCell` method to fill these cells. Guestbook List Screenlet's View class must override `doFillLoadedCell` to set each cell's `textLabel` to a guestbook's name:

      ```
      override public func doFillLoadedCell(row: Int, cell: UITableViewCell,
          object: AnyObject) {

              let guestbook = object as! GuestbookModel
              cell.textLabel?.text = guestbook.name
      }
      ```

    - **Progress cell:** the cell at the bottom of the list that indicates the list is loading the next page of items. Override the `doFillInProgressCell` method to fill this cell. Guestbook List Screenlet's View class must override this method to set the cell's `textLabel` to the string `"Loading..."`:

      ```
      override public func doFillInProgressCell(row: Int, cell: UITableViewCell) {
          cell.textLabel?.text = "Loading..."
      }
      ```

    Your complete View class should look like this:

    ```
    import UIKit
    import LiferayScreens

    class GuestbookListView_default: BaseListTableView {

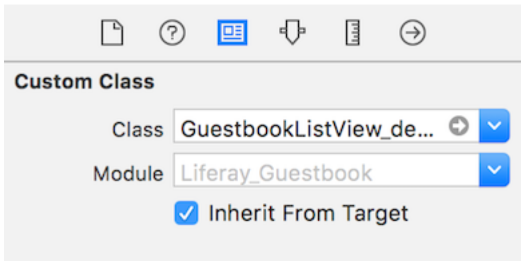
        override public func doFillLoadedCell(row: Int, cell: UITableViewCell,
            object: AnyObject) {

                let guestbook = object as! GuestbookModel
                cell.textLabel?.text = guestbook.name
        }

        override public func doFillInProgressCell(row: Int, cell: UITableViewCell) {
            cell.textLabel?.text = "Loading..."
        }

    }
    ```

4. Return to the Theme's XIB in Interface Builder, and set `GuestbookListView_default` as the the parent View's custom class. To do this, select the Table View's parent View, click the Identity inspector, and enter `GuestbookListView_default` as the Custom Class.



Custom Class
Class: GuestbookListView_de...
Module: Liferay_Guestbook
[✓] Inherit From Target

Figure 48.8: In the XIB file, set the Custom Class of the Table View's parent View to `GuestbookListView_default`.

5. With the Theme's XIB still open in Interface Builder, set the parent View's `tableView` outlet to the Table View. To do this, select the parent View and click the Connections inspector. In the Outlets section, drag and drop from the `tableView`'s circle icon (it turns into a plus icon on mouseover) to the Table View in the XIB. The new outlet then appears in the Connections inspector.

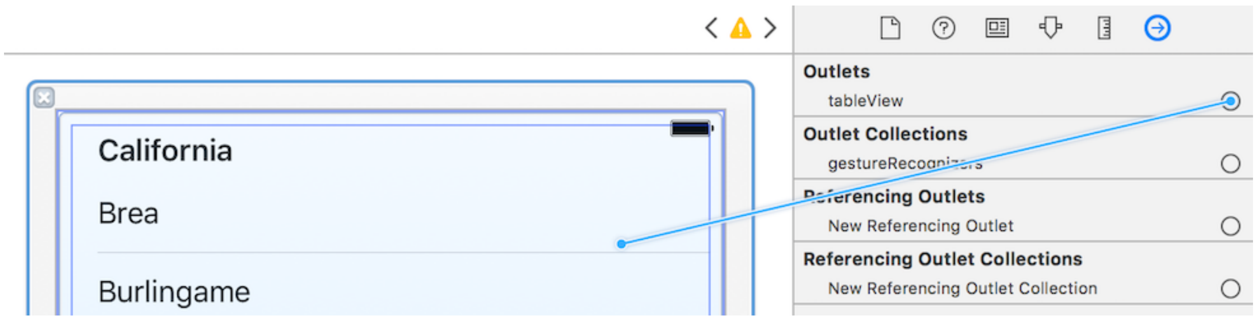


Figure 48.9: In the XIB, drag and drop from the `tableView` outlet to the Table View.

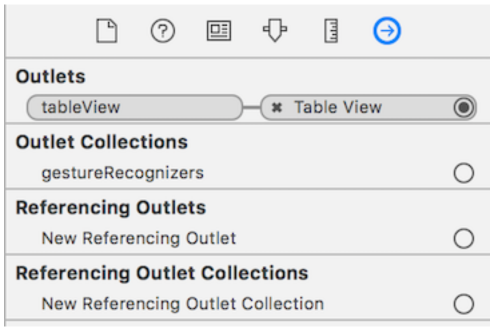

Outlets
tableView — Table View
Outlet Collections
gestureRecognizers
Referencing Outlets
New Referencing Outlet
Referencing Outlet Collections
New Referencing Outlet Collection

Figure 48.10: After creating the connection, it appears in the Connections inspector.

Great! Your Theme is finished. Next, you'll create Guestbook List Screenlet's Connector.

48.3 Creating Guestbook List Screenlet's Connector

Connectors are Screenlet components that make server calls. Non-list Screenlets don't require Connectors–they can make server calls in Interactors instead. Connectors, however, provide a layer of abstraction by making the server call outside the Interactor. This leaves the Interactor to instantiate the Connector and receive the server call's results. List Screenlets exploit this architectural advantage by requiring Connectors.

First, you'll create a folder for the Connector.

Creating Your Connector's Folder

Follow these steps to create your Connector's folder:

1. In the Finder, create the `Connector` folder inside your project's `GuestbookListScreenlet` folder.

2. Drag and drop the `Connector` folder from the Finder into your Xcode project, under the `GuestbookListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `Connector` folder now appears in your project.

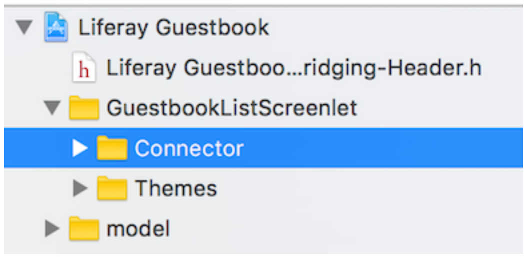

Figure 48.11: The new `Connector` folder should be inside the Screenlet's folder.

Now you're ready to create the Connector.

Creating the Connector

List Screenlet Connectors must extend the `PaginationLiferayConnector` class, which Liferay Screens provides to enable most of the functionality required by list Screenlet Connectors. Extending this class lets you focus on the functionality unique to your Connector. Your list Screenlet's Connector class must contain any properties it needs to make the server call, and an initializer that sets them. To support pagination, the initializer must also contain the following arguments, which you'll pass to the superclass initializer:

- `startRow`: The number representing the page's first row.
- `endRow`: The number representing the page's last row.
- `computeRowCount`: Whether to call the Connector's `doAddRowCountServiceCall` method (you'll learn about this method shortly).

Follow these steps to create Guestbook List Screenlet's Connector:

1. In the Project navigator, right-click the `Connector` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.

- Name the class `GuestbookListPageLiferayConnector`, set it to extend `PaginationLiferayConnector`, select *Swift* for the language, and click *Next*.
- Make sure the `Connector` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. In the new class, import `LiferayScreens` and add a public `Int64` constant called `groupId`. This constant holds the ID of the site the Connector retrieves guestbooks from. Your Connector should now look like this:

```
import UIKit
import LiferayScreens

class GuestbookListPageLiferayConnector: PaginationLiferayConnector {

    public let groupId: Int64

}
```

3. Create an initializer that takes the arguments `startRow`, `endRow`, `computeRowCount`, and `groupId`. In this initializer, set the `groupId` constant to the corresponding argument, then call the superclass initializer with the remaining arguments. Add the initializer as follows:

```
public init(startRow: Int, endRow: Int, computeRowCount: Bool, groupId: Int64) {
    self.groupId = groupId

    super.init(startRow: startRow, endRow: endRow, computeRowCount: computeRowCount)
}
```

4. Override the `doAddPageRowsServiceCall` method to make the server call that retrieves guestbooks from the portlet. This method must call the Guestbook SDK service method `getGuestbooksWithGroupId`, which retrieves guestbooks. To do this, you must first create a `LRGuestbookService_v7` instance from the session. Then call the service's `getGuestbooksWithGroupId` method with `groupId`, `startRow`, and `endRow`:

```
public override func doAddPageRowsServiceCall(session: LRBatchSession, startRow: Int, endRow: Int,
    obc: LRJSONObjectWrapper?) {
        let service = LRGuestbookService_v7(session: session)

        do {
            try service!.getGuestbooksWithGroupId(groupId, start: Int32(startRow), end: Int32(endRow))
        }
        catch {
            // ignore error: the service method returns nil because
            // the request is sent later, in batch
        }

}
```

Note that you don't need to do anything in the `catch` statement because the request is sent later, in batch. The session type `LRBatchSession` handles this for you. You'll receive the request's results elsewhere, once the request completes.

5. Override the `doAddRowCountServiceCall` method to make the server call that retrieves the total number of guestbooks from the portlet. This enables pagination. This method must call the Guestbook SDK service method `getGuestbooksCount`, which retrieves the total number of guestbooks. To do this, you must first create a `LRGuestbookService_v7` service instance from the session. Then call the service's `getGuestbooksCount` method with `groupId`:

```
override public func doAddRowCountServiceCall(session: LRBatchSession) {
    let service = LRGuestbookService_v7(session: session)

    do {
        try service!.getGuestbooksCount(withGroupId: groupId)
    }
    catch {
        // ignore error: the service method returns nil because
        // the request is sent later, in batch
    }
}
```

As in the previous step, you don't need to do anything in the `catch` statement.

Awesome! Your Connector is finished. Now you're ready to create the Interactor.

48.4 Creating Guestbook List Screenlet's Interactor

Interactors implement your Screenlet's actions. In non-list Screenlets, this can include making the server call. List Screenlets, however, make server calls via Connectors. Also, loading entities is usually the only action a user can take in a list Screenlet. Therefore, list Screenlet Interactors typically only need to instantiate the Connector and receive the server call's results. This is the case for Guestbook List Screenlet's Interactor. You'll create this Interactor now.

Creating Your Interactor's Folder

Follow these steps to create your Interactor's folder:

1. In the Finder, create the `Interactor` folder inside your project's `GuestbookListScreenlet` folder.

2. Drag and drop the `Interactor` folder from the Finder into your Xcode project, under the `GuestbookListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `Interactor` folder now appears in your project.

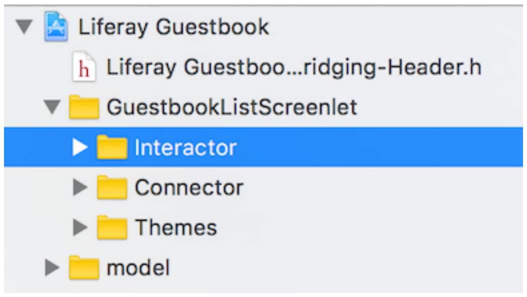

Figure 48.12: The new `Interactor` folder should be inside the Screenlet's folder.

Now you're ready to create the Interactor.

Creating the Interactor

The Interactor class of a list Screenlet that implements fluent pagination must extend Liferay Screens's `BaseListPageLoadInteractor` class. This class provides most of the functionality required by list Screenlet Interactors. Your Interactor class must also contain any properties your Screenlet needs and an initializer that sets them. This initializer needs arguments for the following properties, which it passes to the superclass initializer:

- `screenlet`: A `BaseListScreenlet` reference. This ensures the Interactor always has a Screenlet reference.
- `page`: The page number to retrieve.
- `computeRowCount`: Whether to call the Connector's `doAddRowCountServiceCall` method.

Follow these steps to create Guestbook List Screenlet's Interactor:

1. In the Project navigator, right-click the `Interactor` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
    - Name the class `GuestbookListPageLoadInteractor`, set it to extend `BaseListPageLoadInteractor`, select *Swift* for the language, and click *Next*.
    - Make sure the `Interactor` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. In the new class, import `LiferayScreens` and add a private `Int64` constant called `groupId`. This constant holds the ID of the site guestbooks are retrieved from. Your Interactor should now look like this:

```
import UIKit
import LiferayScreens

class GuestbookListPageLoadInteractor: BaseListPageLoadInteractor {

    private let groupId: Int64

}
```

3. Create an initializer that takes the arguments `screenlet`, `page`, `computeRowCount`, and `groupId`. In this initializer, set the `groupId` constant to the corresponding argument, then call the superclass initializer with the remaining arguments. Note that if the the `groupId` is `0`, the `groupId` setting in `liferay-server-context.plist` is used instead. Add the initializer as follows:

```
init(screenlet: BaseListScreenlet,
    page: Int,
    computeRowCount: Bool,
    groupId: Int64) {

    self.groupId = (groupId != 0) ? groupId : LiferayServerContext.groupId

    super.init(screenlet: screenlet, page: page, computeRowCount: computeRowCount)
}
```

4. Override the `createListPageConnector` method to create and return an instance of your Connector, `GuestbookListPageLiferayConnector`. This method must first get a reference to the Screenlet via the `screenlet` property. When calling the Connector's initializer, use `screenlet.firstRowForPage` to convert the page number (`page`) to the page's start and end indices. You must also pass the initializer any other properties it needs, like `groupId`. Add this `createListPageConnector` method to your Interactor class:

```
public override func createListPageConnector() -> PaginationLiferayConnector {
    let screenlet = self.screenlet as! BaseListScreenlet

    return GuestbookListPageLiferayConnector(
        startRow: screenlet.firstRowForPage(self.page),
        endRow: screenlet.firstRowForPage(self.page + 1),
        computeRowCount: self.computeRowCount,
        groupId: groupId)
}
```

5. Override the `convertResult` method to convert each `[String:AnyObject]` result into a `GuestbookModel` object. The Screenlet calls this method once for each guestbook retrieved from the server. Add this method as follows:

```
override public func convertResult(_ serverResult: [String:AnyObject]) -> AnyObject {

    return GuestbookModel(attributes: serverResult)
}
```

6. Override the `cacheKey` method to return a key that can be used with offline mode. Although Guestbook List Screenlet won't initially support offline mode, this method is still required. For this Screenlet, the `groupId` serves as a sufficient key. Add this method as follows:

```
override public func cacheKey(_ op: PaginationLiferayConnector) -> String {
    return "\(groupId)"
}
```

Great! Your Interactor is finished. Next, you'll create the delegate.

48.5 Creating Guestbook List Screenlet's Delegate

A delegate is a Screenlet component that lets other classes to respond to a Screenlet's actions. For example, Login Screenlet's delegate lets the app developer implement methods that respond to login success or failure. Note that the reference documentation for each Screenlet that comes with Liferay Screens lists the Screenlet's delegate methods.

You can also create a delegate for your own Screenlet. Guestbook List Screenlet should have a delegate protocol that defines the following methods:

- `screenlet(_:onGuestbookListResponse:)`: Receives the `GuestbookModel` results when the server call succeeds. This lets app developers respond to a successful server call.
- `screenlet(_:onGuestbookListError:)`: Receives the `NSError` object when the server call fails. This lets app developers respond to a failed server call.
- `screenlet(_:onGuestbookSelected:)`: Receives the `GuestbookModel` when a user selects it in the list. This lets app developers respond to a guestbook selection by the user.

You'll create this delegate in the same file as the Screenlet class. Later, you'll finish creating the Screenlet class itself.

Follow these steps to create Guestbook List Screenlet's delegate:

1. In the Project navigator, right-click the `GuestbookListScreenlet` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

- Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
- Name the class `GuestbookListScreenlet`, set it to extend `BaseListScreenlet`, select *Swift* for the language, and click *Next*.
- Make sure the `GuestbookListScreenlet` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. In the new `GuestbookListScreenlet` class, import `LiferayScreens`, make the class `public`, and delete any placeholder comments in the class body.

3. In between the `import` statements and the class declaration, add the following code:

   ```
   @objc public protocol GuestbookListScreenletDelegate : BaseScreenletDelegate {

       @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                               onGuestbookListResponse guestbooks: [GuestbookModel])

       @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                               onGuestbookListError error: NSError)

       @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                               onGuestbookSelected guestbook: GuestbookModel)

   }
   ```

   This defines the `GuestbookListScreenletDelegate` protocol, which extends the `BaseScreenletDelegate` protocol. Delegates for custom Screenlets, like Guestbook List Screenlet, must extend `BaseScreenletDelegate`. The rest of `GuestbookListScreenletDelegate` defines the delegate methods you'll use later to respond to the Screenlet's events.

The contents of `GuestbookListScreenlet.swift` should now look like this:

```
import UIKit
import LiferayScreens

@objc public protocol GuestbookListScreenletDelegate : BaseScreenletDelegate {

    @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                            onGuestbookListResponse guestbooks: [GuestbookModel])

    @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                            onGuestbookListError error: NSError)

    @objc optional func screenlet(screenlet: GuestbookListScreenlet,
                            onGuestbookSelected guestbook: GuestbookModel)

}

public class GuestbookListScreenlet: BaseListScreenlet {

}
```

Nice work! Now you're ready to complete the Screenlet class.

48.6 Creating the Screenlet Class

The Screenlet class is the main component that governs the Screenlet's behavior. When using a Screenlet, app developers primarily interact with its Screenlet class. A list Screenlet's Screenlet class must extend the

BaseListScreenlet class. Since BaseListScreenlet provides most of the functionality needed by Screenlet classes, extending it lets you focus on the functionality unique to your Screenlet. The Screenlet class must also define the configurable IBInspectable properties the Screenlet needs, create and return an instance of your Interactor, and respond to the Screenlet's events via the delegate.

The Screenlet class you created while creating the delegate is currently empty. You'll complete it now.

Follow these steps to complete the GuestbookListScreenlet class in GuestbookListScreenlet.swift:

1. Define a public, IBInspectable, Int64 property for the groupId. Although the app developer can set this value via liferay-server-context.plist, it's also a good idea to let them set it in Interface Builder when using the Screenlet. Give this property an initial value of 0. Your Screenlet class should now look like this:

   ```
   public class GuestbookListScreenlet: BaseListScreenlet {

       @IBInspectable public var groupId: Int64 = 0

   }
   ```

2. Override the createPageLoadInteractor method to create and return an instance of your Interactor, GuestbookListPageLoadInteractor. This method includes page and computeRowCount arguments, which you can pass to the Interactor's constructor along with groupId:

   ```
   override public func createPageLoadInteractor(
       page: Int,
       computeRowCount: Bool) -> BaseListPageLoadInteractor {

       return GuestbookListPageLoadInteractor(screenlet: self,
                                              page: page,
                                              computeRowCount: computeRowCount,
                                              groupId: self.groupId)
   }
   ```

3. Create a computed property to get a reference to your delegate, GuestbookListScreenletDelegate:

   ```
   public var guestbookListDelegate: GuestbookListScreenletDelegate? {
       return delegate as? GuestbookListScreenletDelegate
   }
   ```

   You'll use this property to handle the Screenlet's events via the delegate's methods.

4. Override the BaseListScreenlet methods that handle the Screenlet's events. Because these methods correspond to your delegate methods, you'll call your delegate methods in them:

   - onLoadPageResult: Called when the Screenlet loads a page successfully. Override this method to call the superclass's onLoadPageResult method, then call your delegate's screenlet(_:onGuestbookListResponse:) method:

     ```
     override public func onLoadPageResult(page: Int, rows: [AnyObject], rowCount: Int) {
         super.onLoadPageResult(page: page, rows: rows, rowCount: rowCount)

         guestbookListDelegate?.screenlet?(screenlet: self,
             onGuestbookListResponse: rows as! [GuestbookModel])
     }
     ```

- `onLoadPageError`: Called when the Screenlet fails to load a page. Override this method to call the superclass's `onLoadPageError` method, then call your delegate's `screenlet(_:onGuestbookListError:)` method:

```
override public func onLoadPageError(page: Int, error: NSError) {
    super.onLoadPageError(page: page, error: error)

    guestbookListDelegate?.screenlet?(screenlet: self,
        onGuestbookListError: error)
}
```

- `onSelectedRow`: Called when an item is selected in the list. Override this method to call your delegate's `screenlet(_:onGuestbookSelected:)` method:

```
override public func onSelectedRow(_ row: AnyObject) {
    guestbookListDelegate?.screenlet?(screenlet: self,
        onGuestbookSelected: row as! GuestbookModel)
}
```

Awesome! Your Screenlet class is finished. You're also done with Guestbook List Screenlet! The next section in this Learning Path shows you how to create Entry List Screenlet to display a guestbook's entries.

Chapter 49

Creating Entry List Screenlet

In the previous section, you created Guestbook List Screenlet to retrieve and display guestbooks from the Guestbook portlet. You still need a way to retrieve and display each guestbook's entries, though. You'll do this by creating another list Screenlet: Entry List Screenlet. This section walks you through the steps required to create it.

Because you use a consistent development model to create Screenlets, similar Screenlets have similar code. As with guestbooks, it makes sense to display entries in a list using a list Screenlet. This means you can reuse most of Guestbook List Screenlet's code in Entry List Screenlet. You'll therefore create Entry List Screenlet using the same sequence of steps you used to create Guestbook List Screenlet:

1. Getting started: create the Screenlet's folder, and the model class. This model class creates objects that represent entries retrieved from the portlet, making it easier to work with entries in the app.
2. Create the Screenlet's UI (its Theme).
3. Create the Connector. Connectors are Screenlet components that make server calls.
4. Create the Interactor. In list Screenlets, Interactors are Screenlet components that instantiate Connectors and receive their results.
5. Create the delegate. Delegates let other classes respond to the Screenlet's events.
6. Create the Screenlet class. The Screenlet class governs the Screenlet's behavior.

Although this Learning Path section presents complete code snippets, it only discusses the code unique to Entry List Screenlet. Refer back to the previous section for detailed explanations of the code shared with Guestbook List Screenlet.

If you get confused or stuck while creating Guestbook List Screenlet, refer to the finished app that contains the Screenlet code here in GitHub.

49.1 Getting Started with Entry List Screenlet

Like Guestbook List Screenlet, you'll create Entry List Screenlet in its own folder inside your app's project. Create this folder now:

1. In the Finder, create the `EntryListScreenlet` folder inside your root project folder (on the same level as the `GuestbookListScreenlet` folder).

2. Drag and drop the `EntryListScreenlet` folder from the Finder into your Xcode project, under the root project (on the same level as the `GuestbookListScreenlet` folder). In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `EntryListScreenlet` folder now appears in your project.

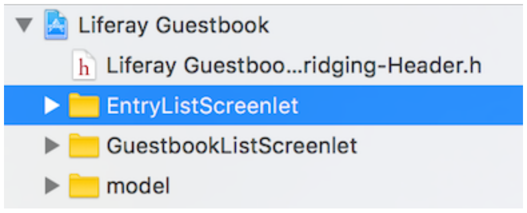

Figure 49.1: After adding the `EntryListScreenlet` folder, your project should look something like this.

Now you're ready to begin!

Creating the Model Class

Recall that you need a model class to represent entities retrieved from Liferay DXP. The model class you'll create for guestbook entries, `EntryModel`, creates `EntryModel` objects that represent guestbook entries retrieved from the Guestbook portlet.

Create the following `EntryModel` class alongside the `GuestbookModel` class in the `model` folder:

1. In the Project navigator, right-click the `model` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

   - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
   - Name the class `EntryModel`, set it to extend `NSObject`, select *Swift* for the language, and click *Next*.
   - Make sure the `model` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

   The new class now opens in the editor.

2. Replace the class file's contents with this code:

```
import UIKit

@objc public class EntryModel: NSObject {

    public let attributes: [String:AnyObject]

    public var entryId: Int64 {
        return attributes["entryId"]?.int64Value ?? 0
    }

    public var groupId: Int64 {
        return attributes["groupId"]?.int64Value ?? 0
    }

    public var companyId: Int64 {
        return attributes["companyId"]?.int64Value ?? 0
    }

    public var userId: Int64 {
        return attributes["userId"]?.int64Value ?? 0
    }

    public var userName: String {
        return attributes["userName"] as? String ?? ""
    }

    public var createDate: Int64 {
        return attributes["createDate"]?.int64Value ?? 0
    }

    public var modifiedDate: Int64 {
        return attributes["modifiedDate"]?.int64Value ?? 0
    }

    public var name: String {
        return attributes["name"] as? String ?? ""
    }

    public var email: String {
        return attributes["email"] as? String ?? ""
    }

    public var message: String {
        return attributes["message"] as? String ?? ""
    }

    public var guestbookId: Int64 {
        return attributes["guestbookId"]?.int64Value ?? 0
    }

    //MARK: Initializer

    public init(attributes: [String:AnyObject]) {
        self.attributes = attributes
    }

}
```

Besides working with entries instead of guestbooks, this class is almost identical to `GuestbookModel`. For an explanation of the code, see the article on getting started with Guestbook List Screenlet.

Next, you'll create the Screenlet's UI.

49.2 Creating Entry List Screenlet's UI

Recall that in Liferay Screens for iOS, Screenlet UIs are called *Themes*, and every Screenlet must have at least one Theme. You'll create Entry List Screenlet's Theme with the same steps you used to create Guestbook List Screenlet's Theme:

1. Create your Theme's folder and add it to your Xcode project.
2. Create an XIB file and use it to construct the UI.
3. Create your Theme's View class and set it as the XIB file's custom class.

Creating Your Theme's Folder

Like Guestbook List Screenlet's Theme, you'll create Entry List Screenlet's Theme in a `Themes/Default` folder. Follow these steps to create this folder structure in Entry List Screenlet's folder:

1. In the Finder, create the `Themes` folder inside your project's `EntryListScreenlet` folder. Then create the `Default` folder inside the new `Themes` folder.

2. Drag and drop the `Themes` folder from the Finder into your Xcode project, under the `EntryListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target (these should be selected by default). Then click *Finish*. The `Themes/Default` folder structure now appears in your project.

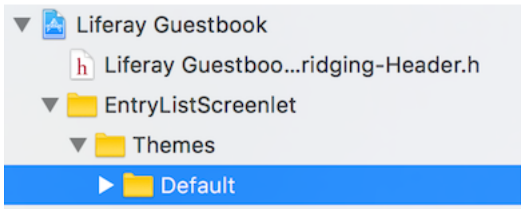

Figure 49.2: After adding the `Themes` folder to Entry List Screenlet, the `Themes/Default` folder structure should look like this in the Project navigator.

Now you're ready to start creating your Theme. First, you'll create its XIB file.

Creating the XIB File

A Theme requires an XIB file to define the UI's components and layout. Use these steps to create your Theme's XIB file:

1. In the Project navigator, right-click the `Default` folder you added above and select *New File*. In the dialog that appears, select *iOS* → *User Interface* → *Empty*, and click *Next*. Name the file `EntryListView_default.xib`, and ensure that *Default* is selected for the save location and group. The *Liferay Guestbook* target should also be selected. Click *Create*. The file then opens in Interface Builder.

2. In Interface Builder, drag and drop a View from the Object Library onto the canvas. Then add a Table View to the View. Set the Table View to take up the entire View.

3. With the Table View selected, open the *Add New Constraints* menu at the bottom-right of the canvas. In this menu, set *Spacing to nearest neighbor* to 0 on all sides, select *Constrain to margins*, and then click the *Add 4 Constraints* button.

Your Theme's XIB is now finished. Next, you'll create your View class.

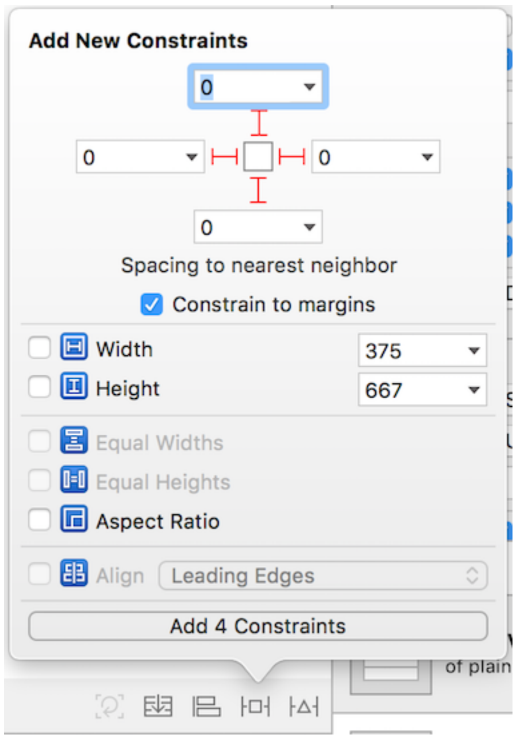
Creating the Theme's View Class

Every Theme needs a View class that controls its behavior. Recall that a list Screenlet's View class gets most of its functionality by extending the `BaseListTableView` class. This lets you focus on the parts of your View class that are unique to your Screenlet.

Follow these steps to create your Screenlet's View class:

1. In the Project navigator, right-click Entry List Screenlet's `Default` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

   - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
   - Name the class `EntryListView_default`, set it to extend `BaseListTableView`, select *Swift* for the language, and click *Next*.
   - Make sure the `Default` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.



Add New Constraints

0

0 0

0

Spacing to nearest neighbor

[✓] Constrain to margins

[ ] Width 375

[ ] Height 667

[ ] Equal Widths

[ ] Equal Heights

[ ] Aspect Ratio

[ ] Align Leading Edges

Figure 49.3: Add these constraints to the Table View in the XIB.

2. Replace the class file's contents with this code:

```
import UIKit
import LiferayScreens

class EntryListView_default: BaseListTableView {

    override public func doFillLoadedCell(row: Int, cell: UITableViewCell, object: AnyObject) {
        let entry = object as! EntryModel

        cell.textLabel?.text = entry.message
        cell.detailTextLabel?.text = entry.name
    }

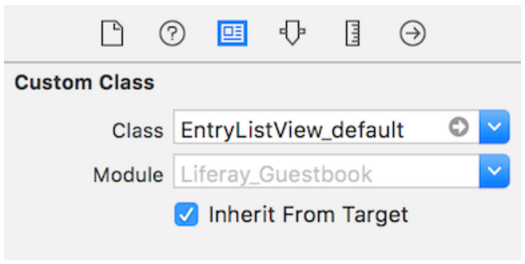
    override open func doCreateCell(_ cellId: String) -> UITableViewCell {
        return UITableViewCell(style: .subtitle, reuseIdentifier: cellId)
    }

    override public func doFillInProgressCell(row: Int, cell: UITableViewCell) {
        cell.textLabel?.text = "Loading..."
    }

}
```

Note that this class is almost identical to Guestbook List Screenlet's View class, `GuestbookListView_default`. The only difference is that `EntryListView_default` handles entries (`EntryModel`) instead of guestbooks (`GuestbookModel`). The `doFillLoadedCell` method sets the cell's main text label to the entry's message, and sets the cell's secondary text label to the name of the person who left the message. This way, a single cell displays both pieces of information. For a description of the code shared with `GuestbookListView_default`, see the article on creating Guestbook List Screenlet's Theme.

3. Return to the Theme's XIB in Interface Builder and set `EntryListView_default` as the the parent View's custom class. To do this, select the Table View's parent View, click the Identity inspector, and enter `EntryListView_default` as the custom class.



Custom Class
Class EntryListView_default
Module Liferay_Guestbook
☑ Inherit From Target

Figure 49.4: In the XIB file, set the custom class of the Table View's parent View to `EntryListView_default`.

4. With the Theme's XIB still open in Interface Builder, set the parent View's `tableView` outlet to the Table View. To do this, select the parent View and click the Connections inspector. In the *Outlets* section, drag and drop from the `tableView`'s circle icon (on mouseover, it turns into a plus icon) to the Table View in the XIB. The new outlet then appears in the Connections inspector.

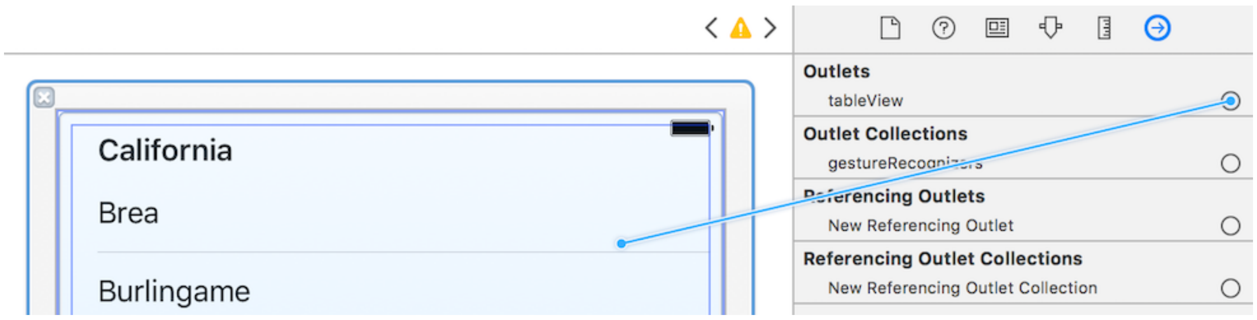


Figure 49.5: Drag and drop from the `tableView` outlet to the Table View in the XIB.

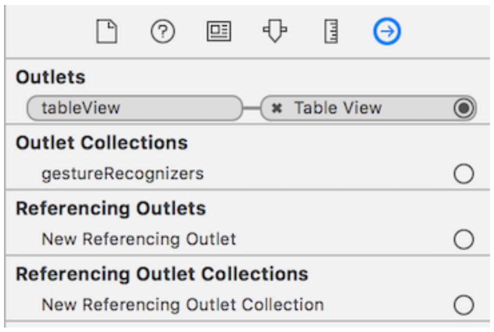

Outlets
tableView — ✖ Table View
Outlet Collections
gestureRecognizers
Referencing Outlets
New Referencing Outlet
Referencing Outlet Collections
New Referencing Outlet Collection

Figure 49.6: After creating the connection, the outlet looks like this in the Connections inspector.

Great! Your Theme is finished. Next, you'll create Entry List Screenlet's Connector.

49.3 Creating Entry List Screenlet's Connector

Recall that Connectors are Screenlet components that make server calls. Also recall that by making your server calls in Connectors instead of Interactors, you gain an additional layer of abstraction.

In this article, you'll create Entry List Screenlet's Connector. Because this Connector is so similar to that of Guestbook List Screenlet, the steps to create it aren't explained in detail. Focus is instead placed on the few places in the code where the Connectors diverge. For a full explanation of the code, see the article on creating Guestbook List Screenlet's Connector.

Creating Your Connector's Folder

Follow these steps to create your Connector's folder:

1. In the Finder, create the `Connector` folder inside your project's `EntryListScreenlet` folder.

2. Drag and drop the `Connector` folder from the Finder into your Xcode project, under the `EntryListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `Connector` folder now appears in your project.

Now you're ready to create the Connector.

Creating the Connector

Recall that list Screenlet Connectors must extend the `PaginationLiferayConnector` class. Your list Screenlet's Connector class must also contain any properties it needs to make the server call, and an initializer that sets them. To support pagination, the initializer must also contain the following arguments, which you'll pass to the superclass initializer:

- `startRow`: The number representing the page's first row.
- `endRow`: The number representing the page's last row.
- `computeRowCount`: Whether to call the Connector's `doAddRowCountServiceCall` method.

Follow these steps to create Guestbook List Screenlet's Connector:

1. In the Project navigator, right-click the `Connector` folder you added above and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS → Source → Cocoa Touch Class*, and click *Next*.
    - Name the class `EntryListPageLiferayConnector`, set it to extend `PaginationLiferayConnector`, select *Swift* for the language, and click *Next*.
    - Make sure the `Connector` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. Replace the class file's contents with this code:

```
import UIKit
import LiferayScreens

class EntryListPageLiferayConnector: PaginationLiferayConnector {

    public let groupId: Int64
    public let guestbookId: Int64

    //MARK: Initializer

    public init(startRow: Int, endRow: Int, computeRowCount: Bool, groupId: Int64,
        guestbookId: Int64) {

            self.groupId = groupId
            self.guestbookId = guestbookId

            super.init(startRow: startRow, endRow: endRow, computeRowCount: computeRowCount)
    }

    //MARK: PaginationLiferayConnector

    public override func doAddPageRowsServiceCall(session: LRBatchSession, startRow: Int, endRow: Int,
        obc: LRJSONObjectWrapper?) {

        let service = LREntryService_v7(session: session)

        do {
            try service!.getEntriesWithGroupId(groupId, guestbookId: guestbookId,
                    start: Int32(startRow), end: Int32(endRow))
        }
        catch {
            // the service method returns nil because the request is sent later, in batch
        }

    }

    override public func doAddRowCountServiceCall(session: LRBatchSession) {
        let service = LREntryService_v7(session: session)

        do {
            try service!.getEntriesCount(withGroupId: groupId, guestbookId: guestbookId)
        }
        catch {
            // the service method returns nil because the request is sent later, in batch
        }
    }

}
```

This class is almost identical to Guestbook List Screenlet's Connector class, `GuestbookListPageLiferayConnector`. The only differences are due to the service calls. To define the guestbook to retrieve entries from, `EntryListPageLiferayConnector` needs a `guestbookId` property. It then uses this property with the service methods `getEntriesWithGroupId` and `getEntriesCount` to retrieve the entries and number of entries, respectively. Also note that the service is an `LREntryService_v7` instance.

Nicely done! Now that Entry List Screenlet has a Connector, you must create its Interactor. The next article shows you how to do this.

49.4 Creating Entry List Screenlet's Interactor

Recall that list Screenlets require an Interactor to instantiate the Connector and receive the server call's results. In this article, you'll create Entry List Screenlet's Interactor.

Because this Interactor is so similar to that of Guestbook List Screenlet, the steps to create it aren't explained in detail. Focus is instead placed on the few places in the code where the Interactors diverge. For a full explanation of the code, see the article on creating Guestbook List Screenlet's Interactor.

Creating Your Interactor's Folder

Follow these steps to create your Interactor's folder:

1. In the Finder, create the `Interactor` folder inside your project's `EntryListScreenlet` folder.

2. Drag and drop the `Interactor` folder from the Finder into your Xcode project, under the `EntryListScreenlet` folder. In the dialog that appears, select *Copy items if needed*, *Create groups*, and the *Liferay Guestbook* target. Then click *Finish*. The `Interactor` folder now appears in your project.

Now you're ready to create the Interactor.

Creating the Interactor

Recall that the Interactor class of a list Screenlet that implements fluent pagination must extend the `BaseListPageLoadInteractor` class. Your Interactor class must also contain any properties the Screenlet needs, and an initializer that sets them. This initializer also needs arguments for the following properties, which it passes to the superclass initializer:

- `screenlet`: A `BaseListScreenlet` reference. This ensures the Interactor always has a Screenlet reference.
- `page`: The page number to retrieve.
- `computeRowCount`: Whether to call the Connector's `doAddRowCountServiceCall` method.

Follow these steps to create Entry List Screenlet's Interactor:

1. In the Project navigator, right-click the `Interactor` folder you added above and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.
    - Name the class `EntryListPageLoadInteractor`, set it to extend `BaseListPageLoadInteractor`, select *Swift* for the language, and click *Next*.
    - Make sure the `Interactor` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. Replace the class file's contents with this code:

```
import UIKit
import LiferayScreens

class EntryListPageLoadInteractor: BaseListPageLoadInteractor {

    private let groupId: Int64
    private let guestbookId: Int64

    init(screenlet: BaseListScreenlet,
         page: Int,
         computeRowCount: Bool,
         groupId: Int64,
         guestbookId: Int64) {

        self.groupId = (groupId ≠ 0) ? groupId : LiferayServerContext.groupId
        self.guestbookId = guestbookId

        super.init(screenlet: screenlet, page: page, computeRowCount: computeRowCount)
    }
    public override func createListPageConnector() -> PaginationLiferayConnector {
        let screenlet = self.screenlet as! BaseListScreenlet

        return EntryListPageLiferayConnector(
            startRow: screenlet.firstRowForPage(self.page),
            endRow: screenlet.firstRowForPage(self.page + 1),
            computeRowCount: self.computeRowCount,
            groupId: groupId,
            guestbookId: guestbookId)
    }

    override public func convertResult(_ serverResult: [String:AnyObject]) -> AnyObject {

        return EntryModel(attributes: serverResult)
    }

    override public func cacheKey(_ op: PaginationLiferayConnector) -> String {
        return "\(groupId)-\(guestbookId)"
    }

}
```

This class is almost identical to Guestbook List Screenlet's Interactor, `GuestbookListPageLoadInteractor`. The only real difference is that `EntryListPageLoadInteractor` handles entries. It therefore needs a `guestbookId` variable to define the guestbook to retrieve entries from. This variable is set in the initializer and then used in the `createListPageConnector` method to create a `EntryListPageLiferayConnector` instance. The `convertResult` method receives each `[String:AnyObject]` entry from the server and transforms it into an `EntryModel` object. Also recall that the `cacheKey` method must return a key that can be used with online mode. For entries, a combination of the `groupId` and `guestbookId` is a sufficient key.

Great! Your Interactor is finished. Next, you'll create the delegate.

49.5 Creating Entry List Screenlet's Delegate

Recall that a delegate lets other classes respond to your Screenlet's actions. Like you did for Guestbook List Screenlet, you'll create a delegate for Entry List Screenlet that can respond to a successful server call, a failed server call, and an item selection in the list. This delegate must therefore define these methods:

- `screenlet(_:onEntryListResponse:)`: Receives the `EntryModel` results when the server call succeeds. This lets app developers respond to a successful server call.
- `screenlet(_:onEntryListError:)`: Receives the `NSError` object when the server call fails. This lets app developers respond to a failed server call.
- `screenlet(_:onEntrySelected:)`: Receives the `EntryModel` when a user selects it in the list. This lets app developers respond to an entry selection by the user.

You'll create this delegate in the same file as the Screenlet class. Later, you'll finish creating the Screenlet class itself.

Follow these steps to create Entry List Screenlet's delegate:

1. In the Project navigator, right-click the `EntryListScreenlet` folder and select *New File*. In the dialog that appears, fill out each screen as follows:

    - Select *iOS* → *Source* → *Cocoa Touch Class*, and click *Next*.

    - Name the class `EntryListScreenlet`, set it to extend `BaseListScreenlet`, select *Swift* for the language, and click *Next*.
    - Make sure the `EntryListScreenlet` folder and group is selected, as well as the *Liferay Guestbook* target (these should be selected by default). Click *Create*.

2. In the new `EntryListScreenlet` class, import `LiferayScreens`, make the class `public`, and delete any placeholder comments in the class body.

3. In between the `import` statements and the class declaration, add the following code:

    ```
    @objc public protocol EntryListScreenletDelegate : BaseScreenletDelegate {

        @objc optional func screenlet(screenlet: EntryListScreenlet,
                              onEntryListResponse entries: [EntryModel])

        @objc optional func screenlet(screenlet: EntryListScreenlet,
                              onEntryListError error: NSError)

        @objc optional func screenlet(screenlet: EntryListScreenlet,
                              onEntrySelected entry: EntryModel)

    }
    ```

    This delegate is almost identical to that of Guestbook List Screenlet, `GuestbookListScreenletDelegate`. The only difference is that `EntryListScreenletDelegate` works with entries instead of guestbooks.

The contents of `EntryListScreenlet.swift` should now look like this:

```
import UIKit
import LiferayScreens

@objc public protocol EntryListScreenletDelegate : BaseScreenletDelegate {

    @objc optional func screenlet(screenlet: EntryListScreenlet,
                          onEntryListResponse entries: [EntryModel])

    @objc optional func screenlet(screenlet: EntryListScreenlet,
                          onEntryListError error: NSError)

    @objc optional func screenlet(screenlet: EntryListScreenlet,
                          onEntrySelected entry: EntryModel)

}

public class EntryListScreenlet: BaseListScreenlet {

}
```

Nice work! Now you're ready to complete the Screenlet class.

49.6 Creating the Screenlet Class

Recall that the Screenlet class is the main component that governs the Screenlet's behavior. Also recall that a list Screenlet's class must do the following:

- Extend `BaseListScreenlet`. Since `BaseListScreenlet` provides most of the functionality needed by Screenlet classes, extending it lets you focus on the functionality unique to your Screenlet.

- Define the configurable IBInspectable properties the Screenlet needs.
- Create and return an instance of your Interactor.
- Respond to the Screenlet's events via the delegate.

The Screenlet class you created when you created the delegate is currently empty. You'll complete it now. Follow these steps to complete the EntryListScreenlet class in EntryListScreenlet.swift:

1. Define public, IBInspectable, Int64 properties for the groupId and guestbookId. Although the app developer can set groupId via liferay-server-context.plist, and the guestbookId is set dynamically, it's also a good idea to let the developer set their values in Interface Builder. Give both properties an initial value of 0. Your Screenlet class should now look like this:

```
public class EntryListScreenlet: BaseListScreenlet {

    @IBInspectable public var groupId: Int64 = 0
    @IBInspectable public var guestbookId: Int64 = 0
}
```

2. Override the createPageLoadInteractor method to create and return an instance of EntryListPageLoadInteractor. This method includes page and computeRowCount arguments, which you pass to the Interactor's constructor along with groupId and guestbookId:

```
override public func createPageLoadInteractor(
    page: Int,
    computeRowCount: Bool) -> BaseListPageLoadInteractor {

    return EntryListPageLoadInteractor(screenlet: self,
                                        page: page,
                                        computeRowCount: computeRowCount,
                                        groupId: self.groupId,
                                        guestbookId: self.guestbookId)
}
```

3. Create a computed property to get a reference to EntryListScreenletDelegate:

```
public var entryListDelegate: EntryListScreenletDelegate? {
    return delegate as? EntryListScreenletDelegate
}
```

   You'll use this property to handle the Screenlet's events via the delegate's methods.

4. Override the BaseListScreenlet methods that handle the Screenlet's events. Because these events correspond to those handled by your delegate, you'll call the corresponding delegate methods in these BaseListScreenlet methods:

   - onLoadPageResult: Called when the Screenlet loads a page successfully. Override this method to call the superclass's onLoadPageResult method, then call your delegate's screenlet(_:onEntryListResponse:) method:

```
override public func onLoadPageResult(page: Int, rows: [AnyObject], rowCount: Int) {
    super.onLoadPageResult(page: page, rows: rows, rowCount: rowCount)

    entryListDelegate?.screenlet?(screenlet: self, onEntryListResponse: rows as! [EntryModel])
}
```

- `onLoadPageError`: Called when the Screenlet fails to load a page. Override this method to call the superclass's `onLoadPageError` method, then call your delegate's `screenlet(_:onEntryListError:)` method:

```
override public func onLoadPageError(page: Int, error: NSError) {
    super.onLoadPageError(page: page, error: error)

    entryListDelegate?.screenlet?(screenlet: self, onEntryListError: error)
}
```

- `onSelectedRow`: Called when an item is selected in the list. Override this method to call your delegate's `screenlet(_:onEntrySelected:)` method:

```
override public func onSelectedRow(_ row: AnyObject) {
    entryListDelegate?.screenlet?(screenlet: self, onEntrySelected: row as! EntryModel)
}
```

Awesome! Your Screenlet class is finished. You're also done with Entry List Screenlet! Now you're ready to use Entry List Screenlet alongside Guestbook List Screenlet. The following section of this Learning Path concludes with both Screenlets working together in harmony.

Chapter 50

Using Your Screenlets

Now that you have the Guestbook List and Entry List Screenlets, you're ready to put them to work. As you'll see, using these Screenlets isn't much more difficult than using Login Screenlet. This is an advantage of Screenlets; it typically takes only a few minutes to get them up and running.

To add your Screenlets to the app, you'll follow these steps:

1. Create the entries scene.
2. Add Guestbook List Screenlet to the guestbooks scene.
3. Add Entry List Screenlet to the entries scene.

If you get confused or stuck at any point in this section of the Learning Path, refer to the finished app that contains the Screenlet code here in GitHub.

First, you'll create the entries scene.

50.1 Creating the Entries Scene

Currently, the login and guestbooks scenes are the only two scenes in your app. The login scene contains Login Screenlet, and you'll put Guestbook List Screenlet in the guestbooks scene. Before you can use Entry List Screenlet, you must create a scene to put it in: the entries scene.

In this article, you'll use these steps to create the entries scene:

1. Add a new view controller to your storyboard, and create a segue to it from the guestbooks scene.
2. Create the entries scene's view controller class.

Adding a View Controller to the Storyboard

Follow these steps to create a view controller for the entries scene:

1. Open your storyboard and drag and drop a *View Controller* from the Object Library to the right of the guestbooks scene.

2. With the new view controller selected in the storyboard, open the Attributes inspector and uncheck *Adjust Scroll View Insets*. This ensures that the scene's contents are flush with the navigation bar.

3. Create a segue from the guestbooks scene's view controller to the new view controller. To do this, control-drag from the guestbooks scene's view controller to the new view controller. In the dialog that appears upon releasing your mouse button, select *show* for the segue type. The segue now connects the two view controllers.

4. Click the new segue, and then enter the Attributes inspector. Enter *entriessegue* in the *Identifier* field, and press *return*. Later, you'll use this identifier to perform the segue programmatically when a user selects a guestbook in Guestbook List Screenlet.

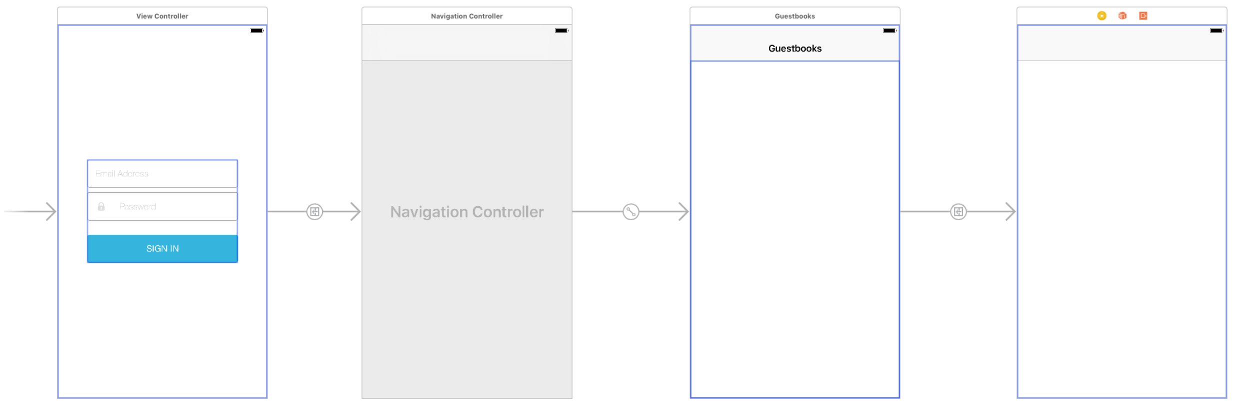

Figure 50.1: The entries scene now exists to the right of the guestbooks scene, with a segue connecting the two scenes.

Great! The entries scene now exists, and there's a segue going to it from the guestbooks scene. Next, you'll create the entries scene's view controller class.

Creating the Entries Scene's View Controller Class

Each view controller must have a class that controls its behavior. In this section, you'll create this class for the entries scene's view controller. In the storyboard, you'll then set this class as the view controller's custom class.

Follow these steps to create the entries scene's view controller class:

1. Right-click the `Liferay Guestbook` folder in Xcode's project navigator and select *New File*. In the *iOS → Source* section of the dialog that appears, select *Cocoa Touch Class* and click *Next*.

2. The next screen in the dialog lets you set the class's name, subclass, and language. You can also choose whether to create an XIB file for the class. Enter the following information and click *Next*:

   - **Class:** `EntriesViewController`
   - **Subclass of:** `UIViewController`
   - **Also create XIB file:** Unchecked
   - **Language:** Swift

3. The final screen in the dialog lets you set the class's location, group, and targets. Make sure *Liferay Guestbook* is selected for both the *Group* and *Targets* menus (it should be by default), and click *Create*.

4. `EntriesViewController` needs a `GuestbookModel` variable to hold the guestbook it shows entries from. Add this variable to the top of the class:

   ```
   var selectedGuestbook: GuestbookModel?
   ```

   As its name implies, this variable holds the guestbook the user selects in Guestbook List Screenlet.

5. In the storyboard, select the entries scene's view controller. In the Identity inspector, set `EntriesViewController` as the custom class.

Nice work! The entries scene's view controller now has a class that governs its behavior. Now you're ready to put your Screenlets to use.

50.2 Using Guestbook List Screenlet

The steps for using Guestbook List Screenlet are the same as those for using any Screenlet:

1. Insert the Screenlet in the storyboard scene where you want it to appear. You do this by adding an empty view to the scene, and then setting the Screenlet class as the view's custom class.
2. Conform the scene's view controller class to the Screenlet's delegate protocol. This lets the view controller respond to the Screenlet's events.

You'll follow these steps to use Guestbook List Screenlet in the guestbooks scene. You'll also take an extra step to trigger the segue to the entries scene when a user selects a guestbook.

Adding Guestbook List Screenlet to the Guestbooks Scene

Follow these steps to add Guestbook List Screenlet to the guestbooks scene:

1. In your storyboard, first select the guestbooks scene's view controller. Then drag and drop a plain view (`UIView`) from the Object Library to the view controller. In the outline view, this new view should be nested under the view controller's existing view.

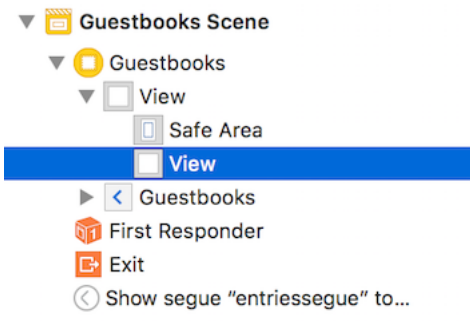

Figure 50.2: The new view is nested under the view controller's existing view.

2. Resize the new view to take up all the space below the navigation bar. With the new view selected, open the *Add New Constraints* menu at the bottom-right of the canvas. In this menu, set *Spacing to nearest neighbor* to 0 on all sides, and click the *Add 4 Constraints* button.

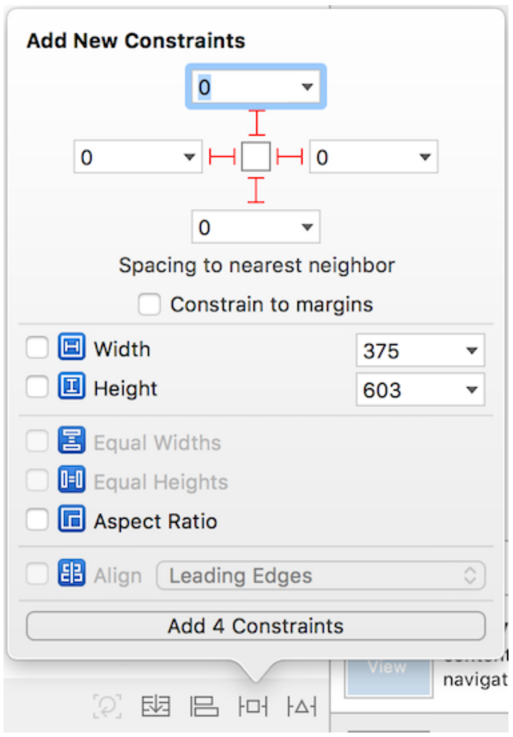

Figure 50.3: Set the new view's *Spacing to nearest neighbor* constraints to 0 on all sides.

3. With the new view still selected, open the Identity inspector and set the view's custom class to `GuestbookListScreenlet`. The view now appears as Guestbook List Screenlet in the outline view.

Fantastic! The guestbooks scene now contains Guestbook List Screenlet. Next, you'll conform the scene's view controller class to the Screenlet's delegate.

Conforming to the Screenlet's Delegate Protocol

Recall that a view controller can respond to a Screenlet's events by conforming to the Screenlet's delegate protocol. To respond to Guestbook List Screenlet's events, `GuestbooksViewController` (the guestbooks scene's view controller class) must conform to the `GuestbookListScreenletDelegate` protocol. You created this delegate when creating the Screenlet. This delegate defines methods for responding to the success or failure to retrieve guestbooks, and the selection of a guestbook in the list.

Follow these steps to conform `GuestbooksViewController` to the `GuestbookListScreenletDelegate` protocol:

1. Import `LiferayScreens`, and in the class declaration set `GuestbooksViewController` to adopt the `GuestbookListScreenletDelegate` protocol. The first few lines of the class should look like this:

```
import UIKit
import LiferayScreens

class GuestbooksViewController: UIViewController, GuestbookListScreenletDelegate {...
```

2. Implement the `GuestbookListScreenletDelegate` method `screenlet(_:onGuestbookListResponse:)`. Recall that this method lets you respond to a successful server call. Its arguments include the `GuestbookModel` objects that result from such a call. Since the Screenlet already displays these objects, you don't need to do anything in this method:

```
func screenlet(screenlet: GuestbookListScreenlet,
    onGuestbookListResponse guestbooks: [GuestbookModel]) {

}
```

3. Implement the `GuestbookListScreenletDelegate` method `screenlet(_:onGuestbookListError:)`. Recall that this method lets you respond to a failed server call. Its arguments include the `NSError` object that results from such a call. You don't have to do anything in this method, but it's a good idea to print the error:

```
func screenlet(screenlet: GuestbookListScreenlet, onGuestbookListError error: NSError) {
    print("Failed to retrieve guestbooks: \(error.localizedDescription)")
}
```

4. Implement the `GuestbookListScreenletDelegate` method `screenlet(_:onGuestbookSelected:)`. Recall that this method lets you respond when a user selects a guestbook in the list. It does so by including the selected `GuestbookModel` object in its arguments. When a user selects a guestbook, the app should transition to the entries scene and display that guestbook's entries with Entry List Screenlet. To do this, you must trigger the segue to the entries scene by using the method `performSegue(withIdentifier:sender:)` with the segue's ID and the selected `GuestbookModel`. Recall that you assigned the segue's ID, `entriessegue`, when you created the segue. Including the selected `GuestbookModel` lets Entry List Screenlet know which guestbook to display entries from:

```
func screenlet(screenlet: GuestbookListScreenlet,
    onGuestbookSelected guestbook: GuestbookModel) {

    performSegue(withIdentifier: "entriessegue", sender: guestbook)
}
```

5. Next, you must set the segue's destination view controller to an `EntriesViewController` instance, and set that instance's `selectedGuestbook` variable to the selected guestbook. This ensures that Entry List Screenlet receives the guestbook you sent in `performSegue(withIdentifier:sender:)`.

   You do this by overriding the `prepare(for:sender:)` method. This method is called by `performSegue(withIdentifier:send`
   before the segue occurs. The `prepare(for:sender:)` method's sender parameter receives the guestbook sent by `performSegue(withIdentifier:sender:)`. Currently, `prepare(for:sender:)` is commented out at the bottom of `GuestbooksViewController`. Xcode created this method for you when you used the Cocoa Touch Class template to create a view controller class. Uncomment the method, and replace it with this:

```
override func prepare(for segue: UIStoryboardSegue, sender: Any?) {

    guard segue.identifier ==  "entriessegue",
        let entriesViewController = segue.destination as? EntriesViewController,
        let selectedGuestbook = sender as? GuestbookModel
        else {return}

    entriesViewController.selectedGuestbook = selectedGuestbook
}
```

   The guard statement ensures that the code only runs when the segue ID is `entriessegue`, the destination view controller is `EntriesViewController`, and the sender is a `GuestbookModel`. In other words, the code only runs in preparation for the segue to the entries scene. The code that runs when that condition is met is only one line long:

```
entriesViewController.selectedGuestbook = selectedGuestbook
```

This sets the guestbook received by `prepare(for:sender:)` to the guestbook in `EntriesViewController`. As the variable names indicate, this is the guestbook the user selects in Guestbook List Screenlet.

6. Now you must get a Guestbook List Screenlet reference. You'll do this by creating an outlet to the Screenlet. Return to your storyboard and enter the Assistant editor to display `GuestbooksViewController`'s code and the storyboard side by side. With Guestbook List Screenlet selected in the storyboard, Control-drag from the Screenlet to the `GuestbooksViewController` class, just below the class declaration. Release your mouse button, enter the following information in the dialog that appears, and click *Connect*:

    - **Connection:** Outlet
    - **Name:** screenlet
    - **Type:** GuestbookListScreenlet
    - **Storage:** Weak

    Xcode then adds the following code inside the `GuestbooksViewController` class:

    ```
    @IBOutlet weak var screenlet: GuestbookListScreenlet!
    ```

7. Use this new `screenlet` variable to set the view controller as the Screenlet's delegate. Do this in the `viewDidLoad()` method by deleting the placeholder comment and inserting this code below the call to `super.viewDidLoad()`:

    ```
    self.screenlet.delegate = self
    ```

Great! The guestbooks scene now contains Guestbook List Screenlet. Next, you'll use Entry List Screenlet in the entries scene.

50.3 Using Entry List Screenlet

You'll use Entry List Screenlet the same way you use any Screenlet: insert it in a storyboard scene, then conform the scene's view controller class to the Screenlet's delegate protocol. You'll follow these steps now to use Entry List Screenlet in the entries scene.

Adding Entry List Screenlet to the Entries Scene

Follow these steps to add Entry List Screenlet to the entries scene:

1. In your storyboard, select the entries scene's view controller. Then drag and drop a plain view (`UIView`) from the Object Library to the view controller. In the outline view, this new view should be nested under the view controller's existing view.

2. Resize the new view to take up all the space below the navigation bar. Then open the *Add New Constraints* menu at the bottom-right of the canvas. In this menu, set *Spacing to nearest neighbor* to 0 on all sides, and click the *Add 4 Constraints* button.

3. With the new view still selected, open the Identity inspector and set the view's custom class to `EntryListScreenlet`. The view now appears as Entry List Screenlet in the outline view.

Great! The entries scene now contains Entry List Screenlet. Next, you'll conform the scene's view controller class to the Screenlet's delegate.

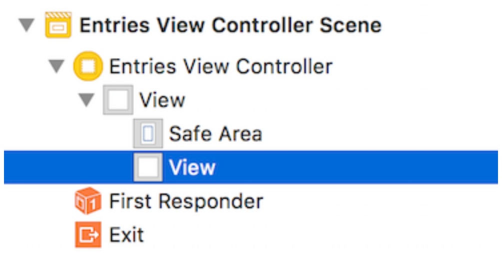

Figure 50.4: The new view is nested under the view controller's existing view.

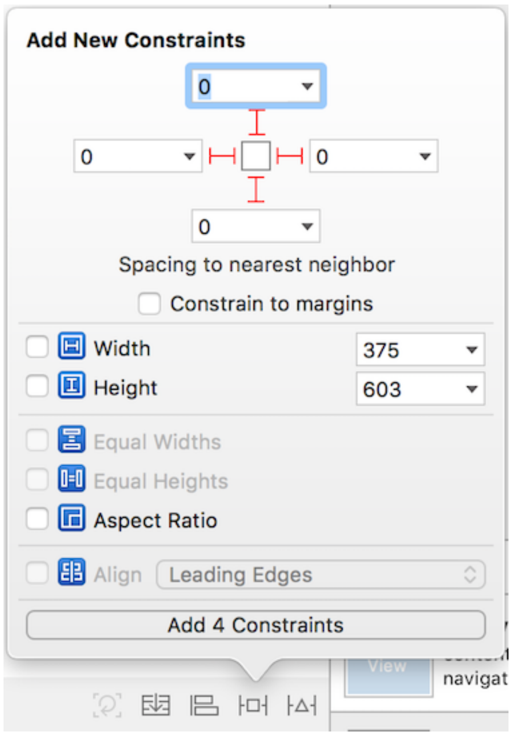

Figure 50.5: Set the new view's *Spacing to nearest neighbor* constraints to 0 on all sides.

Conforming to the Screenlet's Delegate Protocol

To respond to Entry List Screenlet's events, `EntriesViewController` must conform to the `EntryListScreenletDelegate` protocol. You created this delegate when creating the Screenlet. This delegate defines methods for responding to the success or failure to retrieve entries, and the selection of an entry in the list.

Follow these steps to conform `EntriesViewController` to the `EntryListScreenletDelegate` protocol:

1. Import `LiferayScreens`, and in the class declaration set `EntriesViewController` to adopt the `EntryListScreenletDelegate` protocol. The first few lines of the class should look like this:

```
import UIKit
import LiferayScreens

class EntriesViewController: UIViewController, EntryListScreenletDelegate {...
```

2. Implement the `EntryListScreenletDelegate` method `screenlet(_:onEntryListResponse:)`. Recall that this method lets you respond to a successful server call. Its arguments include the `EntryModel` objects

that result from such a call. Since the Screenlet already displays these objects, you don't need to do anything in this method:

```
func screenlet(screenlet: EntryListScreenlet, onEntryListResponse entries: [EntryModel]) {

}
```

3. Implement the `EntryListScreenletDelegate` method `screenlet(_:onEntryListError:)`. Recall that this method lets you respond to a failed server call. Its arguments include the resulting `NSError` object. You don't have to do anything in this method, but it's a good idea to print the error:

```
func screenlet(screenlet: EntryListScreenlet, onEntryListError error: NSError) {
    print("Failed to retrieve guestbook entries: \(error.localizedDescription)")
}
```

4. Implement the `EntryListScreenletDelegate` method `screenlet(_:onEntrySelected:)`. Recall that this method lets you respond when a user selects an entry in the list. It does so by including the selected `EntryModel` object in its arguments. Since there's currently not a scene or other action that handles detailed information about an entry, you don't need to do anything in this method:

```
func screenlet(screenlet: EntryListScreenlet, onEntrySelected entry: EntryModel) {

}
```

5. Now you must get an Entry List Screenlet reference. You'll do this by creating an outlet to the Screenlet. Return to your storyboard and enter the Assistant editor to display `EntriesViewController`'s code and the storyboard side by side. With Entry List Screenlet selected in the storyboard, Control-drag from the Screenlet to the `EntriesViewController` class, just below the class declaration. Release your mouse button, enter the following information in the dialog that appears, and click *Connect*:

    - **Connection:** Outlet
    - **Name:** screenlet
    - **Type:** EntryListScreenlet
    - **Storage:** Weak

   Xcode then adds the following code inside the `EntriesViewController` class:

```
@IBOutlet weak var screenlet: EntryListScreenlet!
```

6. Use this new `screenlet` variable to set the view controller as the Screenlet's delegate. Do this in the `viewDidLoad()` method by deleting the placeholder comment and inserting this code below the call to `super.viewDidLoad()`:

```
self.screenlet.delegate = self
```

7. Next, you must set the guestbook the Screenlet retrieves entries from. To do this, set the Screenlet's `guestbookId` property to the selected guestbook's ID, immediately below the Screenlet's delegate assignment in the `viewDidLoad()` method:

```
self.screenlet.guestbookId = selectedGuestbook!.guestbookId
```

8. Lastly, you must set the selected guestbook's name to the navigation bar's title. This lets the scene reflect the guestbook selection in the UI. To do this, add the following line of code at the end of the `viewDidLoad()` method:

   ```
   self.navigationItem.title = selectedGuestbook!.name
   ```

   Your `viewDidLoad()` method should now look like this:

   ```
   override func viewDidLoad() {
       super.viewDidLoad()

       self.screenlet.delegate = self
       self.screenlet.guestbookId = selectedGuestbook!.guestbookId
       self.navigationItem.title = selectedGuestbook!.name
   }
   ```

Now you're ready to test your handiwork. Make sure your portal containing the Guestbook portlet is running, and that the portlet contains a couple guestbooks that have entries. Then run the app and log in with your credentials. You should see the list of guestbooks displayed by Guestbook List Screenlet. Selecting a guestbook in the list takes you to the entries scene, which uses Entry List Screenlet to display a list of that guestbook's entries. Pressing the back button returns you to the guestbooks scene, where you can select a different guestbook.

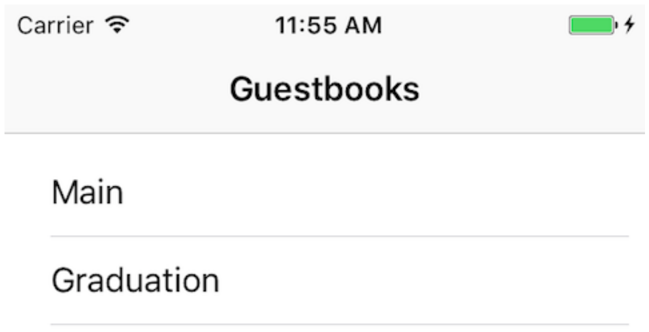

Figure 50.6: After login, Guestbook List Screenlet displays the list of guestbooks from the portlet.

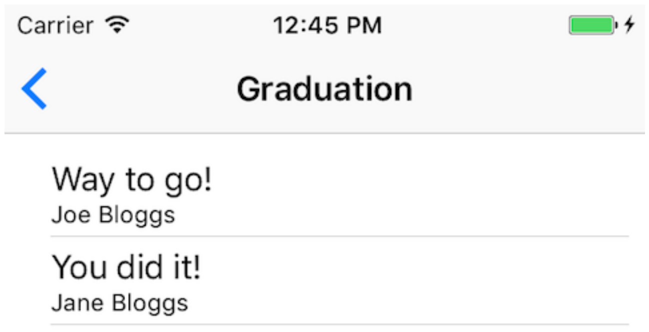

Figure 50.7: Selecting a guestbook displays a list of that guestbook's entries via Entry List Screenlet.

Congratulations! Now you know how to use Liferay Screens and create your own Screenlets. This opens up a world of possibilities for developing apps that leverage Liferay DXP. Although you learned a great deal in this Learning Path, there's still more. You can customize your Screenlet's appearance, package Screenlets and Themes for redistribution, and even add multiple actions to a Screenlet. These topics, and more, are covered in the tutorials on iOS apps with Liferay Screens.

Chapter 51

Tooling

Liferay is very flexible when it comes to supporting different development tooling. Instead of being pigeonholed into using a specific tool, Liferay works with whatever tools you like to use. This set of tutorials describes some of the more popular tools that are used to develop for Liferay. If you're a newbie looking for the best development tool for Liferay, or even a seasoned veteran looking for a tool you may like more than your current setup, this section will answer your tooling questions.

Chapter 52

Liferay @ide@

Liferay @ide@ provides an all-in-one, integrated development environment based on Eclipse that supports development for Liferay DXP. @ide@ includes Liferay IDE plugins and additional enterprise-only features like

- Kaleo Designer for Java
- WebSphere support
- Pre-installed Liferay Digital Enterprise server

@ide@ is also designed to work with build tools such as Gradle and Maven, and configuration tools like BndTools.

Liferay @ide@ makes Liferay development easier. There are editors for Service Builder files, workflow definitions, layout templates, and more. You'll find wizards for creating every kind of Liferay project there is, snippet for tag libraries, and auto-deploy of changes to plugins.

In this section of tutorials, you'll learn how to install Liferay @ide@ and develop/manage Liferay modules using Liferay Workspace and other technologies.

52.1 Installing Liferay @ide@

Liferay @ide@ is a plugin for Eclipse that provides many Liferay-specific features and additional enterprise only features. You can install it into your existing Eclipse environment, or Liferay provides a bundled version. In this tutorial, you'll learn the different methods available for installing Liferay @ide@. Before beginning the installation process, view @ide@'s Compatibility Matrix to get acquainted with its supported Liferay versions and application servers.

Important: If you're upgrading your Liferay @ide@ instance to version 3.1, you must install a new @ide@ bundle. You cannot install an update for this upgrade. Your Liferay Workspace instance and its contents are backwards compatible and can be copied to the new 3.1 version.

Install the Liferay @ide@ Bundle

1. Download and install Java. Liferay DXP runs on Java, so you'll need it to run everything else. Because you'll be developing apps for Liferay DXP in Liferay @ide@, the Java Development Kit (JDK) is required. It is an enhanced version of the Java Environment used for developing new Java technology. You can download the Java SE JDK from the Java Downloads page.

2. Download the Liferay @ide@ installer. Be sure to choose the installer appropriate for your operating system (e.g., Windows, MacOS, Linux).

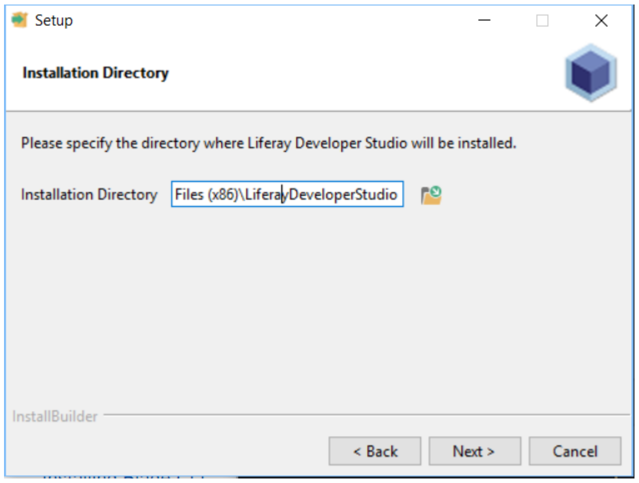
   You may be prompted for your liferay.com username and password before downloading the Liferay DXP installer. Since @ide@ includes access to Liferay DXP, you must verify that you have rights to use it.

   Your credentials are not saved locally; they're saved as a token in the `~/.liferay` folder. The token is used by your @ide@'s Liferay Workspace if you ever decide to redownload a Liferay DXP bundle. Furthermore, the Liferay DXP bundle that was downloaded in your workspace is also copied to your `~/.liferay/bundles` folder, so if you decide to initialize another Liferay DXP instance of the same version, the bundle is not re-downloaded. See the Adding a Liferay Bundle to a Workspace for more information on this topic.

   Important: The token generator sometimes has issues generating a token for workspaces built behind a proxy. If you're unable to automatically generate a workspace token, you can generate one manually.

3. Run the installer. You may need to allow permission for the installer to run, depending on your operating system and where you want to install it.

4. Click *Next* to begin the installation process. Select the installation folder for your Liferay @ide@ instance. Then click *Next*.



Setup

Installation Directory

Please specify the directory where Liferay Developer Studio will be installed.

Installation Directory: Files (x86)\LiferayDeveloperStudio

Figure 52.1: Choose the folder your @ide@ instance should reside.

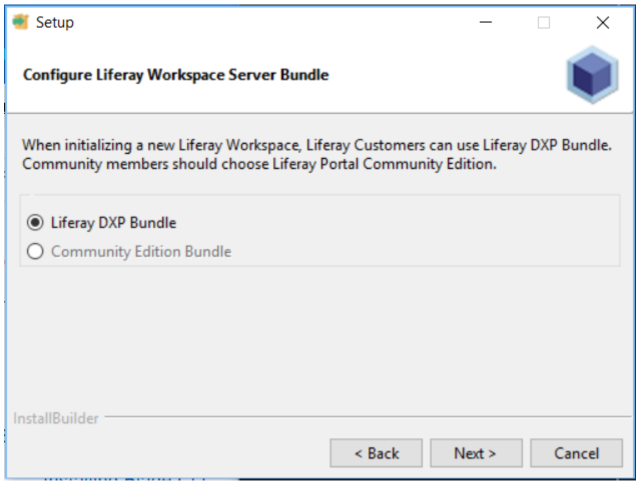
5. Liferay @ide@ provides Liferay Workspace by default, which is a developer environment used to build and manage Liferay DXP projects. The installer automatically installs Liferay Workspace and its dedicated command line tool (Blade CLI).

   You'll need to choose the Liferay bundle you plan to use in your Liferay Workspace: *Liferay DXP Bundle* or *Community Edition Bundle*. Then choose *Next*.

   If you selected *Liferay DXP Bundle*, you're also required to provide your liferay.com email and password.

6. Click *Next* to finish the installation process for your @ide@ instance.

Congratulations! You've installed Liferay @ide@! It's now available in the folder you specified. To run @ide@, execute the `DeveloperStudio` executable. A Liferay Workspace has also been initialized in that same folder. For more information on the Liferay Workspace installation related to this installation process, see the Installing Liferay Workspace section.



When initializing a new Liferay Workspace, Liferay Customers can use Liferay DXP Bundle. Community members should choose Liferay Portal Community Edition.

(●) Liferay DXP Bundle
( ) Community Edition Bundle

Figure 52.2: Choose the Liferay bundle you plan to use.

Install Liferay @ide@ into Eclipse Environment

To install @ide@ using an update URL, follow these steps:

1. In Eclipse, go to *Help* → *Install New Software...*.
2. In the *Work with* field, copy in the URL http://releases.liferay.com/tools/ide/latest/stable/.
3. You'll see the @ide@ components in the list below. Check them off and click *Next*.
4. Accept the terms of the agreements. Click *Next*, and @ide@ is installed. Like other Eclipse plugins, you must restart Eclipse to use them.

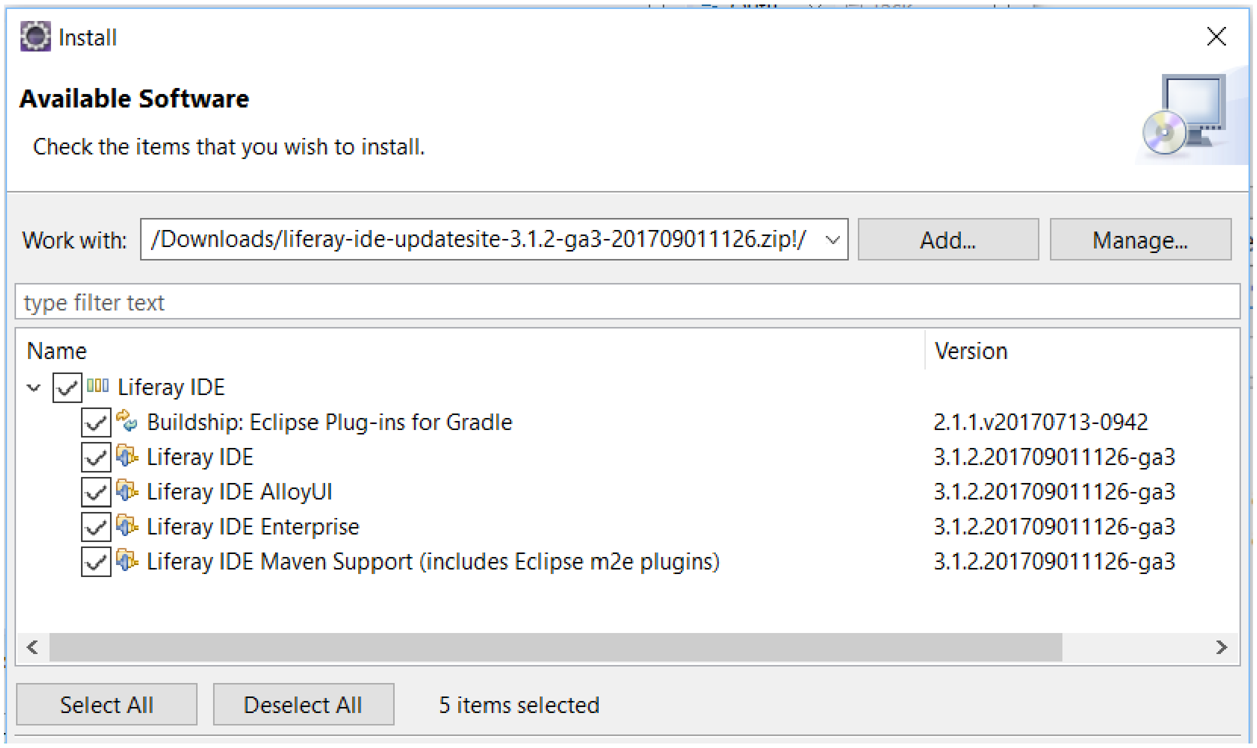
Liferay @ide@ is now installed in your existing Eclipse environment.

Install Liferay @ide@ into Eclipse from a ZIP File

To install @ide@ using a Zip file, follow these steps:

1. Go to the Liferay @ide@ downloads page. From the drop-down menu, select *Developer Studio Update Site Zip* and click *Download*.
2. In Eclipse, go to *Help* → *Install New Software...*.
3. In the *Add* dialog, click the *Archive* button and browse to the location of the downloaded Liferay @ide@ Update Site .zip file. Then press *OK*.
4. You'll see the @ide@ components in the list below. Check them off and click *Next*.
5. Accept the terms of the agreements and click *Next*, and Developer Studio is installed. Like other Eclipse plugins, you must restart Eclipse to use them.

Awesome! You've installed Liferay @ide@ in your existing Eclipse environment.



Install

Available Software

Check the items that you wish to install.

Work with: /Downloads/liferay-ide-updatesite-3.1.2-ga3-201709011126.zip!/

Name	Version
✓ Liferay IDE	
✓ Buildship: Eclipse Plug-ins for Gradle	2.1.1.v20170713-0942
✓ Liferay IDE	3.1.2.201709011126-ga3
✓ Liferay IDE AlloyUI	3.1.2.201709011126-ga3
✓ Liferay IDE Enterprise	3.1.2.201709011126-ga3
✓ Liferay IDE Maven Support (includes Eclipse m2e plugins)	3.1.2.201709011126-ga3

5 items selected

Figure 52.3: Make sure to check all the @ide@ components you wish to install.

Generating a Workspace Token Manually

If you run into any issues with generating your token automatically, you can follow the steps below to manually create one.

1. Navigate to www.liferay.com and log in to your account.
2. Click the Options button (☰) and select *Account Home*.
3. Select *Account Settings* from the left menu.
4. Click *Authorization Tokens* from the right menu under the Miscellaneous heading.
5. Select *Add Token*, give it a device name, and click *Generate*. The device name can be set to any string; it's for bookkeeping purposes only.
6. Create a file named `~/.liferay/token` and copy the generated token into that file.

   Make sure there are no new lines or white space in the file. It should only be one line.

You've successfully generated your token manually and it's now available for your installer to access. If you haven't run the installer, you can do so now. If you've already run the installer, you can set the DXP bundle to download in the `gradle.properties` file of your workspace. See the Adding a Liferay Bundle to a Workspace tutorial for details.

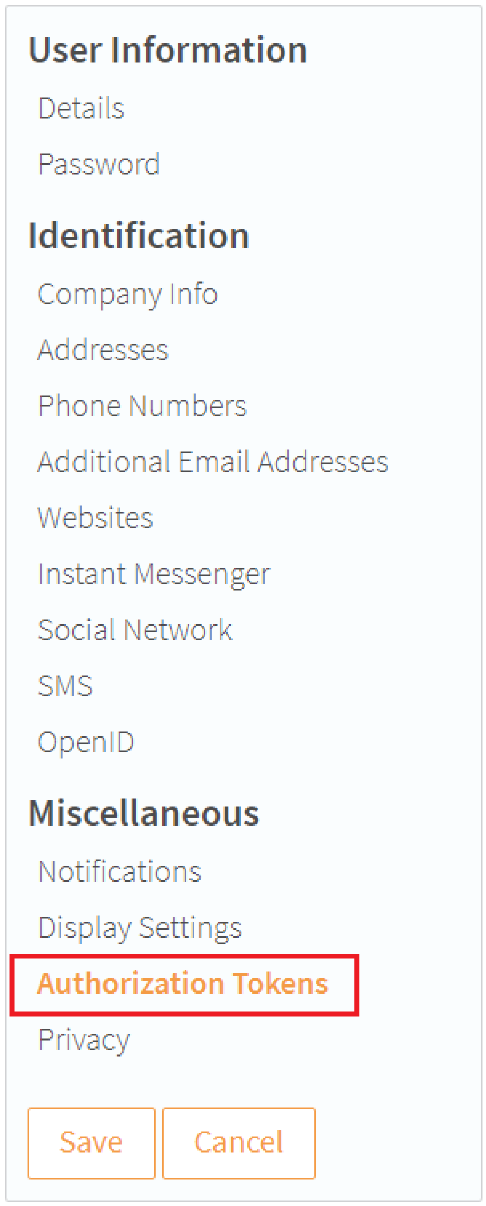


Figure 52.4: You can manually create your workspace token in the Authorization Tokens menu.

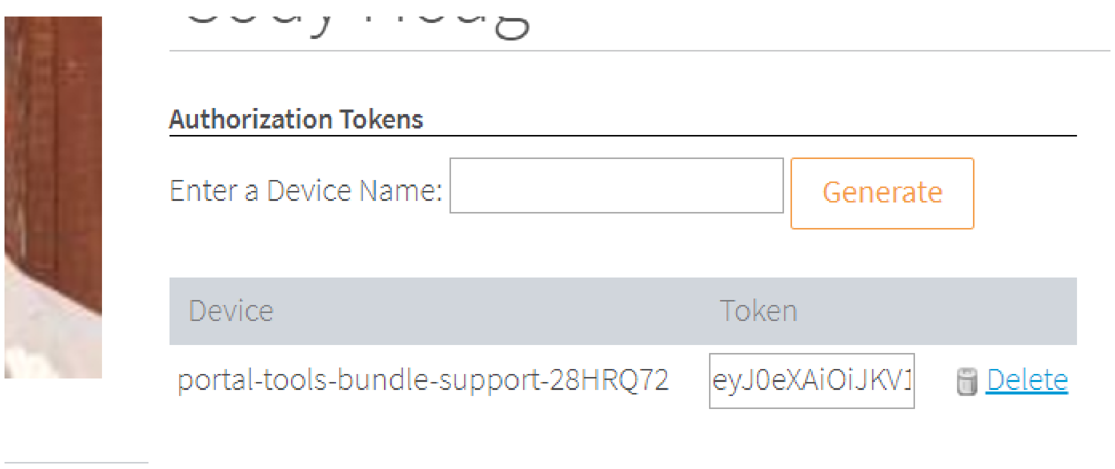

Authorization Tokens

Enter a Device Name:

Generate

Device	Token
portal-tools-bundle-support-28HRQ72	eyJ0eXAiOiJKV1

Delete

Figure 52.5: The generated token is available to copy.

52.2 Creating a Liferay Workspace with Liferay @ide@

In this tutorial, you'll learn how to generate a Liferay Workspace using Liferay @ide@, which runs on the Blade CLI behind the scenes. Liferay @ide@ gives you a graphical interface instead of the command prompt, which can streamline your workflow. To learn more about Liferay Workspaces, visit its dedicated tutorial section.

!PVideo Thumbnail

Before creating your Liferay Workspace, you should understand the available Liferay DXP perspectives specifically designed for Liferay DXP development. You'll notice in the Perspectives view the *Liferay Workspace* and *Liferay* perspectives. If you plan on using a Liferay Workspace for your Liferay DXP development, you should select the *Liferay Workspace* perspective. This offers Gradle related development tools that are helpful when using a Liferay workspace. The *Liferay* perspective is geared towards developers who are using Ant-based development tools such as the Plugins SDK.

To create a Liferay Workspace in @ide@, select *File* → *New* → *Liferay Workspace Project*.

Note: Creating or importing a Liferay Workspace in IDE leverages Gradle scripts provided by the Buildship plugin. When using @ide@ 3.1.x, you should be using Buildship 2.1.x. If you leverage higher versions of Buildship (e.g., 2.2.x), @ide@ cannot successfully create or import a workspace.

A New Liferay Workspace dialog appears, presenting several configuration options. Follow the instructions below to create your workspace.

1. Give your workspace a name.

2. Choose the location where you'd like your workspace to reside. Checking the *Use default location* checkbox places your Liferay Workspace in the Eclipse workspace you're working in.

3. Check the *Download Liferay bundle* checkbox if you'd like to auto-generate a Liferay instance in your workspace. You'll be prompted to name the server, if selected. This Liferay bundle is generated the same way as described in the previous section.

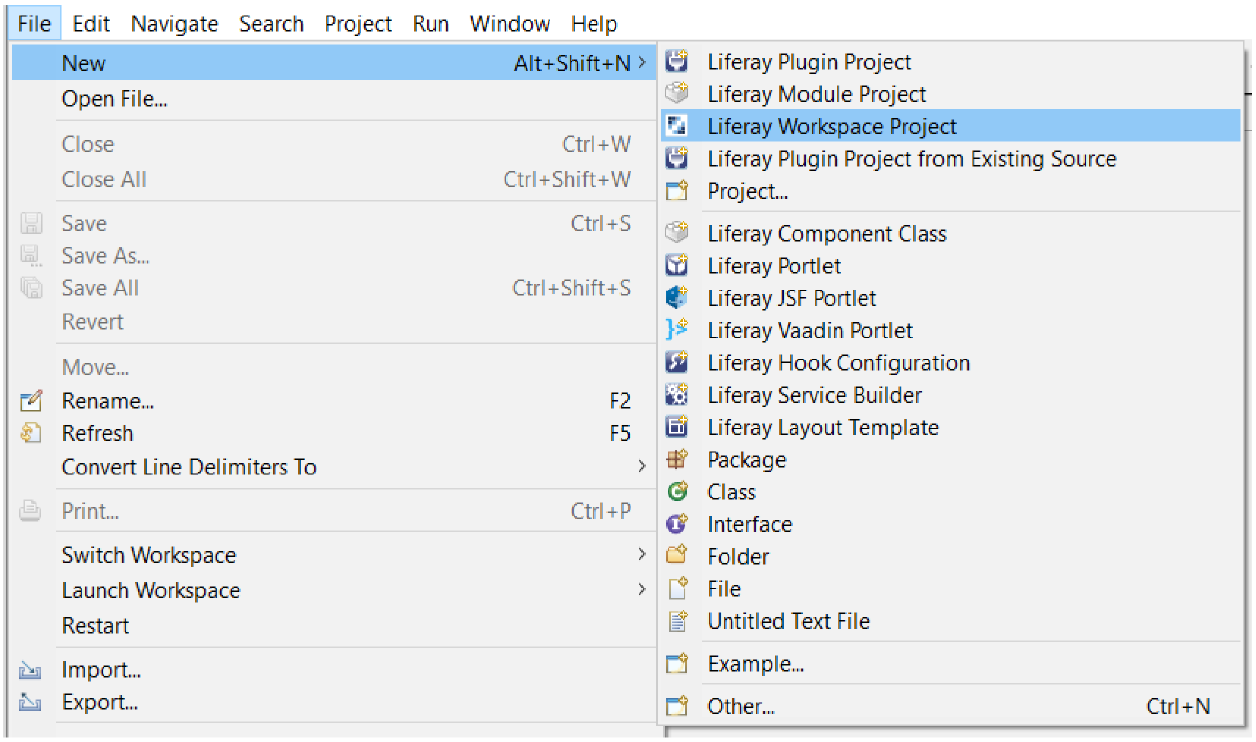

Figure 52.6: By selecting *Liferay Workspace*, you begin the process of creating a new workspace for your Liferay projects.

```
**Note:** If you'd like to configure a pre-existing Liferay bundle to your
workspace, you can create a directory for the bundle in your workspace and
configure it in the workspace's `gradle.properties` file by setting the
`liferay.workspace.home.dir` property.
```

---

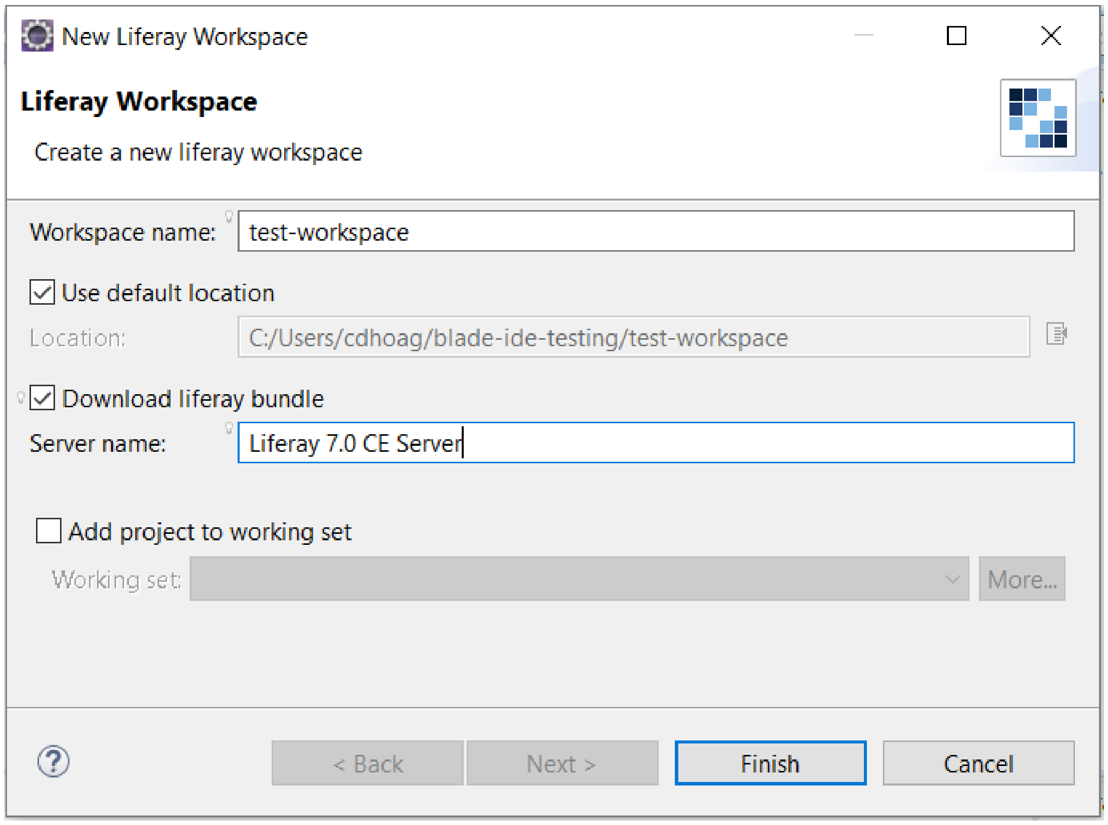
4. Check the *Add project to working set* checkbox if you'd like the workspace to be a part of a larger working set you've already created in @ide@. For more information on working sets, visit Eclipse Help.

5. Click *Finish* to create your Liferay Workspace.

A dialog appears prompting you to open the Liferay Workspace perspective. Click *Yes*, and your perspective will switch to Liferay Workspace.

Note: You can also create a Liferay Workspace during the initial start-up of a Liferay Developer Studio instance.

Awesome! You've successfully created a Liferay Workspace in Liferay @ide@! If you're using Liferay Developer Studio, you can also create a workspace during initial start-up.



New Liferay Workspace

Liferay Workspace

Create a new liferay workspace

Workspace name: test-workspace

☑ Use default location

Location: C:/Users/cdhoag/blade-ide-testing/test-workspace

☑ Download liferay bundle

Server name: Liferay 7.0 CE Server

☐ Add project to working set

Working set:

Figure 52.7: Liferay @ide@ provides an easy-to-follow menu to create your Liferay Workspace.

Liferay Workspace Settings in @ide@

The Liferay Workspace perspective is intended for Gradle development for 7.0 modules. Since Liferay Workspaces are used for Gradle based development and the Liferay Plugins perspective is intended for the Plugins SDK and Ant based development, the two perspectives are independent of each other.

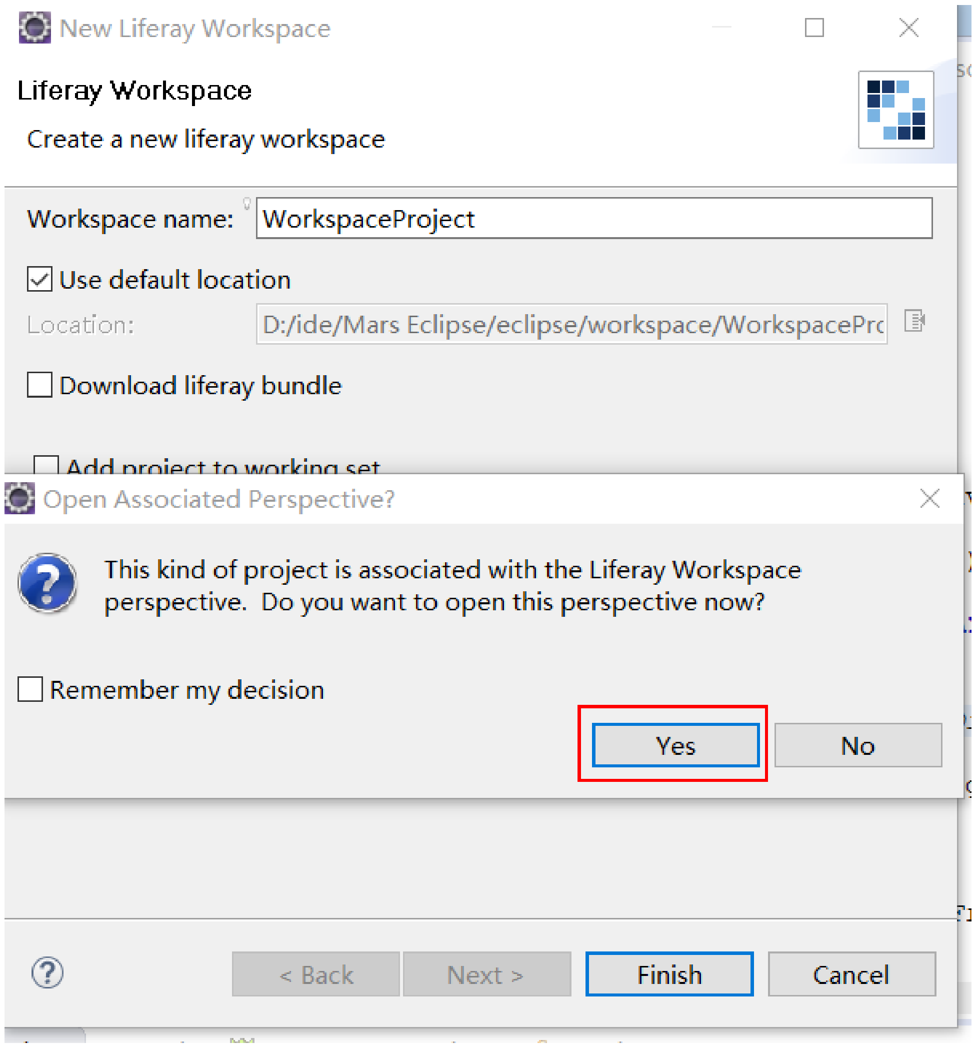
You'll find your new workspace in the Project Explorer and your Liferay server (if you created it) in the Servers menu. It's important to note that an Eclipse workspace can only have one Liferay Workspace project.

You can configure your workspace's module presentation by switching between the default *Hierarchical* or *Flat* views. To do this, navigate to the Project Explorer's *View Menu* (▽), select *Projects Presentation* and then select the presentation mode you'd like to display. The Hierarchical view displays subfolders and subprojects under the workspace project, whereas the Flat view displays the workspace's modules separately from the workspace.

If you've already created a Liferay Workspace and you'd like to import it into your existing @ide@, you can do so by navigating to *File* → *Import* → *Liferay* → *Liferay Workspace Project*. Then click *Next* and browse for your workspace project. Once you've selected you workspace, click *Finish*.

Congratulations! You've learned how to create and configure a Liferay Workspace using Liferay @ide@. Now that your workspace is created, you can begin creating Liferay plugins.

!VVideo Tutorial



New Liferay Workspace

Liferay Workspace

Create a new liferay workspace

Workspace name: WorkspaceProject

[✓] Use default location

Location: D:/ide/Mars Eclipse/eclipse/workspace/WorkspacePrc

[ ] Download liferay bundle

[ ] Add project to working set

Open Associated Perspective?

This kind of project is associated with the Liferay Workspace perspective. Do you want to open this perspective now?

[ ] Remember my decision

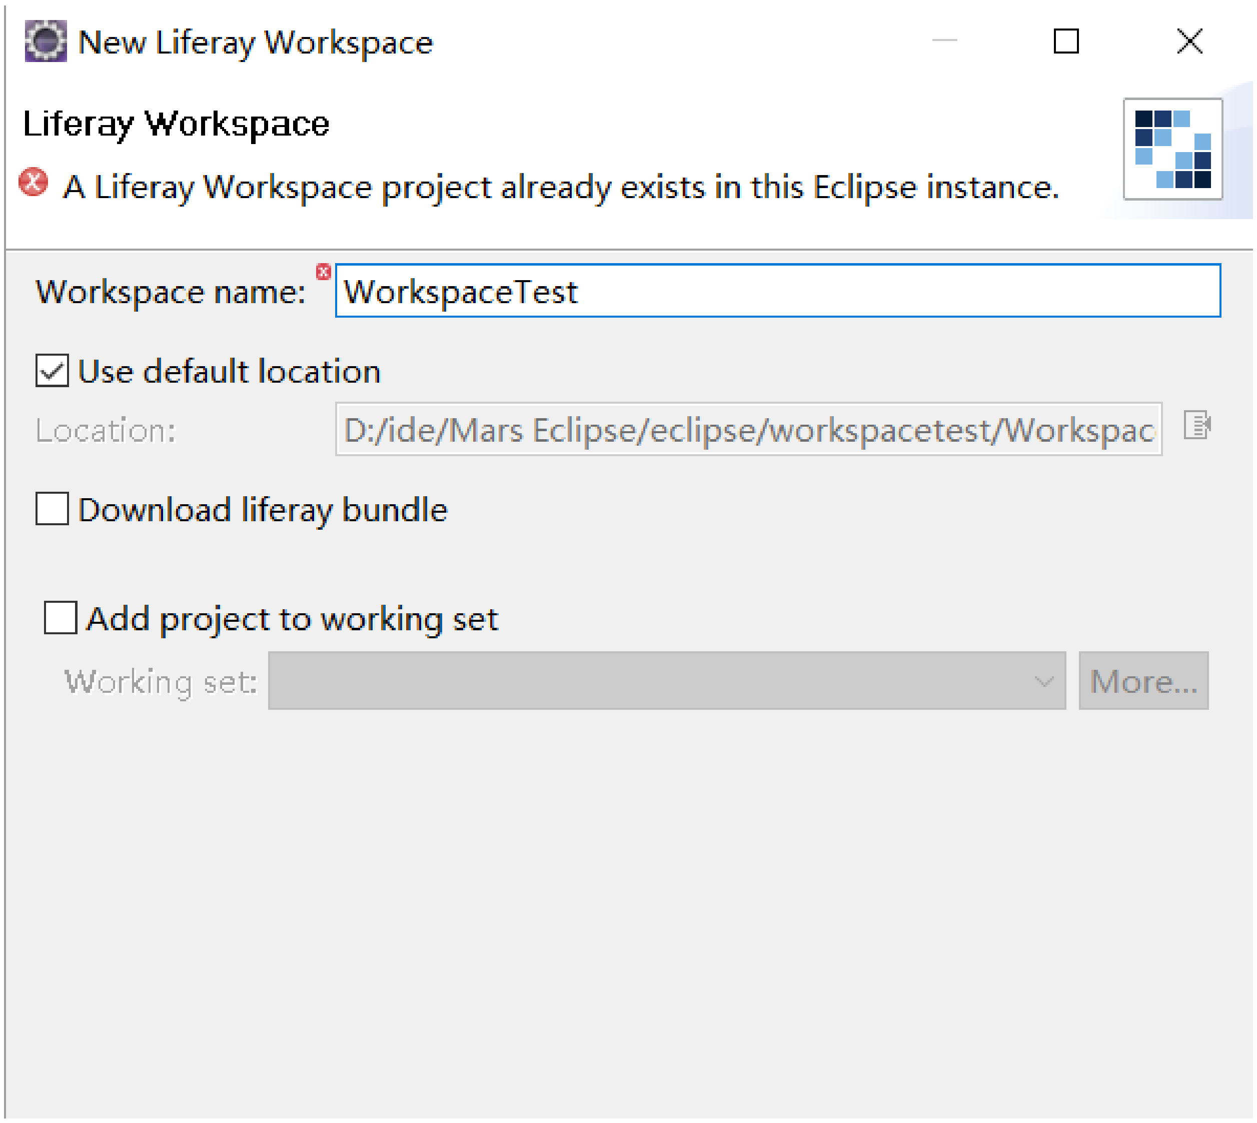
Figure 52.8: The Liferay Workspace perspective is preferred for 7.0 and OSGi module development.

52.3 Setting Proxy Requirements for Liferay @ide@

If you have proxy server requirements and want to configure your http(s) proxy
to work with Liferay @ide@, follow the instructions below.

1. Navigate to Eclipse's *Window* → *Preferences* → *General* → *Network Connections* menu.
2. Set the *Active Provider* drop-down selector to *Manual*.
3. Under *Proxy entries*, configure both proxy HTTP and HTTPS by clicking the field and selecting the *Edit* button.
4. For each schema (HTTP and HTTPS), enter your proxy server's host, port, and authentication settings (if necessary).

   Note: Do not leave whitespace at the end of your proxy host or port settings.
5. Once you've configured your proxy entry, click *OK* → *OK*.



New Liferay Workspace

Liferay Workspace

A Liferay Workspace project already exists in this Eclipse instance.

Workspace name: WorkspaceTest

[✓] Use default location

Location: D:/ide/Mars Eclipse/eclipse/workspacetest/Workspac

[ ] Download liferay bundle

[ ] Add project to working set

Working set:

Figure 52.9: An @ide@ workspace only supports one Liferay Workspace project. If you create another, you'll be given an error message.

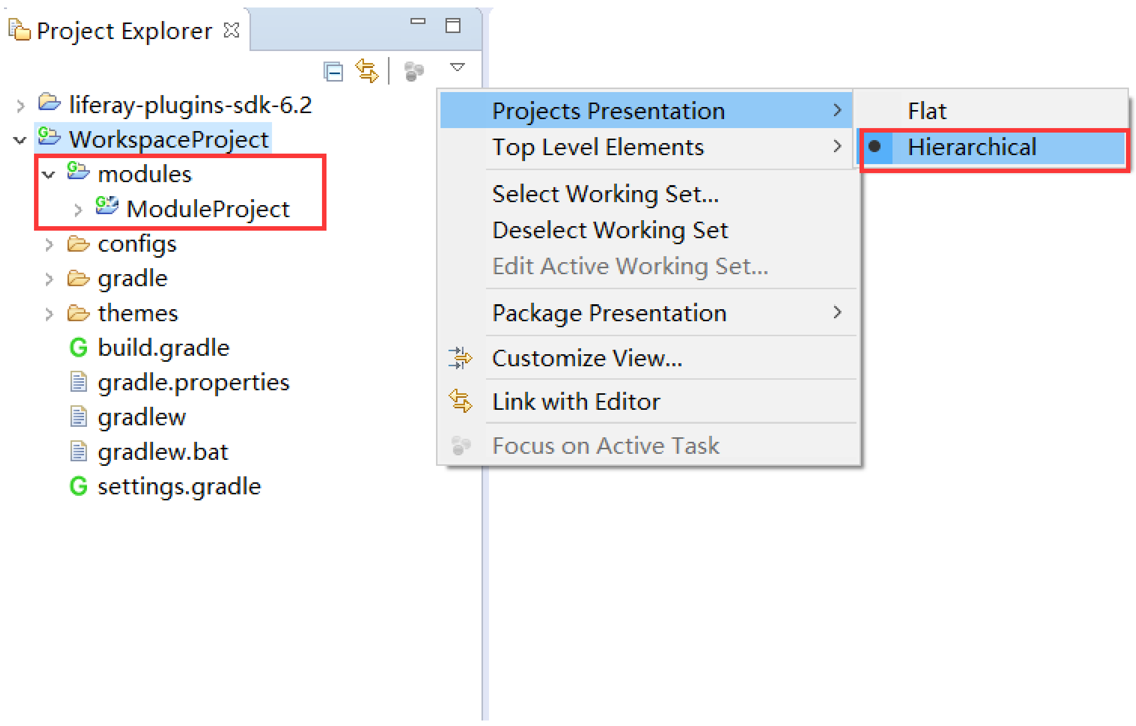


Figure 52.10: The Hierarchical project presentation mode is set, by default.

If you're working with a Liferay Workspace in @ide@, you'll need to configure your proxy settings for that environment too. See the Setting Proxy Requirements for Liferay Workspace for more details.

Awesome! You've successfully configured Liferay @ide@'s proxy settings!

Additional Proxy Settings

Some Eclipse plugins do not properly check the `core.net` proxy infrastructure when setting proxy settings via *Window* → *Preferences* → *General* → *Network Connections*. Therefore, you may need to configure additional proxy settings.

To do so, open the `eclipse.ini` file associated with your Eclipse installation and add the following entries:

```
-vmargs
-Dhttp.proxyHost=www.somehost.com
-Dhttp.proxyPort=1080
-Dhttp.proxyUser=userId
-Dhttp.proxyPassword=somePassword
-Dhttps.proxyHost=www.somehost.com
-Dhttps.proxyPort=1080
-Dhttps.proxyUser=userId
-Dhttps.proxyPassword=somePassword
```

After saving the file, restart Eclipse. Now your additional proxy settings are applied!

52.4 Updating Liferay @ide@

If you're already using Liferay @ide@ but need to update your environment, follow the steps below:

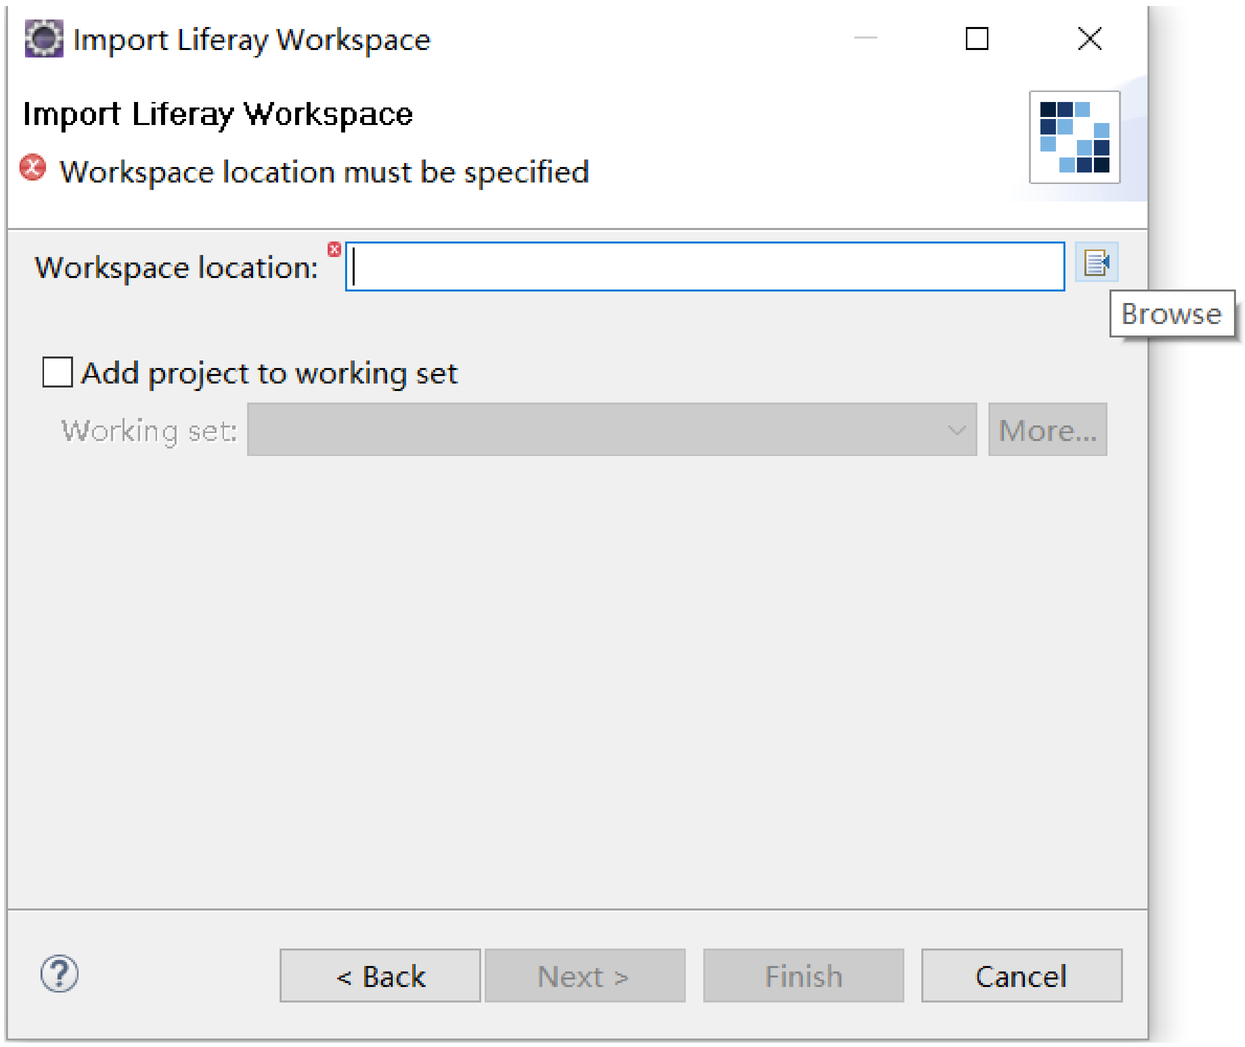

Figure 52.11: You can import an existing Liferay Workspace into your current @ide@ session.

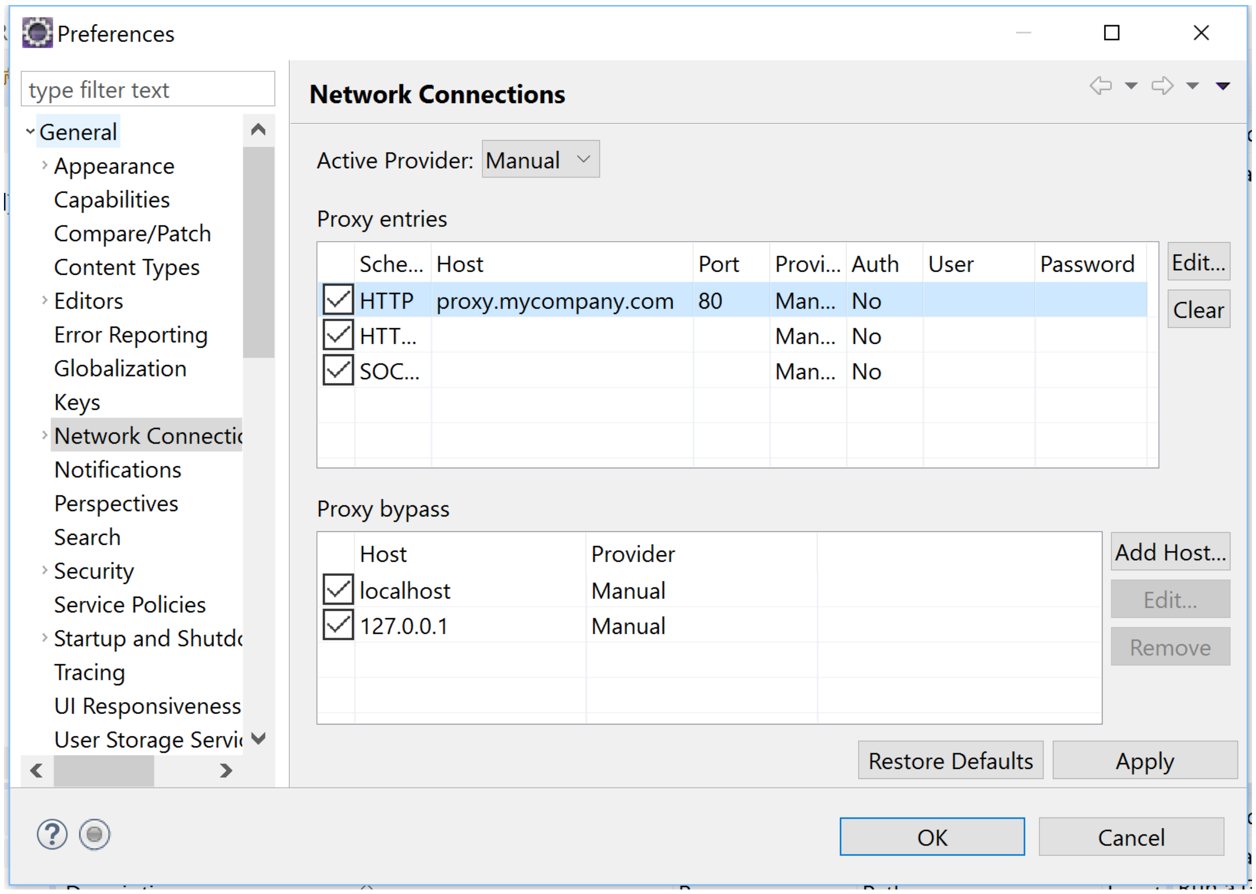
1. In Liferay @ide@, go to *Help* → *Install New Software...*.
2. In the *Work with* field, copy in the URL http://releases.liferay.com/tools/ide/latest/stable/.
3. You'll see the @ide@ components in the list below. Check them off and click *Next*.
4. Accept the terms of the agreements. Click *Next*, and @ide@ is updated. You must restart @ide@ for the updates to take effect.

You're now on the latest version of Liferay @ide@!

52.5 Creating Modules with Liferay @ide@

@ide@ provides a Module Project Wizard for users to create a variety of different module projects. You can create a new Liferay module project by navigating to *File* → *New* → *Liferay Module Project*.



Network Connections

Active Provider: Manual

Proxy entries

	Sche...	Host	Port	Provi...	Auth	User	Password
✓	HTTP	proxy.mycompany.com	80	Man...	No		
✓	HTT...			Man...	No		
✓	SOC...			Man...	No		

Proxy bypass

	Host	Provider
✓	localhost	Manual
✓	127.0.0.1	Manual

Figure 52.12: You can configure your proxy settings in @ide@'s Network Connections menu.

You're given options for project name, location, build type, and template type. You can build your project using Gradle or Maven. If you're unsure for which template type to choose, see the Project Templates reference section. Click *Next* and you're given additional configuration options for a component class.

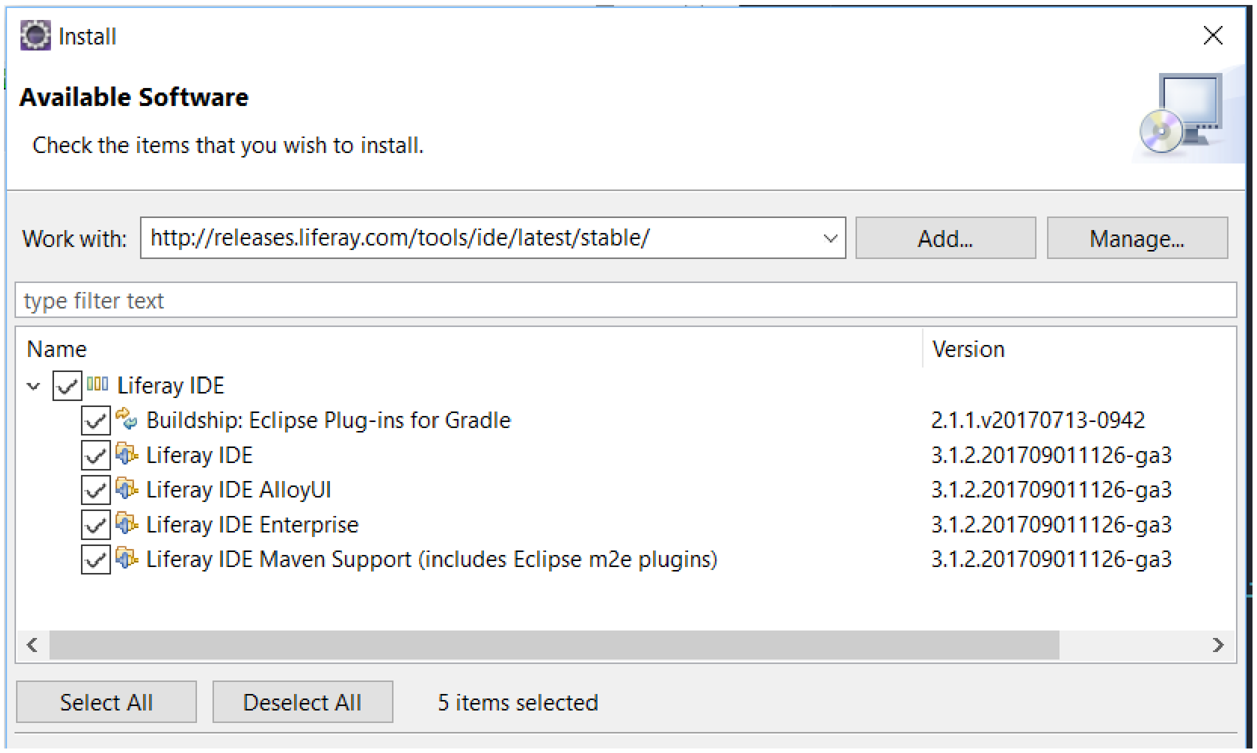
You can specify your component class's name, package name, and its properties. The properties you assign are the ones found in the `@Component` annotation's `property = {...}` assignment.

Once you've configured your module project's component class, click *Finish* to create your project.

Creating Component Classes

You can also create a new component class for a pre-existing module project. Navigate to *File* → *New* → *Liferay Component Class*. This is a similar wizard to the previous component class wizard, except you can select a component class template. There are many templates in the `Component Class Template` list:

- *Auth Failure*: processes a verify login failure
- *Auth Max Failure*: processes maximum number of login failures
- *Authenticator*: authenticates processing
- *Friendly URL Mapper*: processes Friendly URLs
- *GOGO Command*: creates a custom Gogo command
- *Indexer Post Processor*: creates a new Indexer Post Processor
- *Login Pre Action*: creates a login pre action



Install

Available Software

Check the items that you wish to install.

Work with: http://releases.liferay.com/tools/ide/latest/stable/

Name	Version
✓ Liferay IDE	
✓ Buildship: Eclipse Plug-ins for Gradle	2.1.1.v20170713-0942
✓ Liferay IDE	3.1.2.201709011126-ga3
✓ Liferay IDE AlloyUI	3.1.2.201709011126-ga3
✓ Liferay IDE Enterprise	3.1.2.201709011126-ga3
✓ Liferay IDE Maven Support (includes Eclipse m2e plugins)	3.1.2.201709011126-ga3

5 items selected

Figure 52.13: Make sure to check all the @ide@ components you wish to install.

- *Model Listener*: sets a model listener
- *Poller Processor*: creates a new poller processor
- *Portlet*: creates a new portlet class file
- *Portlet Action Command*: creates a new portlet action command
- *Portlet Filter*: creates a new portlet filter
- *Rest*: calls and wraps inner service in the way of Rest
- *Service Wrapper*: creates a new service wrapper
- *Struts in Action*: creates a new struts action
- *Struts Portlet Action*: creates a new struts portlet action

Possible Dependency Issues

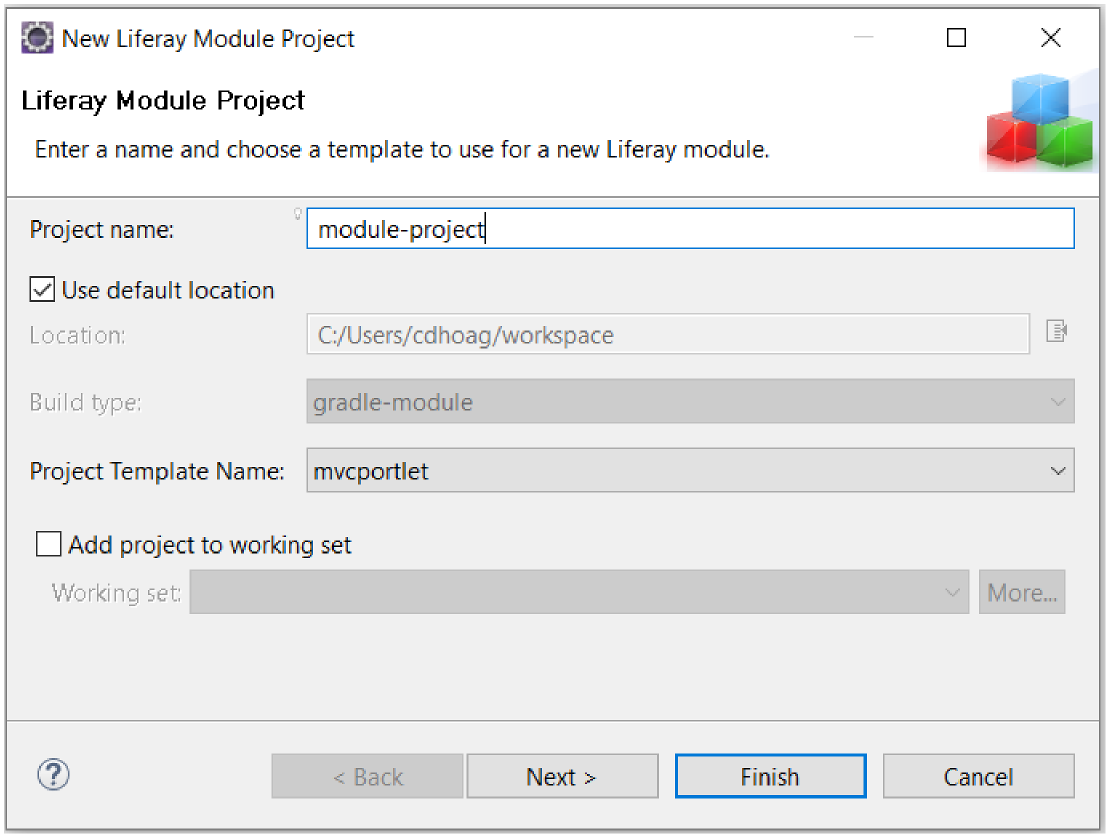
When selecting the `Authenticator`, `Portlet Action Command`, `Rest`, or `Service Wrapper` templates, you may run into some dependency issues that could cause errors in your project. There is a set of steps outlined below that you should follow, with sub-steps for each of the four templates that could cause problems.

1. Open the module project's `build.gradle` file.

2. Check whether the appropriate dependencies exist. These are outlined below.

3. Right-click your project and select *Gradle* → *Refresh Gradle Project*.

4. If you're using the *Portlet Action Command* template, you'll also need to change the component class declaration from implementing the `FreeMarkerPortlet` class to extending it. For instance, your `*Portlet` component class should have the following declared:



New Liferay Module Project

Liferay Module Project

Enter a name and choose a template to use for a new Liferay module.

Project name: module-project

☑ Use default location

Location: C:/Users/cdhoag/workspace

Build type: gradle-module

Project Template Name: mvcportlet

☐ Add project to working set

Working set:

Figure 52.14: When selecting *New → Liferay Module Project*, a Module Project Wizard appears.

YourPortletClass extends FreeMarkerPortlet

The dependencies to check for when using each template are outlined below:
Authenticator

- `compile com.liferay.portal:com.liferay.portal.kernel:VERSION`
- `compile org.osgi:org.osgi.service.component.annotations:VERSION`

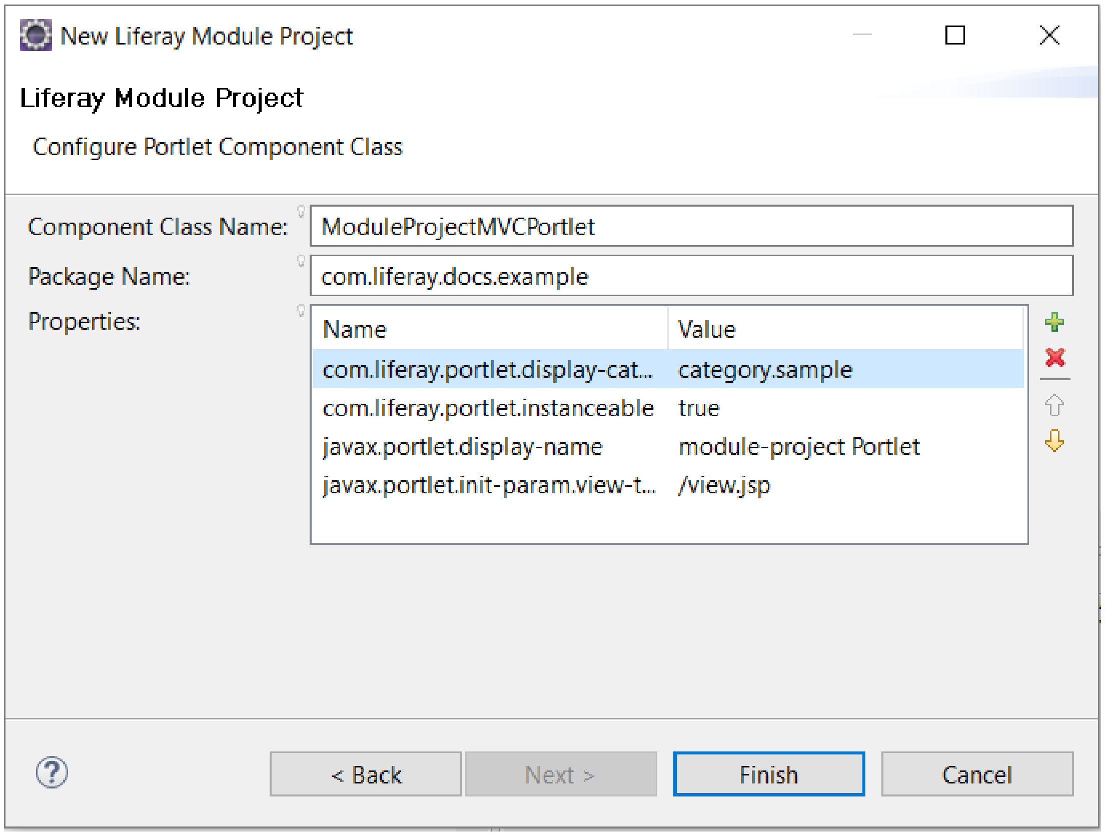
Portlet Action Command

- `compile javax.portlet:portlet-api:VERSION`
- `compile javax.servlet:javax.servlet-api:VERSION`
- `compile org.osgi:org.osgi.service.component.annotations:VERSION`
- `compile com.liferay.portal:com.liferay.portal.kernel:VERSION`
- `compile com.liferay.portal:com.liferay.util.bridges:VERSION`
- `compile com.liferay.portal:com.liferay.util.taglib:VERSION`

Rest

- `compile javax.ws.rs:javax.ws.rs-api:VERSION`

Service Wrapper



New Liferay Module Project

Liferay Module Project

Configure Portlet Component Class

Component Class Name: ModuleProjectMVCPortlet

Package Name: com.liferay.docs.example

Properties:

Name	Value
com.liferay.portlet.display-cat...	category.sample
com.liferay.portlet.instanceable	true
javax.portlet.display-name	module-project Portlet
javax.portlet.init-param.view-t...	/view.jsp

Figure 52.15: Specify your component class's details in the Portlet Component Class Wizard.

- The service wrapper class being used. For example, if you're using the `BookmarksEntryLocalServiceWrapper`, the following dependency would be required:

```
compile com.liferay:com.liferay.bookmarks.api:VERSION
```

Make sure the replace the `VERSION` text with the appropriate version for each specified dependency.

Once you've created your module project, you can configure your project's presentation in the @ide@'s Project Explorer. To change the project's presentation, select the default *Hierarchical* or *Flat* views. To do this, navigate to the Project Explorer's *View Menu* (▽), select *Projects Presentation* and then select the presentation mode you'd like to display. The Hierarchical view displays subfolders and subprojects under the project, whereas the Flat view displays the modules separately from their project.

@ide@ also provides a method to import existing module projects. You can import a module project by navigating to *File* → *Import* → *Liferay* → *Liferay Module Project(s)*. Then point to the project location and click *Finish*.

You now have the knowledge to create a Liferay module project from Liferay @ide@. Now go out there and get stuff done!

52.6 Creating Themes with Liferay @ide@

Liferay @ide@ lets you create and configure Liferay theme projects. You can create a standalone theme or in a Liferay Workspace. You can even create a Gradle or Maven based theme! Read on to learn more about creating themes in @ide@.

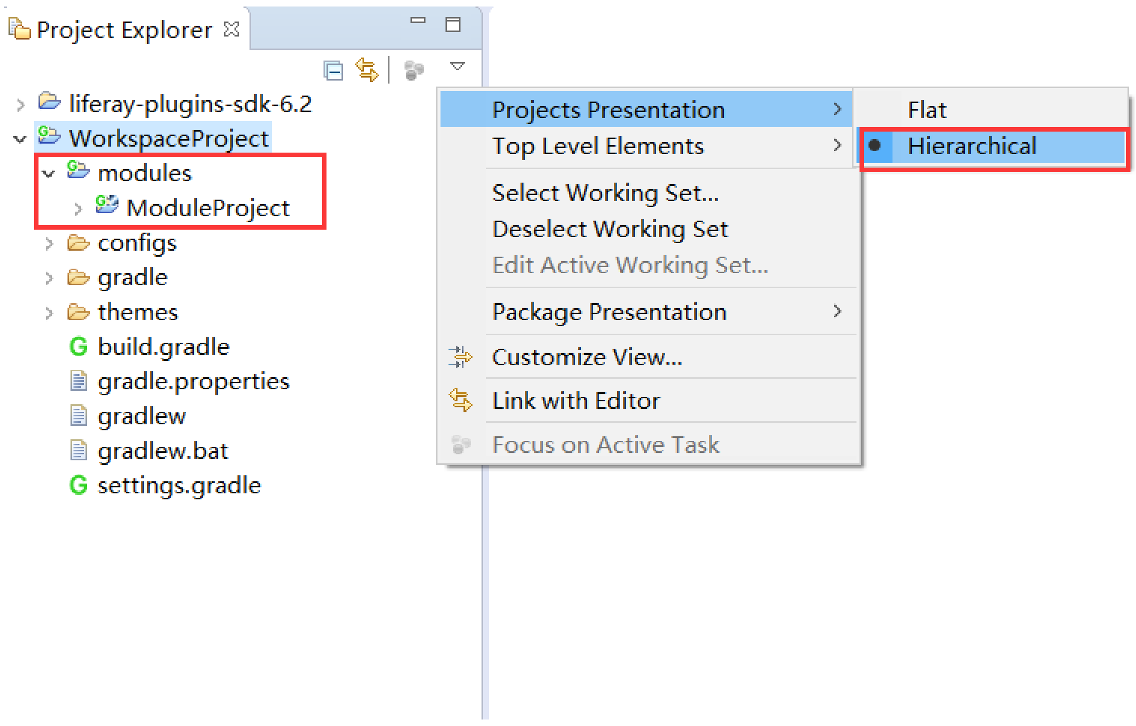


Figure 52.16: The Hierarchical project presentation mode is set, by default.

1. In @ide@, navigate to *File* → *New* → *Liferay Module Project*.

2. In the New Liferay Module Project wizard, give your project a name and select the *theme* project template. Also choose your theme's build type by selecting either *gradle-module* or *maven-module*.

3. Select *Finish*.

That's it! You've created a theme project in @ide@!

If you've configured a Liferay Workspace in your @ide@ instance, your theme is available in the workspace's `wars` folder by default. If you don't have a workspace configured in @ide@, it's available in the root of @ide@'s Project Explorer.

Note that themes created in @ide@ follow a WAR-style layout. This is the default layout of themes in 7.0. Although the wizard can be misleading by calling the theme a new module project, it is a WAR.

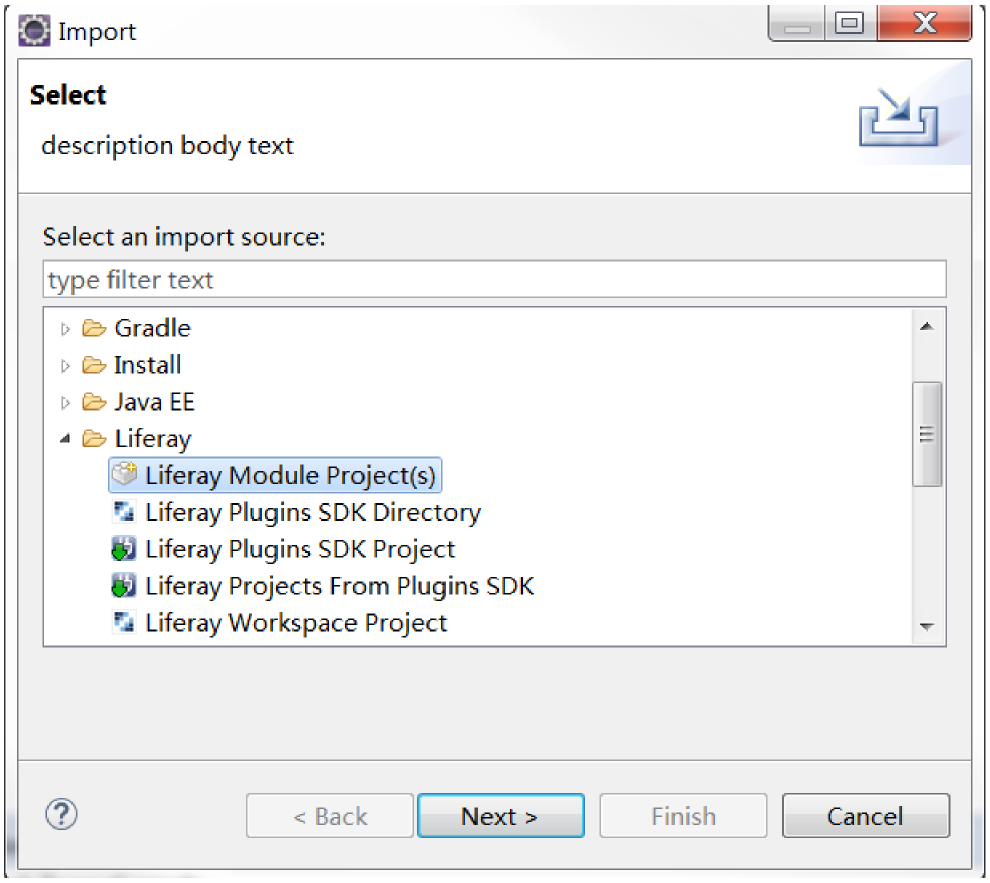
To modify a theme created in @ide@, mirror the folder structure of the files you wish to change and copy them into your theme's `webapp` folder.

Under the hood, @ide@ is using the theme project template. If you're interested in creating Liferay themes using the Liferay Theme Generator, see its dedicated tutorial. For more general information on Liferay themes, visit their dedicated tutorial section Themes and Layout Templates.

52.7 Deploying Modules with Liferay @ide@

Deploying modules in Liferay @ide@ is a cinch. Before deploying your module, make sure you have a Liferay server configured in @ide@. To see how to do this, see the Installing a Server in Liferay @ide@

There are two ways to deploy a module to your Liferay server. You should start your Liferay server before attempting to deploy to it.



Import
Select
description body text
Select an import source:
type filter text
Gradle
Install
Java EE
Liferay
Liferay Module Project(s)
Liferay Plugins SDK Directory
Liferay Plugins SDK Project
Liferay Projects From Plugins SDK
Liferay Workspace Project
< Back
Next >
Finish
Cancel

Figure 52.17: Select the *Liferay Module Project(s)* to import a module project.

1. Select the module from the Package Explorer window and drag it to your Liferay server in the Servers window.

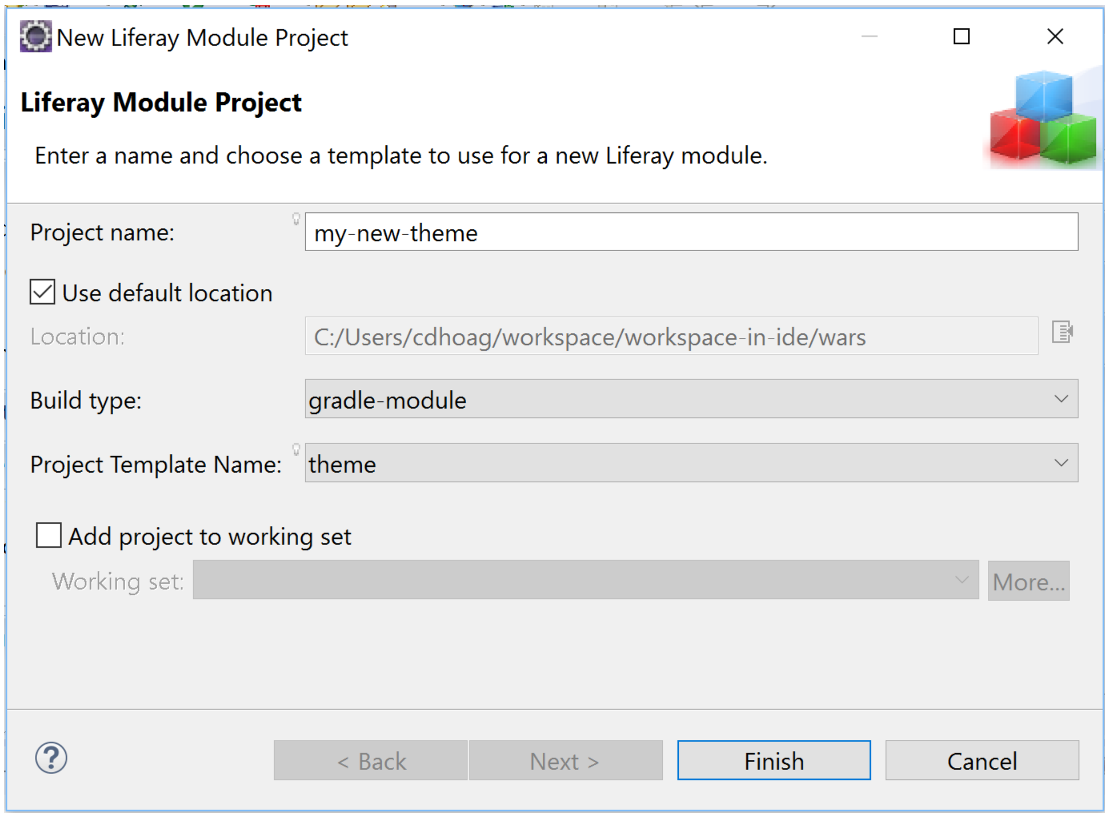
2. Right-click the server from the Servers window and select *Add and Remove....* Add the module(s) you'd like to deploy from the Available window to the Configured window. Then click *Finish*.

Note: For a legacy Maven application, you were able to deploy it by right-clicking it in the Package Explorer and selecting *Liferay* → *Maven* → *liferay:deploy*. This is no longer possible because Liferay's Maven archetypes no longer rely on the legacy `liferay-maven-plugin`. To deploy Maven projects in @ide@, make sure to follow the methods described above.

That's it! Once your module is deployed to the Liferay server, you can verify its installation in @ide@'s Console window.

52.8 Managing Module Projects with Liferay @ide@

Liferay @ide@ provides the ability to manage Liferay module projects from a GUI. Before you begin learning about managing your modules from Liferay @ide@, you should make sure a Liferay server is configured in your Eclipse workspace so you can deploy and run your projects. You can learn how to create a Liferay bundle and link it to your Liferay workspace in the Creating a Liferay Workspace with Liferay @ide@ tutorial.



New Liferay Module Project

Liferay Module Project

Enter a name and choose a template to use for a new Liferay module.

Project name: my-new-theme

[✓] Use default location

Location: C:/Users/cdhoag/workspace/workspace-in-ide/wars

Build type: gradle-module

Project Template Name: theme

[ ] Add project to working set

Working set:

Figure 52.18: Use the theme project template to create a Liferay theme in @ide@.

Once you've created modules, you can deploy them using Liferay @ide@. First, make sure your Liferay server is started by clicking the *Start Server* button (▶). Then navigate to your module project from the Project Explorer and drag-and-drop the project onto the configured Liferay bundle in the *Servers* menu. If at any time you'd like to stop your Liferay server, click the *Stop Server* button (■). Awesome! You've deployed a module to your running Liferay instance!

For the deployed module project, you can check if it has been deployed successfully by using Gogo Shell. Right-click the started portal in server view and select *Open Gogo Shell*.

A Gogo shell terminal appears, allowing you to enter Gogo commands to inspect your Liferay instance and the modules deployed to it. Enter the `lb` command to view a list of deployed modules. If the project status is active, then it deployed successfully.

Since the Liferay Workspace perspective in @ide@ is Gradle-based, you have some additional Gradle features you can take advantage of. The Gradle Tasks toolbar presents Gradle commands for your workspace that you can execute with a click of the mouse.

You can also access various Gradle build operations intended for Liferay module projects. Right-click your module project and select *Liferay* → *Gradle* and then the build command you want to execute.

To learn more about Gradle development in Liferay @ide@, see the Using Gradle in Liferay @ide@ tutorial.

Excellent! You've learned how to manage your Gradle-based Liferay Workspace using Liferay @ide@.

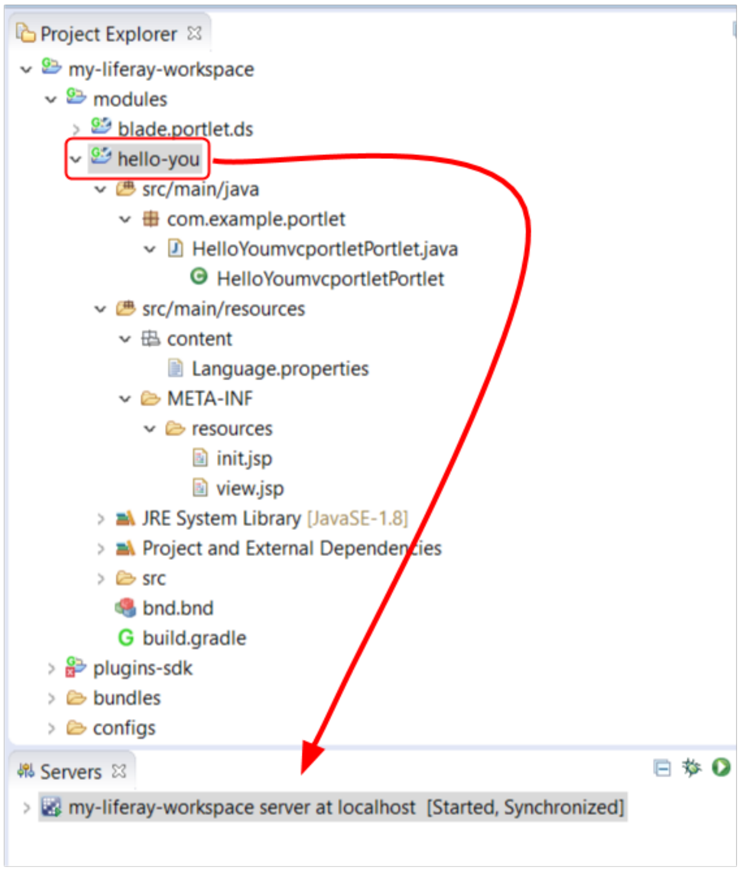


Figure 52.19: You can use the drag-and-drop method to deploy your module to Liferay DXP.

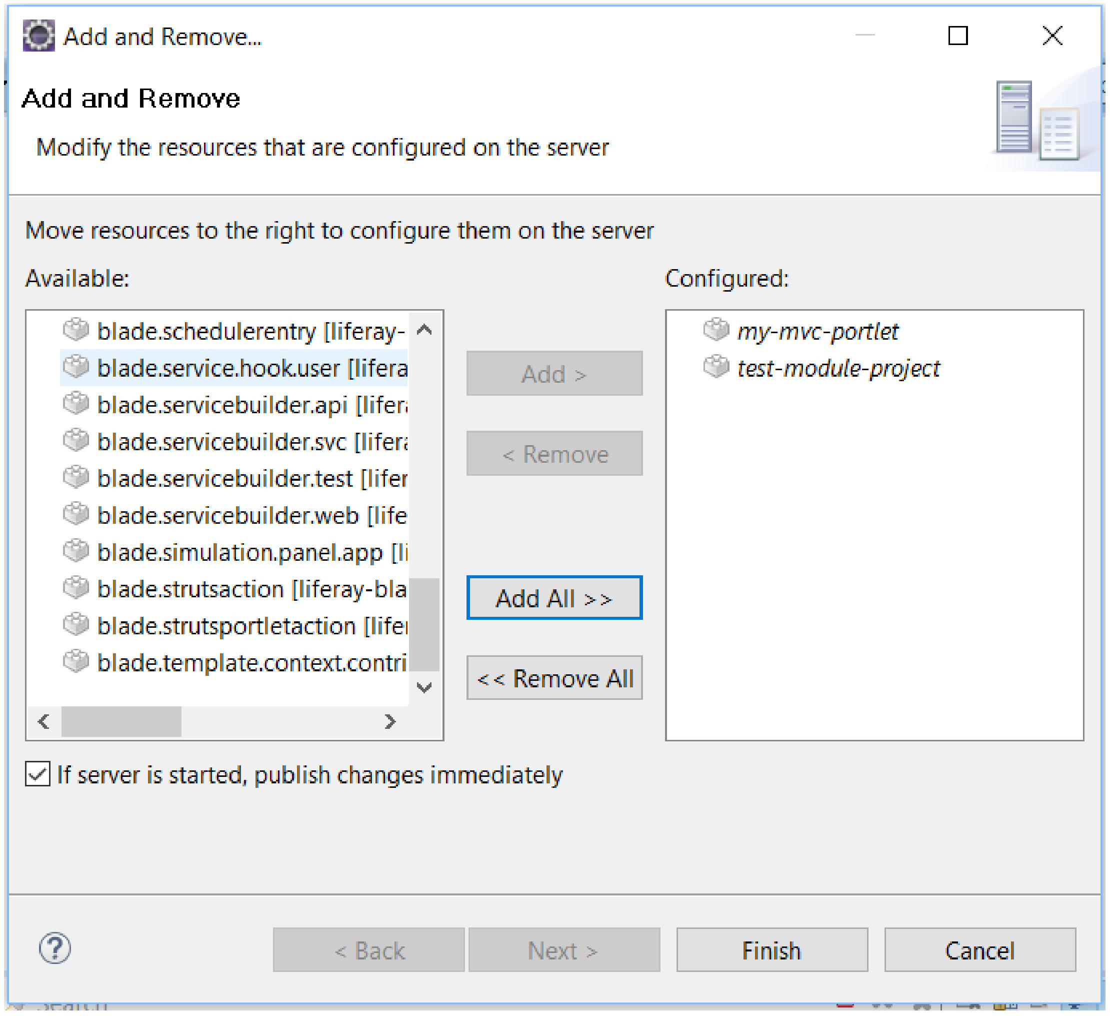
52.9 Installing a Server in Liferay @ide@

Installing a server in Liferay @ide@ is easy. In just a few steps you'll have your server up and running. Follow these steps to install your server:

1. In the Servers view, click the *No Servers are available* link. If you already have a server installed, you can install a new server by right-clicking in the Servers view and selecting *New* → *Server*. This brings up a wizard that walks you through the process of defining a new server.

2. Select the type of server you would like to create from the list of available options. For a standard server, open the *Liferay, Inc.* folder and select the *Liferay 7.x* option. You can change the server name to something more unique too; this is the name displayed in the Servers view. Then click *Next*. If you're creating a server for the first time, continue to the next step.

   Note: If you've already configured previous Liferay servers, you'll be provided the *Server runtime environment* field, which lets you choose previously configured runtime environments. If you want to re-add an existing server, select one from the dropdown menu. You can also add a new server by selecting *Add*, or you can edit existing servers by selecting *Configure runtime environments*. Once you've configured the



Add and Remove...

New Server

Define a New Server

Choose the type of server to create

Select the server type:

- Liferay, Inc.
  - Liferay 7.x
  - Liferay v6.2 Server (Tomcat 7)
  - Remote Liferay Server (Liferay 6.x)
- ObjectWeb
- Red Hat JBoss Middleware
- Resin

Liferay 7.x

Server's host name: localhost

Server name: Liferay 7.x at localhost

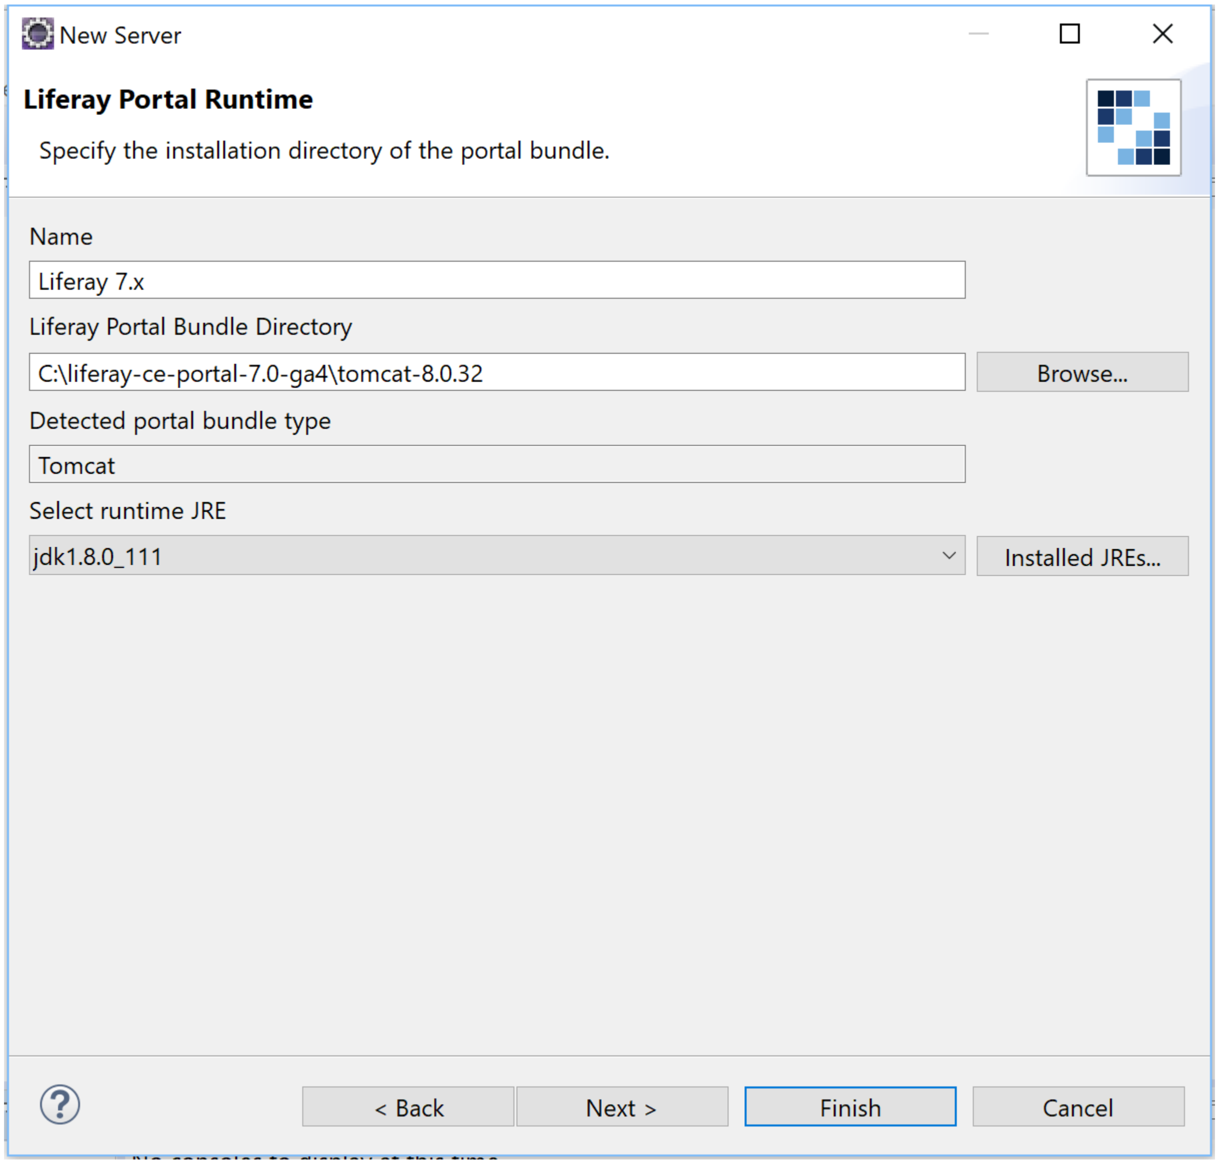
Server runtime environment: Liferay 7.x

Figure 52.25: Choose the type of server you want to create.

server runtime environment, select *Finish*. If you selected an existing server, your server installation is finished; you can skip steps 3-5.

3. Enter a name for your server. This is the name for the Liferay DXP runtime configuration used by @ide@. This is not the display name used in the Servers tab.

4. Browse to the installation folder of the Liferay DXP bundle. For example, `C:\liferay-ce-portal-7.0-ga4\tomcat-8.0.32`.



New Server

Liferay Portal Runtime

Specify the installation directory of the portal bundle.

Name: Liferay 7.x

Liferay Portal Bundle Directory: C:\liferay-ce-portal-7.0-ga4\tomcat-8.0.32

Detected portal bundle type: Tomcat

Select runtime JRE: jdk1.8.0_111

Figure 52.26: Specify the installation folder of the bundle.

5. Select a runtime JRE and click *Finish*. Your new server appears under the Servers view.

Your server is now available in Liferay @ide@!
For reference, here's how the Liferay DXP server buttons work with your Liferay DXP instance:

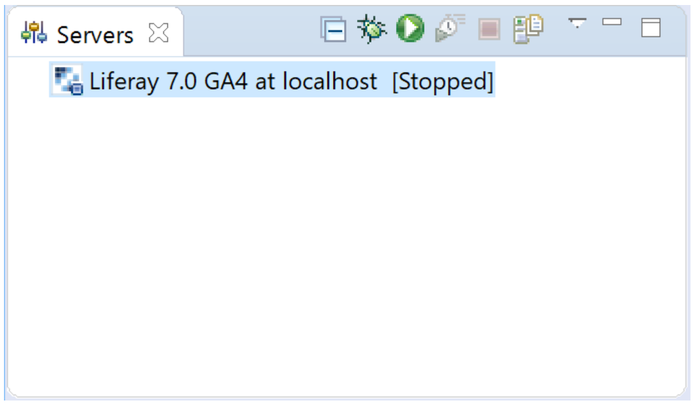


Figure 52.27: Your new server appears under the *Servers* view.

- *Start* (▶): Starts the server.
- *Stop* (■): Stops the the server.
- *Debug* (✱): Starts the server in debug mode. For more information on debugging in Eclipse, see the Eclipse Debugging article.

Now you're ready to use your server in Liferay @ide@!

52.10 Searching Liferay DXP Source in Liferay @ide@

In Liferay Liferay DXP, you can search through Liferay DXP's source code to aid in the development of your project. Liferay provides great resources to help with development (e.g., official documentation, docs.liferay.com, sample projects, etc.), but sometimes, searching through Liferay's codebase (i.e., platform and official apps) for patterns is just as useful. For example, if you're creating a custom app that extends a class provided in Liferay's `portal-kernel` JAR, you can inspect that class and research how it's used in other areas of Liferay DXP's codebase.

To do this, you must be developing in a Liferay Workspace. Liferay Workspace is able to provide this functionality by targeting a specific Liferay DXP version, which indexes the configured Liferay DXP source code to provide advanced search. See the Managing the Target Platform in Liferay Workspace tutorial for more information on how this works.

Workspace does not perform portal source indexing by default. You must enable this functionality by adding the following property to your workspace's `gradle.properties` file:

```
target.platform.index.sources=true
```

Note: Portal source indexing is disabled in Gradle workspace version 2.0.3+ (Target Platform plugin version 2.0.0+).

In this tutorial, you'll explore three use cases where advanced search would be useful.

- Search class hierarchy
- Search declarations
- Search references

These examples are just a small subset of what you can search in Liferay @ide@. See Eclipse's documentation on Java Search for a comprehensive guide.

Search Class Hierarchy

Inspecting classes that extend a similar superclass can help you find useful patterns and examples for how you can develop your own app. For example, suppose your app extends the MVCPortlet class. You an search classes that extend that same class in @ide@ by right-clicking the `MVCPortlet` declaration and selecting *Open Type Hierarchy*. This opens a window that lets you inspect all classes residing in the target platform that extend `MVCPortlet`.

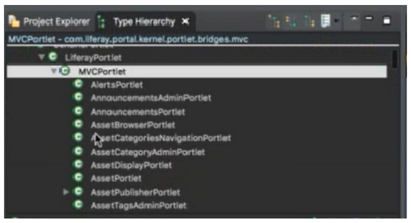

Figure 52.28: Browse the Type Hierarchy window and open the provided classes for examples on how to extend a class.

Great! Now you can search for all extensions and implementations of a class/interface to aid in your quest for developing the perfect app.

Search Method Declarations

Sometimes you want a search to be more granular, exploring the declarations of a specific method provided by a class/interface. Liferay @ide@'s advanced search has no limits; Liferay Workspace's target platform indexing provides method exploration too!

Suppose in the MVCPortlet class you're extending, you'd like to search for declarations of its `doView` method you're overriding. You can do this by right-clicking the `doView` method declaration in your custom app's class and selecting *Declarations → Workspace*.

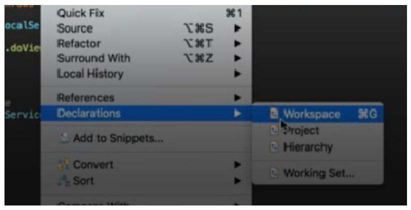

Figure 52.29: All declarations of the method are returned in the Search window.

The rendered Search window displays the other occurrences in the target platform where that method was overridden.

Search Annotation References

Annotations used in Liferay DXP's source code can sometimes be cryptic. With the ability to search where these types of annotations reside in Liferay's target platform, you can find how they could be used in your own app.

For example, you may find some official documentation on using the `@Reference` annotation in an OSGi module and implement it in your custom app. It could be useful to reference real world examples in Liferay

DXP's apps to check how it was used elsewhere. You could search for this by right-clicking the annotation in a class and selecting *References → Workspace*.

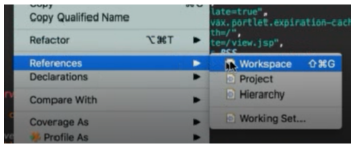

Figure 52.30: All matching annotations are displayed in the Search window.

The rendered Search window displays the other occurrences in the target platform where that annotation was used.

Excellent! You now have the tools to search the configured target platform specified in your Liferay Workspace!

52.11 Debugging Liferay DXP Source in Liferay @ide@

You can use Liferay Liferay DXP to debug Liferay DXP source code to help resolve errors. Debugging Liferay DXP code follows most of the same techniques associated with debugging in Eclipse. If you need some help with general debugging, you can visit Eclipse's documentation. Here's some helpful Eclipse links to visit:

- Debugger
- Local Debugging
- Remote Debugging

There are a couple Liferay-specific configurations to know before debugging Liferay DXP code:

- Configure your target platform.
- Configure a Liferay server and start it in debug mode.

Let's explore these Liferay-specific debugging configurations.

Configure Your Target Platform

To configure your target platform, you must be developing in a Liferay Workspace. Liferay Workspace is able to provide debugging capabilities by targeting a specific Liferay DXP version, which indexes the configured Liferay DXP source code. You must enable this functionality by adding the following property to your workspace's `gradle.properties` file:

```
target.platform.index.sources=true
```

Note: Portal source indexing is disabled in Gradle workspace version 2.0.3+ (Target Platform plugin version 2.0.0+).

Without specifying a target platform, Liferay DXP's source code cannot be accessed by @ide@. See the Managing the Target Platform for Liferay Workspace tutorial for more information on how this works.

Important: The target platform should match the Liferay server version you configure in the next section.

Once the target platform is configured in your workspace, Eclipse has access to all of Liferay DXP's source code. Next, you'll configure a Liferay server and learn how to start it in Debug mode.

Configure a Liferay Server and Start It in Debug Mode

Configuring your target platform gives Eclipse Liferay DXP's source code to reference. Now you must configure a Liferay server matching the target platform version so you can deploy the custom code you wish to debug.

1. Set up your Liferay DXP server to run in @ide@. See the Installing a Server in Liferay @ide@ for more details.

2. Start the server in debug mode. To do this, click the debug button in the Servers pane of Liferay @ide@.

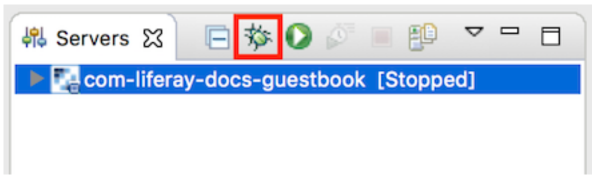

Figure 52.31: The red box in this screenshot highlights the debug button. Click this button to start the server in debug mode.

Awesome! You're now equipped to begin debugging in Liferay @ide@!

52.12 Enabling Code Assist Features in Your Project

Liferay @ide@'s integration of Tern provides many valuable front-end and back-end development tools for code inference and completion. This tutorial covers how to enable Tern features for your projects.

Before beginning this tutorial, make sure your @ide@ instance has the necessary development tooling and Tern integration installed. To to this, go to *Help* → *Installation Details* and search for *Liferay IDE AlloyUI* under *Installed Software*. If you have it installed, you can continue to the *Setting Up Tern Features* section; if you do not, you'll need to install it by following the instructions below.

Navigate to *Help* → *Install New Software...* and paste the following link into the *Work with* field:

```
http://releases.liferay.com/tools/ide/latest/stable/
```

Make sure the *Liferay IDE AlloyUI* option is checked and finish the installation process.

Now that the necessary features are installed, follow the steps below to learn how to enable Tern's code assist features in your project.

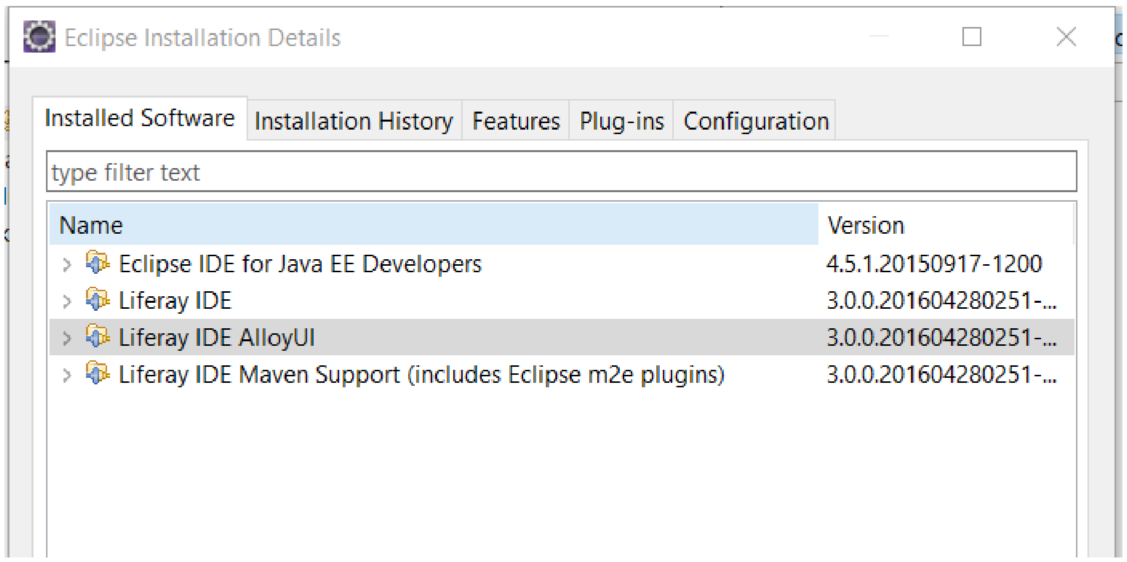
Setting Up Tern Features

Tern features are enabled on a project-by-project basis. By default, Tern is already enabled for Liferay portlet plugins. For all other project types, you'll need to follow the steps below:

1. Right-click on your project and select *Configure* → *Convert to Tern Project*.

   Your project is now configured to use Tern. Now that you have your project configured, you need to enable the modules you want to use for your project.

2. Right-click your project and select *Properties*.



Eclipse Installation Details

Name	Version
Eclipse IDE for Java EE Developers	4.5.1.20150917-1200
Liferay IDE	3.0.0.201604280251-...
Liferay IDE AlloyUI	3.0.0.201604280251-...
Liferay IDE Maven Support (includes Eclipse m2e plugins)	3.0.0.201604280251-...

Figure 52.32: The *Liferay IDE AlloyUI* option is actually a sub-option listed within the *Liferay IDE* option.

3. Select *Tern → Modules*.

   Here you'll find a list of all the available Tern modules you currently have installed. To use AlloyUI features, you'll need the *AlloyUI*, *Browser*, *JSCS*, *Liferay*, and *YUI Library* modules enabled. The figure below shows the Tern Modules menu.

4. Check any additional modules you wish to use in your project and click *OK*.

Your project is now set up to use @ide@'s Tern features.

52.13 Using Gradle in Liferay @ide@

Gradle is a popular open source build automation system. You can take full advantage of Gradle in Liferay @ide@ by utilizing Buildship, which is a collection of Eclipse plugin-ins that provide support for building software using Gradle with Liferay @ide@. Buildship is bundled with Liferay @ide@ versions 3.0 and higher.

The first thing you'll learn about in this tutorial is creating Gradle projects in @ide@.

Creating and Importing Gradle Projects

You can create a Gradle project by using the Gradle Project wizard.

1. Navigate to *File → New → Project...* and select *Gradle → Gradle Project*. Finally, click *Next → Next*.

2. Enter a valid project name. You can also specify your project location and working sets.

Figure 52.33: By selecting these Tern modules, you can use AlloyUI code assist features in your project.

3. Optionally, you can navigate to the next page and specify your Gradle distribution and other advanced options. Once you're finished, select *Finish*.

You can also import existing Gradle projects in Liferay @ide@.

1. Go to *File* → *Import...* → *Gradle* → *Gradle Project* → *Next* → *Next*.
2. Click the *Browse...* button to choose a Gradle project.
3. Optionally, you can navigate to the next page and specify your Gradle distribution and other advanced options. Once you're finished, click *Next* again to review the import configuration. Select *Finish* once you've confirmed your Gradle project import.

Next you'll learn about Gradle tasks and executions, and learn how to run and display them in Liferay @ide@.

Gradle Tasks and Executions

Liferay @ide@ provides two views to enhance your developing experience using Gradle: Gradle Tasks and Gradle Executions. You can open these views by following the instructions below.

1. Go to *Window* → *Show View* → *Other...*.
2. Navigate to the *Gradle* folder and open *Gradle Tasks* and *Gradle Executions*.

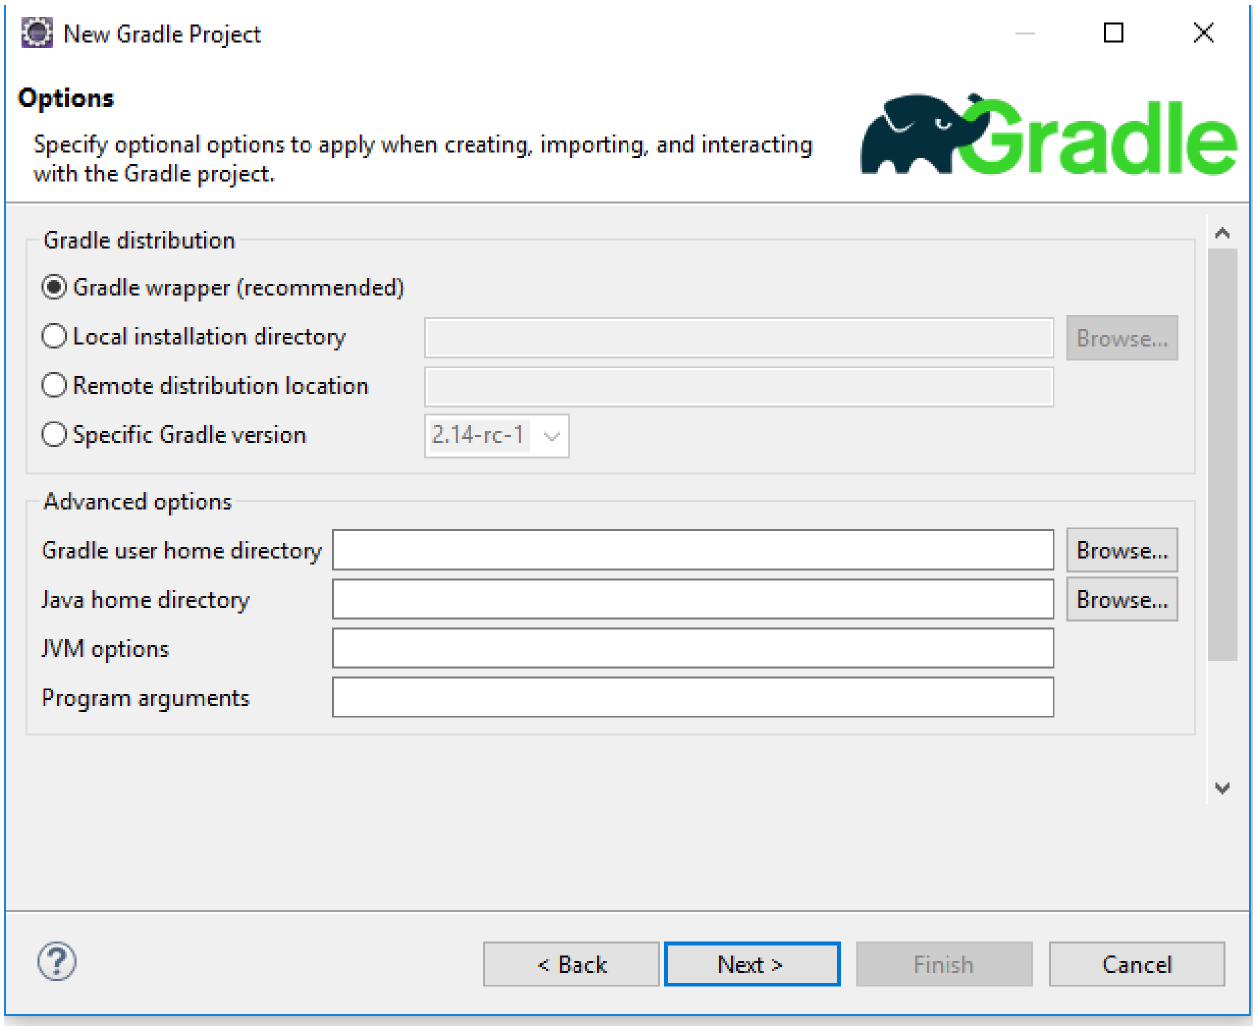
Gradle tasks and executions views open automatically once you create or import a Gradle project.

The Gradle Tasks view allows you to display the Gradle tasks available for you to use in your Gradle project. Users can execute a task listed under the Gradle project by double-clicking it.

Once you've executed a Gradle task, you can open the Gradle Executions view to inspect its output.

Keep in mind that if you change the Gradle build scripts inside your Gradle projects (e.g., `build.gradle` or `settings.gradle`), you must refresh the project so Liferay @ide@ can account for the change and display it properly in your views. To refresh a Gradle project, right-click on the project and select *Gradle* → *Refresh Gradle Project*.

If you prefer Eclipse refresh your Gradle projects automatically, navigate to *Window* → *Preferences* → *Gradle* and enable the *Automatic Project Synchronization* checkbox. If you'd like to enable Gradle's automatic synchronization for just one Gradle project, you can right-click a Gradle project and select *Properties* → *Gradle* and enable auto sync that way. This feature is available in Buildship version 2.2+, so make sure you have the required version.



New Gradle Project

Options

Specify optional options to apply when creating, importing, and interacting with the Gradle project.

Gradle distribution

- [✓ Gradle wrapper (recommended)]
- Local installation directory
- Remote distribution location
- Specific Gradle version: 2.14-rc-1

Advanced options

- Gradle user home directory
- Java home directory
- JVM options
- Program arguments

Figure 52.35: You can specify your Gradle distribution and advanced options such as home directories, JVM options, and program arguments.

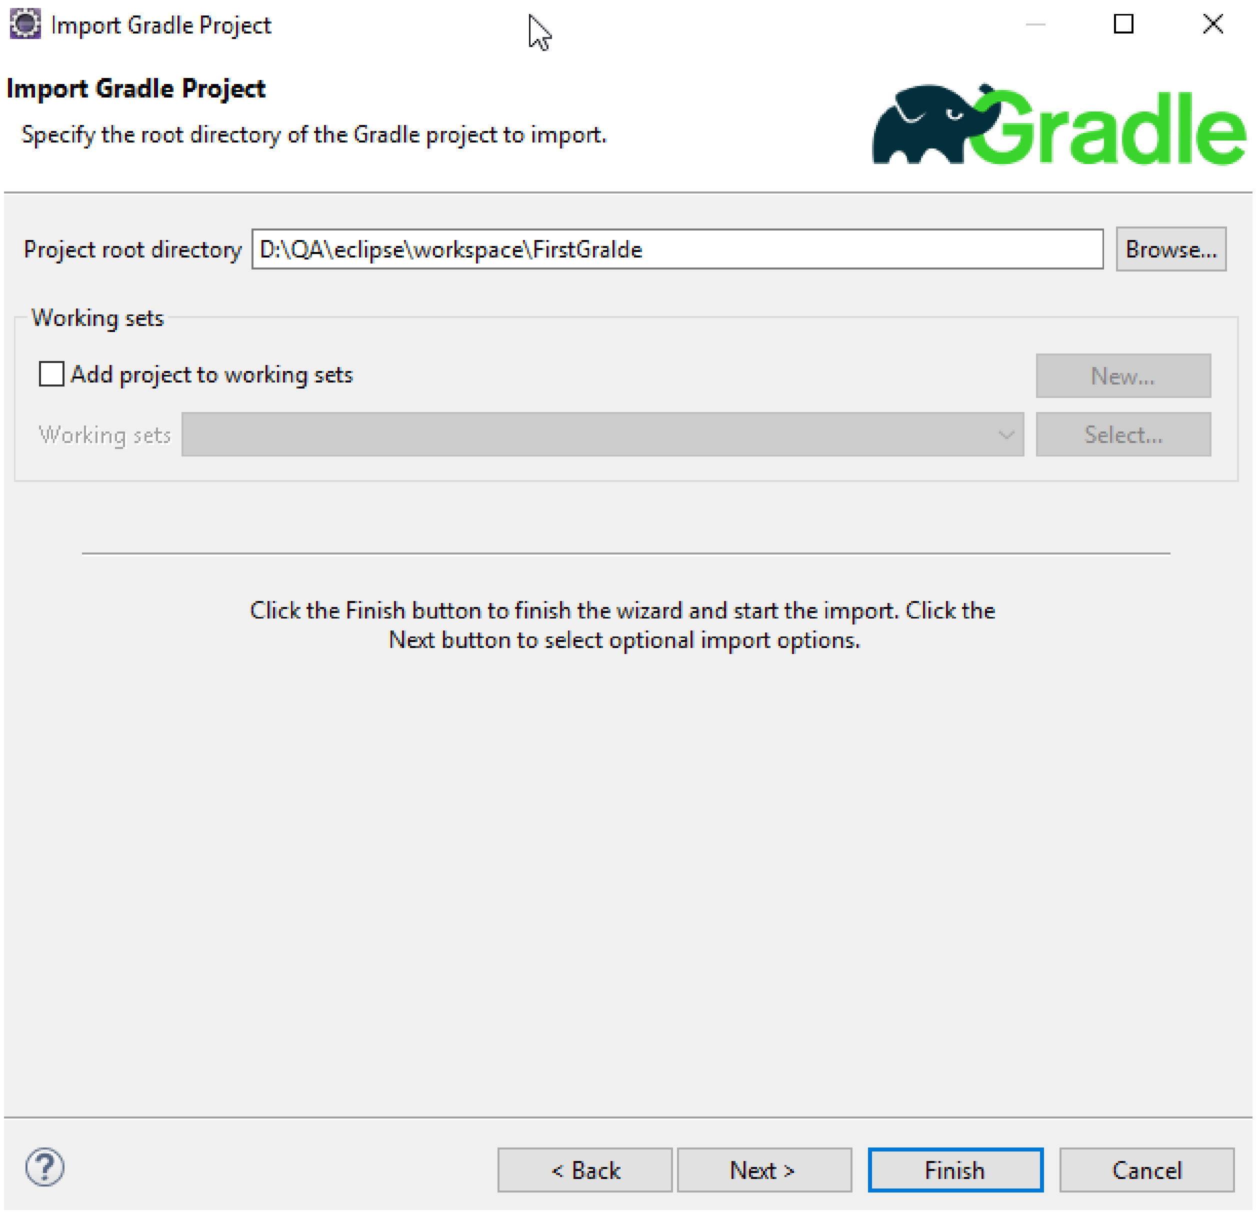
Excellent! You're now equipped with the knowledge to add, import, and build your Gradle projects in Liferay @ide@!

52.14 Using Maven in Liferay @ide@

You can take full advantage of Maven in Liferay @ide@ with its built-in Maven support. In this tutorial, you'll learn about the following topics:

- Installing Maven Plugins for Liferay @ide@
- Creating Maven Projects
- Importing Maven Projects
- Using the POM Graphic Editor

First you'll install the necessary Maven plugins for Liferay @ide@.



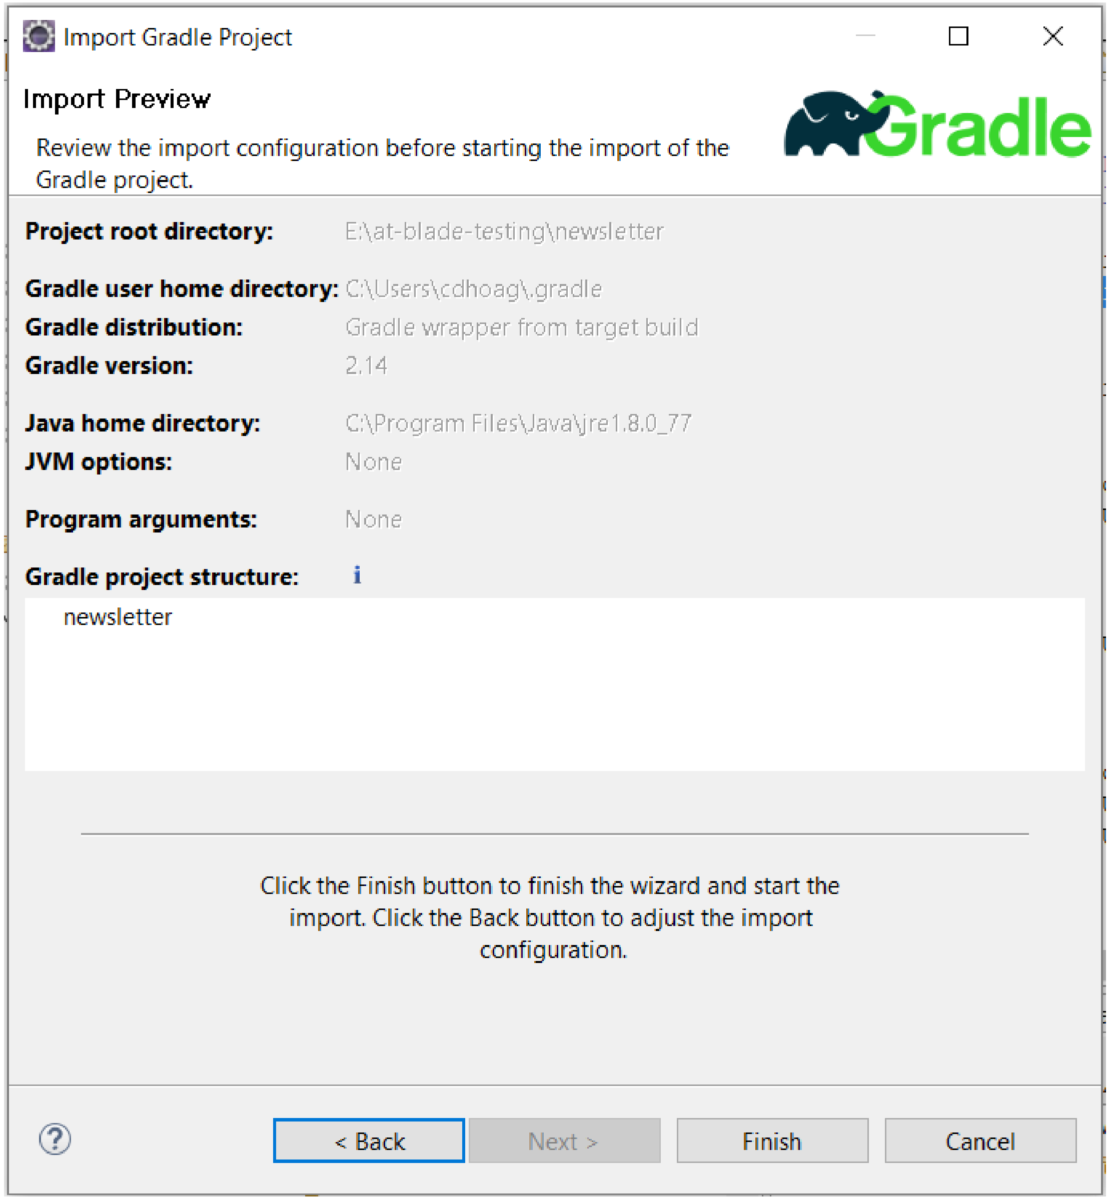
Import Gradle Project

Specify the root directory of the Gradle project to import.

Project root directory: D:\QA\eclipse\workspace\FirstGralde

Click the Finish button to finish the wizard and start the import. Click the Next button to select optional import options.

Figure 52.36: You can specify what Gradle project to import from the *Import Gradle Project* wizard.



Import Gradle Project

Import Preview

Review the import configuration before starting the import of the Gradle project.

Project root directory: E:\at-blade-testing\newsletter

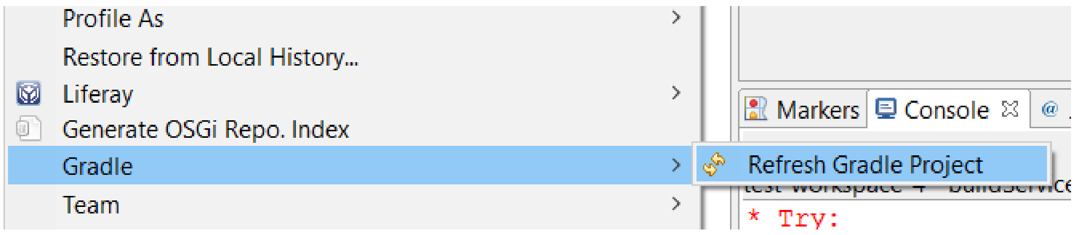

Figure 52.40: Make sure to always refresh your Gradle project in Liferay @ide@ after build script edits.

Installing Maven Plugins for Liferay @ide@

In order to support Maven projects in @ide@ properly, you first need a mechanism to recognize Maven projects as Liferay @ide@ projects. @ide@ projects are recognized in Eclipse as faceted web projects that include the appropriate Liferay plugin facet. Therefore, all @ide@ projects are also Eclipse web projects (faceted projects with the web facet installed). In order for @ide@ to recognize the Maven project and for it to be able to leverage Java EE tooling features (e.g., the Servers view) with the project, the project must be a flexible web project. Liferay @ide@ relies on the following Eclipse plugins to provide this capability:

- `m2e-core` (Maven integration for Eclipse)
- `m2e-wtp` (Maven integration for WTP)

All you have to do is install them so you can begin developing Maven projects for Liferay DXP.

When first installing Liferay @ide@, the installation startup screen lets you select whether you'd like to install the Maven plugins automatically. Don't worry if you missed this during setup. You'll learn how to install the required Maven plugins for @ide@ manually below.

1. Navigate to *Help* → *Install New Software*. In the *Work with* field, insert the following value:

   ```
   Liferay IDE repository - http://releases.liferay.com/tools/ide/latest/milestone/
   ```

2. Check the *Liferay IDE Maven Support* option. This bundles all the required Maven plugins you need to begin developing Maven projects for Liferay DXP.

   If the *Liferay IDE Maven Support* option does not appear, then it's already installed. To verify that it's installed, uncheck the *Hide items that are already installed* checkbox and look for *Liferay IDE Maven Support* in the list of installed plugins. Also, if you'd like to view everything that is bundled with the *Liferay IDE Maven Support* option, uncheck the *Group items by category* checkbox.

3. Click *Next*, review the install details, accept the term and license agreements, and select *Finish*.

Awesome! Your Liferay DXP is ready to develop Maven projects for Liferay DXP!

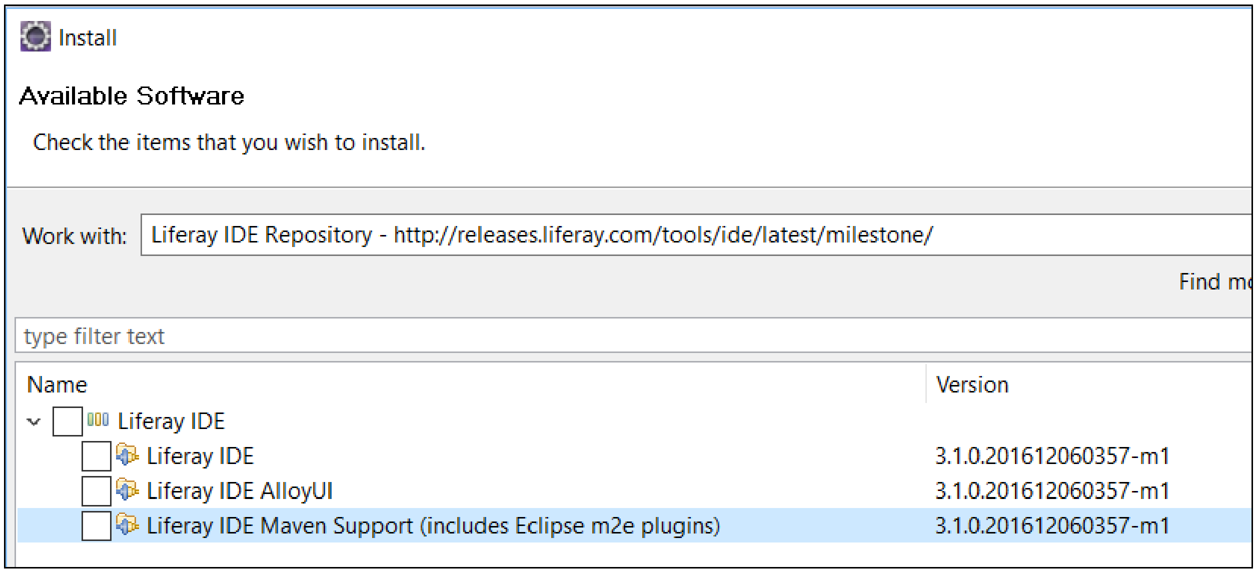
You'll learn about creating Maven projects in @ide@ next.

Creating Maven Projects

You can create a Maven project based on Liferay's provided Maven archetypes.

1. Navigate to *File* → *New* → *Liferay Module Project*.

2. Give your project a name, select the `maven-module` build type, and choose the project template (archetype) you'd like to use.



Install

Available Software

Check the items that you wish to install.

Work with: Liferay IDE Repository - http://releases.liferay.com/tools/ide/latest/milestone/

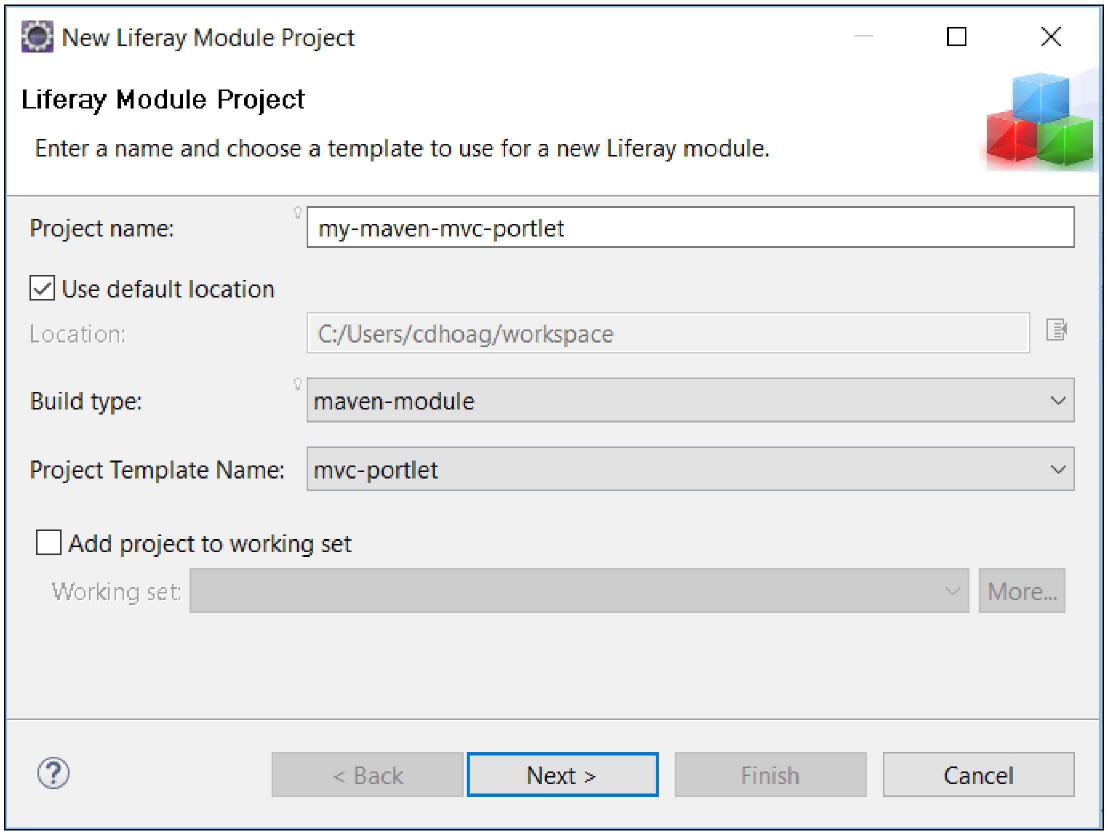
Liferay IDE AlloyUI	3.1.0.201612060357-m1
Liferay IDE Maven Support (includes Eclipse m2e plugins)	3.1.0.201612060357-m1

Figure 52.41: You can install all the necessary Maven plugins for @ide@ by installing the *Liferay IDE Maven Support* option.



New Liferay Module Project

Liferay Module Project

Enter a name and choose a template to use for a new Liferay module.

Project name: my-maven-mvc-portlet

[✓] Use default location

Location: C:/Users/cdhoag/workspace

Build type: maven-module

Project Template Name: mvc-portlet

[ ] Add project to working set

Working set:

Figure 52.42: The New Liferay Module Project wizard lets you generate a Maven module project.

3. (Optional) Click *Next* and name your component class name and package. You can also specify your component class's properties in the Properties menu.

4. Click *Finish*.

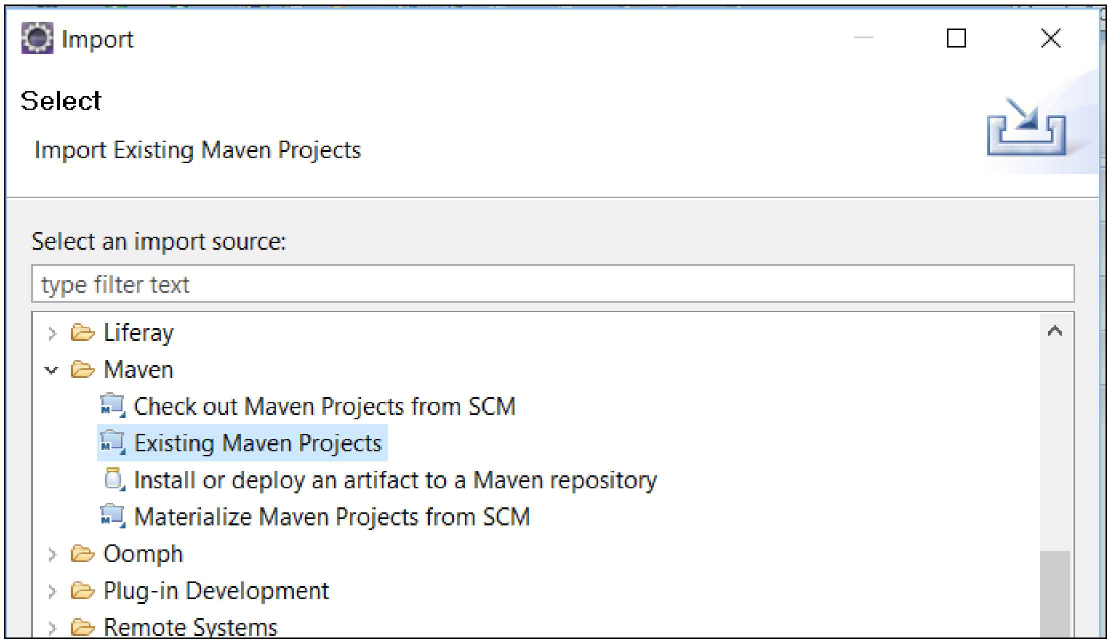
That's it! You've created a Liferay module project using Maven!

If you created your Maven project outside of @ide@ with another tool, you can still manage that project in @ide@, but you must first import it. You'll learn how to do this next.

Importing Maven Projects

To import a pre-existing Maven project into Liferay @ide@, follow the steps outlined below:

1. Navigate to *File* → *Import* → *Maven* → *Existing Maven Projects* and click *Next*.



Import

Select

Import Existing Maven Projects

Select an import source:

type filter text

- Liferay
- Maven
  - Check out Maven Projects from SCM
  - Existing Maven Projects
  - Install or deploy an artifact to a Maven repository
  - Materialize Maven Projects from SCM
- Oomph
- Plug-in Development
- Remote Systems

Figure 52.43: @ide@ offers the Maven folder in the Import wizard.

2. Click *Browse...* and select the root folder for your Maven project. Once you've selected it, the `pom.xml` for that project should be visible in the Projects menu.

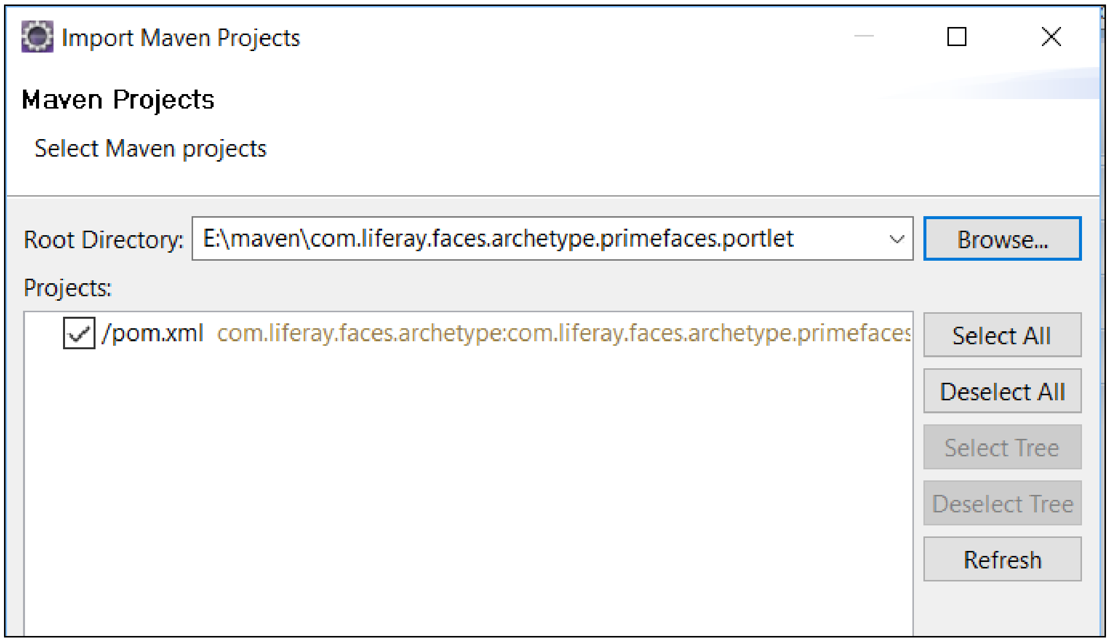
3. Click *Finish*.

Now your Maven project is available from the Package Explorer. Next you'll learn about Liferay @ide@'s POM graphical editor.

Using the POM Graphic Editor

You're provided a nifty POM graphic editor when opening your Maven project's `pom.xml` in Liferay @ide@. This gives you several different ways to leverage the power of Maven in your project:

- **Overview:** provides a graphical interface where you can add to and edit the `pom.xml` file.



E:\maven\com.liferay.faces.archetype.primefaces.portlet

☑ /pom.xml com.liferay.faces.archetype:com.liferay.faces.archetype.primefaces

Figure 52.44: Use the Import Maven Projects wizard to import your pre-existing project.

- **Dependencies:** provides a graphical interface for adding and editing dependencies in your project, as well as modifying the `dependencyManagement` section of the `pom.xml` file.
- **Effective POM:** provides a read-only version of your project POM merged with its parent POM(s), `settings.xml`, and the settings in Eclipse for Maven.
- **Dependency Hierarchy:** provides a hierarchical view of project dependencies and an interactive listing of resolved dependencies.
- **pom.xml:** provides an editor for your POM's source XML.

The figure below shows the `pom.xml` file editor and its modes.

By taking advantage of these interactive modes, Liferay @ide@ makes modifying and organizing your POM and its dependencies a snap!

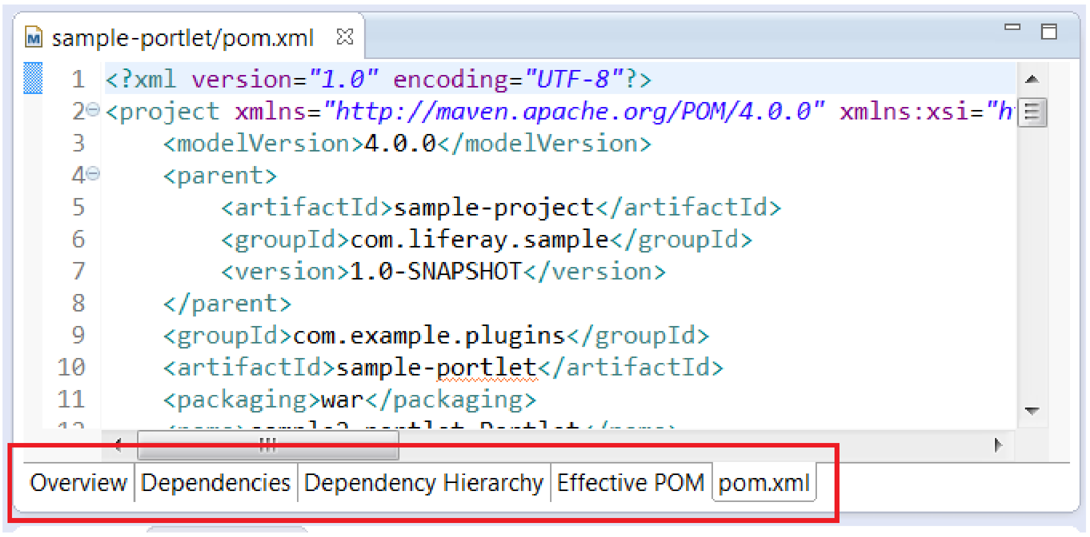
52.15 Using Front-End Code Assist Features in @ide@

Liferay @ide@ provides extended front-end development tools to assist in Liferay development. You now have access to code inferencing and code completion features for AlloyUI, JavaScript, CSS, and jQuery.

This tutorial covers how to use the code assist features for AlloyUI, JavaScript, CSS, and jQuery in @ide@. Each language is covered in its own section, so you can navigate to the language you're most interested in. Continue reading to find out how to use @ide@'s code assist features in your project.

Using Code Assist Features

@ide@'s integration of Tern gives you access to code assist in JavaScript, AlloyUI, and CSS. To access these features, you must be working in a JavaScript, JSP, HTML, or CSS file.



sample-portlet/pom.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="h
    <modelVersion>4.0.0</modelVersion>
    <parent>
        <artifactId>sample-project</artifactId>
        <groupId>com.liferay.sample</groupId>
        <version>1.0-SNAPSHOT</version>
    </parent>
    <groupId>com.example.plugins</groupId>
    <artifactId>sample-portlet</artifactId>
    <packaging>war</packaging>
```

Figure 52.45: Liferay @ide@ provides five interactive modes to help you edit and organize your POM..

You must have Tern features enabled in your project in order to use them. By default, Liferay portlet plugins already have Tern features enabled. Visit the Enabling Code Assist Features in your Project tutorial to learn how to enable Tern features for non-Liferay specific projects.

Note: For those developing with the Plugins SDK, the taglib descriptions that @ide@ makes available to users are dependent upon the Plugins SDK version. @ide@ uses taglib descriptions from the current SDK's `util-taglib.jar` file, so a more up-to-date Plugins SDK means more up-to-date taglib descriptions.

You'll begin testing the AlloyUI code assist features next.

AlloyUI Code Assist Features

There are several helpful code assist features that can improve your productivity when writing code for AlloyUI. The example below shows how to access the AlloyUI code assist features in the `main.js` of your project:

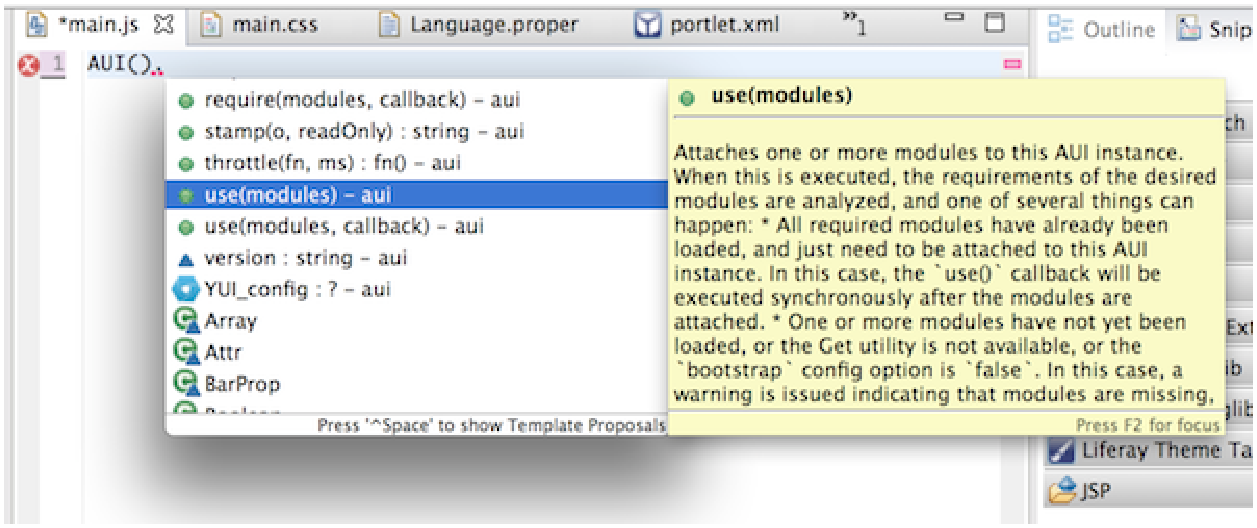
1. Open your project's `main.js` file and type the following code:

   ```
   AUI().
   ```

2. Press *Ctrl+Space* with your cursor to the right of `AUI().`. This brings up the code inference for the `AUI()` global object. Notice the AlloyUI framework's own API documentation is also displayed. Press *Enter* to use code completion.

Note: Code assist not only works for methods of an object, but also works for AUI-specific Tern completions for objects. For instance, you could type `AU` and press *Ctrl+Space* to see a list of objects to choose from.

By default, code inference is triggered by a keystroke combination; however, you can enable auto activation in @ide@'s Preferences menu. Follow the steps below to enable auto activation:



use(modules)

Attaches one or more modules to this AUI instance. When this is executed, the requirements of the desired modules are analyzed, and one of several things can happen: * All required modules have already been loaded, and just need to be attached to this AUI instance. In this case, the `use()` callback will be executed synchronously after the modules are attached. * One or more modules have not yet been loaded, or the Get utility is not available, or the `bootstrap` config option is `false`. In this case, a warning is issued indicating that modules are missing,

Figure 52.46: This figure demonstrates code inference in a JS file.

1. Navigate to *Window* → *Preferences* → *JavaScript* → *Editor* → *Content Assist*.
2. Check the *Enable auto activation* box and click *Apply*. Then click *OK*.

The figure below shows how to enable auto activation:

Now, if you follow the previous example, code inference activates as soon as you press the trigger key, which in this case is the . (period) key.

In addition to general code inference for AlloyUI, you have access to code templates. AUI JavaScript templates are available in Eclipse's JavaScript editor as well as in the HTML/JSP editor when working with `<script>` and `<aui-script>` tags. Follow the steps below to use AUI code templates:

1. Type the following code in your `main.js`:

   ```
   AUI
   ```

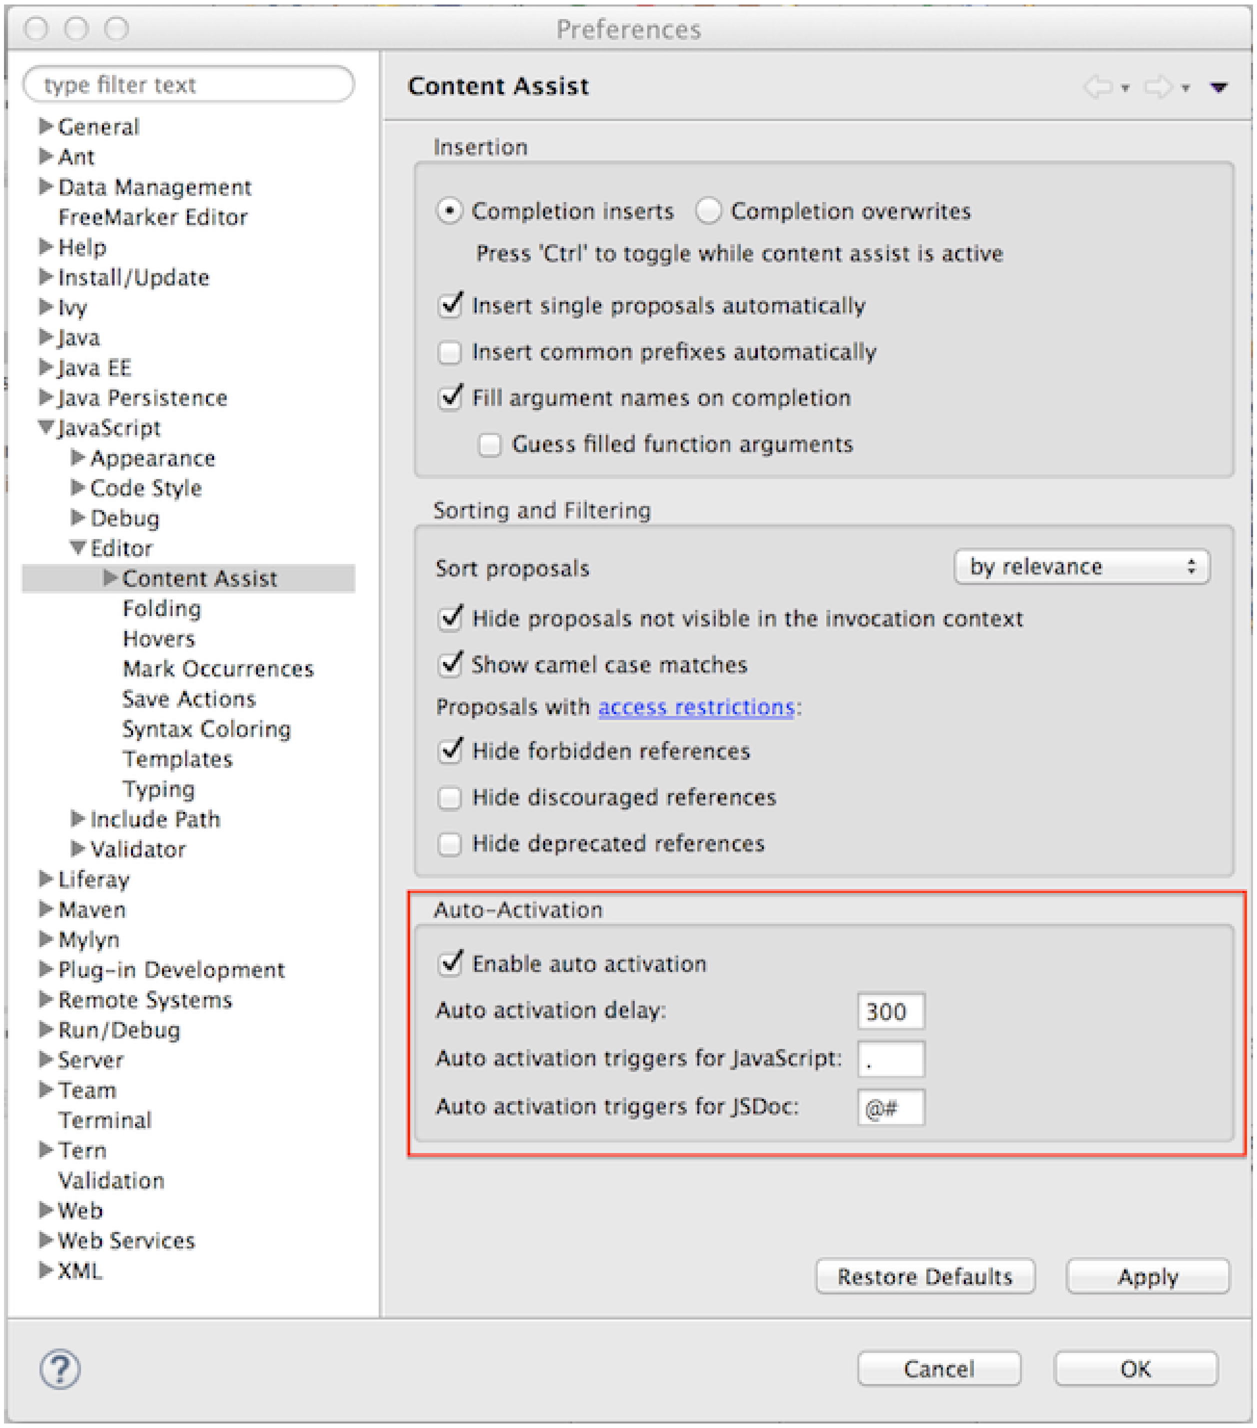
2. Press *Ctrl+Space* to bring up the code inference for `AUI`, and you'll see a list of all the available AlloyUI code templates, along with documentation.
3. Select your template and hit *Enter* to paste its contents into your `main.js`.

```
**Note:** You can view all the AlloyUI code templates you have
installed by going to @ide@'s Preferences menu and selecting *JavaScript*
&rarr; *Editor* &rarr; *Templates*.
```

In addition to code inference in your JS files, you can also use code inference in your JSP/HTML files using `<aui:script>` tags.

Open one of your project's JSPs and add the AUI taglib directive if it is not already in your JSP:

```
<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
```



Content Assist

Insertion

[● Completion inserts] ○ Completion overwrites

```
AUI().use('aui-carousel', function(A) {
    new A.Carousel({
        contentBox : '#myCarousel',
        height : 250,
        width : 700
    }).render();
});
```

Figure 52.48: @ide@ gives you access to AUI code templates in the JS and JSP editors.

You can also add the import from the Snippets menu under *Taglib imports → Liferay AUI Taglib Import v6.1*.

1. Add an `<aui:script>` tag inside your JSP and configure it to look like the following code:

```
<aui:script>
    aui
</aui:script>
```

2. Press *Ctrl+Space* with your cursor placed to the right of `aui` to bring up code inference.

There you go! Whether in a JavaScript file or inside a JSP, you now have access to code assist features that improve your workflow.

Next, you'll examine the JavaScript code assist features for @ide@.

JavaScript Code Assist Features

In addition to AlloyUI code assist features, you also have access to code inference and completion using raw JavaScript. This code assist feature is available in your project because the Tern module `Liferay` is enabled. This plugin provides code completions for the static JavaScript object APIs available to portlets when running in Liferay Portal. To learn more about enabling Tern modules in Eclipse, refer to the Enabling Code Assist Features in Your Project tutorial.

The example below shows how you can use code assist features to easily access functions in your portlet project.

1. Open the `main.js` of your portlet and add the following function:

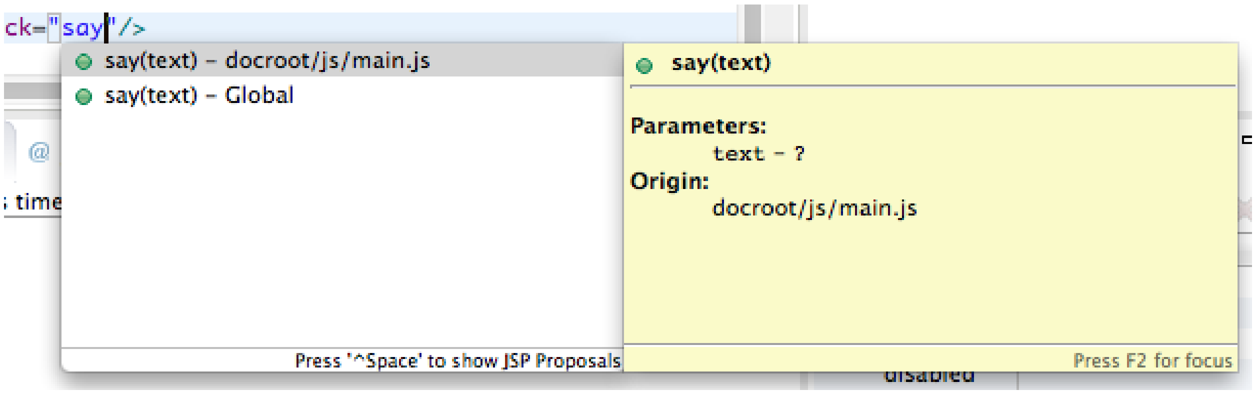
```
function say(text){
    alert(text);
}
```

2. Add the following button to the `view.jsp` of your portlet:

```
<aui:button onClick=""/>
```

3. Place your cursor within the quotation marks of the `onClick` attribute and press *Ctrl+Space*. The code inference dialog pops up with a list of possible JavaScript functions available for you to use.

4. Type *say* and you'll notice the list is narrowed down to your new `say(text)` function.



ck="say"/>
say(text) - docroot/js/main.js
say(text) - Global
Press '^Space' to show JSP Proposals

say(text)
Parameters:
text - ?
Origin:
docroot/js/main.js
Press F2 for focus

Figure 52.49: JavaScript code assist features give easy access to your functions.

5. Select the `say(text)` function, and you'll notice that it's accompanied by documentation that provides the parameter for the function, as well as the file path where the function is located.

6. Press *Enter* to use code completion and add the function to your button.

As you can see, JavaScript development is a breeze using @ide@'s code assist features. Now that you know how to use the AlloyUI and JavaScript code assist features, you can learn how to use the CSS code assist features next.

CSS Code Assist Features

@ide@ offers code inference and completion tools for CSS. In order to use these tools, you'll need to install an additional plugin.

Note: The plugin described below is planned to be bundled with Liferay @ide@ in the near future. Initial tests of the plugin revealed performance issues in some cases, which is why it is not yet a part of Liferay @ide@. Problems were not consistent, so you may have no issues installing the plugin, but we wanted to give full disclosure about it.

Follow the steps below to install the plugin in @ide@:

1. Go to *Help* → *Install New Software...*.

2. Paste the following link into the `Work with:` input field:

```
http://oss.opensagres.fr/eclipse-wtp-webresources/1.1.0/
```

3. Click *Add...* and check the box next to *WTP HTML - Web Resources*.

4. Click *Next* and follow the installation instructions.

Now that your plugin is installed, you'll need to enable the CSS features in your project. Right-click your project and go to *Properties* → *Web Resources* → *CSS*. Check both boxes to enable CSS features in your project.

You have successfully installed and enabled the new CSS features in your project!

Now that you have the CSS features enabled, you'll find out how to use them next. Follow the steps below to use the CSS code assist features to locate a CSS class. Note that the process below can also be used to locate an ID.

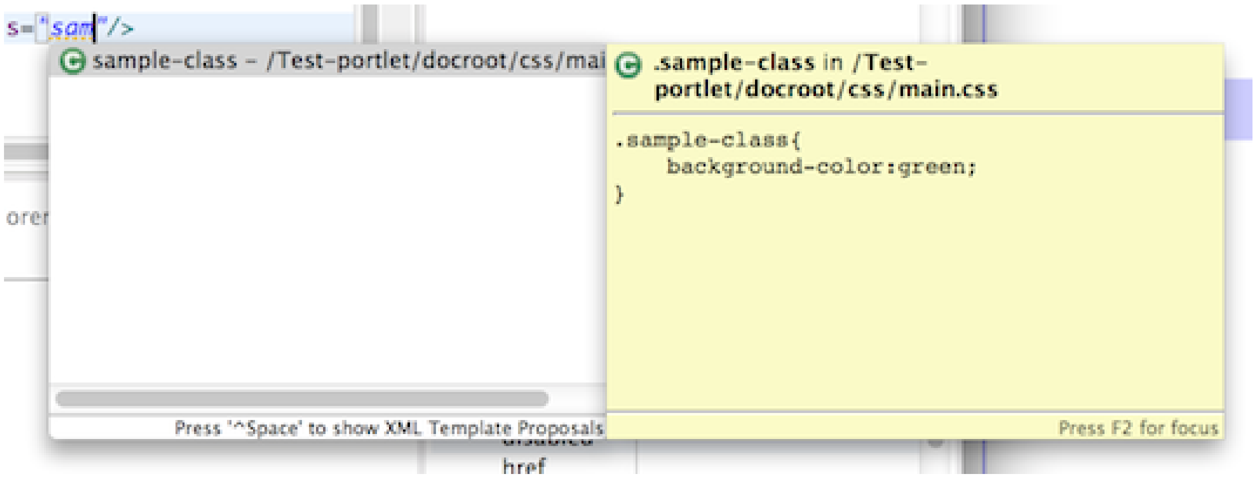
1. Open your `main.css` file and add the following class to it:

   ```
   .sample-class {
       background-color:green;
   }
   ```

2. Inside your `view.jsp` add an `<aui:button/>` tag and configure it to match the following code:

   ```
   <aui:button name="test" value="test" cssClass=""/>
   ```

3. Within the quotations of the `cssClass`×attribute, press *Ctrl+Space* to bring up the code inference for CSS. Begin typing *sample-class* to narrow down the classes to the one you're looking for.



```
s="sam"/>
```

sample-class - /Test-portlet/docroot/css/mai

.sample-class in /Test-portlet/docroot/css/main.css

```
.sample-class{
    background-color:green;
}
```

Figure 52.50: CSS code inference improves your workflow when developing in CSS.

   Notice, along with code inference, you can also view the styling you have for the class, as well as the file in which it is located.

4. Press *Enter* to use code completion and add the CSS class to the JSP.

If you look at the code inference dialog for CSS classes, you'll also notice that in addition to your own CSS classes, you also have access to Bootstrap CSS classes found in Liferay Portal.

Note: You can go to the file that the class, ID, or function is located in by hovering over top of it in your JSP and holding down the `Ctrl` (Windows) or `command` (Mac) key, and clicking the hyperlink that appears.

Lastly, you'll learn about the code assist features for jQuery.

jQuery Code Assist Features

You can also use code assist with jQuery. To do this, you must enable the `jQuery` Tern module. Follow the instructions in the Enabling Code Assist Features in Your Project tutorial to learn how to enable Tern modules in your project.

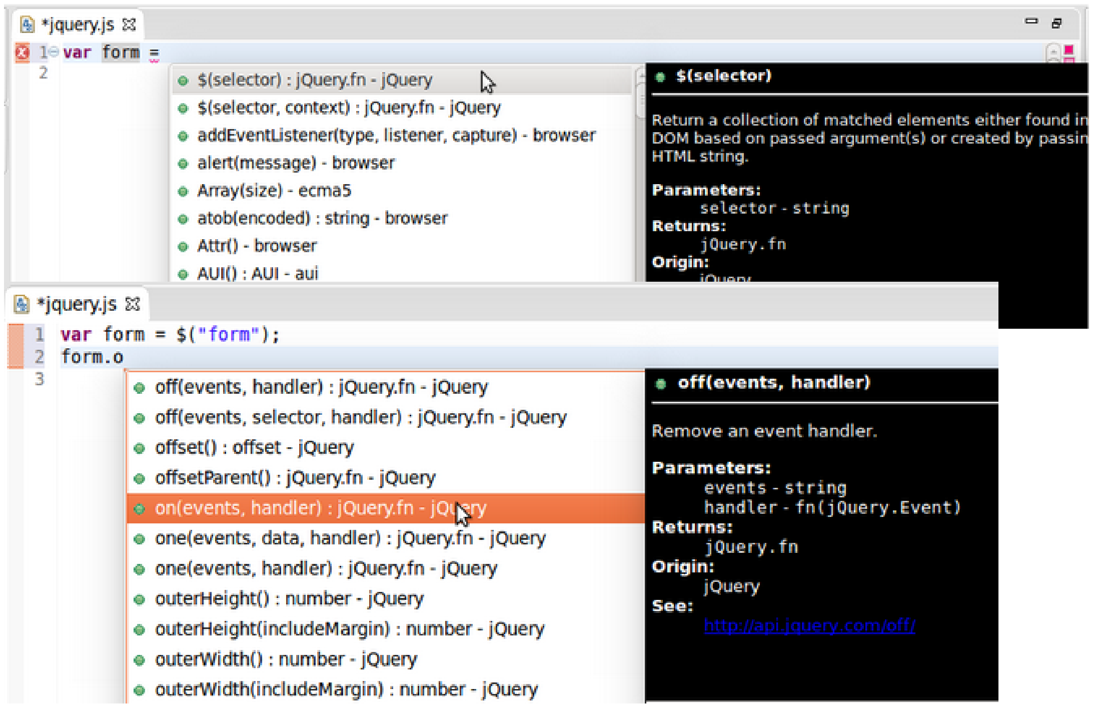
The jQuery Tern plugin gives type information for the jQuery framework. In the example below, you'll test the jQuery code assist feature.

1. Open your project's `jquery.js` file.

2. In the file, type the following sample variable:

```
var form =
```

3. Press *Ctrl+Space* to bring up the code inference for the variable you're declaring, and you'll see a list of everything that is available. Also notice jQuery documentation is available for each method. Take a look at the figure below for an example of using code assit in jQuery.



*jquery.js

```
var form =
```

- $(selector) : jQuery.fn - jQuery
- $(selector, context) : jQuery.fn - jQuery
- addEventListener(type, listener, capture) - browser
- alert(message) - browser
- Array(size) - ecma5
- atob(encoded) : string - browser
- Attr() - browser
- AUI() : AUI - aui

$(selector)

Return a collection of matched elements either found in DOM based on passed argument(s) or created by passin HTML string.

Parameters:
`selector - string`
Returns:
`jQuery.fn`
Origin:

*jquery.js

```
var form = $("form");
form.o
```

- off(events, handler) : jQuery.fn - jQuery
- off(events, selector, handler) : jQuery.fn - jQuery
- offset() : offset - jQuery
- offsetParent() : jQuery.fn - jQuery
- on(events, handler) : jQuery.fn - jQuery
- one(events, data, handler) : jQuery.fn - jQuery
- one(events, handler) : jQuery.fn - jQuery
- outerHeight() : number - jQuery
- outerHeight(includeMargin) : number - jQuery
- outerWidth() : number - jQuery
- outerWidth(includeMargin) : number - jQuery

off(events, handler)

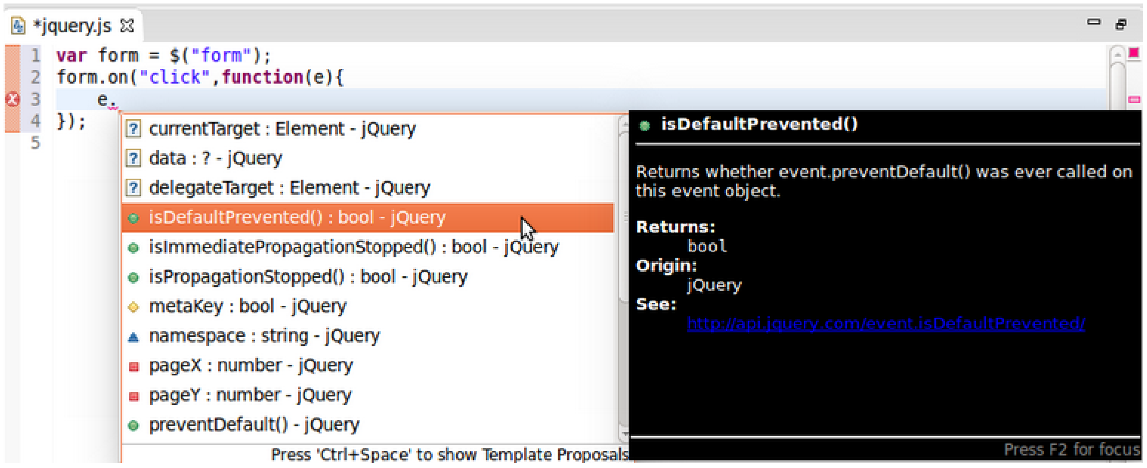
Remove an event handler.

Parameters:
`events - string`
`handler - fn(jQuery.Event)`
Returns:
`jQuery.fn`
Origin:
jQuery
See:
http://api.jquery.com/off/

Figure 52.51: Using the jQuery code assist features gives you the convenience of showing you what's available, and the documentation behind each option.

Furthermore, for jQuery callback handlers, the type information for parameters is also made available.

Excellent! You now know how to use @ide@'s front-end development code assist features to improve your workflow.



*jquery.js

```
var form = $("form");
form.on("click",function(e){
    e.
});
```

- currentTarget : Element - jQuery
- data : ? - jQuery
- delegateTarget : Element - jQuery
- isDefaultPrevented() : bool - jQuery
- isImmediatePropagationStopped() : bool - jQuery
- isPropagationStopped() : bool - jQuery
- metaKey : bool - jQuery
- namespace : string - jQuery
- pageX : number - jQuery
- pageY : number - jQuery
- preventDefault() - jQuery

Press 'Ctrl+Space' to show Template Proposals

isDefaultPrevented()

Returns whether event.preventDefault() was ever called on this event object.

Returns:
bool
Origin:
jQuery
See:
http://api.jquery.com/event.isDefaultPrevented/

Press F2 for focus

Figure 52.52: jQuery code assist also displays type information for parameters.

Enabling Code Assist Features in your Project

Liferay Workspace

From Liferay 6 to 7.0

Chapter 53

Blade CLI

The Blade CLI is the easiest way for Liferay developers to create new Liferay modules. Although the Plugins SDK is also supported, Blade CLI lets you create projects that can be used with any IDE or development environment. Blade CLI is a command line tool bootstrapped on to a Gradle based environment that is used to build Liferay 7.0 modules. This tool set provides a host of sub-commands that help Liferay developers create and deploy modules to a Liferay instance. The following sub-commands are callable in the Blade CLI environment:

- *convert*: Converts a Plugins SDK plugin project to a Gradle Workspace project.
- *create*: Creates a new Liferay module project from available templates.
- *deploy*: Builds and deploys bundles to the Liferay module framework.
- *gw*: Executes Gradle command using the Gradle Wrapper, if detected.
- *help*: Gives help on a specific command.
- *init*: Initializes a new Liferay Workspace.
- *install*: Installs a bundle into Liferay's module framework.
- *open*: Opens or imports a file or project in Liferay @ide@.
- *samples*: Generates a sample project.
- *server*: Starts or stops server defined by your Liferay project.
- *sh*: Connects to Liferay and executes Gogo command and returns output.
- *update*: Updates Blade CLI to latest version.
- *upgradeProps:* Analyzes your old `portal-ext.properties` and your newly installed 7.x server to show you properties moved to OSGi configuration files or removed from the product.
- *version*: Displays version information about Blade CLI.

In this set of tutorials, you'll learn how to use these commands to create and test Liferay modules.

53.1 Installing Blade CLI

You can install Blade CLI using the Liferay Project SDK installer. This installs JPM and Blade CLI into your user home folder and optionally initializes a Liferay Workspace folder.

Note: In the past, if you've installed Blade CLI globally (e.g., using `sudo`), you should not run the installer to *update* your Blade CLI version. Since the installer only installs Blade CLI to your user home folder, your previous global installation would always override the installer's installation. Therefore, always follow the Updating Blade CLI tutorial to update your Blade CLI instance.

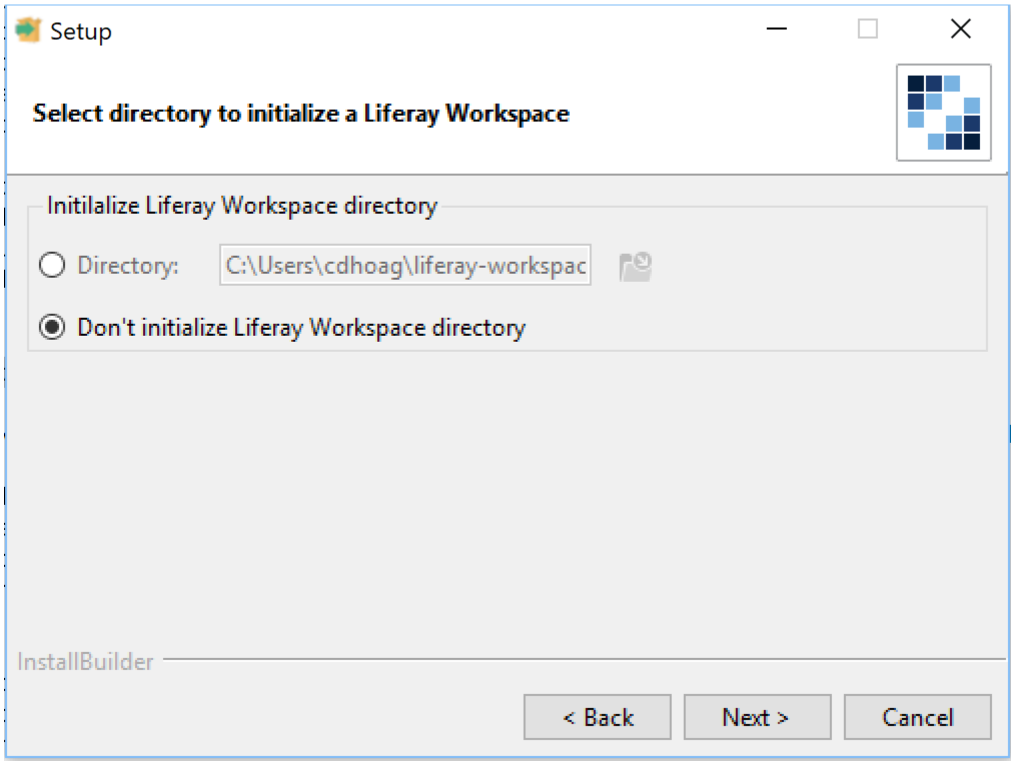
If you need to configure proxy settings for Blade CLI, follow the Installing Blade CLI with Proxy Requirements

Follow the steps below to download and install Blade CLI:

1. Download the latest Liferay Project SDK installer that corresponds with your operating system (e.g., Windows, MacOS, or Linux). The Project SDK installer is listed under *Liferay IDE*, so the folder versions are based on IDE releases. You can select an installer that does not include @ide@, if you don't intend to use it. The Project SDK installer is available for versions 3.2.0+. Do **not** select the large green download button; this downloads Liferay Portal instead.

2. Run the installer. Click *Next* to step through the installer's introduction.

3. If you'd like to initialize a Liferay Workspace, you can set the directory where it should go.



Setup

Select directory to initialize a Liferay Workspace

Initilalize Liferay Workspace directory

Directory: C:\Users\cdhoag\liferay-workspac

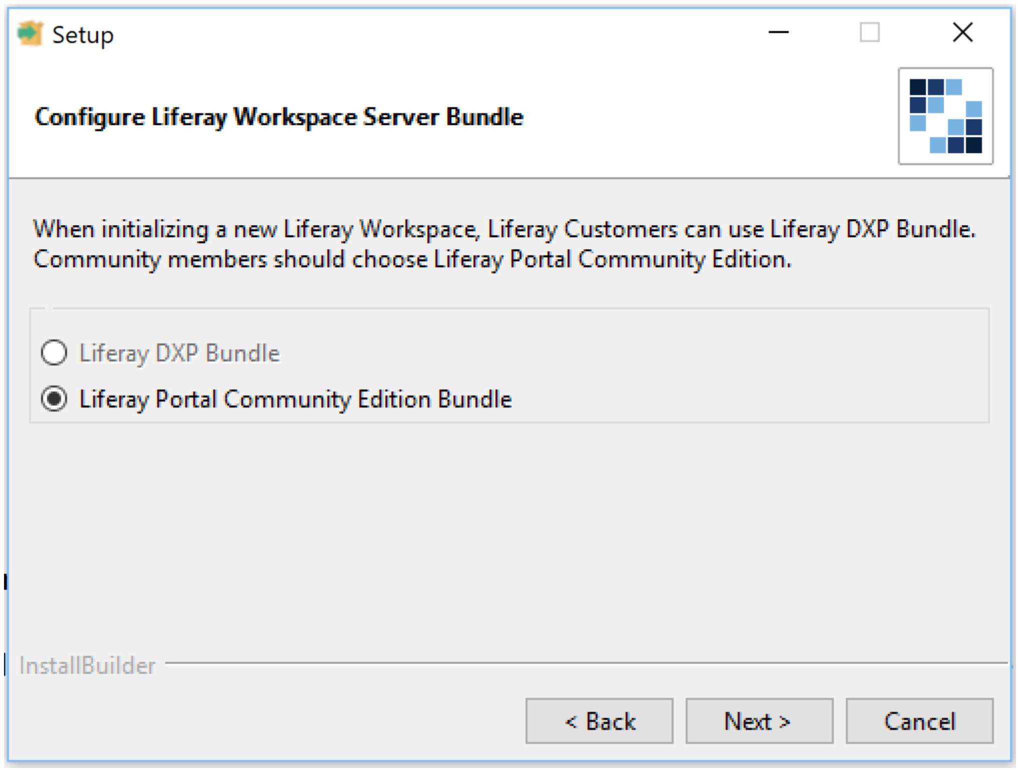
[✓ Don't initialize Liferay Workspace directory]

Figure 53.1: Determine where your Liferay Workspace should reside, if you want one.

Select the *Don't initialize Liferay Workspace directory* option if you only want to install Blade CLI. Then click *Next*.

4. If you decided to initialize a Liferay Workspace folder in the previous step, you'll have an additional option to select the Liferay product type you'll use with your workspace. Choose the product type and click *Next*.

5. Click *Next* to begin installing Blade CLI/Liferay Workspace on your computer.



Setup

Configure Liferay Workspace Server Bundle

When initializing a new Liferay Workspace, Liferay Customers can use Liferay DXP Bundle. Community members should choose Liferay Portal Community Edition.

○ Liferay DXP Bundle

● Liferay Portal Community Edition Bundle

Figure 53.2: Select the product version you'll use with your Liferay Workspace.

That's it! Blade CLI is installed on your machine! If you specified a location to initialize a Liferay Workspace folder, that is also available.

Blade CLI offers many `create` templates to help build 7.0 applications. It also offers various ways to deploy those apps and interact with your Liferay server. Be sure to explore more Blade CLI tutorials to learn how.

Installer Issues on macOS

If you're using macOS or Linux, you could experience an issue where the `blade` command is not available via command line. This is caused by the installer being unable to add JPM's `bin` folder to your user path. JPM is a Java package manager used in Blade CLI.

To add the required `bin` folder, execute the appropriate command based on your operating system.

macOS:

```
echo 'export PATH="$PATH:$HOME/Library/PackageManager/bin"' >> ~/.bash_profile
```

Linux:

```
echo 'export PATH="$PATH:$HOME/jpm/bin"' >> ~/.bash_profile
```

Once you restart the command line, the `blade` command should be available.

53.2 Installing Blade CLI with Proxy Requirements

If you have proxy server requirements and want to use Blade CLI, you must configure your http(s) proxy for it using JPM. Before beginning, make sure you've installed JPM and Blade CLI using a Liferay Workspace installer. Read the Installing Blade CLI tutorial for more details.

Once Blade CLI and JPM are installed, execute the following command to configure your proxy requirements for Blade CLI:

```
jpm command --jvmargs "-Dhttp(s).proxyHost=[your proxy host] -Dhttp(s).proxyPort=[your proxy port]" jpm
```

Excellent! You've configured Blade CLI with your proxy settings using JPM.

Note: When executing `blade update`, your Blade CLI's proxy settings are sometimes reset. Be sure to verify your proxy settings after every Blade CLI update.

53.3 Creating a Liferay Workspace with Blade CLI

In this tutorial, you'll learn how to generate a Liferay Workspace using Blade CLI. The Blade CLI tool you installed in the Installing Blade CLI section provides many different commands to help build and customize Liferay projects. The first thing you should do before building and customizing projects is create a Liferay Workspace. The workspace generated by Blade CLI is Gradle based; if you'd like to generate a Liferay Workspace built with Maven, see the Maven Workspace tutorial.

Your workspace is the home for all your custom Liferay projects. Navigate to the folder where you want your workspace and run the following command:

```
blade init -v 7.0 [WORKSPACE_NAME]
```

Note: Workspace automatically sets the default Liferay DXP version to develop against when it's first initialized. The default version is set to `7.2`. When adding the `-v 7.0` param to Blade's init command, the version is set for `7.0` Liferay DXP development. This is applied to create projects using appropriately versioned project templates.

You can update the default version after it has been set by opening your workspace's `.blade.properties` file and setting the `liferay.version.default` property.

Initializing a workspace requires no downloading or access to the internet.

If you still plan on using a Plugins SDK and wish to use it in conjunction with a workspace, navigate to your Plugins SDK root folder and run the following command:

```
blade init -u
```

This command builds a workspace and automatically adds and configures your current Plugins SDK environment for use inside the workspace. See the Using a Plugins SDK From Your Workspace section for more information on how to use a Plugins SDK from within a workspace.

Once your workspace is generated, look at its folder structure. Several folders and build/properties files were autogenerated:

- `configs`
- `gradle`

- `modules`
- `themes`
- `build.gradle`
- `gradle-local.properties`
- `gradle.properties`
- `gradlew`
- `settings.gradle`

The build/properties files included in your workspace's root directory sets your workspace's Gradle properties and facilitates the build processes of your modules. You can learn more about these generated files/folders in the Liferay Workspace tutorial. You'll learn about how to use these folders and properties files throughout the next few tutorials.

Next you'll learn about generating and using a Liferay DXP instance from within your workspace.

Running a Liferay Instance from Your Workspace

As discussed in the Liferay Workspace tutorial, Liferay Workspaces can generate and hold a Liferay Server. This lets you build/test your plugins against a running Liferay instance. Once you've properly generated and installed a Liferay server in your workspace, you can begin using it with the Blade CLI. To start your Liferay instance, run

```
blade server start -b
```

This command starts your Liferay server in a separate window. You also have the option to run your server in debug mode (`-d`).

Awesome! You have a built-in Liferay server in your workspace and can start the server using Blade CLI. Next you'll learn how to use a legacy Plugins SDK from your workspace.

Configuring a Plugins SDK in Your Workspace

Because Liferay DXP 7.0 uses a module-based framework, the current structure of a Liferay Workspace is centered around module development. There are still, however, many situations where you must create WAR-style plugins using the Plugins SDK. Because of this, your workspace can also work with the Plugins SDK. When configuring your SDK in a workspace, you can take advantage of all the new functionality workspaces provide and also use the SDK environment that you're used to.

Running the `blade init -u` command converted the Plugins SDK to a workspace that includes the Plugins SDK. If you created your workspace from scratch instead with `blade init`, you'll need to configure your Liferay workspace's Gradle properties.

If you revisit your workspace's `gradle.properties` file, you'll notice the Plugins SDK folder is set to `plugins-sdk`. This folder was not generated by default, so you must create it yourself. In your workspace's root folder, create the `plugins-sdk` folder. Then copy your legacy Plugins SDK files into the `plugins-sdk` folder. Lastly, generate its requirements by running `gradlew tasks`. Once this command successfully downloads all your Plugins SDK dependencies, it's ready to use in your workspace. For more information on manually configuring a Plugins SDK, see the Using a Plugins SDK from Your Workspace section.

53.4 Creating Projects with Blade CLI

When you use Blade CLI to create a project, your project's folder structure, build script (e.g., `build.gradle`), Java classes, and other resources (such as JSPs) are created based on the chosen template. In this tutorial, you'll learn how to use Blade CLI to create modules based on pre-existing templates and samples.

Using Blade CLI gives you the flexibility to choose how you want to create your application. You can do so in your own standalone environment, or within a Liferay Workspace. You can also create a project using either the Gradle or Maven build tool. Creating Liferay modules in a workspace using Blade CLI is very similar to creating them in a standalone environment.

When creating projects in a workspace, you should navigate to the appropriate folder corresponding to that type of project (e.g., the `/modules` folder for a module project). You can also provide further directory nesting into that folder, if preferred. For example, the Gradle workspace, by default, sets the directory where your modules should be stored by setting the following property in the workspace's `gradle.properties` file:

```
liferay.workspace.modules.dir=modules
```

Change this property if you'd like to store your modules in a different directory.

Note: Your projects should define a repository where external dependencies can be downloaded. Unlike Maven, Gradle does not define any repositories by default. For convenience, Gradle projects created with Blade CLI define Liferay's public Nexus repository as its default repository. This is defined, however, in different files depending on where the project was created.

If you used Blade CLI to create a Gradle project outside of a workspace, your repository is defined in the module's `build.gradle` file. Likewise, if you created your module inside a workspace, your repository is defined in the `settings.gradle` file located in the workspace's ROOT folder. This ensures that all modules residing in the workspace share the same repository URL.

First, you'll learn how to create a module using a template.

Project Templates

To create a new Liferay project, you can run the Blade `create` command, which offers many available templates. There are, however, many other options you can specify to help mold your project just the way you want it. To learn how to use the Blade `create` command and the many options it provides, enter `blade help create` into a terminal. A list of the `create` options are listed below:

- `-b, --build <string>`: The build type of the project. Available options are `gradle` (default) and `maven`.
- `-c, --classname <string>`: If a class is generated in the project, provide the name of the class to be generated. If not provided, the class name defaults to the project name.
- `C, --contributorType <string>`: Identifies your module as a theme contributor. This is also used to add the `Liferay-Theme-Contributor-Type` and `Web-ContextPath` bundle headers to the BND file.
- `-d, --dir <file>`: The directory to create the new project.
- `-h, --hostbundlebsn <string>`: If a new JSP hook fragment needs to be created, provide the name of the host bundle symbolic name.
- `-H, --hostbundleversion <string>`: If a new JSP hook fragment needs to be created, provide the name of the host bundle version.
- `-l, --listtemplates`: Prints a list of available project templates.
- `-p, --packagename <string>`: The package name to use when creating the project.
- `-s, --service <string>`: If a new Declarative Services (DS) component needs to be created, provide the name of the service to be implemented. Note that in this context, the term *service* refers to an OSGi service, not to a Liferay API.
- `-t, --template <string>`: The project template to use when creating the project. Run `blade create -l` for a listing of available Blade CLI templates.
- `-v, --liferay-version`: The Liferay DXP version to target when creating a project (e.g., `7.0`).

To create a module project, use the following syntax:

```
blade create [OPTIONS] <NAME>
```

For example, if you wanted to create an MVC portlet project with Gradle, you could execute the following:

```
blade create -t mvc-portlet -p com.liferay.docs.guestbook -c GuestbookPortlet my-guestbook-project
```

This command creates an MVC portlet project based on the template `mvc-portlet`. It uses the package name `com.liferay.docs.guestbook` and creates the portlet class `GuestbookPortlet`. The project name is `my-guestbook-project`. Since the directory was not specified, it is created in the folder you executed the command. When generating a project using Blade CLI, there is no downloading, which means internet access is not required.

Blade CLI can also create the same project with Maven by specifying the `-b maven` parameter. Using Blade CLI's Maven option isn't the only way leverage Liferay's Maven project templates; you can also generate them using Maven archetypes. See Liferay's Project Templates articles to see how.

When using Blade CLI, you'll have to manually edit your project's component class. Blade CLI gives you the ability to specify the class's name, but all other contents of the class can only be edited after the class is created. See the Creating Modules with Liferay @ide@ tutorial for further details and important dependency information on component classes.

Now that you know the basics on creating Liferay projects using `blade create`, you can visit the Project Templates reference section to view specific `create` templates and how they work.

Next, you'll explore Liferay's provided project samples and how to generate them using Blade CLI.

Project Samples

Liferay provides many sample projects that are useful for those interested in learning best practices on structuring their projects to accomplish specific tasks in Liferay DXP. These samples can be found in the liferay-blade-samples Github repository. You can also learn more about these samples by visiting the Liferay Sample Projects article.

You can generate these samples using Blade CLI for convenience, instead of cloning the repository and manually copy/pasting them to your environment. To do this, use the following syntax:

```
blade samples <NAME>
```

For example, if you wanted to generate the portlet-ds sample, you could execute

```
blade samples ds-portlet
```

For a full listing of all the available Blade samples, run

```
blade samples
```

Awesome! Now you know the basics on creating Liferay projects with Blade CLI.

53.5 Deploying Modules with Blade CLI

Deploying modules to a Liferay server using Blade CLI is easy. To use the Blade `deploy` command, you must first have built a module to deploy. See the Creating Projects with Blade CLI tutorials for more information about creating Liferay projects. Once you've built a module, navigate to it with your CLI and execute the following command to deploy it:

```
blade deploy
```

This can be used for WAR-style projects and modules (JARs). You can also deploy all projects in a folder by running the `deploy` command from the parent folder (e.g., `[WORKSPACE_ROOT]/modules`).

If you're using Liferay Workspace, the `deploy` command deploys your project based on the build tool's deployment configuration. For example, leveraging Blade CLI in a default Gradle Liferay Workspace uses the underlying Gradle deployment configuration. The build tool's deployment configuration is found by reading the Liferay Home folder set in your workspace's `gradle.properties` or `pom.xml` file. The `deploy` command works similarly if you're working outside of workspace; the Liferay Home folder, in contrast, is set by loading the Liferay extension object (Gradle) or the effective POM (Maven) and searching for the Liferay Home property stored there. If it's not stored, Blade prompts you to set it so it's available.

Note: If you prefer using pure Gradle or Maven to deploy your project, you can do this by applying the appropriate plugin and configuring your Liferay Home property. Here's how you can do this for Gradle and Maven:

Gradle:

First ensure the Liferay Gradle plugin is applied in your `build.gradle` file:

```
apply plugin: "com.liferay.plugin"
```

Then extend the Liferay extension object to set your Liferay Home and `deploy` folder:

```
liferay {
    liferayHome = "../../../../liferay-ce-portal-7.0.1-ga2"
    deployDir = file("${liferayHome}/deploy")
}
```

Maven:

Ensure the Bundle Support plugin is applied and configure Liferay Home in your `pom.xml`. See the Deploying a Module Built with Maven to Liferay Portal for details.

If you prefer not to use your underlying build tool's (Gradle or Maven) module deployment configuration, and instead, you want to deploy straight to Liferay DXP's OSGi container, run this command instead:

```
blade deploy -l
```

Blade CLI also offers a way to *watch* a deployed project, which compiles and redeploys a project when changes are detected. There are two ways to do this:

- `blade watch`
- `blade deploy -w`

The `blade watch` command is the fastest way to develop and test module changes, because the `watch` command does not rebuild your project every time a change is detected. When running `blade watch`, your project is not copied to Portal, but rather, is installed into the runtime as a reference. This means that the Portal does not make a cached copy of the project. This allows the Portal to see changes that are made to your project's files immediately. When you cancel the `watch` task, your module is uninstalled automatically.

Note: The `blade watch` command is available for Liferay Workspace versions 1.10.9+ (i.e., the `com.liferay.gradle.plugins.workspace` dependency). Maven projects cannot leverage the `watch` feature at this time.

The `blade deploy -w` command works similarly to `blade watch`, except it manually recompiles and deploys your project every time a change is detected. This causes slower update times, but does preserve your deployed project in Portal when it's shut down.

Cool! You've successfully deployed your module project using Blade CLI.

53.6 Managing Your Liferay Server with Blade CLI

In this tutorial, you'll learn how to manage a Liferay server using Blade CLI. For example, Blade CLI lets you install, start, stop, inspect, and modify a Liferay server.

Make sure you're in a Liferay Workspace and have a bundle installed and configured in the workspace before testing the Blade CLI commands on your own. To learn more about installing a Liferay server in a Liferay Workspace, see the Creating a Liferay Workspace with Liferay @ide@ section. The following Blade CLI commands are covered in this sub-section:

- `server`
- `sh`

The first thing that comes to mind when interacting with a server is simply turning it on/off. You can use the `server` sub-command to accomplish this. To turn on a Liferay server (Tomcat or Wildfly/JBoss), you can run

```
blade server start -b
```

Likewise, to turn off a server, run

```
blade server stop
```

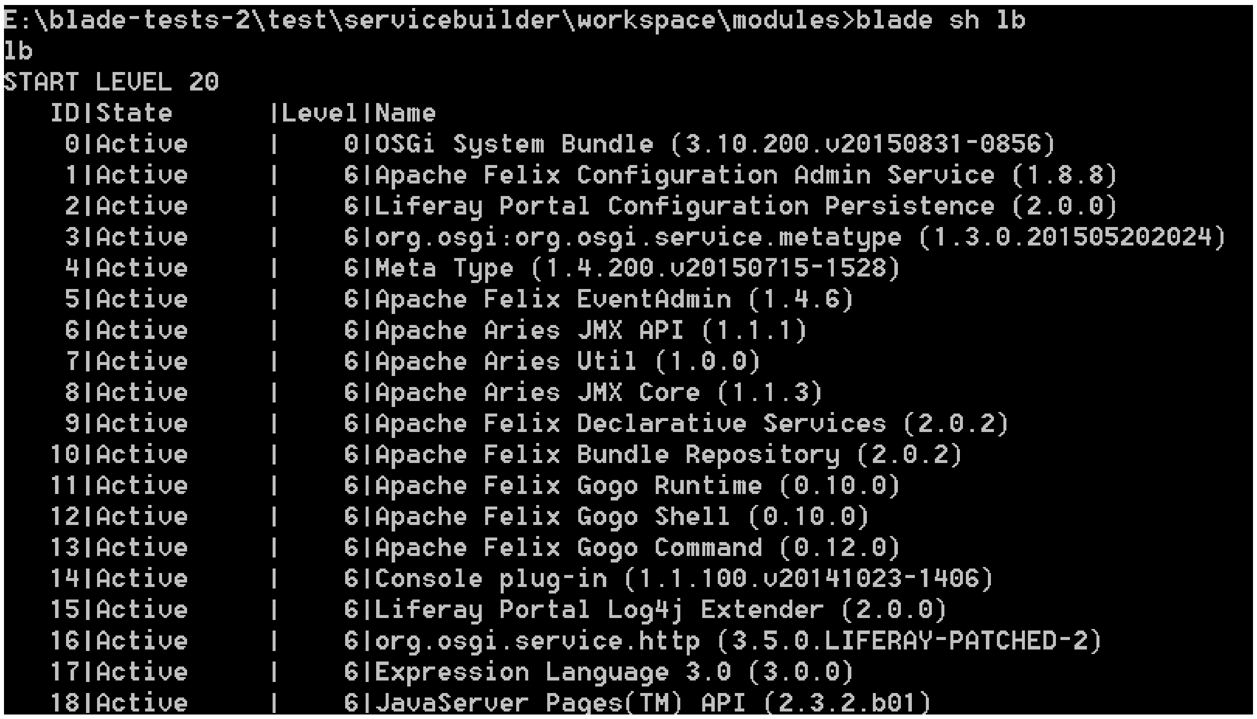
Once you've started your bundle, you can examine your server's OSGi container by using the `sh` command, which provides access to your server using the Felix Gogo shell. For example, to check if you successfully deployed your application from the previous section, you could run:

```
blade sh lb
```

Your output lists a long list of modules that are active/installed in your server's OSGi container.

You can run any Gogo command using `blade sh`. See the Using the Felix Gogo Shell section for more information on this tool.

Awesome! You learned how to conveniently interact with Liferay DXP using Blade CLI.



```
E:\blade-tests-2\test\servicebuilder\workspace\modules>blade sh lb
lb
START LEVEL 20
   ID|State      |Level|Name
    0|Active     |    0|OSGi System Bundle (3.10.200.v20150831-0856)
    1|Active     |    6|Apache Felix Configuration Admin Service (1.8.8)
    2|Active     |    6|Liferay Portal Configuration Persistence (2.0.0)
    3|Active     |    6|org.osgi:org.osgi.service.metatype (1.3.0.201505202024)
    4|Active     |    6|Meta Type (1.4.200.v20150715-1528)
    5|Active     |    6|Apache Felix EventAdmin (1.4.6)
    6|Active     |    6|Apache Aries JMX API (1.1.1)
    7|Active     |    6|Apache Aries Util (1.0.0)
    8|Active     |    6|Apache Aries JMX Core (1.1.3)
    9|Active     |    6|Apache Felix Declarative Services (2.0.2)
   10|Active     |    6|Apache Felix Bundle Repository (2.0.2)
   11|Active     |    6|Apache Felix Gogo Runtime (0.10.0)
   12|Active     |    6|Apache Felix Gogo Shell (0.10.0)
   13|Active     |    6|Apache Felix Gogo Command (0.12.0)
   14|Active     |    6|Console plug-in (1.1.100.v20141023-1406)
   15|Active     |    6|Liferay Portal Log4j Extender (2.0.0)
   16|Active     |    6|org.osgi.service.http (3.5.0.LIFERAY-PATCHED-2)
   17|Active     |    6|Expression Language 3.0 (3.0.0)
   18|Active     |    6|JavaServer Pages(TM) API (2.3.2.b01)
```

Figure 53.3: Blade CLI accesses the Gogo shell script to run the lb command.

53.7 Updating Blade CLI

If your Blade CLI version is outdated, you can run the following command to automatically download and install the latest version of Blade CLI:

```
blade update
```

For Windows users, the `blade update` command does not work because Windows cannot update a file that is currently in use. To bypass this issue, you can use JPM to update your version of Blade CLI:

```
jpm install -f https://releases.liferay.com/tools/blade-cli/latest/blade.jar
```

Blade CLI is updated frequently, so it's recommended to update your Blade CLI environment for new features. You can check the released versions of Blade CLI at https://releases.liferay.com/tools/blade-cli/. You can check your current installed version by running `blade version`.

Note: If you run `blade version` after updating, but don't see the expected version installed, you may have two separate Blade CLI installations on your machine. This is typically caused by users who installed an earlier version of Blade CLI, and then used the Liferay Workspace installer (at any time prior) to update the older Blade CLI instance. This is not recommended. Doing this installs Blade CLI in the global and user home folder of your machine. The latest Blade CLI update process installs to your user home folder, so you must delete the legacy Blade files in your global folder, if present. To do this, navigate to your `GLOBAL_FOLDER/JPM4J` folder and delete

- `/bin/blade`

- `/commands/blade`

The newest Blade CLI installation in your user home folder is now recognized and available.

Although Blade CLI is frequently released, if you want bleeding edge features not yet available, you can install the latest snapshot version:

```
blade update -s
```

This pulls the latest snapshot version of Blade CLI and installs it to your local machine. Running `blade version` after installing a snapshot displays output similar to this:

```
blade version 3.3.1.SNAPSHOT201811301746
```

Be careful; snapshot versions are unstable and should only be used for experimental purposes.

Awesome! You've successfully learned how to update Blade CLI.

53.8 Converting Plugins SDK Projects with Blade CLI

Blade CLI can automatically migrate a Plugins SDK project to a Liferay Workspace. During the process, the Ant-based Plugins SDK project is copied to the applicable workspace folder based on its project type (e.g., `wars`) and is converted to a Gradle-based Liferay Workspace project. This drastically speeds up the migration process when upgrading to a Liferay Workspace from a legacy Plugins SDK.

Note: There is no Maven command for the migration process yet, so you must complete it manually for Maven-based workspaces.

To copy your Plugins SDK project and convert it to Gradle, use the Blade `convert` command:

1. Navigate to the root folder of your workspace in a command line tool.

2. Execute the following command:

   ```
   blade convert -s [PLUGINS_SDK_PATH] [PLUGINS_SDK_PROJECT_NAME]
   ```

   You must provide the path of the Plugins SDK your project resides in and the project name you want to convert. If you prefer converting all the Plugins SDK projects at once, replace the project name variable with `-a` (i.e., specifying all plugins).

```
**Note:** If the `convert` task doesn't work as described above, you may
need to update your Blade CLI version. See the
[Updating Blade CLI](/docs/7-0/tutorials/-/knowledge_base/t/updating-blade-cli)
article for more information.
```

```
This Gradle conversion process also works for themes; they're converted to
automatically leverage NodeJS. If you're converting a Java-based theme, add
the `-t` option to your command too. This will incorporate the
[Theme Builder](/docs/reference/7-0/-/knowledge_base/r/theme-builder-gradle-plugin)
Gradle plugin for the theme instead. For more information on upgrading
6.2 themes, see the
[Upgrade a 6.2 Theme to 7.0](/docs/7-0/tutorials/-/knowledge_base/t/upgrading-themes)
article.
```

Note: When converting a Service Builder project, the `convert` task automatically extracts the project's service interfaces and implementations into OSGi modules (i.e., *-impl and -*api) and places them in the workspace's `modules` folder. Your portlet and controller logic remain a WAR and reside in the `wars` folder.

Your project is successfully converted to a Gradle-based workspace project! Great job!

Chapter 54

Liferay Workspace

A *Liferay Workspace* is a generated environment that is built to hold and manage your Liferay projects. This workspace is intended to aid in the management of Liferay projects by providing various Gradle build scripts and configured properties. This is the official way to create 7.0 modules using Gradle. For those developers that still want to develop WAR-style plugins using the Plugins SDK, this way is also supported using a Liferay Workspace. Do you prefer Maven over Gradle? See the Maven Workspace tutorial to learn about using Liferay Workspace with Maven.

Liferay Workspaces can be used in many different development environments, which makes it flexible and applicable to many different developers. You can download the Liferay Workspace installer and run it to install Blade CLI (default CLI for workspace) and initialize a new Liferay Workspace.

You can also use it with other developer IDEs. For example, a Liferay Workspace easily integrates with Liferay @ide@, providing a seamless development experience. To learn more about Liferay @ide@ and using workspace with it, see the Creating a Liferay Workspace with Liferay @ide@ tutorial.

Your workspace also offers Gradle properties that you can modify to help manage the generated folders. There are also some folders that aren't generated by default, but can be manually created and set. This provides you the power to customize your workspace's folder structure any way you'd like. To learn more info on a workspace's folder structure and how you can configure a workspace, see the Configuring a Liferay Workspace tutorial.

Liferay Workspaces offer a full development lifecycle for your modules to make your Liferay development easier than ever. The development lifecycle includes creating, building, deploying, testing, and releasing modules. To learn more about the development lifecycle of a Liferay Workspace, see the Development Lifecycle for a Liferay Workspace tutorial.

54.1 Installing Liferay Workspace

You can install Liferay Workspace using the Liferay Project SDK installer. This installs JPM and Blade CLI into your user home folder and optionally initializes a Liferay Workspace folder. This is the same installer used to install Blade CLI, which is covered in the Installing Blade CLI tutorial.

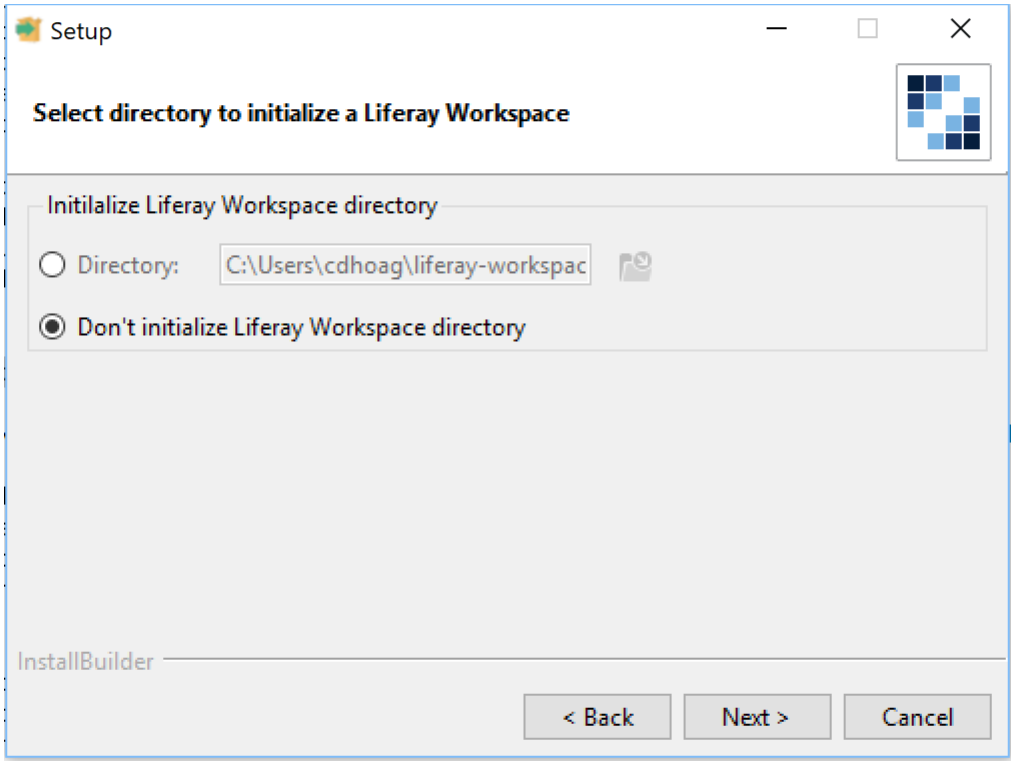
Follow the steps below to download and install Liferay Workspace:

1. Download the latest Liferay Project SDK installer that corresponds with your operating system (e.g., Windows, MacOS, or Linux). The Project SDK installer is listed under *Liferay IDE*, so the folder versions are based on IDE releases. You can select an installer that does not include @ide@, if you don't intend

to use it. The Project SDK installer is available for versions 3.2.0+. Do **not** select the large green download button; this downloads Liferay Portal instead.

2. Run the installer. Click *Next* to step through the installer's introduction.

3. Set the directory where your Liferay Workspace should be initialized.



Setup

Select directory to initialize a Liferay Workspace

Initilalize Liferay Workspace directory

Directory: C:\Users\cdhoag\liferay-workspac

[✓ Don't initialize Liferay Workspace directory]

Figure 54.1: Determine where your Liferay Workspace should reside.

Then click *Next*.

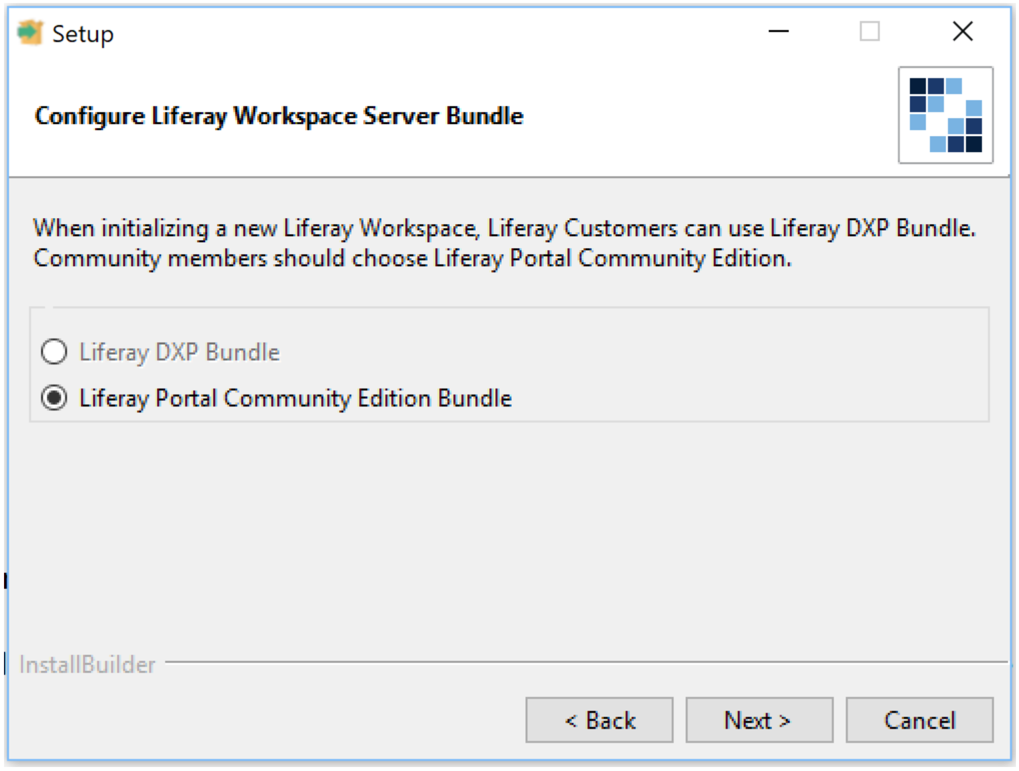
4. Choose the Liferay product type you intend to use with the workspace. Then click *Next*.

```
**Note:** You'll be prompted for your liferay.com username and password
before downloading the Liferay DXP bundle. Your credentials are not saved
locally; they're saved as a token in the `~/.liferay` folder. The token is
used by your workspace if you ever decide to redownload a DXP bundle.
Furthermore, the bundle that is downloaded in your workspace is also copied
to your `~/.liferay/bundles` folder, so if you decide to initialize another
Liferay DXP instance of the same version, the bundle is not re-downloaded. See
the
[Adding a Liferay Bundle to a Workspace](/docs/7-0/tutorials/-/knowledge_base/t/configuring-a-liferay-workspace#adding-a-liferay-
bundle-to-a-workspace)
for more information on this topic.
```

---

5. Click *Next* to begin installing Liferay Workspace on your machine.

That's it! Liferay Workspace is now installed on your machine!



Setup

Configure Liferay Workspace Server Bundle

When initializing a new Liferay Workspace, Liferay Customers can use Liferay DXP Bundle. Community members should choose Liferay Portal Community Edition.

( ) Liferay DXP Bundle
(●) Liferay Portal Community Edition Bundle

Figure 54.2: Select the product version you'll use with your Liferay Workspace.

54.2 Configuring a Liferay Workspace

A Liferay Workspace offers a development environment that can be configured to fit your development needs. You'll learn about the files/folders a workspace provides by default, and then you'll dive into configuring your workspace.

The top-level files/folder of a Liferay workspace are outlined below:

- `bundles` (generated): the default folder for Liferay DXP bundles.
- `configs`: holds the configuration files for different environments. These files serve as your global configuration files for all Liferay servers and projects residing in your workspace. To learn more about using the `configs` folder, see the Testing Modules section.
- `gradle`: holds the Gradle Wrapper used by your workspace.
- `modules`: holds your custom modules.
- `plugins-sdk` (generated): holds plugins to migrate from previous releases.
- `themes`: holds your custom themes which are built using the Theme Generator.
- `wars` (generated): holds traditional WAR-style web application projects.
- `build.gradle`: the common Gradle build file.
- `gradle-local.properties`: sets user-specific properties for your workspace. This lets multiple users use a single workspace, letting them configure specific properties for the workspace on their own machine.
- `gradle.properties`: specifies the workspace's project locations and Liferay DXP server configuration globally.
- `gradlew`: executes the Gradle command wrapper
- `settings.gradle`: applies plugins to the workspace and configures its dependencies.

The build/properties files included in your workspace's root folder sets your workspace's Gradle properties and facilitates the build processes of your modules.

Before you begin using your workspace, you should set your workspace Gradle properties in the `gradle.properties` file. There are several commented out properties in this file. These are the default properties set in your workspace. If you'd like to change a variable, uncomment the variable and set it to a custom value. For instance, if you want to store your modules in a folder other than `[ROOT]/modules`, uncomment the `liferay.workspace.modules.dir` variable and set it to a different value.

If you'd like to keep the global Gradle properties the same, but want to change them for yourself only (perhaps for local testing), you can override the `gradle.properties` file with your own `gradle-local.properties` file.

Note: Liferay Workspace provides many subprojects for you behind the scenes, which hides some complexities of Gradle. You can learn more about this in the Building Modules section.

Now that you know about a workspace's default folder structure and how to modify its Gradle properties, you'll learn how to add a Liferay bundle to your workspace.

Adding a Liferay Bundle to a Workspace

Liferay Workspaces can generate and hold a Liferay Server. This lets you build/test your plugins against a running Liferay instance. Before generating a Liferay instance, open the `gradle.properties` file located in your workspace's root folder. There are several configurable properties for your workspace's Liferay instance. You can set the version of the Liferay bundle you'd like to generate and install by setting the download URL for the `liferay.workspace.bundle.url` property (e.g., `https://releases-cdn.liferay.com/portal/7.0.6-ga7/liferay-ce-portal-tomcat-7.0-ga7-20180507111753223.zip`). You can also set the folder where your Liferay bundle is generated with the `liferay.workspace.home.dir` property. It's set to `bundles` by default.

You can download a Liferay DXP bundle for your workspace if you're a DXP subscriber. Do this by setting the `liferay.workspace.bundle.url` property to a ZIP hosted on *api.liferay.com*. For example,

`liferay.workspace.bundle.url=https://api.liferay.com/downloads/portal/7.0.10.8/liferay-dxp-digital-enterprise-tomcat-7.0-sp8-20180717152749345.zip`

It can be tricky to find the fully qualified ZIP name/number for the DXP bundle you want. You cannot access Liferay's API site directly to find it, so you must start to download DXP manually, take note of the file name, and append it to `https://api.liferay.com/downloads/portal/`.

You must also set the `liferay.workspace.bundle.token.download` property to `true` to allow your workspace to access Liferay's API site.

Once you've finalized your Gradle properties, navigate to your workspace's root folder and run

```
blade server init
```

This uses workspace's pre-bundled Blade CLI tool to download the version of Liferay DXP you specified in your Gradle properties and installs your Liferay instance in the `bundles` folder.

If you want to skip the downloading process, you can create the `bundles` folder manually in your workspace's ROOT folder and unzip your Liferay DXP bundle to that folder.

You can also produce a distributable Liferay bundle (Zip or Tar) from within a workspace. To do this, navigate to your workspace's root folder and run the following command:

```
./gradlew distBundle[Zip|Tar]
```

Your distribution file is available from the workspace's `/build` folder.

Note: You can define different environments for your Liferay bundle for easy testing. You can learn more about this in the Testing Modules section.

The Liferay Workspace is a great development environment for Liferay module development; however, what if you'd like to also stick with developing WAR-style applications? Liferay Workspace can handle that request too!

Using a Plugins SDK from Your Workspace

Because 7.0 uses a module-based framework, the current structure of a Liferay Workspace is centered around module development. There are still, however, many situations where you must create WAR-style plugins using the Plugins SDK. Because of this, your workspace can also work with the Plugins SDK. When configuring your SDK in a workspace, you can take advantage of all the new functionality workspaces provide and also use the SDK environment that you're used to. To learn more about upgrading legacy applications to 7.0 and what you should consider before converting them to modules, visit the tutorial Planning Plugin Upgrades and Optimizations.

The Blade CLI offers a command that adds and configures your current Plugins SDK environment automatically for use inside a newly generated workspace (e.g., `blade init -u`). You can learn more about this in the Creating a Liferay Workspace with Blade CLI tutorial. If you created your workspace from scratch and want to use a Plugins SDK, however, you can add one to your workspace by completing one of the two options:

1. Copy your existing Plugins SDK's files into the workspace.
2. Generate a new Plugins SDK to use in the workspace.

Follow the appropriate section based on the option you want to follow.

Copying an Existing Plugins SDK into Workspace

If you open your workspace's `gradle.properties` file, you'll notice the `liferay.workspace.plugins.sdk.dir` property sets the Plugins SDK folder to `plugins-sdk`. This is where the workspace expects any Plugins SDK files to reside. This folder was not generated by default, so you must create it yourself. In your workspace's root folder, create the `plugins-sdk` folder. Then copy your legacy Plugins SDK files into the `plugins-sdk` folder.

The copied Plugins SDK requires many build-related artifacts. To start the artifact download process, execute the following command in your workspace's root folder:

```
./gradlew upgradePluginsSDK
```

The Plugins SDK's artifacts are downloaded. The Plugins SDK is now ready for use!

Generating a New Plugins SDK in Workspace

You can easily generate a new Plugins SDK for your workspace by executing a single Gradle command in your workspace's root folder:

```
./gradlew upgradePluginsSDK
```

This generates a new 7.0 Plugins SDK into the folder set by the `liferay.workspace.plugins.sdk.dir` property, which is configured to `plugins-sdk` by default in the workspace's `gradle.properties` file. You can change the folder name by updating the property. The downloaded Plugins SDK version is the latest release at the time of execution. You can reference the latest Plugins SDK releases here.

Once the downloading is complete, your Plugins SDK is ready to use in your workspace!

54.3 Setting Proxy Requirements for Liferay Workspace

If you're working behind a corporate firewall that requires using a proxy server to access external repositories, you need to add some extra configuration to make Liferay Workspace work within your environment. You'll learn how to set proxy requirements for both Gradle and Maven environments.

Using Gradle

1. Open your `~/.gradle/gradle.properties` file. Create this file if it does not exist.

2. Add the following properties to the file:

```
systemProp.http.proxyHost=www.somehost.com
systemProp.http.proxyPort=1080
systemProp.https.proxyHost=www.somehost.com
systemProp.https.proxyPort=1080
```

   Make sure to replace the proxy host and port values with your own.

3. If the proxy server requires authentication, also add the following properties:

```
systemProp.http.proxyUser=userId
systemProp.http.proxyPassword=yourPassword
systemProp.https.proxyUser=userId
systemProp.https.proxyPassword=yourPassword
```

Excellent! Your proxy settings are set in your Liferay Workspace's Gradle environment.

Using Maven

1. Open your `~/.m2/settings.xml` file. Create this file if it does not exist.

2. Add the following XML snippet to the file:

```
<?xml version="1.0" encoding="UTF-8"?>
    <settings xmlns="http://maven.apache.org/SETTINGS/1.0.0"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:schemaLocation="http://maven.apache.org/SETTINGS/1.0.0 http://maven.apache.org/xsd/settings-1.0.0.xsd">
        <proxies>
            <proxy>
                <id>httpProxy</id>
                <active>true</active>
                <protocol>http</protocol>
                <host>www.somehost.com</host>
                <port>1080</port>
            </proxy>
            <proxy>
                <id>httpsProxy</id>
                <active>true</active>
                <protocol>https</protocol>
                <host>www.somehost.com</host>
                <port>1080</port>
            </proxy>
        </proxies>
    </settings>
```

Make sure to replace the proxy host and port values with your own.

3. If the proxy server requires authentication, also add the `username` and `password` proxy properties. For example, the HTTP proxy authentication configuration would look like this:

```
<proxy>
  <id>httpProxy</id>
  <active>true</active>
  <protocol>http</protocol>
  <host>www.somehost.com</host>
  <port>1080</port>
  <username>userID</username>
  <password>somePassword</password>
</proxy>
```

Excellent! Your Maven proxy settings are now set.

54.4 Development Lifecycle for a Liferay Workspace

Liferay Workspaces provide an environment that supports all phases of a Liferay module's development lifecycle:

- Creating modules
- Building modules
- Deploying modules
- Testing modules
- Releasing modules

In this tutorial, you'll explore the development lifecycle phases Liferay Workspace provides for you. Then you'll be directed to other tutorials that go into further detail for leveraging the workspace's particular lifecycle phase for a specific tool (e.g., Blade CLI or Liferay @ide@). Let's get started!

Creating Modules

The first step of Liferay Workspace's development phase is the module creation process. Workspace provides a slew of templates that you can use to create many different types of Liferay modules.

You can configure where your workspace creates modules by editing the `liferay.workspace.modules.dir` property in the workspace's `gradle.properties` file. By default, modules are created in the `[ROOT]/modules` folder.

You can also control where themes are generated by specifying the `liferay.workspace.themes.dir` property in the `gradle.properties` file. Themes are typically migrated to the `themes` folder after being created using the Liferay Theme Generator.

To learn more about creating modules in a workspace using Blade CLI or Liferay @ide@, visit the Creating Modules with Blade CLI and Creating Modules with Liferay @ide@ tutorials, respectively.

Building Modules

Liferay Workspace abstracts many build requirements away so you can focus on developing modules instead of worrying about how to build them. Liferay Workspace is built using Gradle, so your modules leverage the Gradle build lifecycle.

Workspace includes a Gradle wrapper in its ROOT folder (e.g., `gradlew`), which you can leverage to execute Gradle commands. This means that you can run familiar Gradle build commands (e.g., `build`, `clean`, `compile`, etc.) from a Liferay Workspace without having Gradle installed on your machine.

Note: You can also use the workspace's Gradle wrapper by executing `blade gw` followed by the Gradle command. This is an easier way to run the workspace's Gradle wrapper without specifying its path. Since the workspace's Gradle wrapper resides in its root folder, it can sometimes be a hassle running it for a deeply nested module (e.g., `../../../../gradlew compileJava`). Running the Gradle wrapper from Blade CLI automatically detects the Gradle wrapper and can run it anywhere.

When using Liferay Workspace, the workspace plugin is automatically applied which adds a multitude of subprojects for you, hiding some complexities of Gradle. For example, a typical project's `settings.gradle` file could contain many included subprojects like this:

```
...
include images:base:oracle-jdk:oracle-jdk-6
include images:base:oracle-jdk:oracle-jdk-7
include images:base:oracle-jdk:oracle-jdk-8
include images:base:liferay-portal:liferay-portal-ce-tomcat-7.0-ga1
include images:source-bundles:glassfish
include images:source-bundles:jboss-eap
include images:source-bundles:tomcat
include images:source-bundles:websphere
include images:source-bundles:wildfly
include compose:jboss-eap-mysql
include compose:tomcat-mariadb
include compose:tomcat-mysql
include compose:tomcat-mysql-elastic
include compose:tomcat-postgres
include file-server
...
```

You don't have to worry about applying these subprojects because the workspace plugin does it for you. Likewise, if a folder in the `/themes` folder includes a `liferay-theme.json` file, the `gulp` plugin is applied to it; if a folder in the `/modules` folder includes a `bnd.bnd` file, the liferay-gradle plugin is applied to it. See the Gradle reference article for a list of Liferay Gradle plugins automatically provided for all Workspace apps. As you can see, Liferay Workspace provides many plugins and build configurations behind the scenes to make your development process convenient.

A good example of the Gradle build lifecycle abstraction is the module deployment process in a workspace. You can build/deploy your modules from workspace without ever running a Gradle command. You'll learn how to do this next.

Deploying Modules

Liferay Workspace provides easy-to-use deployment mechanisms that let you deploy your module to a Liferay server without any custom configuration. To learn more about deploying modules from a workspace using Blade CLI or Liferay @ide@, visit the Deploying Modules with Blade CLI and Deploying Modules with Liferay @ide@ tutorials, respectively.

Testing Modules

Liferay provides many configuration settings for 7.0. Configuring several different Liferay DXP installations to simulate/test certain behaviors can become cumbersome and time consuming. With Liferay Workspace, you can easily organize environment settings and generate an environment installation with those settings.

Liferay Workspace provides the `configs` folder, which lets you configure different environments in the same workspace. For example, you could configure separate Liferay DXP environment settings for development, testing, and production in a single Liferay Workspace. So how does it work?

The `configs` folder offers five subfolders:

- `common`: holds a common configuration that you want applied to all environments.
- `dev`: holds the development configuration.
- `local`: holds the configuration intended for testing locally.
- `prod`: holds the configuration for a production site.
- `uat`: holds the configuration for a UAT site.

You're not limited to just these environments. You can create any subfolder in the `configs` folder (e.g., `aws`, `docker`, etc.) to simulate any environment. Each environment folder can supply its own database, `portal-ext.properties`, Elasticsearch, etc. The files in each folder overlay your Liferay DXP installation, which you generate from within workspace.

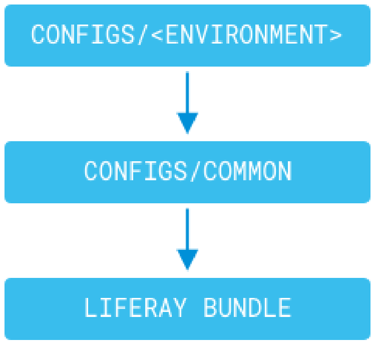


Figure 54.3: The `configs/common` and `configs/[environment]` overlay you Liferay DXP bundle when it's generated.

When workspace generates a Liferay DXP bundle, these things happen:

1. Configuration files found in the `configs/common` folder are applied to the Liferay DXP bundle.
2. The configured workspace environment (`dev`, `local`, `prod`, `uat`, etc.) is applied on top of any existing configurations from the `common` folder.

To generate a Liferay DXP bundle with a specific environment configuration to the workspace's `/bundles` folder, run

```
./gradlew initBundle -Pliferay.workspace.environment=[ENVIRONMENT]

<!-- `blade server init` is not able to pass the environment param in
currently. This new feature is requested in BLADE-343. -Cody -->
```

To generate a distributable Liferay DXP installation to the workspace's `/build` folder, run

```
./gradlew distBundle[Zip|Tar] -Pliferay.workspace.environment=[ENVIRONMENT]
```

The `ENVIRONMENT` variable should match the configuration folder (`dev`, `local`, `prod`, `uat`, etc.) you intend to apply.

Note: You may prefer to set your workspace environment in the `gradle.properties` file instead of passing it via Gradle command. If so, it's recommended to set the workspace envrionment variable inside the `[USER_HOME]/.gradle/gradle.properties` file.

```
liferay.workspace.environment=local
```

The variable is set to `local` by default.

To simulate using the `configs` folder, let's explore a typical scenario. Suppose you want a local Liferay DXP installation for testing and a UAT installation for simulating a production site. Assume you want the following configuration for the two environments:

Local Environment

- Use MySQL database pointing to localhost
- Skip setup wizard

UAT Environment

- Use MySQL database pointing to a live server
- Skip setup wizard

To configure these two environments in your workspace, follow the steps below:

1. Open the `configs/common` folder and add the `portal-setup-wizard.properties` file with the `setup.wizard.enabled=false` property.

2. Open the `configs/local` folder and configure the MySQL database settings for localhost in a `portal-ext.properties` file.

3. Open the `configs/uat` folder and configure the MySQL database settings for the live server in a `portal-ext.properties` file.

4. Now that your two environments are configured, generate one of them:

   ```
   ./gradlew distBundle[Zip|Tar] -Pliferay.workspace.environment=uat
   ```

   You've successfully configured two environments and generated one of them.

Awesome! You can now test various Liferay DXP bundle environments using Liferay Workspace.

Releasing Modules

Liferay Workspace does not provide a built-in release mechanism, but there are easy ways to use external release tools with workspace. The most popular choice is uploading your modules to a Maven Nexus repository. You could also use other release tools like Artifactory.

Uploading modules to a remote repository is useful if you need to share them with other non-workspace projects. Also, if you're ready for your modules to be in the spotlight, uploading them to a public remote repository gives other developers the chance to use them.

For more instructions on how to set up a Maven Nexus repository for your workspace's modules, see the Creating a Maven Repository and Deploying Liferay Maven Artifacts to a Repository tutorials.

54.5 Managing the Target Platform for Liferay Workspace

Liferay Workspace helps you target a specific release of Liferay DXP, so dependencies get resolved properly. This makes upgrades easy: specify your target platform, and Workspace points to the new version. All your dependencies are updated to the latest ones provided in the targeted release.

Note: There are times when configuring dependencies based on a version range is better than tracking exact versions. See the Semantic Versioning tutorial for more details.

Liferay @ide@ 3.2+ helps you streamline targeting a specific version even more. @ide@ can index the configured Liferay DXP source code to

- provide advanced Java search (Open Type and Reference Searching) (tutorial)
- debug Liferay DXP sources (tutorial)

To enable this functionality, set the following property in your workspace's `gradle.properties` file:

```
target.platform.index.sources=true
```

Note: Portal source indexing is disabled in Gradle workspace version 2.0.3+ (Target Platform plugin version 2.0.0+).

These options in @ide@ are only available when developing in a Liferay Workspace, or if you have the Target Platform Gradle plugin applied to your multi-module Gradle project with specific configurations. See the Targeting a Platform Outside of Workspace section for more info on applying the Target Platform Gradle plugin.

Next, you'll discover how all of this is possible.

Dependency Management with BOMs

You can target a version by importing a predefined bill of materials (BOM). This only requires that you specify a property in your workspace's `gradle.properties` file. You'll see how to do this later.

Each Liferay DXP version has a predefined BOM that you can specify for your workspace to reference. Each BOM defines the artifacts and their versions used in the specific release. BOMs list all dependencies in a management fashion, so it doesn't **add** dependencies to your project; it only **provides** your build tool (e.g., Gradle or Maven) the versions needed for the project's defined artifacts. This means you don't need to specify your dependency versions; the BOM automatically defines the appropriate artifact versions based on the BOM.

You can override a BOM's defined artifact version by specifying a different version in your project's `build.gradle`. Artifact versions defined in your project's build files override those specified in the predefined BOM. Note that overriding the BOM can be dangerous; make sure the new version is compatible in the targeted platform.

For more information on BOMs, see the Importing Dependencies section in Maven's official documentation.

Pretty cool, right? Next, you'll step through an example configuration.

Setting the Target Platform

Setting the version to develop for takes two steps:

1. Open the workspace's `gradle.properties` file and set the `liferay.workspace.target.platform.version` property to the version you want to target. For example,

   ```
   liferay.workspace.target.platform.version=7.0.6
   ```

   If you're using Liferay DXP, the versions are specified based on service packs. For example, you could set your target platform workspace Gradle property to

   ```
   liferay.workspace.target.platform.version=7.0.10.7
   ```

   Important: You can leverage the target platform features in Liferay Portal GA6+ and Liferay DXP 7.0 SP7+. Previous versions do not provide these features.

   The versions following the SP7 release of DXP follow fix pack versions (e.g., `7.0.10.fp69`, `7.0.10.fp70`, etc.).

2. Once the target platform is configured, check to make sure no dependencies in your Gradle build files specify a version. The versions are now imported from the configured target platform's BOM. For example, a simple MVC portlet's `build.gradle` may look something like this:

   ```
   dependencies {
       compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel"
       compileOnly group: "com.liferay.portal", name: "com.liferay.util.taglib"
       compileOnly group: "javax.portlet", name: "portlet-api"
       compileOnly group: "javax.servlet", name: "javax.servlet-api"
       compileOnly group: "jstl", name: "jstl"
       compileOnly group: "org.osgi", name: "osgi.cmpn"
   }
   ```

Note: The `liferay.workspace.target.platform.version` property also sets the distro JAR, which can be used in to validate your projects during the build process. See the Validating Modules Against the Target Platform tutorials for more info.

The target platform functionality is available in Liferay Workspace version 1.9.0+. If you have an older version, you must update it to leverage platform targeting. See the Updating Liferay Workspace tutorial to do this.

You now know how to configure a target platform in workspace and how dependencies without versions appear in your Gradle build files. You're all set!

Targeting a Platform Outside of Workspace

If you prefer to not use Liferay Workspace, but still want to target a platform, you must apply the Target Platform Gradle plugin to the root `build.gradle` file of your custom multi-module Gradle build.

To do this, your `build.gradle` file should look similar to this:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.target.platform", version: "1.1.6"
    }
    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.target.platform"

dependencies {
    targetPlatformBoms group: "com.liferay.portal", name: "release.portal.bom", version: "7.0.6"
    targetPlatformBoms group: "com.liferay.portal", name: "release.portal.bom.compile.only", version: "7.0.6"
}
```

Liferay DXP users must replace the artifact names and versions:

- `release.portal.bom` → `release.dxp.bom`
- `release.portal.bom.compile.only` → `release.dxp.bom.compile.only`
- `7.0.6` → `7.0.10.7`

This Gradle code

- applies Liferay's Target Platform Gradle plugin
- configures the repository that provides the necessary artifacts for your project build
- sets the Target Platform plugin's dependencies:
  - `release.portal.bom`: provides all the artifacts included in Liferay DXP.
  - `release.portal.bom.compile.only`: provides artifacts that are not included in Liferay DXP, but are necessary to reference during the build (e.g., `org.osgi.core`).

If you're interested in advanced search and/or debugging Liferay DXP's source using Liferay @ide@, you must also apply the following configuration:

```
targetPlatformIDE {
    includeGroups "com.liferay", "com.liferay.portal"
}
```

This indexes the target platform's source code and makes it available to @ide@.

Now you can define your target platform!

Chapter 55

Validating Modules Against the Target Platform

Important: Validating modules with the `resolve` task is deprecated. It only functions as it's documented here in versions prior to Liferay Workspace (Gradle only) version 2.0.3. It is being redesigned for workspace versions 2.0.3+ and is still in development at this time.

After you write a module in Liferay Workspace, you can validate it before deployment to make sure of several things:

- Will my app deploy successfully?
- Will there be some sort of missing requirement?
- If there's an issue, how do I diagnose it?

These are all common worries that can be frustrating.

Instead of deploying your app and checking for errors in the log, you can validate your app before deployment. This is done by calling Liferay Workspace's `resolve` task, which validates your modules against a targeted platform. Continue on to learn how this works.

55.1 Resolving Your Modules

Deploying your modules only to be met with console errors or mysterious problems can be frustrating. You can avoid this painful process by resolving your modules before deployment. This can be done by calling the `resolve` Gradle task provided by Liferay Workspace.

```
../gradlew resolve
```

This task gathers all the capabilities provided by

- the specified version of Liferay DXP (i.e., targeted platform)
- the current workspace's modules

Some capabilities/information gathered by the `resolve` task that are validated include

- declared required capabilities
- module versions
- package imports/use constraints
- service references

It also computes a list of run requirements for your project. Then it compares the current project's requirements against the gathered capabilities. If your project requires something not available in the gathered list of capabilities, the task fails.

The task can only validate OSGi modules. It does not work with WAR-style projects, themes, or npm portlets.

Note: The `resolve` task can be executed from a specific project folder or from the workspace's root folder. Running the task from the root folder validates all the modules in your workspace.

The `resolve` task can automatically gather the available capabilities from your workspace, but you must specify this for your targeted Liferay DXP version. To do this, open your workspace's `gradle.properties` file and set the `liferay.workspace.target.platform.version` property to the version you want to target. For example,

```
liferay.workspace.target.platform.version=7.0.6
```

If you're using Liferay DXP, the versions are specified based on service packs. For example, you could set your target platform workspace Gradle property to

```
liferay.workspace.target.platform.version=7.0.10.7
```

Important: You can leverage the target platform features in Liferay Portal GA6+ and Liferay DXP 7.0 SP7+. Previous versions do not provide these features.

The versions following the SP7 release of DXP follow service pack versions (e.g., `7.0.10.8` (SP8), `7.0.10.9` (SP9), etc.).

This provides a static *distro* JAR for the specified version of Liferay DXP, which contains all the metadata (i.e., capabilities, packages, versions, etc.) running in that version. The distro JAR is a complete snapshot of everything provided in the OSGi runtime; this serves as the target platform's list of capabilities that your modules are validated against.

You can now validate your module projects before deploying them! Sometimes, you must modify the `resolve` task's default behavior to successfully validate your app. See the Modifying the Target Platform's Capabilities tutorial for more information. For help resolving common output errors printed by the `resolve` task, see the Resolving Common Output Errors Reported by the resolve Task article.

55.2 Modifying the Target Platform's Capabilities

In a perfect world, everything the `resolve` task gathers and checks against would work during your development process. Unfortunately, there are exceptions that may force you to modify the default functionality of the `resolve` task. If you're unfamiliar with workspace's `resolve` task, see the Resolving Your Modules tutorial for more information.

There are two scenarios you may run into during development that require a modification for your project to pass the resolver check.

- You're depending on a third party library that is not available in the targeted Liferay DXP instance or the current workspace.

- You're depending on a customized distribution of Liferay DXP.

You'll explore these use cases next.

Depending on Third Party Libraries Not Included in Liferay DXP

The `resolve` task, by default, gathers all of Liferay DXP's capabilities and the capabilities of your workspace's modules. What if, however, your module depends on a third party project that is not included in either space (e.g., Google Guava)?. The `resolve` task fails by default if your project depends on this project type. You probably plan to have this project deployed and available at runtime, so it's not a concern, but the resolver doesn't know that; you must customize the resolver to bypass this.

There are three ways you can do this:

- Embed the third party library in your module
- Add the third party library's capabilities to the current static set of resolver capabilities
- Skip the resolving process for your module

For help resolving third party dependency errors, see the Resolving Third Party Library Package Dependencies tutorial.

Embed the Third Party Library in Your Module

If you only have one module that depends on the third party project, you can bypass the resolver failure by embedding the JAR in your module. This is not a best practice if more than one project in the OSGi container depends on that module. See the Embedding Libraries in a Module

section for more details.

Add the Third Party Library's Capabilities to the Current Static Set of Resolver Capabilities

You can add your third party dependencies to the target platform's default list of capabilities by listing them as provided modules. Do this by adding the following Gradle code into your workspace's root `build.gradle` file:

```
dependencies {
    providedModules group: "GROUP_ID", name: "NAME", version: "VERSION"
}
```

For example, if you wanted to add Google Guava as a provided module, it would look like this:

```
dependencies {
    providedModules group: "com.google.guava", name: "guava", version: "23.0"
}
```

This both provides the third party dependency to the resolver, and it downloads and includes it in your Liferay DXP bundle's `osgi/modules` folder when you initialize it (e.g., `blade server init`).

Skip the Resolving Process for Your Module

It may be easiest to skip validating a particular module during the resolve process. To do this, open your workspace's root `build.gradle` file and insert the following Gradle code at the bottom of the file:

```
targetPlatform {
    resolveOnlyIf { project ->
        project.name ≠ 'PROJECT_NAME'
    }
}
```

Be sure to replace the `PROJECT_NAME` filler with your module's name (e.g., `test-api`).

If you prefer to disable the Target Platform plugin altogether, you can add a slightly different directive to your `build.gradle` file:

```
targetPlatform {
    onlyIf { project ->
        project.name ≠ 'PROJECT_NAME'
    }
}
```

This both skips the `resolve` task execution and disables BOM dependency management.

Now the `resolve` task skips your module project.

Depending on a Customized Distribution of Liferay DXP

There are times when manually specifying your project's list of dependent JARs does not suffice. If your app requires a customized Liferay DXP instance to run, you must regenerate the target platform's default list of capabilities with an updated list. Two examples of a customized Liferay DXP instance are described below:

Example 1: Leveraging an External Feature

There are many external features/frameworks available that are not included in the downloadable bundle by default. After deploying a feature/framework, it's available for your module projects to leverage. When validating your app, however, the `resolve` task does not have access to external capabilities not included by default. For example, Audience Targeting is an example of this type of external framework. If you're creating a Liferay Audience Targeting rule that depends on the Audience Targeting framework, you can't easily provide a slew of JARs for your module. In this case, you should install the platform your code depends on and regenerate an updated list of capabilities that your Liferay DXP instance provides.

Example 2: Leveraging a Customized Core Feature

You can extend Liferay DXP's core features to provide a customized experience for your intended audience. Once deployed, you can assume these customizations are present and build other things on top of them. The new capabilities resulting from your customizations are not available, however, in the target platform's default list of capabilities. Therefore, when your application relies on non-default capabilities, it fails during the `resolve` task. To get around this, you must regenerate a new list of capabilities that your customized Liferay DXP instance provides.

To regenerate the target platform's capabilities (distro JAR) based on the current workspace's Liferay DXP instance, follow the steps below:

1. Start the Liferay DXP instance stored in your workspace. Make sure the platform you want to depend on is installed.

2. Download the BND Remote Agent JAR file and copy it into the `osgi/modules` folder.

3. From the root folder of your workspace, run the following command:

```
bnd remote distro -o custom_distro.jar release.portal.distro 7.0.6
```

Liferay DXP users must replace the `release.portal.distro` artifact name with `release.dxp.distro` and use the `7.0.10.7` version syntax.

This connects to the newly deployed BND agent running in Liferay DXP and generates a new distro JAR named `custom_distro.jar`. All other capabilities inherit their functionality based on your Liferay DXP instance, so verify the workspace bundle is the version you plan to release in production.

4. Navigate to your workspace's root `build.gradle` file and add the following dependency:

```
dependencies {
    targetPlatformDistro files('custom_distro.jar')
}
```

Now your workspace is pointing to a custom distro JAR file instead of the default one provided. Run the `resolve` task to validate your modules against the new set of capabilities.

55.3 Including the Resolver in Your Gradle Build

By default, Liferay Workspace provides the `resolve` task as an independent executable. It's provided by the Target Platform Gradle plugin and is not integrated in any other Gradle processes. This gives you control over your Gradle build without imposing strategies you may not want included in your default build process.

With that said, the `resolve` task can be useful to include in your build process if you want to check for errors in your module projects before deployment. Instead of resolving your projects separately from your standard build, you can build and resolve them all in one shot.

In Liferay Workspace, the recommended path for doing this is adding it to the default `check` Gradle task. The `check` task is provided by default in a workspace by the Java plugin. Adding the `resolve` task to the `check` lifecycle task also promotes the `resolve` task to run for CI and other test tools that typically run the `check` task for verification. Of course, Gradle's `build` task also depends on the `check` task, so you can run `gradlew build` and run the resolver too.

To call the `resolve` task during the `check` task automatically, open your workspace's root `build.gradle` file and add the following directive:

```
check.dependsOn resolve
```

You can also configure this for specific projects in a workspace if you don't want all modules to be included in the global `check`.

If the `resolve` task runs during every Gradle build, you may want to prevent the build from failing if there are errors reported by the resolver. To do this, open your workspace's root `build.gradle` file and add the following code:

```
targetPlatform {
    ignoreResolveFailures = true
}
```

This reports the failures without failing the build. Note, this can only be configured in the workspace's root `build.gradle` file.

Awesome! You can now run the `resolve` task in your current Gradle lifecycle.

55.4 Validating Modules Outside of Workspace

If you prefer to not use Liferay Workspace, but still want to validate modules against a target platform, you must apply the Target Platform Gradle plugin to the root `build.gradle` file of your multi-module Gradle build. Follow the Targeting a Platform Outside of Workspace section to do this.

Once you have the Target Platform plugin and its BOM dependencies configured, you must configure the `targetPlatformDistro` dependency. Open your project's root `build.gradle` file and add it to the list of dependencies. It should look like this:

```
dependencies {
    targetPlatformBoms group: "com.liferay.portal", name: "release.portal.bom", version: "7.0.6"
    targetPlatformBoms group: "com.liferay.portal", name: "release.portal.bom.compile.only", version: "7.0.6"
    targetPlatformDistro group: "com.liferay.portal", name "release.portal.distro", version: "7.0.6"
}

Liferay DXP users must replace the artifact names and versions:

- `release.portal.bom` &rarr; `release.dxp.bom`
- `release.portal.bom.compile.only` &rarr; `release.dxp.bom.compile.only`
- `release.portal.distro` &rarr; `release.dxp.distro`
- `7.0.6` &rarr; `7.0.10.7`
```

Now you can validate your modules against a target platform!

55.5 Updating Liferay Workspace

Liferay Workspace is continuously being updated with new features. If you created your Workspace a while ago, you may be missing out on some of the latest features that could improve your Liferay development experience. Updating your Liferay Workspace is easy; you'll learn how to do it next.

1. Find the latest Liferay Workspace version. To do this, open the Liferay Gradle Plugins Workspace Change Log and copy the version to which you want to upgrade. You can find the updates and new features associated with each version by browsing the change log too.

2. Open your Liferay Workspace's `settings.gradle` file. This file resides in your Workspace's root folder.

3. In the `dependencies` block, you'll find code similar to below:

   ```
   dependencies {
       classpath group: "com.liferay", name: "com.liferay.gradle.plugins.workspace", version: "[WORKSPACE_VERSION]"
   }
   ```

   Update the `com.liferay.gradle.plugins.workspace` dependency's `version` to the version number you copied from the change log in step 1.

4. Execute any Gradle command to initiate the update process for your Workspace (e.g., `blade gw tasks`).

Awesome! You learned where to check for Liferay Workspace's latest version, how to update your Workspace to that version, and how to initiate the update process.

Chapter 56

Maven

Maven is a viable option for managing Liferay projects if you don't want to use Liferay's default Gradle management system. Liferay provides several Maven plugins to let you generate and manage your project. Liferay also provides Maven artifacts that are easy to obtain and are required for Liferay Maven module development. In the Maven tutorials, you'll learn how to

- Install Liferay Maven artifacts.
- Generate Liferay projects using Maven archetypes.
- Create a Module JAR using Maven.
- Deploy a module built with Maven to Liferay DXP.
- Create a remote repository for Maven projects.
- Deploy a Maven project to a remote repository.
- Use Service Builder in a Maven project.
- Compile Sass files in a Maven project.
- Build a Liferay theme in a Maven project.
- Leverage the Maven Workspace.

Because Liferay DXP is tool agnostic, Maven is fully supported for Liferay DXP development. Read on to learn more!

56.1 Installing Liferay Maven Artifacts

To create Liferay modules using Maven, you'll need the archives required by Liferay (e.g., JAR and WAR files). This isn't a problem–Liferay provides them as Maven artifacts. You can retrieve them from a remote repository.

There are two repositories that contain Liferay artifacts: Central Repository and Liferay Repository. The Central Repository is the default repository used to download artifacts if you don't have a remote repository configured. The Central Repository *usually* offers the latest Liferay Maven artifacts, but using the the Liferay Repository *guarantees* the latest artifacts released by Liferay. Other than a slight delay between artifact releases between the two repositories, they're identical. You'll learn how to reference both of them next.

Using the Central Repository to install Liferay Maven artifacts only requires that you specify your module's dependencies in its `pom.xml` file. For example, the snippet below sets a dependency on Liferay's `com.liferay.portal.kernel` artifact:

```
<dependencies>
    <dependency>
        <groupId>com.liferay.portal</groupId>
        <artifactId>com.liferay.portal.kernel</artifactId>
        <version>2.0.0</version>
        <scope>provided</scope>
    </dependency>
    ...
</dependencies>
```

When packaging your module, the automatic Maven artifact installation process only downloads the artifacts necessary for that module from the Central Repository.

You can view the published Liferay Maven artifacts on the Central Repository by searching for *liferay maven* in the repo's Search bar. For convenience, you can reference the available artifacts at http://search.maven.org/#search|ga|1|liferay maven. Use the Latest Version column as a guide to see what's available for the intended version of Liferay DXP for which you're developing.

If you'd like to access Liferay's latest Maven artifacts, you can configure Maven to use Liferay's Nexus repository instead by inserting the following snippet in your project's parent `pom.xml`:

```
<repositories>
    <repository>
        <id>liferay-public-releases</id>
        <name>Liferay Public Releases</name>
        <url>https://repository.liferay.com/nexus/content/repositories/liferay-public-releases</url>
    </repository>
</repositories>

<pluginRepositories>
    <pluginRepository>
        <id>liferay-public-releases</id>
        <url>https://repository.liferay.com/nexus/content/repositories/liferay-public-releases/</url>
    </pluginRepository>
</pluginRepositories>
```

The above configuration retrieves artifacts from Liferay's release repository.

Note: Liferay also provides a snapshot repository that you can access by modifying the `<id>`, `<name>`, and `<url>` tags to point to that repo. This repository should only be used in special cases. You'll also need to enable accessing the snapshot artifacts:

```
 <snapshots>
     <enabled>true</enabled>
 </snapshots>
```

If you've configured the Liferay Nexus repository to access Liferay Maven artifacts and you've already been syncing from the Central Repository, you may need to clear out parts of your local repository to force Maven to re-download the newer artifacts. Also, do not leave the Liferay repository configured when publishing artifacts to Maven Central. You must comment out the Liferay Repository credentials when publishing your artifacts.

The Liferay Maven repository offers a good alternative for those who want the most up-to-date Maven artifacts produced by Liferay.

Congratulations! You've downloaded the Liferay artifacts and installed them to your chosen repository.

56.2 Generating New Projects Using Archetypes

Creating Maven projects from scratch can be a lot of work. What dependencies does my Liferay portlet project need? What does a Liferay Maven Service Builder project look like? How do I create a Liferay Maven-based context contributor? These questions can be answered with three words: Liferay Maven Archetypes.

Liferay provides a slew of Maven archetypes for easy Liferay module projects. In this tutorial, you'll learn how to use Liferay's Maven archetypes to generate your module project.

At the time of this writing, Liferay provides just under 40 Maven archetypes for you to use; expect this number to continue growing! These archetypes are generated from the Central Repository, unless you've configured for them to be generated from another remote repository (e.g., Liferay Repository. You can view the Liferay-provided Maven archetypes by running the following command:

```
mvn archetype:generate -Dfilter=liferay
```

The generated archetypes are not all intended for the latest Liferay DXP release. Some are intended for earlier versions of Liferay Portal (e.g., 6.2, 6.1, etc.). An easy way to tell if the archetype is compatible with 7.0 is by inspecting the archetype's package name. Archetypes with the `com.liferay.maven.archetypes` prefix are legacy archetypes. Those prefixed with `com.liferay.project.templates.[TYPE]` or `com.liferay.faces.archetype:[TYPE]` are compatible with 7.0.

Here's a brief list of some popular Maven archetypes provided by Liferay:

- Activator
- Context Contributor
- Liferay Faces portlets
  - Alloy
  - ICEfaces
  - JSF
  - PrimeFaces
  - RichFaces
- MVC Portlet
- Panel App
- Portlet Provider
- Service Builder
- Service Wrapper
- Vaadin Liferay portlet

For documentation on the archetypes (project templates) compatible with 7.0, see the Project Templates reference section. Visit Maven's Archetype Generation documentation for further details on how to modify the Maven archetype generation process.

Note: If you're creating a JSF portlet using Liferay Faces, you can find example archetype declarations for JSF component suites at http://www.liferayfaces.org.

Here's an example that creates a Liferay MVC portlet using its Liferay Maven archetype.

1. On the command line, navigate to where you want your Maven project. Run the Maven archetype generation command filtered for Liferay archetypes only:

```
mvn archetype:generate -Dfilter=liferay
```

2. Select the `com.liferay.project.templates.mvc.portlet` archetype by choosing its corresponding number (e.g., `8`).

   In most cases, you should choose the latest archetype version. The archetype versions provided are compatible with all 7.x versions of Liferay DXP.

3. Depending on the Maven archetype you selected, you're given a set of archetype options to fill out for your Maven project. For the MVC portlet archetype, you could use these properties:

   - `groupId`: `com.liferay`
   - `artifactId`: `com.liferay.project.templates.mvc.portlet`
   - `version`: `1.0.0`
   - `package`: `com.liferay.docs`
   - `className`: `SampleMVC`

   Once you've filled out the required property values, you're given a summary of the properties configuration you defined. Enter `Y` to confirm your project's configuration.

Your Maven project is generated and available from the folder for which you ran the archetype generation command. If you have an existing parent `pom.xml` file in that folder, your module project is automatically accounted for there:

```
<modules>
    ...
    <module>com.liferay.project.templates.mvc.portlet</module>
</modules>
```

The Liferay Maven archetypes generate deployable Liferay module projects, but they're bare bones and likely require further customizations.

If you want to generate a quick foundation for a Liferay module built with Maven, using Liferay Maven archetypes is your best option.

56.3 Creating a Module JAR Using Maven

If you have an existing Liferay module built with Maven that you created from scratch, or you're upgrading your Maven project from a previous version of Liferay, your project probably can't generate an executable OSGi JAR. Don't fret! You can do this by making a few minor configurations in your module's POMs.

Note: If you used Liferay's Maven archetypes to generate your module project, the project already has the Maven plugins required to generate an OSGi JAR.

Continue on to see how this is done.

1. In your project's `pom.xml` file, add the BND Maven Plugin declaration:

```
<plugin>
    <groupId>biz.aQute.bnd</groupId>
    <artifactId>bnd-maven-plugin</artifactId>
    <version>3.3.0</version>
    <executions>
        <execution>
            <goals>
                <goal>bnd-process</goal>
            </goals>
        </execution>
    </executions>
</plugin>
```

The BND Maven plugin prepares all your Maven module's resources (e.g., `MANIFEST.MF`) and inserts them into the generated `[Maven Project]/target/classes` folder. This plugin prepares your module to be packaged as an OSGi JAR deployable to Liferay DXP.

```
**Note:** Although WABs can be generated using the `bnd-maven-plugin`, this
is not supported by Liferay. WABs should be created as a standard WAR
project and deployed to the
[Liferay WAB Generator](/docs/7-0/tutorials/-/knowledge_base/t/using-the-wab-generator),
which generates a WAB for you.
```

---

2. In your project's `pom.xml` file, add the Maven JAR Plugin declaration:

```
<build>
    <plugins>
        <plugin>
            <groupId>org.apache.maven.plugins</groupId>
            <artifactId>maven-jar-plugin</artifactId>
            <version>2.6</version>
            <configuration>
                <archive>
                    <manifestFile>${project.build.outputDirectory}/META-INF/MANIFEST.MF</manifestFile>
                </archive>
            </configuration>
        </plugin>
    </plugins>
</build>
```

The Maven JAR plugin builds your Maven project as a JAR file, including the resources generated by the BND Maven plugin. The above configuration also sets the default project `MANIFEST.MF` file path for your project, which is essential when packaging your module using the BND Maven plugin. By default, the Maven JAR Plugin ignores the `target/classes/META-INF/MANIFEST.MF` generated by the BND Maven plugin, so you must explicitly set it as the manifest file so it's included properly in the generated JAR file.

3. Make sure you've added a `bnd.bnd` file to your Liferay Maven project, residing in the same folder as your project's `pom.xml` file.

4. Build your Maven OSGi JAR by running

```
mvn package
```

Your Maven JAR is generated in your project's /target folder. You can deploy it manually into Liferay DXP's /deploy folder, or you can configure your project to deploy automatically to Liferay DXP by following the Deploying a Module Built with Maven to Liferay DXP tutorial.

Fantastic! You've configured your Liferay Maven project to package itself into a deployable OSGi module.

56.4 Deploying a Module Built with Maven to Liferay DXP

There are two ways to deploy a Maven-built Liferay module:

1. Copy your generated Maven module JAR to your Liferay DXP instance's /deploy folder.
2. Configure your Maven project to deploy to the Liferay DXP instance automatically by running a Maven command via the command prompt.

Although manually copying your module JAR for deployment is a viable option, this is an inefficient way to deploy your projects. With a small configuration in your Maven POMs, you can deploy a module to Liferay DXP with one command execution.

In previous versions of Liferay Portal, you were able to execute the liferay:deploy command to deploy your configured Maven project to a Liferay server. This is no longer possible since the liferay-maven-plugin is not applied to Maven projects built from Liferay archetypes.

A prerequisite for this tutorial is to have your project configured to generate an OSGi module JAR; if you haven't done this, visit the Creating a Module JAR Using Maven tutorial for more information.

1. Add the following plugin configuration to your Liferay Maven project's parent pom.xml file.

```
<build>
    <plugins>
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.bundle.support</artifactId>
            <version>2.0.1</version>
            <executions>
                <execution>
                    <id>default-deploy</id>
                    <goals>
                        <goal>deploy</goal>
                    </goals>
                    <phase>pre-integration-test</phase>
                </execution>
            </executions>
        </plugin>
    </plugins>
</build>
```

   This POM configuration applies Liferay's Bundle Support plugin by defining its groupId, artifactId, and version. You can learn more about this plugin in the Maven Workspace tutorial. The logic also defines the executions tag, which configures the Bundle Support plugin to run during the pre-integration-test phase of your Maven project's build lifecycle. The deploy goal is defined for that lifecycle phase.

2. By default, the Bundle Support plugin deploys to the Liferay installation in the bundles folder, located in your plugin's parent folder. If you do not have your project set up this way, you must define your Liferay home folder in your POM. You can do this by adding the following logic within the plugin tags, but outside of the execution tags:

```
<configuration>
    <liferayHome>LIFERAY_HOME_PATH</liferayHome>
</configuration>
```

An example configuration would look like this:

```
<configuration>
    <liferayHome>C:/liferay/liferay-ce-portal-7.0-ga7</liferayHome>
</configuration>
```

```
**Note:** Maven applications built for previous Liferay Portal versions
required the `<liferay.maven.plugin.version>` tag to do various tasks (e.g.,
deploying to a Liferay server). This tag is not needed since the old
`liferay-maven-plugin` is no longer used.
```

---

3. Run this command to deploy your project:

   ```
   mvn verify
   ```

That's it! Your Liferay Maven project is built and deployed automatically to your Liferay DXP instance.

56.5 Creating a Maven Repository

You'll frequently want to share Liferay artifacts and modules with teammates or manage your repositories using a GUI. Sonatype Nexus is a valuable tool for managing your repositories. It's a Maven repository management server that facilitates creating and managing release servers, snapshot servers, and proxy servers. There are several other Maven repository management servers you can use (for example, Artifactory), but this tutorial focuses on Nexus.

To create a Maven repository using Nexus, download Nexus and follow the instructions at http://books.sonatype.com/nexus-book/reference/install.html to install and start it.

To create your own repository using Nexus, follow these steps:

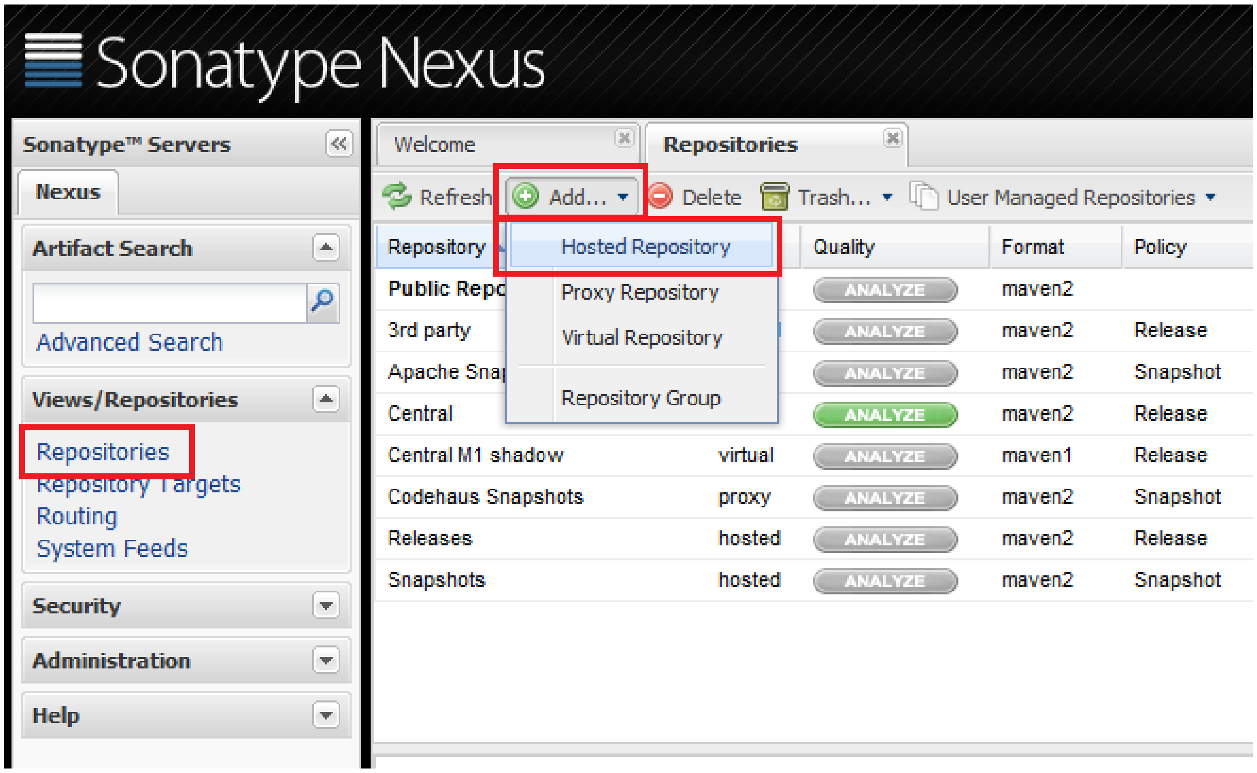
1. Open your web browser; navigate to your Nexus repository server (e.g., http://localhost:8081/nexus) and log in. The default user name is `admin` with password `admin123`.

2. Click on *Repositories* and navigate to *Add...* → *Hosted Repository*.

   To learn more about each type of Nexus repository, read Sonatype's Managing Repositories guide.

3. Enter repository properties appropriate for the type of artifacts it will hold. If you're installing release version artifacts into the repository, specify *Release* as the repository policy. Below are example repository property values:

   - **Repository ID:** *liferay-releases*
   - **Repository Name:** *Liferay Release Repository*
   - **Provider:** *Maven2*
   - **Repository Policy:** *Release*



Repository		Quality	Format	Policy
Public Repo		ANALYZE	maven2	
3rd party		ANALYZE	maven2	Release
Apache Snap		ANALYZE	maven2	Snapshot
Central		ANALYZE	maven2	Release
Central M1 shadow	virtual	ANALYZE	maven1	Release
Codehaus Snapshots	proxy	ANALYZE	maven2	Snapshot
Releases	hosted	ANALYZE	maven2	Release
Snapshots	hosted	ANALYZE	maven2	Snapshot

Figure 56.1: Adding a repository to hold your Liferay artifacts is easy with Nexus.

4. Click *Save*.

You just created a Liferay Maven repository accessible from your Nexus repository server! Congratulations!

It's also useful to create a Maven repository to hold snapshots of each Liferay module you create. Creating a snapshot repository is almost identical to creating a release repository. The only difference is that you specify *Snapshot* as its repository policy. For example, examine an example snapshot repository's property values:

- **Repository ID:** *liferay-snapshots*
- **Repository Name:** *Liferay Snapshot Repository*
- **Provider:** *Maven2*
- **Repository Policy:** *Snapshot*

Voila! You've created a repository for your Liferay releases (i.e., `liferay-releases`) and Liferay snapshots (i.e., `liferay-snapshots`). To learn how to deploy your Liferay Maven artifacts to a Nexus repository, see the Deploying Liferay Maven Artifacts to a Repository tutorial.

Next, you'll configure your new repository servers in your Maven settings to install artifacts to them.

Configuring Local Maven Settings

Before using your repository servers, you must specify them in your Maven environment settings. Your repository settings let Maven find the repository and retrieve and install artifacts. You can configure your local Maven settings in the `[USER_HOME]/.m2/settings.xml` file.

You only need to configure a repository server if you're sharing artifacts (e.g., Liferay artifacts and/or your modules) with others. If you're automatically installing Liferay artifacts from the Central/Liferay Repository and aren't interested in sharing artifacts, you don't need a repository server specified in your Maven settings. You can find out more about installing artifacts from the Central Repository or Liferay's own Nexus repository in the Installing Liferay Maven Artifacts tutorial.

To configure your Maven environment to access your `liferay-releases` and `liferay-snapshots` repository servers, do the following:

1. Navigate to your `[USER_HOME]/.m2/settings.xml` file. Create it if it doesn't yet exist.

2. Provide settings for your repository servers. Here are contents from a `settings.xml` file that has `liferay-releases` and `liferay-snapshots` repository servers configured:

```
<?xml version="1.0"?>
<settings>
    <servers>
        <server>
            <id>liferay-releases</id>
            <username>admin</username>
            <password>admin123</password>
        </server>
        <server>
            <id>liferay-snapshots</id>
            <username>admin</username>
            <password>admin123</password>
        </server>
    </servers>
</settings>
```

The user name `admin` and password `admin123` are the credentials of the default Nexus administrator account. If you changed these credentials for your Nexus server, make sure to update `settings.xml` with these changes.

Now that your repositories are configured, they're ready to receive all the Liferay Maven artifacts you'll download and the Liferay module artifacts you'll create!

56.6 Deploying Liferay Maven Artifacts to a Repository

Deploying artifacts to a remote repository is important if you intend to share your Maven projects with others. First, you must have a remote repository that can hold deployed Maven artifacts. If you do not currently have a remote repository, see the Creating a Maven Repository tutorial to learn how you can set up a Nexus repository. Also make sure your `[USER_HOME]/.m2/settings.xml` file specifies your remote repository's ID, user name, and password.

To deploy to a remote repository, your Liferay module should be packaged using Maven. Maven provides a packaging command that creates an artifact (JAR) that can be easily deployed to your remote repository. You'll learn how to do this with a Liferay portlet module.

Once you've created a deployable artifact, you'll configure your module project to communicate with your remote repository and use Maven's deploy command to send it on its way. Once your module project resides on the remote repository, other developers can configure your remote repository in their projects and set dependencies in their project POMs to reference it.

To follow this tutorial, you'll need a Liferay module built with Maven. For demonstration purposes, this tutorial uses the `portlet.ds` sample module project. To follow along with this module, download the portlet.ds ZIP.

1. Create a folder anywhere on your machine to serve as the parent folder for your Liferay modules. Unzip the `portlet.ds` module project into that folder.

2. Create a `pom.xml` file inside this folder. Copy the following logic into the parent POM:

```
<?xml version="1.0" encoding="UTF-8"?>
<project
    xmlns="http://maven.apache.org/POM/4.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd"
>

    <modelVersion>4.0.0</modelVersion>
    <groupId>liferay.sample</groupId>
    <artifactId>liferay.sample.maven</artifactId>
    <version>1.0.0</version>
    <name>Liferay Maven Module Projects</name>
    <packaging>pom</packaging>

    <distributionManagement>
        <repository>
            <id>liferay-releases</id>
            <url>http://localhost:8081/nexus/content/repositories/liferay-releases</url>
        </repository>
    </distributionManagement>

    <modules>
        <module>portlet.ds</module>
    </modules>
</project>
```

   The tags `<modelVersion>` through `<packaging>` are POM tags that are used frequently in parent POMs. Visit Maven's POM Reference documentation for more information.

   The `<distributionManagement>` tag specifies the deployment repository for all module projects residing in the parent folder. You should include the repository's ID and URL. The above `distributionManagement` declaration is configured for the Liferay Nexus repository created in the Creating a Maven Repository tutorial. That tutorial also created the `[USER_HOME]/.m2/settings.xml`, which specified the remote repository's ID, user name, and password. Both the parent POM and `settings.xml` file's repository declarations are required to deploy your modules to that remote repository.

   Finally, you must list the modules residing in the parent folder that you want deployed using the `<modules>` tag. The `portlet.ds` module is specified within that tag.

3. Open the `portlet.ds` module's `pom.xml` file. If you did not download the `portlet.ds` module project Zip, you can reference its POM below.

```
<project
    xmlns="http://maven.apache.org/POM/4.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd"
>

    <modelVersion>4.0.0</modelVersion>
    <artifactId>portlet.ds</artifactId>
    <version>1.0.0</version>
    <packaging>jar</packaging>

    <parent>
        <groupId>liferay.sample</groupId>
        <artifactId>liferay.sample.maven</artifactId>
        <version>1.0.0</version>
        <relativePath>../pom.xml</relativePath>
    </parent>

    <dependencies>
        <dependency>
            <groupId>javax.portlet</groupId>
            <artifactId>portlet-api</artifactId>
            <version>2.0</version>
            <scope>provided</scope>
        </dependency>
        <dependency>
            <groupId>org.osgi</groupId>
            <artifactId>org.osgi.service.component.annotations</artifactId>
            <version>1.3.0</version>
            <scope>provided</scope>
        </dependency>
    </dependencies>
</project>
```

The `portlet.ds` module's POM specifies its own attributes first, followed by the parent POM's attributes. Declaring the `<parent>` tag like above links the `portlet.ds` module to its parent POM, which is necessary to deploy to the remote repository. Then the module's dependencies are listed. These dependencies are downloaded from the Central Repository and installed to your local `.m2` repository when you package the `portlet.ds` module.

4. Now that you've configured your parent POM and module POM, package your Maven project. Navigate to your module project (e.g., `project.ds`) in your command prompt and run the Maven package command:

   ```
   mvn package
   ```

   This downloads and installs all your module's dependencies and packages the project into a JAR file. Navigate to your module project's generated build folder (e.g., `/target`). You'll notice there is a newly generated JAR file. This is the artifact you'll deploy to your Nexus repository.

5. Run Maven's deploy command to deploy your module project's artifact to your configured remote repository.

   ```
   mvn deploy
   ```

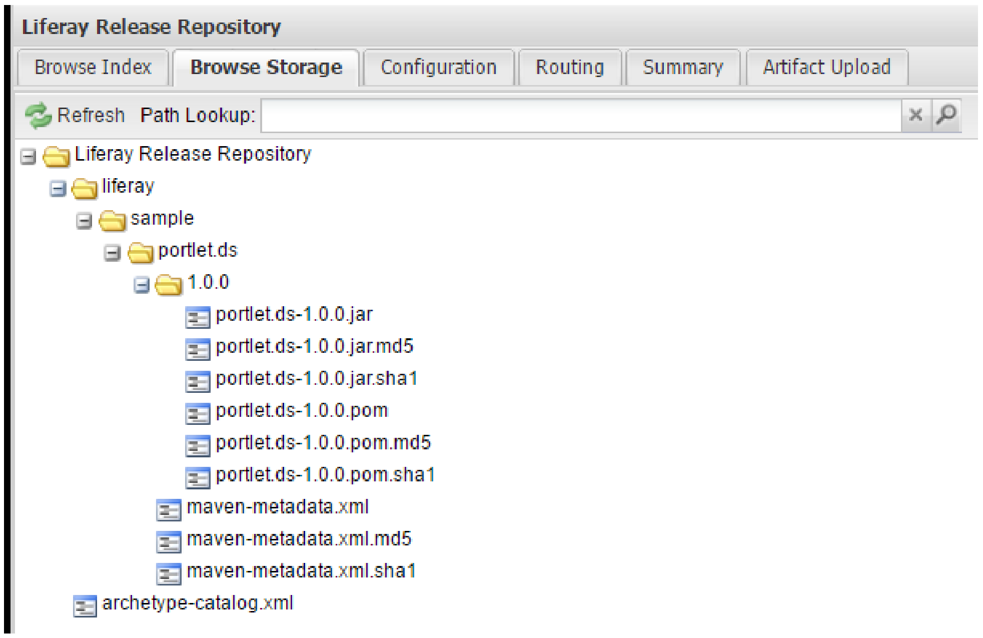
   Your console shows output from the artifact being deployed into your repository server.

To verify that your artifact is deployed, navigate to the Repositories page of your Nexus server and select your repository. A window appears below showing the Liferay artifact now deployed to your repository.

Awesome! You can now share your Liferay module projects with anyone by deploying them as artifacts to a remote repository!

56.7 Using Service Builder in a Maven Project

Liferay's Service Builder is a model-driven service generation tool that is frequently used by many Liferay module projects. If you have a Liferay Maven project, you may be wondering if Service Builder works with your Maven modules; the answer is a resounding yes!



Liferay Release Repository

Browse Index | Browse Storage | Configuration | Routing | Summary | Artifact Upload

Refresh Path Lookup:

```
Liferay Release Repository
    liferay
        sample
            portlet.ds
                1.0.0
                    portlet.ds-1.0.0.jar
                    portlet.ds-1.0.0.jar.md5
                    portlet.ds-1.0.0.jar.sha1
                    portlet.ds-1.0.0.pom
                    portlet.ds-1.0.0.pom.md5
                    portlet.ds-1.0.0.pom.sha1
                maven-metadata.xml
                maven-metadata.xml.md5
                maven-metadata.xml.sha1
    archetype-catalog.xml
```

Figure 56.2: Your repository server now provides access to your Liferay Maven artifacts.

The easiest way to add Service Builder to your Maven project is to create a new Maven project using Liferay's provided Service Builder archetype. You can learn how to generate a Service Builder Maven project by visiting the Service Builder Template tutorial. In some cases, this may not be possible due to a number of reasons:

- You're updating a legacy Maven project to follow OSGi modular architecture.
- You have a pre-existing modular Maven project and don't want to start over.

Time to get started!

1. Apply the Service Builder plugin in your Maven project's `pom.xml` file:

```
<build>
    <plugins>
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.service.builder</artifactId>
            <version>1.0.174</version>
            <configuration>
                <apiDirName>../blade.servicebuilder.api/src/main/java</apiDirName>
                <autoImportDefaultReferences>true</autoImportDefaultReferences>
                <autoNamespaceTables>true</autoNamespaceTables>
                <buildNumberIncrement>true</buildNumberIncrement>
                <hbmFileName>src/main/resources/META-INF/module-hbm.xml</hbmFileName>
                <implDirName>src/main/java</implDirName>
                <inputFileName>service.xml</inputFileName>
                <mergeModelHintsConfigs>src/main/resources/META-INF/portlet-model-hints.xml</mergeModelHintsConfigs>
                <modelHintsFileName>src/main/resources/META-INF/portlet-model-hints.xml</modelHintsFileName>
                <osgiModule>true</osgiModule>
                <propsUtil>com.liferay.blade.samples.servicebuilder.service.util.PropsUtil</propsUtil>
                <resourcesDirName>src/main/resources</resourcesDirName>
                <springFileName>src/main/resources/META-INF/spring/module-spring.xml</springFileName>
                <springNamespaces>beans,osgi</springNamespaces>
                <sqlDirName>src/main/resources/META-INF/sql</sqlDirName>
                <sqlFileName>tables.sql</sqlFileName>
                <testDirName>src/main/test</testDirName>
            </configuration>
        </plugin>
    </plugins>
</build>
```

Service Builder is applied by specifying its `groupId`, `artifactId`, and `version`. The `configuration` tag used above is an example of what a Service Builder project's configuration could look like. All the configuration attributes above should be modified to fit your project.

The above code configures Service Builder for a `blade.servicebuilder.svc` module. When running Service Builder with this configuration, the project's API classes are generated in the `blade.servicebuilder.api` module's `src/main/java` folder. You can also specify your hibernate module mappings, implementation directory name, model hints file, Spring configurations, SQL configurations, etc. You can reference all the configurable Service Builder properties in the Service Builder with Maven reference article. Also, visit the Defining an Object-Relational Map with Service Builder tutorial for more information on defining a `service.xml` file to configure Service Builder.

2. Apply the WSDD Builder plugin declaration directly after the Service Builder plugin declaration:

```
<plugin>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.portal.tools.wsdd.builder</artifactId>
    <version>1.0.8</version>
    <configuration>
        <inputFileName>service.xml</inputFileName>
        <outputDirName>src/main/java</outputDirName>
        <serverConfigFileName>src/main/resources/server-config.wsdd</serverConfigFileName>
    </configuration>
</plugin>
```

The WSDD Builder is necessary to generate your project's remote services. Visit the Creating Remote Services tutorial for more information on WSDD (Web Service Deployment Descriptor). Similar to the Service Builder configuration, the `service.xml` file is set to define your project's remote services. Also, the `outputDirName` defines where the `*_deploy.wsdd` and `*_undeploy.wsdd` files are generated. Make sure to define your `server-config.wsdd` file, as well.

Terrific! You've successfully configured your Maven project to use Service Builder by applying the `com.liferay.portal.tools.service.builder` and `com.liferay.portal.tools.wsdd.builder` plugins in your project's POM. To run Service Builder, see the Running Service Builder and Understanding the Generated Code tutorial for instructions.

56.8 Compiling Sass Files in a Maven Project

If your Liferay Maven project uses Sass files to style its UI, you must configure the project to convert its Sass files into CSS files so they are recognizable for Maven's build lifecycle. It would be a real pain to convert your Sass files into CSS files manually before building your Maven project!

Liferay provides the `com.liferay.css.builder` plugin. The CSS Builder converts Sass files into CSS files so the Maven build can parse your style sheets.

Here's how to apply Liferay's CSS builder to your Maven project.

1. Open your project's `pom.xml` file and apply Liferay's CSS Builder:

```
<plugin>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.css.builder</artifactId>
    <version>2.0.1</version>
    <executions>
        <execution>
            <id>default-build</id>
            <phase>compile</phase>
            <goals>
                <goal>build</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <docrootDirName>${com.liferay.portal.tools.theme.builder.outputDir}</docrootDirName>
        <outputDirName>/</outputDirName>
        <portalCommonPath>target/deps/com.liferay.frontend.css.common.jar</portalCommonPath>
    </configuration>
</plugin>
```

The above configuration applies the CSS Builder by specifying its `groupId`, `artifactId`, and `version`. It then defines the CSS Builder's execution and configuration.

- The `executions` tag configures the CSS Builder to run during the `compile` phase of your Maven project's build lifecycle. The `build` goal is defined for that lifecycle phase.
- The `configuration` tag defines two important properties:
    - `docrootDirName`: The base resources folder containing the Sass files to compile.
    - `outputDirName`: The name of the sub-directories where the SCSS files are compiled to.
    - `portalCommonPath`: The file path for the Liferay Frontend Common CSS JAR file.

2. If you're using Bourbon in your Sass files, you'll need to add an additional plugin dependency to your project's POM. If you're not using Bourbon, skip this step. Add the following plugin dependency:

```
<plugin>
    <artifactId>maven-dependency-plugin</artifactId>
    <executions>
        <execution>
            <phase>generate-sources</phase>
            <goals>
                <goal>copy</goal>
            </goals>
            <configuration>
                <artifactItems>
                    <artifactItem>
                        <groupId>com.liferay</groupId>
                        <artifactId>com.liferay.frontend.css.common</artifactId>
                        <version>2.0.4</version>
                    </artifactItem>
                </artifactItems>
                <outputDirectory>${project.build.directory}/deps</outputDirectory>
                <stripVersion>true</stripVersion>
            </configuration>
        </execution>
    </executions>
</plugin>
```

The maven-dependency-plugin copies the `com.liferay.frontend.css.common` dependency from Maven Central to your project's build folder so the CSS Builder can leverage it.

3. Use this command to compile your Maven project's Sass files:

   ```
   mvn compile
   ```

Note: Liferay's CSS Builder is supported for Oracle's JDK and uses a native compiler for increased speed. If you're using an IBM JDK, you may experience issues when building your SASS files (e.g., when building a theme). It's recommended to switch to using the Oracle JDK, but if you prefer using the IBM JDK, you must use the fallback Ruby compiler. To do this, add the following tag to your CSS Builder configuration in your POM:

```
<sassCompilerClassName>ruby</sasscompilerClassName>
```

Be aware that the Ruby-based compiler doesn't perform as well as the native compiler, so expect longer compile times.

Awesome! You can now compile Sass files in your Liferay Maven project.

56.9 Building Themes in a Maven Project

Liferay's Theme Builder is a tool used to build Liferay DXP theme files in your project. You can incorporate the Theme Builder into your Maven project to generate WAR-style themes deployable to Liferay DXP. To learn more about theming in Liferay DXP, see the Themes and Layout Templates tutorial section.

The easiest way to create a Liferay theme with Maven is to create a new Maven project using Liferay's provided Theme archetype. You can learn how to generate a Maven Theme project by visiting the Generating New Projects Using Archetypes tutorial. In some cases, however, this may not be convenient. For instance, if you have a legacy theme project and don't want to start over, generating a new project is not ideal.

For cases like this, you should manually configure your Maven project to build a theme. You'll learn how to do this next.

1. Configure Liferay's Theme Builder plugin in your project's `pom.xml` file:

   ```
   <build>
       <plugins>
           <plugin>
               <groupId>com.liferay</groupId>
               <artifactId>com.liferay.portal.tools.theme.builder</artifactId>
               <version>${com.liferay.portal.tools.theme.builder.version}</version>
               <executions>
                   <execution>
                       <phase>generate-resources</phase>
                       <goals>
                           <goal>build</goal>
                       </goals>
                       <configuration>
                           <diffsDir>${maven.war.src}</diffsDir>
                           <name>${project.artifactId}</name>
                           <outputDir>${project.build.directory}/${project.build.finalName}</outputDir>
                           <parentDir>${project.build.directory}/deps/com.liferay.frontend.theme.styled.jar</parentDir>
                           <parentName>_styled</parentName>
                           <templateExtension>ftl</templateExtension>
                           <unstyledDir>${project.build.directory}/deps/com.liferay.frontend.theme.unstyled.jar</unstyledDir>
                       </configuration>
                   </execution>
               </executions>
   ```

```
        </plugin>
    </plugins>
</build>
```

The above configuration applies the Theme Builder by specifying its `groupId`, `artifactId`, and `version`. It then defines the Theme Builder's execution and configuration.

- The `executions` tag configures the Theme Builder to run during the `generate-resources` phase of your Maven project's build lifecycle. The `build` goal is defined for that lifecycle phase.
- The `configuration` tag defines several important properties:
    - `diffsDir`: The folder holding the files to copy over the parent theme.
    - `name`: The new theme's name.
    - `outputDir`: The folder to build the theme.
    - `parentDir`: The parent theme's folder.
    - `parentName`: The parent theme's name.
    - `templateExtension`: The extension of the template files (e.g., `ftl` or `vm`).
    - `unstyledDir`: The unstyled theme's folder.

2. Apply the CSS Builder plugin, which is required to use the Theme Builder:

```
<plugin>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.css.builder</artifactId>
    <version>${com.liferay.css.builder.version}</version>
    <executions>
        <execution>
            <id>default-build</id>
            <phase>compile</phase>
            <goals>
                <goal>build</goal>
            </goals>
        </execution>
    </executions>
    <configuration>
        <docrootDirName>target/${project.build.finalName}</docrootDirName>
        <outputDirName>/</outputDirName>
        <portalCommonPath>target/deps/com.liferay.frontend.css.common.jar</portalCommonPath>
    </configuration>
</plugin>
```

You can learn more about the CSS Builder's Maven configuration by visiting the Compiling Sass Files in a Maven Project tutorial.

3. You can configure your project to exclude Sass files from being packaged in your theme. This is optional, but is a nice convenience to keep any unnecessary source code out of your WAR. Since the Theme Builder creates a WAR-style theme, you should apply the maven-war-plugin so it instructs the WAR file packaging process to exclude Sass files:

```
<plugin>
    <artifactId>maven-war-plugin</artifactId>
    <version>3.0.0</version>
    <configuration>
        <packagingExcludes>**/*.scss</packagingExcludes>
    </configuration>
</plugin>
```

4. Insert the <packaging> tag in your project's POM so your project is correctly packaged as a WAR file. This tag can be placed with your project's `groupId`, `artifactId`, and `version` specifications like this:

```
<groupId>com.liferay</groupId>
<artifactId>com.liferay.project.templates.theme</artifactId>
<version>1.0.0</version>
<packaging>war</packaging>
```

5. Building themes requires certain dependencies. You can configure these dependenices in your project's `pom.xml` as directories or JAR files. If you choose to use JARs, you must apply the maven-dependency-plugin and have it copy JAR dependencies into your project from Maven Central:

```
<plugin>
    <artifactId>maven-dependency-plugin</artifactId>
    <executions>
        <execution>
            <phase>generate-sources</phase>
            <goals>
                <goal>copy</goal>
            </goals>
            <configuration>
                <artifactItems>
                    <artifactItem>
                        <groupId>com.liferay</groupId>
                        <artifactId>com.liferay.frontend.css.common</artifactId>
                        <version>${com.liferay.frontend.css.common.version}</version>
                    </artifactItem>
                    <artifactItem>
                        <groupId>com.liferay</groupId>
                        <artifactId>com.liferay.frontend.theme.styled</artifactId>
                        <version>${com.liferay.frontend.theme.styled.version}</version>
                    </artifactItem>
                    <artifactItem>
                        <groupId>com.liferay</groupId>
                        <artifactId>com.liferay.frontend.theme.unstyled</artifactId>
                        <version>${com.liferay.frontend.theme.unstyled.version}</version>
                    </artifactItem>
                </artifactItems>
                <outputDirectory>${project.build.directory}/deps</outputDirectory>
                <stripVersion>true</stripVersion>
            </configuration>
        </execution>
    </executions>
</plugin>
```

This configuration copies the `com.liferay.frontend.css.common`, `com.liferay.frontend.theme.styled`, and `com.liferay.frontend.theme.unstyled` dependencies into your Maven project. Notice that you've set the `stripVersion` tag to `true` and you're setting the artifact versions within each `artifactItem` tag. You'll set these versions and a few other properties for your Maven project next.

6. Configure the properties for your project in its `pom.xml` file:

```
<properties>
    <com.liferay.css.builder.version>2.0.1</com.liferay.css.builder.version>
    <com.liferay.frontend.css.common.version>2.0.4</com.liferay.frontend.css.common.version>
    <com.liferay.frontend.theme.styled.version>2.0.28</com.liferay.frontend.theme.styled.version>
    <com.liferay.frontend.theme.unstyled.version>2.2.5</com.liferay.frontend.theme.unstyled.version>
    <com.liferay.portal.tools.theme.builder.version>1.1.4</com.liferay.portal.tools.theme.builder.version>
</properties>
```

The properties above set the versions for the CSS and Theme Builder plugins and their dependencies.

You've successfully configured your Maven project to build a Liferay theme! For info on running the Theme Builder in your Maven project, see the Theme Builder tutorial.

56.10 Maven Workspace

A Liferay Maven Workspace is a generated environment that is built to hold and manage Liferay projects built with Maven. This workspace aids in Liferay project management by applying various Maven plugins and configured properties. The Liferay Maven Workspace offers a full development lifecycle for your Maven projects to make developing them for Liferay DXP easier than ever. In this tutorial, you'll learn how to leverage the development lifecycle of a Liferay Maven Workspace.

First, you'll learn how to install a Maven Workspace.

Installation

The Maven Workspace is installed by generating the workspace project from an archetype. You can do this by executing the following command with your command line tool:

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.workspace \
    -DgroupId=[GROUP_ID] \
    -DartifactId=[WORKSPACE_NAME] \
    -Dversion=[VERSION]
```

A Maven Workspace is generated in the current folder. No other tools or CLIs are required for Maven Workspace.

Anatomy

The default Maven Workspace contains the following folders/files:

- `[MAVEN_WORKSPACE]`
    - `configs`
        - `common`
        - `dev`
        - `local`
        - `prod`
        - `uat`
    - `modules`
        - `pom.xml`
    - `themes`
        - `pom.xml`
    - `wars`
        - `pom.xml`

    - pom.xml

For more information on the configs folder, see the Testing Modules section. The modules, themes, and wars folders hold projects of that type. The parent pom.xml configures your workspace as a Maven project and applies the Bundle Support plugin, which is required for your Maven Workspace to handle 7.0 projects. You can also configure workspace properties in your POM, which you'll learn about later.

Next, you'll learn how to initialize and package Liferay DXP bundles using workspace.

Adding a Liferay Bundle to a Maven Workspace

Liferay Maven Workspaces can generate and hold a Liferay Server. This lets you build/test your plugins against a running Liferay instance. Before generating a Liferay instance, open the pom.xml file located in your workspace's root folder and set the version of the Liferay bundle to generate and install by setting the download URL for the liferay.workspace.bundle.url property. For example,

```
<properties>
    <liferay.workspace.bundle.url>
        https://releases-cdn.liferay.com/portal/7.0.6-ga7/liferay-ce-portal-tomcat-7.0-ga7-20180507111753223.zip
    </liferay.workspace.bundle.url>
    ...
</properties>
```

You can also set location of your Liferay bundle with the liferay.workspace.home.dir property. It's set to bundles by default.

Important: Make sure the com.liferay.portal.tools.bundle.support plugin in your POM is configured to use version 3.2.0+. The liferay.workspace.bundle.url property does not work for workspaces using an older version of the Bundle Support plugin. See the Updating a Maven Workspace section for instructions on how to update the plugin.

Once you've finalized your workspace properties, navigate to your workspace's root folder and run

```
blade server init
```

This uses workspace's pre-bundled and installs your Liferay DXP instance in the bundles folder. Blade CLI tool to download the version of Liferay DXP you specified in your POM file and installs your Liferay DXP instance in the bundles folder. If you prefer to not use Blade CLI or do not have it installed, the pure Maven equivalent for this command is mvn bundle-support:init.

If you want to skip the downloading process, you can create the bundles folder manually in your workspace's ROOT folder and extract your Liferay Portal bundle to that folder.

You can also produce a distributable Liferay DXP bundle (Zip) from within a workspace. To do this, navigate to your workspace's root folder and run the following command:

```
mvn bundle-support:dist
```

Your distribution file is available from the workspace's /target folder.

Configuring Maven Workspace Properties

There are many configurable workspace properties you can set in the root pom.xml file:

- liferay.workspace.bundle.dest: the destination folder for downloaded Liferay DXP bundle ZIP files.
- liferay.workspace.bundle.url: the URL used to download the Liferay DXP bundle. For more information, see Adding a Liferay Bundle to a Maven Workspace.

- `liferay.workspace.default.repository.enabled`: whether Liferay CDN is set as the default repository in the root project.
- `liferay.workspace.deploy.war.dir`: the deployment folder for WAR projects.
- `liferay.workspace.deploy.modules.dir`: the deployment folder for module projects.
- `liferay.workspace.environment`: the name of a `configs` subfolder holding the Liferay DXP server configuration to use. See Testing Modules for more information.
- `liferay.workspace.home.dir`: the Liferay DXP bundle root folder.
- `liferay.workspace.modules.default.repository.enabled`: whether the Liferay CDN is set as the default repository for module projects.
- `liferay.workspace.modules.dir`: the module projects' root folder.
- `liferay.workspace.plugins.sdk.dir`: the converted Plugins SDK's root folder. For more information, see Using a Plugins SDK from Your Workspace
- `liferay.workspace.themes.dir`: the theme projects' root folder.
- `liferay.workspace.wars.dir`: the WAR projects' root folder.

Properties can be set by adding tags with the property name. See the property configurations below for an example on how these can be set in your POM:

```
<properties>
    <liferay.workspace.home.dir>${liferay.workspace.basedir}/bundles</liferay.workspace.home.dir>
    <liferay.workspace.bundle.dest>${user.home}/.liferay/bundles/liferay-ce-portal-tomcat-7.0-ga7-20180507111753223.zip</liferay.workspace.bundle.dest>
    <liferay.workspace.bundle.url>https://releases-cdn.liferay.com/portal/7.0.6-ga7/liferay-ce-portal-tomcat-7.0-ga7-20180507111753223.zip</liferay.workspac
    <liferay.workspace.deploy.war.dir>${liferay.workspace.home.dir}/osgi/war</liferay.workspace.deploy.war.dir>
    <liferay.workspace.deploy.modules.dir>${liferay.workspace.home.dir}/osgi/modules</liferay.workspace.deploy.modules.dir>
    <liferay.workspace.environment>local</liferay.workspace.environment>
</properties>
```

Next, you'll learn how to add and deploy modules/projects in your Maven Workspace.

Module Management

Maven Workspace makes managing your Maven project easier than ever. To create a project, navigate to the appropriate workspace folder for that type of project (e.g., `modules`, `wars`, etc.). Then generate the project archetype. You can view a full listing of the available archetypes in the Project Templates reference section. Once the project is generated, it can leverage all of Maven Workspace's functionality.

Maven Workspace also lets you deploy your projects to Liferay DXP using Maven. See the Deploying a Module Built with Maven to Liferay DXP tutorial for more information.

Want to leverage Maven Workspace's testing infrastructure so you can simulate your Maven projects in a specific environment? See the Testing Modules section for more information.

Once you have your Maven projects solidified and ready for the limelight, it'd be great to release your projects to the public. Maven Workspace doesn't provide this functionality, but there are easy ways to use external release tools with workspace. See the Releasing Modules section for more information.

Next, you'll learn how to update a Maven Workspace.

Updating a Maven Workspace

Liferay Workspace is updated periodically with new features, so you'll want to update your workspace instance accordingly. To update your Maven Workspace, you must update the Bundle Support plugin configured in your workspace's root `pom.xml` file:

```
<plugin>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.portal.tools.bundle.support</artifactId>
    <version>3.2.5</version>
    ...
</plugin>
```

Update the version to the latest available release. You can reference the available releases for the Bundle Support plugin here.

Chapter 57

IntelliJ IDEA

The Liferay IntelliJ plugin provides support for Liferay DXP development in IntelliJ IDEA. Liferay's IntelliJ plugin provides the following built-in features:

- Creating a Liferay Workspace (Gradle and Maven based)
- Creating Liferay projects (Gradle and Maven based)
- Liferay DXP Tomcat server support for project deployment and debugging
- Support for adding line markers for each entity in the service editor
- Syntax checking, highlighting, and code completion (e.g., Bnd and XML files)

In these tutorials, you'll learn how to install the Liferay IntelliJ plugin and leverage its features to improve Liferay development with IntelliJ IDEA.

57.1 Installing the Liferay IntelliJ Plugin

To install the Liferay IntelliJ plugin in IntelliJ IDEA, follow the steps below:

1. Navigate to the JetBrains' Liferay IntelliJ plugin page and download it to your local machine.

2. In IntelliJ, navigate to *File* → *Settings* → *Plugins* and select *Install plugin from disk...*.

3. Select the Liferay IntelliJ plugin ZIP and select *OK* → *OK* → *Restart*.

Once IntelliJ restarts, the Liferay IntelliJ plugin is installed and ready for use. Great job! You're now ready to develop for Liferay DXP in IntelliJ!

57.2 Creating a Liferay Workspace with IntelliJ IDEA

In this tutorial, you'll learn how to generate a Liferay Workspace using IntelliJ IDEA, which runs on Blade CLI behind the scenes. IntelliJ gives you a graphical interface instead of the command prompt, which can streamline your workflow. You'll also learn how to import an existing Liferay Workspace into IntelliJ. To learn more about Liferay Workspaces, visit its dedicated tutorial section.

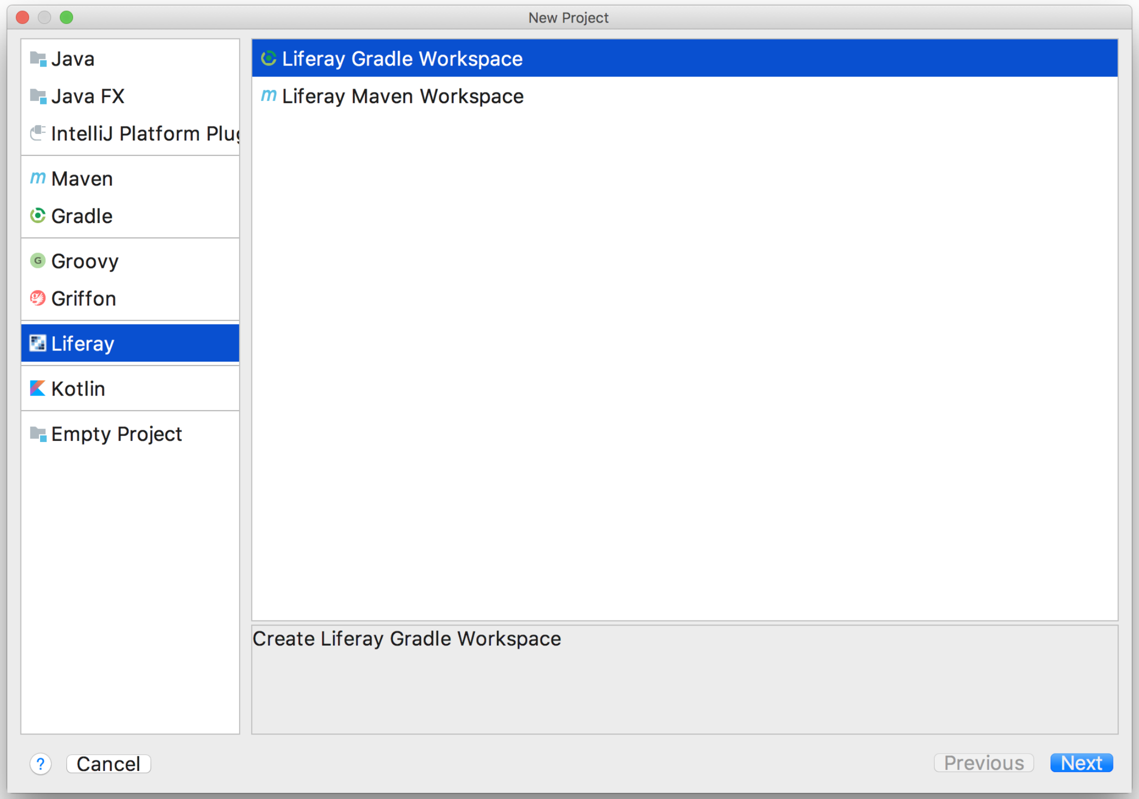
Creating a Liferay Workspace

Follow the steps below to create a Liferay Workspace:

1. Open the New Project wizard by selecting *File* → *New* → *Project*. If you're starting IntelliJ for the first time, you can do this by selecting *Create New Project* in the opening window.

2. Select *Liferay* from the left menu.

3. Choose the build type for your workspace (i.e., Gradle or Maven). Then click *Next*.



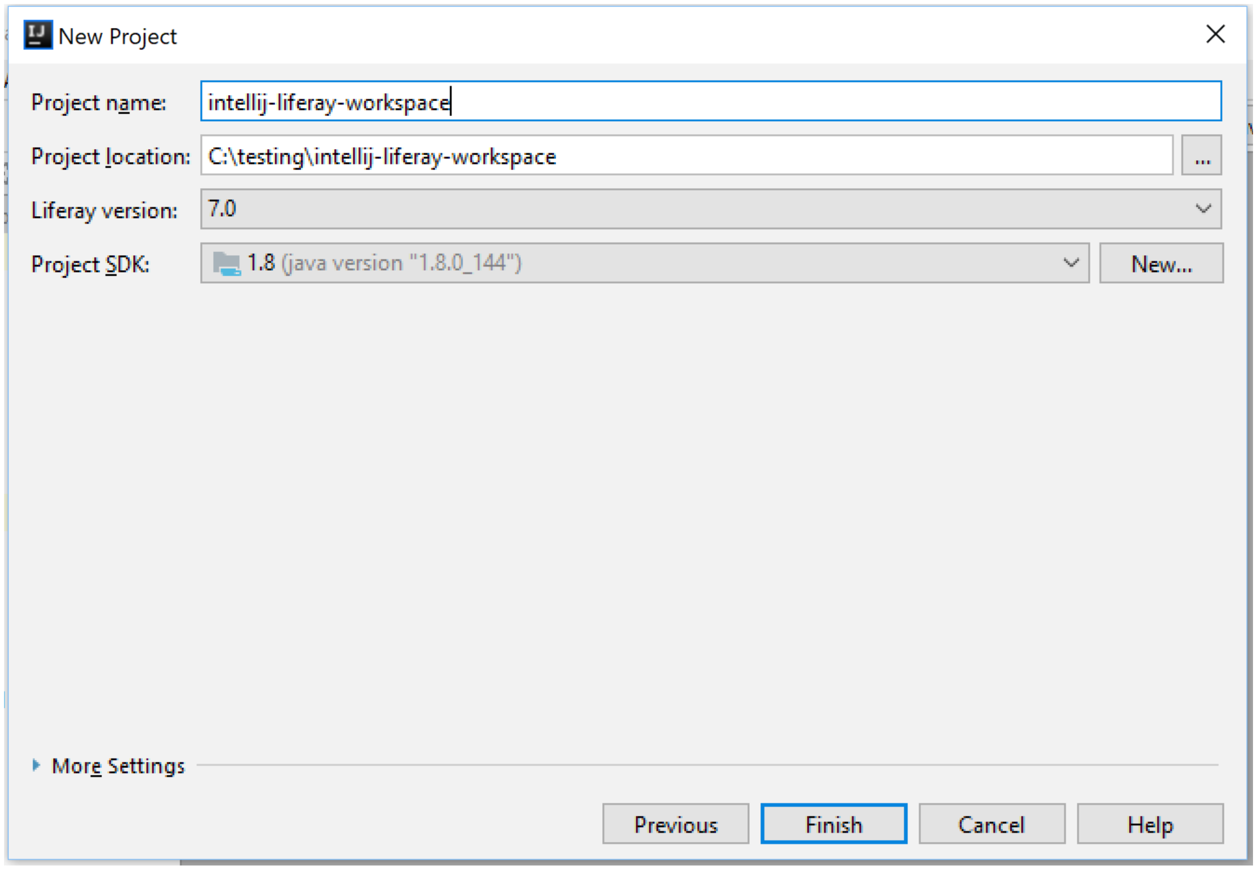
Create Liferay Gradle Workspace

Figure 57.1: Choose *Liferay Gradle Workspace* or *Liferay Maven Workspace*, depending on the build you prefer.

4. Specify your workspace's name, location, intended Liferay DXP version, and SDK (i.e., Java JDK). Then click *Finish*.

5. A window opens for additional build configurations for the build type you selected (i.e., Gradle or Maven). Verify the settings and click *OK*.

Awesome! You've successfully created a Liferay Workspace in IntelliJ IDEA!



New Project

Project name: intellij-liferay-workspace

Project location: C:\testing\intellij-liferay-workspace

Liferay version: 7.0

Project SDK: 1.8 (java version "1.8.0_144")

Figure 57.2: Specify your workspace's configurations.

Importing a Liferay Workspace

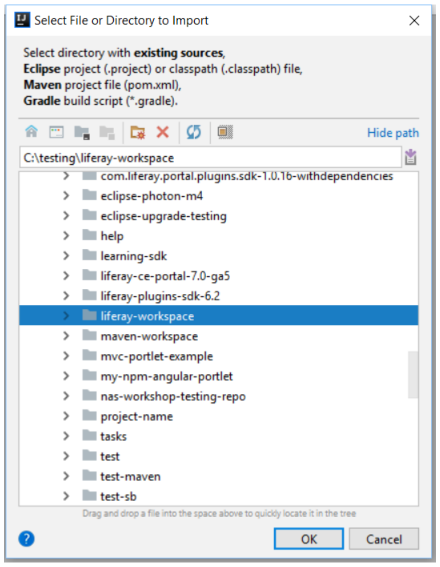
To import an existing workspace into IntelliJ, follow the steps below:

1. Select *File* → *New* → *Project from Existing Sources...*.
2. Select the workspace you want to import. Then click *OK*.
3. Click the *Import project from external model* radio button and select the build tool your workspace uses (e.g., Gradle or Maven).
4. Configure the project import (if necessary) and then click *Finish*. See the Import a Project section of IntelliJ's official documentation for more information.
5. Step through the remaining import prompts and then open your imported workspace as you desire (i.e., in the current window or a new window).

Excellent! Your existing Liferay Workspace is now imported in IntelliJ IDEA!

57.3 Creating Projects with IntelliJ IDEA

IntelliJ IDEA provides a New Liferay Modules wizard to create a variety of different module projects. You can also use the same wizard to create theme projects, WAR-style projects, and more. Before beginning,



Select File or Directory to Import

Select directory with **existing sources**,
Eclipse project (.project) or classpath (.classpath) file,
Maven project file (pom.xml),
Gradle build script (*.gradle).

C:\testing\liferay-workspace

- com.liferay.portal.plugins.sdk-1.0.16-withdependencies
- eclipse-photon-m4
- eclipse-upgrade-testing
- help
- learning-sdk
- liferay-ce-portal-7.0-ga5
- liferay-plugins-sdk-6.2
- liferay-workspace
- maven-workspace
- mvc-portlet-example
- my-npm-angular-portlet
- nas-workshop-testing-repo
- project-name
- tasks
- test
- test-maven
- test-sb

Drag and drop a file into the space above to quickly locate it in the tree

Figure 57.3: Specify your workspace's configurations.

ensure you've created/imported a Liferay Workspace in your IntelliJ environment. Follow the steps below to create a Liferay DXP module:

1. Navigate to *File* → *New* → *Liferay Module*.

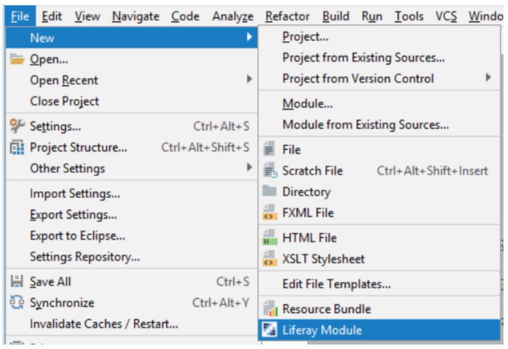


Figure 57.4: Selecting *Liferay Module* opens the New Liferay Modules wizard.

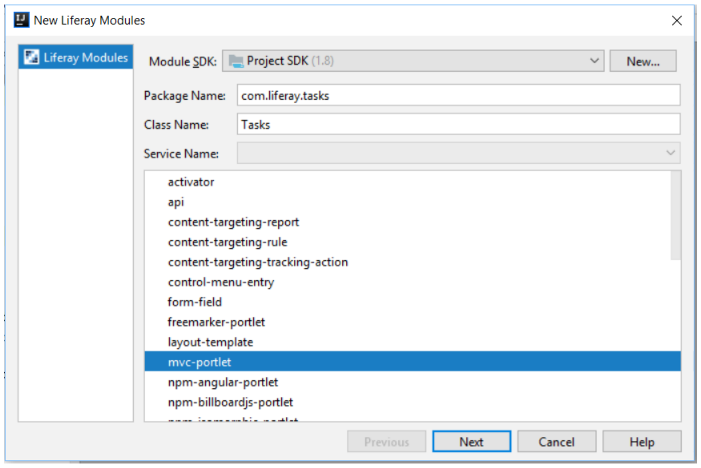
2. Select the project you want to create. Although the wizard characterizes itself for *modules*, there are many available projects that are not OSGi-based modules (e.g., `theme`, `war-mvc-portlet`, etc.). See the Project Templates reference section for more information on the available templates.

3. Configure your project's SDK (i.e., JDK), package name, class name, and service name, if necessary. Then click *Next*.

4. Give your project a name. Then click *Finish*.

Awesome! Your project is available under its project type folder in your workspace.



New Liferay Modules

Liferay Modules

Module SDK: Project SDK (1.8)

Package Name: com.liferay.tasks

Class Name: Tasks

Service Name:

activator
api
content-targeting-report
content-targeting-rule
content-targeting-tracking-action
control-menu-entry
form-field
freemarker-portlet
layout-template
mvc-portlet
npm-angular-portlet
npm-billboardjs-portlet

Figure 57.5: Choose the project template to create your module.

57.4 Installing a Server in IntelliJ IDEA

Installing a Liferay server in IntelliJ is easy. In just a few steps, you'll have your server up and running.

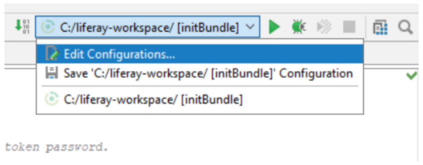
Note: Tomcat and Wildfly are the only supported Liferay app server bundles available to install in IntelliJ.

Follow these steps to install your server:

1. Right-click your Liferay workspace and select *Liferay → InitBundle*.

   This downloads the Liferay DXP bundle specified in your workspace's `gradle.properties` file. You can change the default bundle by updating the `liferay.workspace.bundle.url` property. For example, this is required to update the default bundle version and/or type (e.g., Wildfly). The downloaded bundle is stored in the workspace's `bundles` folder.

2. Navigate to the top right Configurations dropdown menu and select *Edit Configurations*. From here, you can configure your server's run and debug configurations.



C:/liferay-workspace/ [initBundle]

Edit Configurations...

Save 'C:/liferay-workspace/ [initBundle]' Configuration

C:/liferay-workspace/ [initBundle]

token password.

Figure 57.6: You have several options to choose from the server dropdown menu.

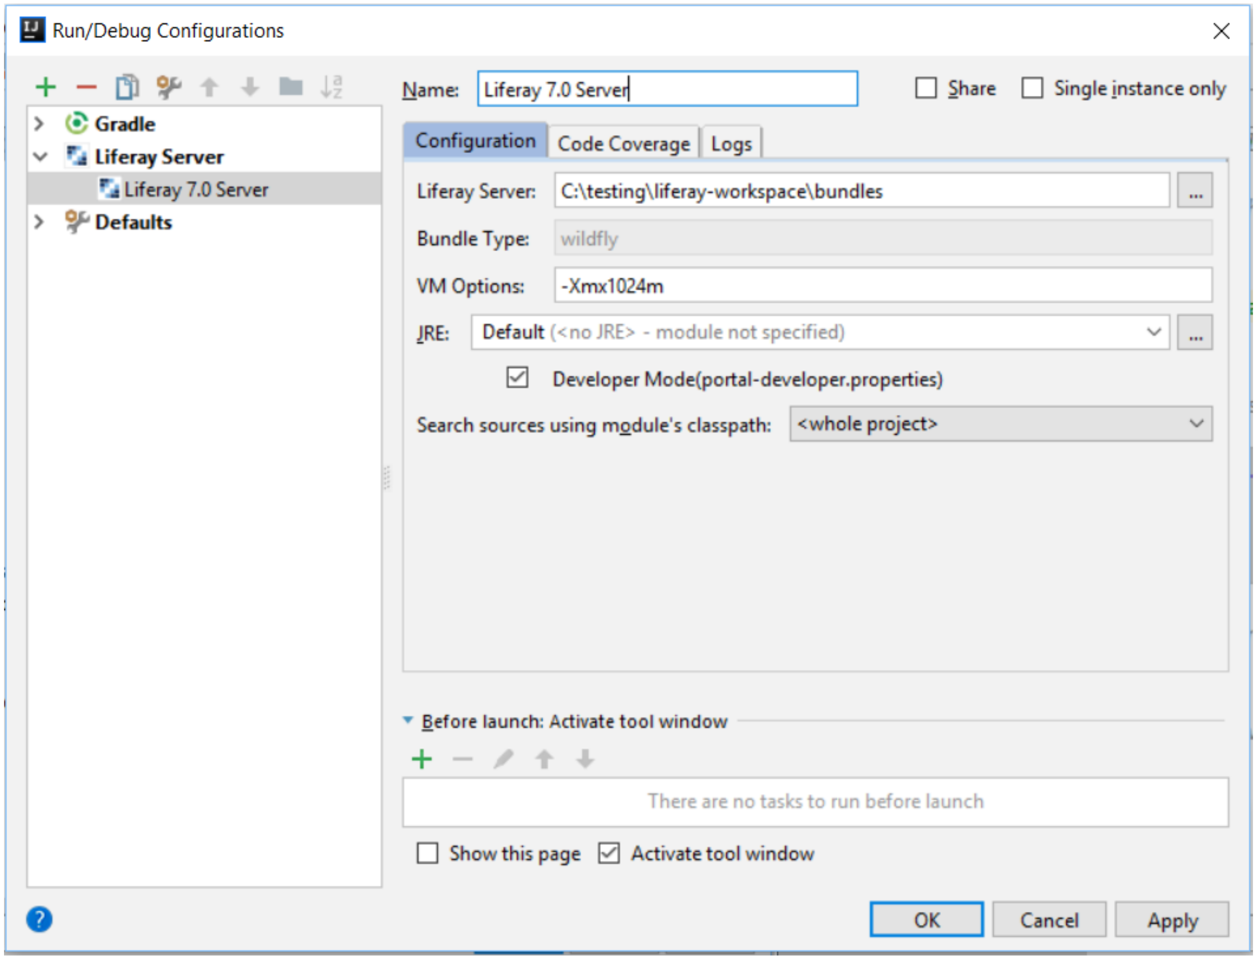
3. Click the *Add New Configuration* button (+) and select *Liferay Server*.

4. Give your server a better name and modify any other configurations, if necessary. Then select *OK* .

Your server is now available in IntelliJ! Make sure to select it in the Configurations dropdown before executing the configuration buttons (below).

For reference, here's how the IntelliJ configuration buttons work with your Liferay DXP instance:

- *Start* (▶): Starts the server.



Run/Debug Configurations

Name: Liferay 7.0 Server ☐ Share ☐ Single instance only

Configuration | Code Coverage | Logs

Liferay Server: C:\testing\liferay-workspace\bundles

Bundle Type: wildfly

VM Options: -Xmx1024m

JRE: Default (<no JRE> - module not specified)

☑ Developer Mode(portal-developer.properties)

Search sources using module's classpath: <whole project>

Before launch: Activate tool window

There are no tasks to run before launch

☐ Show this page ☑ Activate tool window

Figure 57.7: Set your Liferay server's configurations in the Run/Debug Configurations menu.

- *Stop* (■): Stops the server.
- *Debug* (●): Starts the server in debug mode. For more information on debugging in IntelliJ, see the IntelliJ Debugging article.

Now you're ready to use your server in IntelliJ!

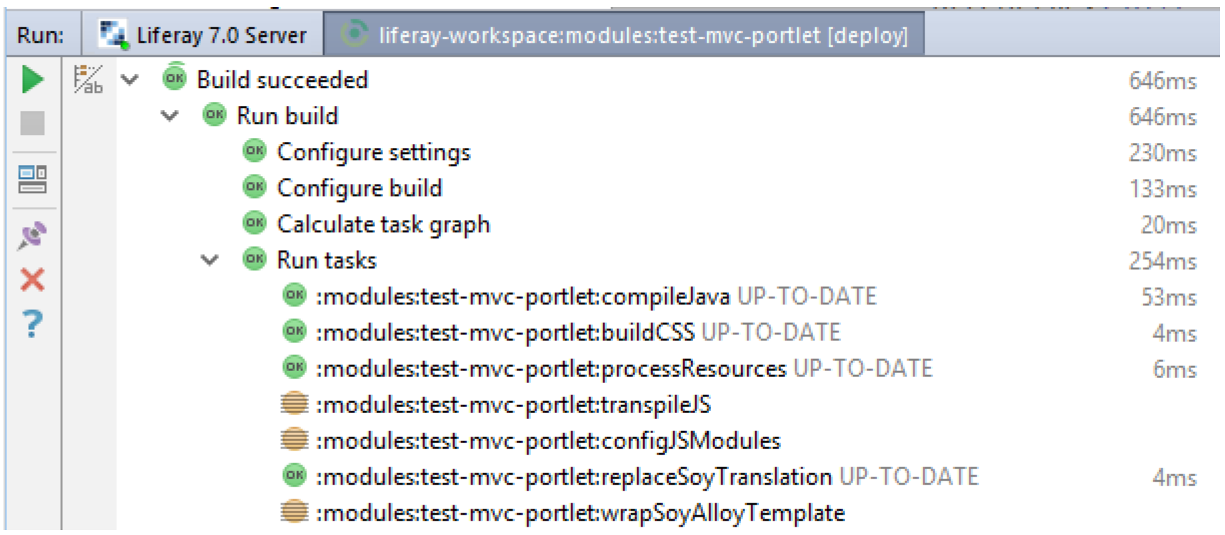
57.5 Deploying Projects with IntelliJ IDEA

Once you've created a project and installed your Liferay server in IntelliJ, you'll want to deploy your project. Follow the steps below to do this:

1. Right-click your project from within the Liferay Workspace folder structure and select *Liferay* → *Deploy*.

   This automatically loads a build progress window viewable at the bottom of your IntelliJ instance.

2. Verify that your project builds successfully from the build progress window. Then navigate back to your server's window and confirm it starts in your configured Liferay DXP instance. You should receive a message like this:



```
Build succeeded                                                       646ms
  Run build                                                           646ms
    Configure settings                                                230ms
    Configure build                                                   133ms
    Calculate task graph                                               20ms
    Run tasks                                                         254ms
      :modules:test-mvc-portlet:compileJava UP-TO-DATE                 53ms
      :modules:test-mvc-portlet:buildCSS UP-TO-DATE                     4ms
      :modules:test-mvc-portlet:processResources UP-TO-DATE             6ms
      :modules:test-mvc-portlet:transpileJS
      :modules:test-mvc-portlet:configJSModules
      :modules:test-mvc-portlet:replaceSoyTranslation UP-TO-DATE        4ms
      :modules:test-mvc-portlet:wrapSoyAlloyTemplate
```

Figure 57.8: Verify that your project build successfully.

```
INFO  [fileinstall-C:/liferay-workspace/bundles/osgi/modules][BundleStartStopLogger:35] STARTED com.liferay.docs_1.0.0 [652]
```

That's it! You've successfully deployed your project to Liferay DXP!

Chapter 58

Liferay Sample Projects

Liferay provides working examples of sample projects that target different integration points in Liferay DXP. These working examples can be copy/pasted into your own independent project so you can take advantage of various Liferay extension points. Each sample is a standalone project and includes its own build files. Liferay's sample projects can be found in the liferay-blade-samples repository on GitHub. You can find documentation for Liferay's sample projects in the Sample Projects reference section.

If you'd like to browse the repository locally or copy sample projects into your own project, fork and clone the `liferay-blade-samples` repository.

At first glance, you'll notice that the repository is broken up into three primary folders:

- `gradle`
- `liferay-workspace`
- `maven`

The provided sample projects are organized by their development toolchains to cater to a variety of developers. Each folder offers the same set of sample Liferay projects. Their only difference is that the build files are specific to their toolchain. For example, the `gradle` folder contains projects using standard OSS Gradle plugins that can be added to any Gradle composite build. The same concept also applies to the `liferay-workspace` and `maven` projects.

The `gradle` folder also uses the Liferay Gradle plugin (e.g., `com.liferay.plugin`) which encompasses additional functionality for various types of Liferay projects. The Liferay Gradle plugin is recommended for Gradle users developing for Liferay.

Some samples also come configured with logging to help you fully understand what the sample is accomplishing behind the scenes. For example, OSGi module logging is implemented for several samples (e.g., action-command-portlet, document-action, service-builder/jdbc, etc.), which lets OSGi modules supply their own logging configuration defaults without external configuration. See the Adjusting Module Logging tutorial for more information.

For a list of sample template projects available, visit the Liferay extension points sub-section in the Liferay Blade Samples repository. This list is not comprehensive. A subset of missing extension point samples can be found in the Liferay extension points without template projects sub-section. Visit the repo's Contribution Guidelines section for details on contributing to this repository.

58.1 Liferay Upgrade Planner

The Liferay Upgrade Planner provides an automated way to adapt your installation's data and legacy plugins to your desired Liferay DXP upgrade version. We recommend leveraging this tool for any of the following upgrades:

- Liferay Portal 6.2 → Liferay DXP 7.0, 7.1, or 7.2
- Liferay DXP 7.0 → Liferay DXP 7.1 or 7.2
- Liferay DXP 7.1 → Liferay DXP 7.2

The Upgrade Planner is provided in Liferay Dev Studio (versions 3.6+). Here's what the Upgrade Planner does:

- Updates your development environment.
- Identifies code affected by the API changes.
- Describes each API change related to the code.
- Suggests how to adapt the code.
- Provides options, in some cases, to adapt code automatically.
- Transfers database and server data to your new environment.

Even if you prefer tools other than Dev Studio (which is based on Eclipse), you should upgrade your data and legacy plugins using the Upgrade Planner first–you can use your favorite tools afterward.

To start the Upgrade Planner in Dev Studio, do this:

1. Navigate to *Project* → *New Liferay Upgrade Plan…*.

2. In the New Liferay Upgrade Plan wizard, assign your plan a name and choose an upgrade plan outline. The data and code upgrade processes are separate, so you must step through each process independently.

3. Choose your current Liferay version and the new version you're upgrading to.

4. If you chose to complete a code upgrade, you must also select the folder where your legacy plugins reside (e.g., Plugins SDK for Liferay 6.2 projects).

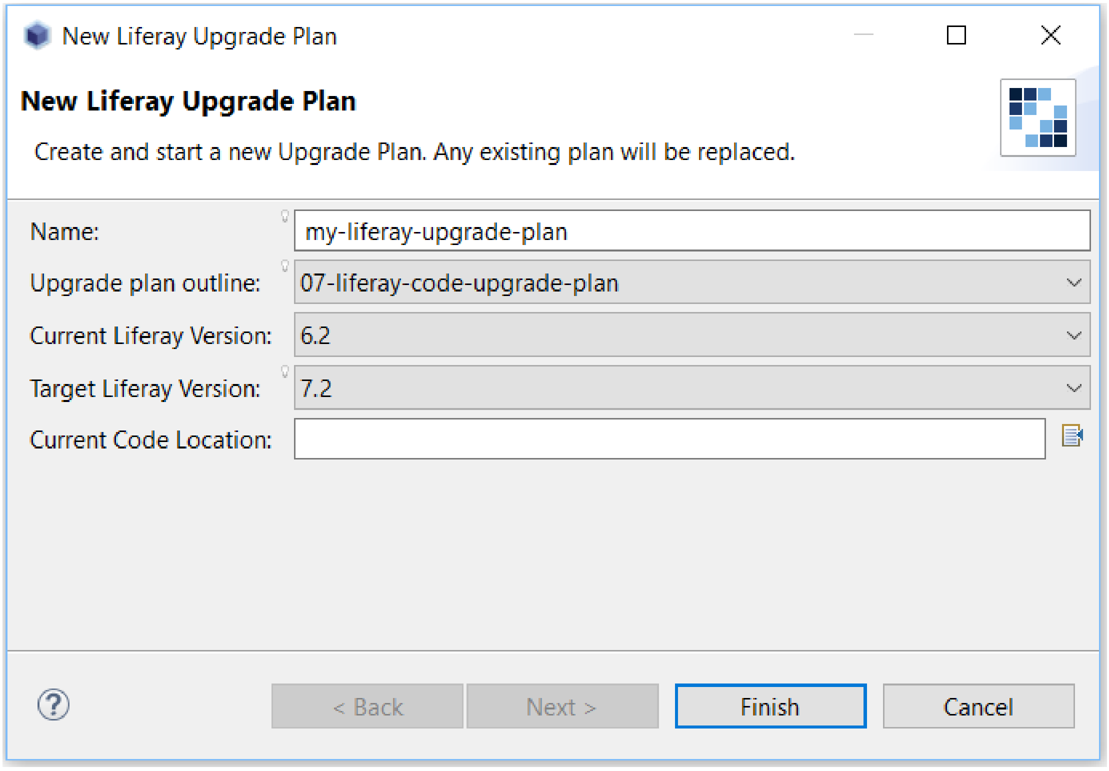
5. Click *Finish*.

Switch to the new Liferay Upgrade Planner perspective (prompted automatically). You're now offered several windows in the UI:

- *Project Explorer:* displays your legacy plugin environment and new development environment. It also displays your upgrade problems that are detected during the *Fix Upgrade Problems* step.
- *Liferay Upgrade Plan:* outlines the upgrade plan's steps and step summaries.
- *Liferay Upgrade Plan Info:* shows official documentation that describes the upgrade step.

To progress through your upgrade plan, click the steps outlined in the Liferay Upgrade Plan window. Each step can have several options:

- *Click to preview:* previews what an automated step will perform.
- *Click to perform:* executes an automated process provided with the step. This is only offered for steps where the Upgrade Planner can assist.



New Liferay Upgrade Plan

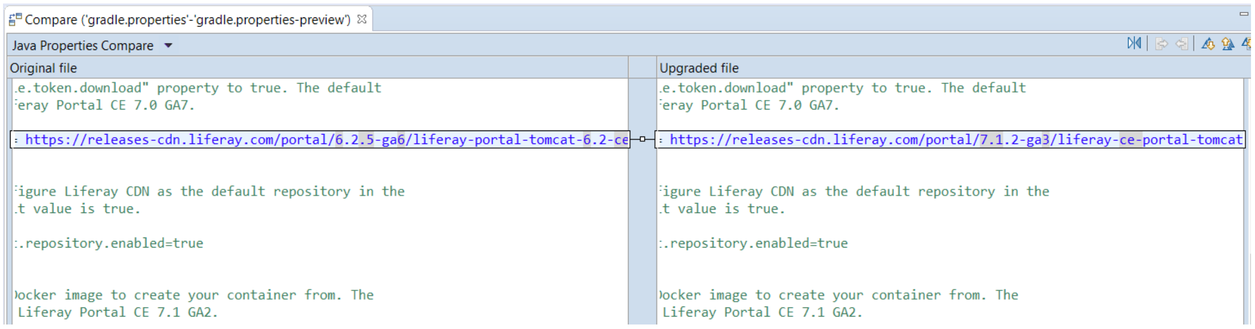
New Liferay Upgrade Plan

Create and start a new Upgrade Plan. Any existing plan will be replaced.

Name:	my-liferay-upgrade-plan
Upgrade plan outline:	07-liferay-code-upgrade-plan
Current Liferay Version:	6.2
Target Liferay Version:	7.2
Current Code Location:	

Figure 58.1: Configure your upgrade plan before beginning the upgrade process.

- *Click when complete:* marks the step as complete. This is only offered when the Upgrade Planner cannot provide automated assistance and, instead, only offers documentation to assist in completing the step manually.
- *Restart:* marks a completed step as unfinished. The step is performed again if automation is involved.
- *Skip:* skips the step and jumps to the next step in the outline.



Compare ('gradle.properties'-'gradle.properties-preview')

Figure 58.2: You can preview the Upgrade Planner's automated updates before you perform them.

Great! You now have a good understanding of the Liferay Upgrade Planner's UI and how to get started.

Note: The Upgrade Planner upgrades data and code to Liferay DXP versions that include 7.0 and the latest DXP version. It links to the latest Liferay DXP upgrade documentation. 7.0 upgrade documentation is available here:

- Data Upgrade
- Code Upgrade

58.2 Using the Upgrade Planner with Proxy Requirements

If you have proxy server requirements and want to configure your http(s) proxy
to work with the Liferay Upgrade Planner, follow the instructions below.

1. In Dev Studio's `DeveloperStudio.ini/eclipse.ini` file, add the following parameters:

   ```
   -Djdk.http.auth.proxying.disabledSchemes=
   -Djdk.http.auth.tunneling.disabledSchemes=
   ```

2. Launch Dev Studio.

3. Go to *Window* → *Preferences* → *General* → *Network Connections*.

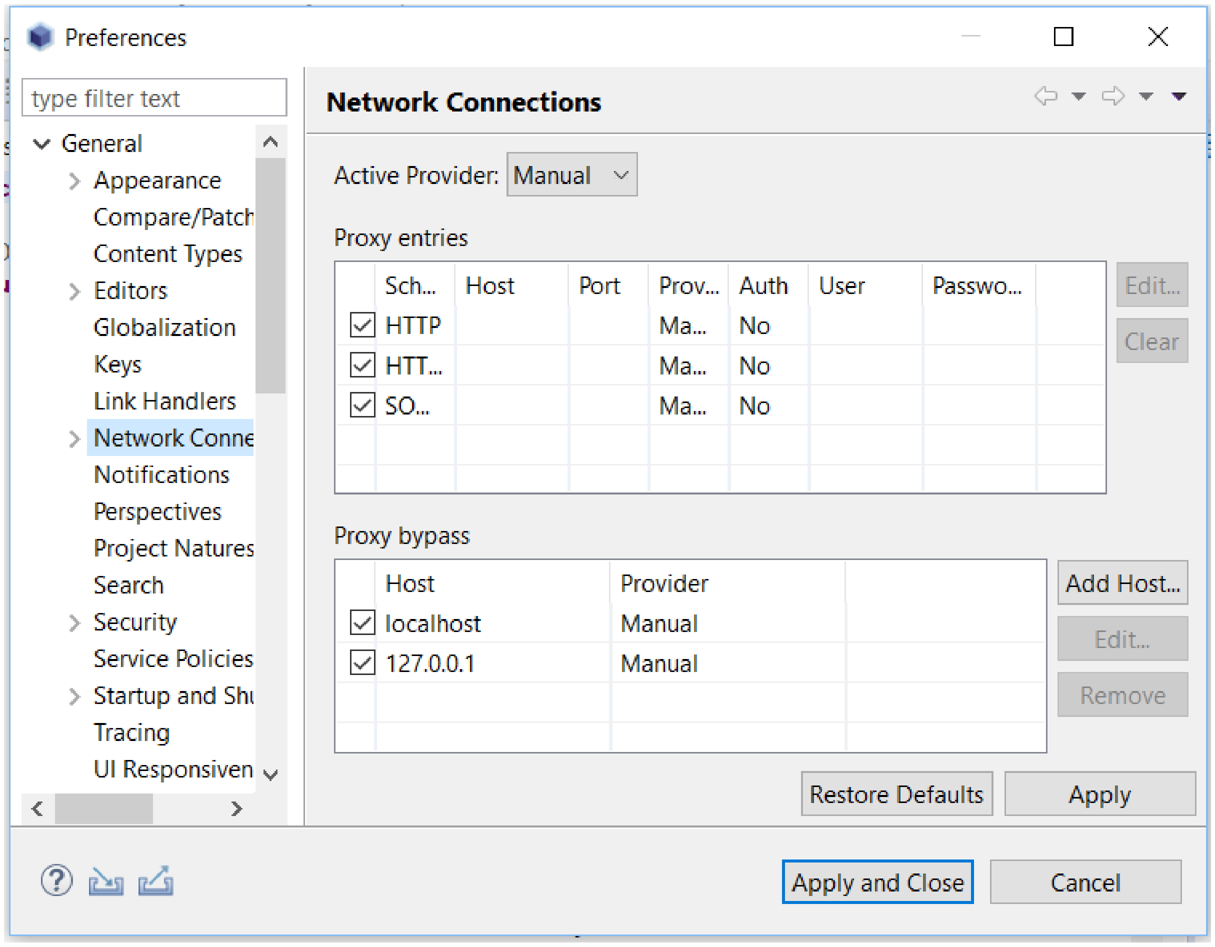
4. Set the *Active Provider* drop-down selector to *Manual*.

5. Under *Proxy entries*, configure both proxy HTTP and HTTPS by clicking the field and selecting the *Edit* button.

6. For each schema (HTTP and HTTPS), enter your proxy server's host, port, and authentication settings (if necessary). Do not leave whitespace at the end of your proxy host or port settings.

7. Once you've configured your proxy entry, click *Apply and Close*.

Awesome! You've successfully configured the Upgrade Planner's proxy settings!



Active Provider: Manual

Proxy entries

	Sch...	Host	Port	Prov...	Auth	User	Passwo...
✓	HTTP			Ma...	No		
✓	HTT...			Ma...	No		
✓	SO...			Ma...	No		

Proxy bypass

	Host	Provider
✓	localhost	Manual
✓	127.0.0.1	Manual

Figure 58.3: You can configure your proxy settings in Dev Studio's Network Connections menu.

Chapter 59

Portlets

Web apps in Liferay DXP are called *portlets*. Like many web apps, portlets process requests and generate responses. In the response, the portlet returns content (e.g. HTML, XHTML) for display in browsers. You might now be thinking, "Ok, besides the funky name, how are portlets different from other types of web apps?" This is a fantastic question! One key difference is that portlets run in a portion of the web page. When you're writing a portlet application, you only need to worry about that application: the rest of the page–the navigation, the top banner, and any other global component of the interface–is handled by other components. Another difference is that portlets run only in a portal server, like the one in Liferay DXP. Portlets can therefore use the portal's existing support for user management, authentication, permissions, page management, and more. This frees you to focus on developing the portlet's core functionality. In many ways, writing your application as a portlet is easier than writing a standalone application.

Portlets can be placed on pages by users or portal administrators, who can place several different portlets on a single page. For example, a page in a community site could have a calendar portlet for community events, an announcements portlet for important announcements, and a bookmarks portlet for links of interest to the community. And because the portal controls page layout, you can reposition and resize one or more portlets on a page without altering any portlet code. Doing all this in other types of web apps would require manual re-coding. Alternatively, a single portlet can take up an entire page if it's the only app you need on that page. For example, a message boards or wiki portlet is best suited on its own page. In short, portlets alleviate many of the traditional pain points associated with developing web apps.

What's more, portals and portlets are standards-based. In 2003, Java Portlet Specification 1.0 (JSR-168) first defined portal and portlet behavior. In 2008, Java Portlet Specification 2.0 (JSR-286) refined and built on JSR-168, while maintaining backwards compatibility, to define features like inter-portlet communication (IPC) and more. The recently released Java Portlet Specification 3.0 (JSR-362) continues portal and portlet evolution. Liferay leads in this space by having a member in the Expert Group.

So what do these specifications define? We won't bore you with the gory details; if that's what you want you can read the specifications. We will tell you, however, how portlets differ from other types of servlet-based web apps. Portlets handle requests in multiple phases. This makes portlets much more flexible than servlets. Each portlet phase executes different operations:

- **Render:** Generates the portlet's contents based on the portlet's current state. When this phase runs on one portlet, it also runs on all other portlets on the page. The Render phase runs when any portlets on the page complete the Action or Event phases.

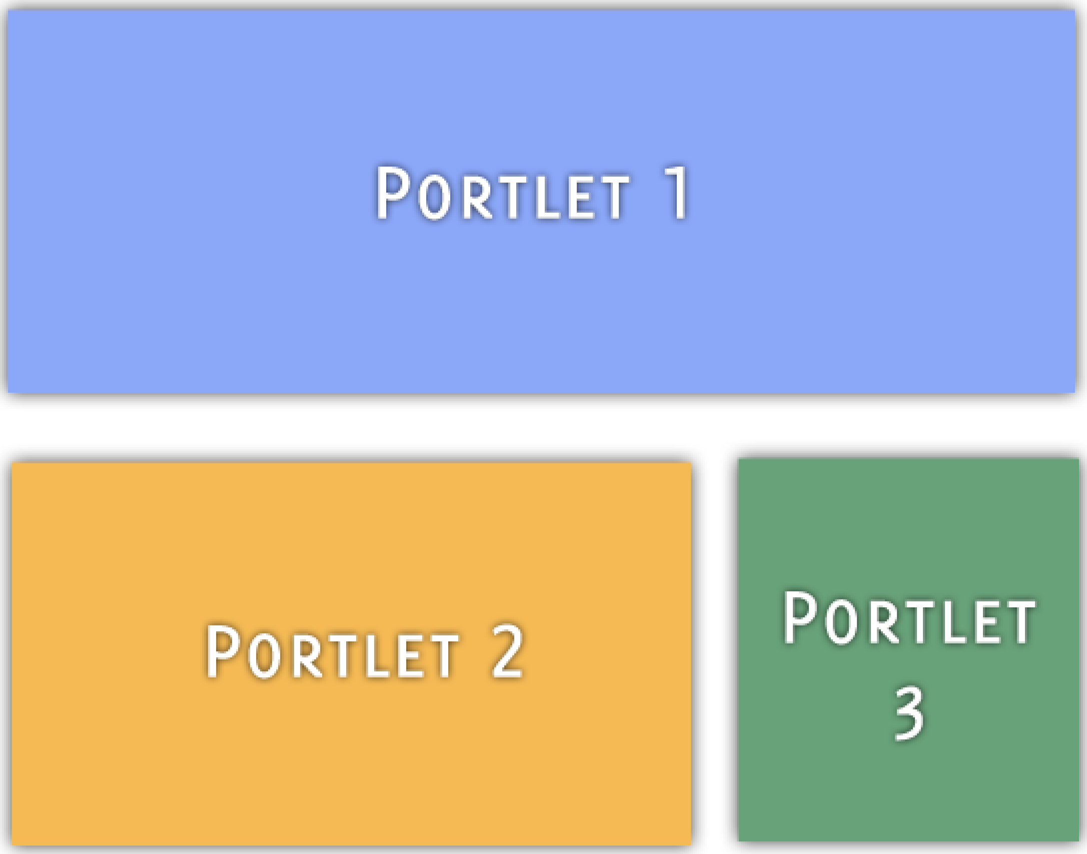


Figure 59.1: You can place multiple portlets on a single page.

- **Action:** In response to a user action, performs some operation that changes the portlet's state. The Action phase can also trigger events that are processed by the Event phase. Following the Action phase and optional Event phase, the Render phase then regenerates the portlet's contents.
- **Event:** Processes events triggered in the Action phase. Events are used for IPC. Once the portlet processes all events, the portal calls the Render phase on all portlets on the page.
- **Resource-serving:** Serves a resource independent from the rest of the lifecycle. This lets a portlet serve dynamic content without running the Render phase on all portlets on a page. The Resource-serving phase handles AJAX requests.

Compared to servlets, portlets also have some other key differences. Since portlets only render a portion of a page, tags like `<html>`, `<head>`, and `<body>` aren't allowed. And because you don't know the portlet's page ahead of time, you can't create portlet URLs directly. Instead, the portlet API gives you methods to create portlet URLs programmatically. Also, because portlets don't have direct access to the `javax.servlet.ServletRequest`, they can't read query parameters directly from a URL. Portlets instead access a `javax.portlet.PortletRequest` object. The portlet specification only provides a mechanism for a portlet to read its own URL parameters or those declared as public render parameters. Liferay DXP does, however, provide utility methods that can access the `ServletRequest` and query parameters. Portlets also have a *portlet filter* available for each phase in the portlet lifecycle. Portlet filters are similar to servlet filters in that they allow request and response modification on the fly.

Portlets also differ from servlets by having distinct modes and window states. Modes distinguish the portlet's current function:

- **View mode:** The portlet's standard mode. Use this mode to access the portlet's main functionality.
- **Edit mode:** The portlet's configuration mode. Use this mode to configure a custom view or behavior. For example, the Edit mode of a weather portlet could let you choose a location to retrieve weather data from.
- **Help mode:** A mode that displays the portlet's help information.

Most modern applications use View Mode only.

Portlet window states control the amount of space a portlet takes up on a page. Window states mimic window behavior in a traditional desktop environment:

- **Normal:** The portlet can be on a page that contains other portlets. This is the default window state.
- **Maximized:** The portlet takes up an entire page.
- **Minimized:** Only the portlet's title bar shows.

When you develop portlets for Liferay DXP, you can leverage all the features defined by the portlet specification. Depending on how you develop and package your portlet, however, it may not be able to run on other portal containers. You may now be saying, "Hold on a minute! I thought Liferay DXP was standards-compliant? What gives?" Liferay DXP is standards-compliant, but it contains some sweeteners in the form of APIs designed to make developers' lives easier. For example, Liferay DXP contains an MVC framework that makes it simpler to implement MVC in your portlet. This framework, however, is only available in Liferay's portal. Without modification, a portlet that uses this framework won't run if deployed to a non-Liferay portal container. Note, though, that we don't force you to use Liferay DXP's MVC framework or any of its other unique APIs. For example, you can develop your portlet with strictly standards-compliant frameworks and APIs, package it in a WAR file, and then deploy it on any standards-compliant portal container.

Liferay DXP also contains an OSGi runtime. This means that you don't have to develop and deploy your portlet as a traditional WAR file; you can do so as OSGi modules instead. We recommend the latter, so you can take advantage of the modularity features inherent in OSGi. For a detailed description of these features, see the tutorial OSGi and Modularity. Note, however, that Liferay DXP portlets you develop as OSGi modules won't run on other portlet containers that lack an OSGi runtime. Even so, the advantages of modularity are so great that we still recommend you develop your portlets as OSGi modules.

With that said, you can use a variety of technologies to develop portlets that run on Liferay DXP. Have you ever heard the saying, "There's more than one way to skin a cat?" It's gross, but it's probably true. Liferay DXP doesn't force you to use a single tool or set of tools to develop portlets. This section shows you how to develop portlets using the following frameworks and techniques:

- Liferay's `MVCPortlet`
- Soy Portlet
- Spring MVC
- JavaServer Faces (JSF) Portlets with Liferay Faces
- Making URLs Friendlier
- Preparing Your JavaScript Files for ES2015
- Applying Lexicon Styles to Your App

- Automatic Single Page Applications
- Creating Layouts Inside Custom Portlets

Chapter 60

Liferay MVC Portlet

Web applications are often developed following the Model View Controller (MVC) pattern. But Liferay has developed a groundbreaking new pattern called the *Modal Veal Contractor* (MVC) pattern. Okay, that's not true: the framework is actually another implementation of Model View Controller. If you're an experienced developer, this will not be the first time you've heard about Model View Controller. In this article you'll need to stay focused, because there will be several attempts to show you why Liferay's implementation of Model View Controller is different, when instead you're hearing about another MVC framework. With that in mind, let's get back to the *Medial Vein Constriction* pattern we were discussing.

If there are so many implementations of MVC frameworks in Java, why did Liferay create yet another one? Stay with us and you'll see that Liferay MVC provides these benefits:

- It's lightweight, as opposed to many other Java MVC frameworks.
- There are no special configuration files that need to be kept in sync with your code.
- It's a simple extension of `GenericPortlet`.
- You avoid writing a bunch of boilerplate code, since Liferay's MVC framework simply looks for some pre-defined parameters when the `init()` method is called.
- The controller can be broken down into MVC command classes, each of which handles the controller code for a particular portlet phase (render, action, and resource serving phases).
- Liferay's portlets use it. That means there are plenty of robust implementations to reference when you need to design or troubleshoot your Liferay applications.

The Liferay MVC portlet framework is light, it hides part of the complexity of portlets, and it makes the most common operations easier. The default `MVCPortlet` project uses separate JSPs for each portlet mode: For example, `edit.jsp` is for *edit* mode and `help.jsp` is for *help* mode.

Before diving in to the Liferay MVC swimming pool with all the other cool kids (applications), review how each layer of the *Moody Vase Conscription* pattern helps you separate the concerns of your application.

60.1 MVC Layers and Modularity

In MVC, there are three layers, and you can probably guess what they are.

Model: The model layer holds the application data and logic for manipulating it.

View: The view layer contains logic for displaying data.

Controller: The middle man in the MVC pattern, the Controller contains logic for passing the data back and forth between the view and the model layers.

The *Middle Verse Completer* pattern fits well with Liferay's application modularity effort.

Liferay's applications are divided into multiple discrete modules. With Service Builder, the model layer is generated into a `service` and an `api` module. That accounts for the model in the MVC pattern. The view and the controller share a module, the `web` module.

Generating the skeleton for a multi-module Service Builder driven MVC application using Liferay Blade CLI saves you lots of time and gets you started on the more important (and interesting, if we're being honest) development work.

60.2 Liferay MVC Command Classes

In a larger application, your `-Portlet` class can become monstrous and unwieldy if it holds all of the controller logic. Liferay provides MVC command classes to break up your controller functionality.

- **`MVCActionCommand`:** Use `-ActionCommand` classes to hold each of your portlet actions, which are invoked by action URLs.
- **`MVCRenderCommand`:** Use `-RenderCommand` classes to hold a `render` method that dispatches to the appropriate JSP, by responding to render URLs.
- **`MVCResourceCommand`:** Use `-ResourceCommand` classes to execute resource serving in your MVC portlet, by responding to resource URLs.

There must be some confusing configuration files to keep everything wired together and working properly, right? Wrong: it's all easily managed in the OSGi component in the `-Portlet` class.

60.3 Liferay MVC Portlet Component

Whether or not you plan to split up the controller into MVC command classes, you use a portlet component class with a certain set of properties. Here's a simple portlet component as an example:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.css-class-wrapper=portlet-hello-world",
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.icon=/icons/hello_world.png",
        "com.liferay.portlet.preferences-owned-by-group=true",
        "com.liferay.portlet.private-request-attributes=false",
        "com.liferay.portlet.private-session-attributes=false",
        "com.liferay.portlet.remoteable=true",
        "com.liferay.portlet.render-weight=50",
        "com.liferay.portlet.use-default-template=true",
        "javax.portlet.display-name=Hello World",
        "javax.portlet.expiration-cache=0",
        "javax.portlet.init-param.always-display-default-configuration-icons=true",
        "javax.portlet.name=" + HelloWorldPortletKeys.HELLO_WORLD,
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=guest,power-user,user",
        "javax.portlet.supports.mime-type=text/html"
    },
    service = Portlet.class
)
public class HelloWorldPortlet extends MVCPortlet {
}
```

When using MVC commands, the `javax.portlet.name` property is important. This property is one of two that must be included in each MVC command component; it links a particular portlet URL/command combination to the correct portlet.

Important: Make your portlet name unique, considering how Liferay DXP uses the name to create the portlet's ID.

There can be some confusion over exactly what kind of `Portlet.class` implementation you're publishing with this component. Liferay's service registry expects this to be `javax.portlet.Portlet`, so make sure that's the class you import, and not, for example, `com.liferay.portal.kernel.model.Portlet`.

Note: To find a list of all the Liferay-specific attributes you can specify as properties in your portlet components, check out the liferay-portlet-app_7_0_0.dtd.

Consider the `<css-class-wrapper>` element from the above link as an example. To specify that property in your component, use this syntax in your property list:

```
"com.liferay.portlet.css-class-wrapper=portlet-hello-world",
```

The properties namespaced with `javax.portlet....` are elements of the portlet.xml descriptor.

60.4 A Simpler MVC Portlet

With all for this focus on MVC commands, you might be concerned that you'll be forced into a more complex pattern than is necessary, especially if you're developing only a small Liferay MVC application. Not so; just put all of your logic into the `-Portlet` class if you don't want to split up your MVC commands.

In simpler applications, if you don't have an MVC command to rely on, your portlet render URLs specify the path to the JSP in an `mvcPath` parameter.

```
<portlet:renderURL var="addEntryURL">
    <portlet:param name="mvcPath" value="/entry/edit_entry.jsp" />
    <portlet:param name="redirect" value="<%= redirect %>" />
</portlet:renderURL>
```

As you've seen, Liferay's *Medical Vortex Concentrator* (MVC) portlet framework gives you a well-structured controller layer that takes very little time to implement. With all your free time, you could

- Learn a new language
- Take pottery classes
- Lift weights
- Work on your application's business logic

It's entirely up to you.

60.5 Creating an MVC Portlet

You're convinced that Liferay's MVC Framework is right for you, and you want to learn how to configure it.

You'll need:

- A module that publishes a portlet component with the necessary properties.

- Controller code to handle the request and response.
- JSPs to implement your view layer.

Along the way you'll want to know how to call services from your controller and how to pass information from the view layer to the controller.

Keep in mind that you can take two paths with your Liferay MVC portlet implementation. If you have a small application that won't be heavy on controller logic (maybe just a couple of action methods), you can put all your controller code in the `-Portlet` class. If you have more complex needs (lots of actions, complex render logic to implement, or maybe even some resource serving code), consider breaking the controller into MVC Action Command classes, MVC Render Command classes, and MVC Resource Command classes.

In this tutorial you'll learn to implement a Liferay MVC portlet with all the controller code in the `-Portlet` class.

Configuring a WEB Module

As a naming convention, the module with your controller code and view layer is referred to as the WEB module. A very basic WEB module might look like this:

```
docs.liferaymvc.web/
    src/main/java/
        com/liferay/docs/liferaymvc/web/portlet/LiferayMVCPortlet.java
    src/main/resources/
        content/
            Language.properties
        META/-INF/resources/
            init.jsp
            view.jsp
    build.gradle
    bnd.bnd
```

Of course you're not tied to the use of Gradle or BndTools to build your project. However, you do need a JAR with the proper OSGi headers defined, which is easily done if you provide a `bnd.bnd` file. To see Liferay MVC portlets built with Maven and Gradle, you can check out the tutorial on Liferay Sample Projects.

Specifying OSGi Metadata

At a minimum, you should specify the bundle symbolic name and the bundle version for the OSGi runtime. Providing a human readable bundle name is also recommended.

```
Bundle-Name: Example Liferay MVC Web
Bundle-SymbolicName: com.liferay.docs.liferaymvc.web
Bundle-Version: 1.0.0
```

If you don't specify a `Bundle-SymbolicName`, one will be generated from the project's directory path, which is suitable for many cases. If you specify the bundle symbolic name yourself, it's a nice convention to use the root package name as the bundle symbolic name.

Creating a Portlet Component

Using the OSGi Declarative Services component model makes it easy to publish service implementations to the OSGi runtime. In this case an implementation of the `javax.portlet.Portlet` service must be published. Declare this using an `@Component` annotation in the portlet class:

```
@Component(
    immediate = true,
    service = Portlet.class
)
public class LiferayMVCPortlet extends MVCPortlet {
}
```

Since Liferay's `MVCPortlet` class is itself an extension of `javax.portlet.Portlet`, you've provided the right implementation. That's good in itself, but the component needs to be fleshed out with some properties:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.instanceable=true",
        "javax.portlet.display-name=Liferay MVC Portlet",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=power-user,user"
    },
    service = Portlet.class
)
public class LiferayMVCPortlet extends MVCPortlet {
}
```

Some of those properties might look familiar to you if you've developed Liferay MVC portlets before 7.0. That's because they correspond with the XML attributes you used to specify in `liferay-portlet.xml`, `liferay-display.xml`, and `portlet.xml`. To find a list of all the Liferay-specific attributes you can specify as properties in your portlet components, check out the liferay-portlet-app_7_0_0.dtd. This is still maintained as a DTD to keep compatibility with the JSR-168 and JSR-286 portlet specs.

Consider the `<instanceable>` element from the above link as an example. To specify that property in your component, use this syntax in your property list:

```
"com.liferay.portlet.instanceable=true",
```

The properties namespaced with `javax.portlet....` are elements of the portlet.xml descriptor.

Also note that it is possible to create nested categories using the `com.liferay.portlet.display-category` property. The format for creating these categories is to write out the category path starting with the root and separating each category in descending order by the use of `//`. Here's an example:

```
com.liferay.portlet.display-category=root//category.category1//category.category2
```

Liferay's DTD files can be found here.

You can publish this portlet component, but it doesn't do anything yet. You'll implement the Controller code next.

Writing Controller Code

In MVC, your controller receives requests from the front end, and it receives data from the back end. It's responsible for sending that data to the right front end view so it can be displayed to the user, and it's responsible for taking data the user entered in the front end and passing it to the right back end service. For this reason, it needs a way to process requests from the front end and respond to them appropriately, and it needs a way to determine the appropriate front end view to pass data back to the user.

For data coming from the user to the back end, Liferay's MVC portlet framework offers you two ways to do this. One of these is designed for smaller applications, and the other is designed for larger applications.

First, you'll learn about processing requests in smaller applications. After that, you'll learn about how data is rendered from the back end to the user. For processing requests in larger applications, see the tutorials MVC Action Command, MVC Render Command, and MVC Resource Command. But read these after you finish this one, so you can understand how the whole framework works.

Action Methods

If you have a small application, you can implement all your controller code in your portlet class (the same one you annotated with `@Component`), which acts as your controller by itself. For processing requests, you use action methods. Here's what an action method might look like:

```
public void addGuestbook(ActionRequest request, ActionResponse response)
        throws PortalException, SystemException {

    ServiceContext serviceContext = ServiceContextFactory.getInstance(
        Guestbook.class.getName(), request);

    String name = ParamUtil.getString(request, "name");

    try {
        _guestbookService.addGuestbook(serviceContext.getUserId(),
                name, serviceContext);

        SessionMessages.add(request, "guestbookAdded");

    } catch (Exception e) {
        SessionErrors.add(request, e.getClass().getName());

        response.setRenderParameter("mvcPath",
            "/html/guestbook/edit_guestbook.jsp");
    }

}
```

In this action method, the `javax.portlet.ActionRequest` object is used to retrieve two pieces of information that are needed to call the `addGuestbook` service, which is the point of the method. If successful, the `SessionMessages` object is used to store a success message. If an exception is thrown, it's caught, and the appropriate `SessionErrors` object is used to store the exception message. Note the call to the `setRenderParameter` method on the `ActionResponse`. This is used to render the `edit_guestbook.jsp` if a guestbook could not be added, by setting the `mvcPath` parameter. This parameter is a convention in Liferay's `MVCPortlet` framework that denotes the next view that should be displayed to the user.

Render Logic

So what might a render method look like? First, note that implementing render logic might not be necessary at all. Note the `init-param` properties you set in your Component:

```
"javax.portlet.init-param.template-path=/",
"javax.portlet.init-param.view-template=/view.jsp",
```

With these, you're directing the default rendering to your `view.jsp`. The `template-path` property tells the MVC framework where your JSP files live. In the above example, / means that the JSP files are located in your project's root resources folder. That's why it's important to follow Liferay's standard folder structure, outlined above. Here's the path of a hypothetical Web module's resource folder:

```
docs.liferaymvc.web/src/main/resources/META-INF/resources
```

In this case, the `view.jsp` file is found at

```
docs.liferaymvc.web/src/main/resources/META-INF/resources/view.jsp
```

and that's the default view of the application. When the `init` method is called, the initialization parameters you specify are read and used to direct rendering to the default JSP. Throughout the controller, you can render a different view (JSP file) by setting the render parameter `mvcPath`, like this:

```
actionResponse.setRenderParameter("mvcPath", "/error.jsp");
```

In some cases, the uses of initialization parameters and render parameters obviates the need for additional render logic. However, it's often necessary to provide additional render logic. To do this, override the render method. Here's an example:

```
@Override
public void render(RenderRequest renderRequest,
        RenderResponse renderResponse) throws PortletException, IOException {

    try {
        ServiceContext serviceContext = ServiceContextFactory.getInstance(
                Guestbook.class.getName(), renderRequest);

        long groupId = serviceContext.getScopeGroupId();

        long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");

        List<Guestbook> guestbooks = _guestbookService
                .getGuestbooks(groupId);

        if (guestbooks.size() == 0) {
            Guestbook guestbook = _guestbookService.addGuestbook(
                    serviceContext.getUserId(), "Main", serviceContext);

            guestbookId = guestbook.getGuestbookId();

        }

        if (!(guestbookId > 0)) {
            guestbookId = guestbooks.get(0).getGuestbookId();
        }

        renderRequest.setAttribute("guestbookId", guestbookId);

    } catch (Exception e) {

        throw new PortletException(e);
    }

    super.render(renderRequest, renderResponse);

}
```

With render logic, you're providing the view layer with information to display the data properly to the user. In this case, there's some information needed at the outset, and then there's some logic in the `if` statements that determine if there are any Guestbooks that can be displayed. If not, a Guestbook should be created by default. If there are Guestbooks in the database, the ID that's first in the list retrieved via the `getGuestbooks` method should be displayed. This is accomplished by passing the appropriate ID to the `RenderRequest` using the `setAttirbute` method. Since this logic should be executed before the default `render` method, the method concludes by calling `super.render`.

Note: Are you wondering how to call Service Builder services in 7.0? Refer to the tutorial on Finding and Invoking Liferay Services for a more detailed explanation. In short, obtain a reference to the service by annotating a setter method with the `@Reference` Declarative Services annotation and set the service object as a private variable.

```
private GuestbookService _guestbookService;

@Reference(unbind = "-")
protected void setGuestbookService(GuestbookService guestbookService) {
    _guestbookService = guestbookService;
}
```

Once done, you can call the service's methods.

```
_guestbookService.addGuestbook(serviceContext.getUserId(), "Main",
        serviceContext);
```

Setting and Retrieving Request Parameters and Attributes

In the portlet class's render method action methods, and even in your JSPs, you can use a handy utility class called `ParamUtil` to retrieve parameters from an `ActionRequest` or a `RenderRequest`.

```
long guestbookId = ParamUtil.getLong(renderRequest, "guestbookId");
```

In the above example, the parameter was set into an action request in a JSP:

```
<portlet:param name="guestbookId"
        value="<%= String.valueOf(entry.getGuestbookId()) %>" />
```

You can also set attributes into the request using the method

```
request.setAttribute();
```

in your portlet class. To read the attribute in a JSP, use the method

```
request.getAttribute();
```

To set parameters into the response in your controller code, you can use the `setRenderParameter` method.

```
actionResponse.setRenderParameter("mvcPath", "/error.jsp");
```

Passing information back and forth from your view and controller is important, but there's more to the view layer than that.

Configuring the View Layer

You now know how to extend Liferay's `MVCPortlet` to write controller code and register a Component in the OSGi runtime. You also need a view layer, of course, and for that, you'll use JSPs. Lexicon can be used to guide your app's styling so it matches Liferay's. To learn about Lexicon and about some of Liferay's taglibs, refer to the tutorial Applying Lexicon Styles to Your App. This section will briefly cover how to get your view layer working, from organizing your imports in one JSP file, to configuring URLs that direct processing to your code in the portlet class.

It's a good practice to put all your Java imports, tag library declarations, and variable initializations into an `init.jsp` file. If you use Liferay @ide@ to create your Web module, these taglib declarations and initializations are automatically added to your `init.jsp`:

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>

<%@ taglib uri="http://java.sun.com/portlet_2_0" prefix="portlet" %>

<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>
<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>
<%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

<liferay-theme:defineObjects />

<portlet:defineObjects />
```

Make sure you include the `init.jsp` in your other JSP files:

```
<%@include file="/html/init.jsp"%>
```

You can, if necessary, write Java code in your JSPs using scriptlets. Perhaps you set an attribute into the request in your controller:

```
renderRequest.setAttribute("guestbookId", guestbookId);
```

You can reference it in your JSP by calling the `renderRequest.getAttribute` method:

```
<%
    long guestbookId = Long.valueOf((Long) renderRequest
            .getAttribute("guestbookId"));
%>
```

To construct a URL that calls the `render` method of your controller, you can use the `portlet:renderURL` tag:

```
<portlet:renderURL var="searchURL">
        <portlet:param name="mvcPath" value="/admin/view.jsp" />
</portlet:renderURL>
```

You create a variable to hold the generated URL with the var attribute. Then you can set any parameters you need using the `portlet:param` tag. The `mvcPath` parameter is used to direct to another JSP. The example above points to a JSP in

```
docs.liferaymvc.web/src/main/resources/META-INF/resources/admin/view.jsp
```

You can then use the var value to invoke the URL in your JSP code, perhaps in a button or navigation bar item.

Action URLs can be similarly created with the `portlet` taglib:

```
<portlet:actionURL name="doSomething" var="doSomethingURL">
    <portlet:param name="redirect" value="<%= redirect %>" />
</portlet:actionURL>
```

The name of the action URL should match the action method name in your portlet class; that's all Liferay's MVC framework needs in order to know that the action method of the same name should run when this action URL is invoked. Use the var attribute like you did the var attribute in the render URL; to call the action URL in your JSP code, whether it's in an icon, a button, or somewhere else.

As you can see, with Liferay MVC it's pretty easy to make your controller talk to your view layer.

Beyond the Basics

This tutorial should get you up and running with a Liferay MVC Web module, but there's more to know about creating an app in Liferay. Here are a few useful jumping off points:

- Making URLs Friendlier
- Applying Lexicon Styles to your App
- Localizing your Application
- Liferay's Workflow Framework
- Model Listeners
- Application Security
- Asset Framework
- Service Builder

60.6 MVC Action Command

Liferay's MVC framework lets you split your portlet's action methods into separate classes. This can be very helpful in portlets that have many actions. Each action URL in your portlet's JSPs then calls the appropriate action class when necessary.

First, use the `<portlet:actionURL>` tag to create the action URL in your JSP. For example, the edit blog entry action in Liferay's Blogs app is defined in the `edit_entry.jsp` file as follows:

```
<portlet:actionURL name="/blogs/edit_entry" var="editEntryURL" />
```

When the action URL is triggered, the matching action class processes the action. Implement the action by creating a class that implements the `MVCActionCommand` interface. To avoid writing oodles of boilerplate code, your `*MVCActionCommand` class should extend the `BaseMVCActionCommand` class instead of implementing `MVCActionCommand` directly. The `BaseMVCActionCommand` class already implements `MVCActionCommand` and provides many useful method implementations. Naming your `*MVCActionCommand` class after the action it performs is a good convention. For example, if your action edits some kind of entry, you could name its class `EditEntryMVCActionCommand`.

Your `*MVCActionCommand` class must also have a `@Component` annotation like the following. Set the property `javax.portlet.name` to your portlet's internal ID, and the property `mvc.command.name` to the value of the `name` property in your JSP's matching `actionURL`. To register the component in the OSGi container as using the `MVCActionCommand` class, you must set the `service` property to `MVCActionCommand.class`:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=your_portlet_name_YourPortlet",
        "mvc.command.name=/your/jsp/action/url"
    },
    service = MVCActionCommand.class
)
public class YourMVCActionCommand extends BaseMVCActionCommand {
    // implement your action
}
```

For example, this is the @Component annotation for the Blogs app's EditEntryMVCActionCommand class:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS,
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS_ADMIN,
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS_AGGREGATOR,
        "mvc.command.name=/blogs/edit_entry"
    },
    service = MVCActionCommand.class
)
public class EditEntryMVCActionCommand extends BaseMVCActionCommand {
    // the app's edit blog entry action implementation
}
```

Note that you can use multiple javax.portlet.name values to indicate the component works with multiple portlets.

In your *MVCActionCommand class, process the action by overriding the BaseMVCActionCommand class's doProcessAction method. This method takes javax.portlet.ActionRequest and javax.portlet.ActionResponse parameters that you can use to process your action. Your *MVCActionCommand class should also contain any other code required to implement your action. For a real-world example of a *MVCActionCommand class, see the Blogs app's EditEntryMVCActionCommand class.

MVC Command Overrides

60.7 MVC Render Command

If you're here, that means you know that MVCRenderCommands are used to respond to portlet render URLs, and you want to know how to create and use MVC render commands. If you just want to learn about Liferay's MVC Portlet framework in general, that information is in a separate article.

To use MVC render commands, you need these things:

- An implementation of the MVCRenderCommand interface.
- A portlet render URL in your view layer.
- a Component that publishes the MVCRenderCommand service, with two properties.

Implementing MVCRenderCommand

What is it you want to do when a portlet render URL is invoked? Using the mvcRenderCommandName parameter, direct the request to an MVCRenderCommand implementation. Now override the render method.

Some MVCRenderCommands will simply render a particular JSP. Here's what BlogsViewMVCRenderCommand looks like:

```
@Override
public String render(
    RenderRequest renderRequest, RenderResponse renderResponse) {

    return "/blogs/view.jsp";
}
```

Sometimes you'll want to add logic to render a certain JSP based on one or more conditions:

```
@Override
public String render(
    RenderRequest renderRequest, RenderResponse renderResponse)
    throws PortletException {

    try {
        ActionUtil.getEntry(renderRequest);
    }
    catch (Exception e) {
        if (e instanceof NoSuchEntryException ||
            e instanceof PrincipalException) {

            SessionErrors.add(renderRequest, e.getClass());

            return "/hello/error.jsp";
        }
        else {
            throw new PortletException(e);
        }
    }

    return "/hello/edit_entry.jsp";
}
```

If there's an error caught following the call to `ActionUtil.getEntry` in the code above, the `error.jsp` is rendered. If the call is returned without an exception being caught, `edit_entry.jsp` is rendered.

How does a request get directed to your MVC render command? Using a portlet render URL.

Creating a Portlet Render URL

You can generate a render URL for your portlet using the `<portlet:renderURL>` taglib. To invoke your MVC render command from the render URL, you need to specify the parameter `mvcRenderCommandName` with the same value as your Component property `mvc.command.name`.

For example, you can create a URL that directs the user to a page with a form for editing an entry like this (in a JSP):

```
<portlet:renderURL var="editEntryURL">
    <portlet:param name="mvcRenderCommandName" value="/hello/edit_entry" />
    <portlet:param name="entryId" value="<%= String.valueOf(entry.getEntryId()) %>" />
</portlet:renderURL>
```

Now the request will contain a parameter named `mvcRenderCommandName`. To find the proper MVC render command, the OSGi runtime needs to have a `mvc.command.name` property with a matching value.

Registering the MVC Render Command

In order to respond to a particular render URL, you need an `MVCRenderCommand` Component that with two properties:

```
 "javax.portlet.name=" + HelloWorldPortletKeys.HELLO_WORLD,
 "mvc.command.name=/hello/edit_entry"
```

Using the above properties as an example, any portlet render URL for the portlet that includes a parameter called mvcRenderCommand with the value /hello/edit_entry will be handled by this MVCRenderCommand.

The Component must also publish a MVCRenderCommand.class service to the OSGi runtime. Here's a basic Component that publishes an MVC render command.

```
@Component(
    immediate = true,
    property = {
       "javax.portlet.name=" + HelloWorldPortletKeys.HELLO_WORLD,
       "mvc.command.name=/hello/edit_entry"
    },
    service = MVCRenderCommand.class
)
public class EditEntryMVCRenderCommand implements MVCRenderCommand {
```

One command can be used by one portlet, as the example above shows. If you want, one command can be used for multiple portlets by adding more javax.portlet.name entries in the property list. Likewise, multiple commands can invoke the MVC command class by adding more mvc.command.name entries. If you're really feeling wild, you can specify multiple portlets and multiple command URLs in the same command component, like this:

```
@Component(
    immediate = true,
    property = {
       "javax.portlet.name=" + HelloWorldPortletKeys.HELLO_MY_WORLD,
       "javax.portlet.name=" + HelloWorldPortletKeys.HELLO_WORLD,
       "mvc.command.name=/hello/edit_super_entry",
       "mvc.command.name=/hello/edit_entry"
    },
    service = MVCRenderCommand.class
)
```

As you can see, MVC render commands are flexible and very easy to implement.

MVC Resource Command

MVC Action Command

MVC Command Overrides

60.8 MVC Resource Command

When using Liferay's MVC framework, you can create resource URLs in your JSPs to retrieve images, XML, or any other kind of resource from a Liferay instance. The resource URL then invokes the corresponding MVC resource command class (*MVCResourceCommand) that processes the resource request and response.

First, use the <portlet:resourceURL> tag to create the resource URL in a JSP. For example, the Login Portlet's /login-web/src/main/resources/META-INF/resources/navigation/create_account.jsp file defines the following resource URL for retrieving a CAPTCHA image during account creation:

```
<portlet:resourceURL id="/login/captcha" var="captchaURL" />
```

When the resource URL is triggered, the matching *MVCResourceCommand class processes the resource request and response. You can create this class by implementing the MVCResourceCommand interface, or extending the BaseMVCResourceCommand class. The latter may save you time, since it already implements MVCResourceCommand.

Also, it's a good idea to name your *MVCResourceCommand class after the resource it handles, and suffix it with MVCResourceCommand. For example, the resource command class matching the preceding CAPTCHA resource URL in the Login Portlet is CaptchaMVCResourceCommand. In an application with several MVC command classes, this will help differentiate them.

Your *MVCResourceCommand class must also have a @Component annotation like the following. Set the property javax.portlet.name to your portlet's internal ID, and the property mvc.command.name to the value of the id property in your JSP's matching resourceURL. To register the component in the OSGi container as using the MVCResourceCommand class, you must set the service property to MVCResourceCommand.class:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=your_portlet_name_YourPortlet",
        "mvc.command.name=/your/jsp/resource/url"
    },
    service = MVCResourceCommand.class
)
public class YourMVCResourceCommand implements MVCResourceCommand {
    // your resource handling code
}
```

As a real-world example, consider the Login Portlet's CaptchaMVCResourceCommand class (find this class in the Liferay source code at modules/apps/foundation/login/login-web/src/main/java/com/liferay/login/web/internal/portle

```
@Component(
    property = {
        "javax.portlet.name=" + LoginPortletKeys.FAST_LOGIN,
        "javax.portlet.name=" + LoginPortletKeys.LOGIN,
        "mvc.command.name=/login/captcha"
    },
    service = MVCResourceCommand.class
)
public class CaptchaMVCResourceCommand implements MVCResourceCommand {

    @Override
    public boolean serveResource(
        ResourceRequest resourceRequest, ResourceResponse resourceResponse) {

        try {
            CaptchaUtil.serveImage(resourceRequest, resourceResponse);

            return false;
        }
        catch (Exception e) {
            _log.error(e, e);

            return true;
        }
    }

    private static final Log _log = LogFactoryUtil.getLog(
        CaptchaMVCResourceCommand.class);
}
```

In the @Component annotation, note that javax.portlet.name has two different settings. This lets multiple portlets use the same component. In this example, the portlet IDs are defined as constants in the LoginPortletKeys class. Also note that the mvc.command.name property setting /login/captcha matches the resourceURL's id setting shown earlier in this tutorial, and that the service property is set to MVCResourceCommand.class.

The CaptchaMVCResourceCommand class implements the MVCResourceCommand interface with only a single method: serveResource. This method processes the resource request and response via the javax.portlet.ResourceRequest and javax.portlet.ResourceResponse parameters, respectively. Note that the try block uses the helper class CaptchaUtil to serve the CAPTCHA image. Though you don't have to create such a helper class, doing so often simplifies your code.

Great! Now you know how to use MVCResourceCommand to process resources in your Liferay MVC portlets.

Chapter 61

Liferay Soy Portlet

A Soy portlet is an extension of Liferay's MVC portlet framework. This gives you access to all the MVC Portlet functionality you are familiar with, plus the added bonus of using Soy templates for writing your front-end. Soy templates use an easy templating language that also lets you use MetalJS components. With all these benefits and more, Soy portlets can be a good front-end tool to have in your utility belt.

You can learn about Liferay MVC portlets in the Creating an MVC Portlet tutorial.

This section covers how to implement a Soy portlet.

61.1 Creating a Soy Portlet

To create a Soy portlet, you'll need these key components:

- A module that publishes a portlet component with the necessary properties
- Controller code to handle the request and response
- Soy templates to implement your view layer

Configuring the Web Module

First, familiarize yourself with a Soy portlet's anatomy. You may recognize it, since a Soy portlet extends an MVC portlet:

- `my-soy-portlet`
    - `bnd.bnd`
    - `build.gradle`
    - `package.json`
    - `src/main/`
        - `java/path/to/portlet/`
            - `MySoyPortlet.java`
            - `action/`
            - `*MVCRenderCommand.java`

* resources/META-INF/resources/

  - content/
  - Language.properties

  - View.es.js (MetalJS component)
  - View.soy (Soy template)

Now that you know the basic structure of a Soy portlet module, you can configure it. You can use the soy portlet Blade template to build your initial project if you wish. Otherwise, you can follow the instructions in this section to manually configure the module.

Specifying OSGi Metadata

Add the OSGi metadata to your module's `bnd.bnd` file. A sample BND configuration is shown below:

```
Bundle-Name: Liferay Hello Soy Web
Bundle-SymbolicName: com.liferay.hello.soy.web
Bundle-Version: 1.0.3
Require-Capability:\
    soy;\
        filter:="(type=metal)"
Include-Resource: package.json
```

In addition to the standard metadata, notice the `Require-Capability` property. This specifies that this bundle requires modules that provide the capability `soy` with a `type` of `metal` to work. Also note the `Include-Resource` property. **You must include your `package.json` file to load the Soy Portlet's JavaScript files.**

Specifying JavaScript Dependencies

Specify the JavaScript module dependencies in your `package.json`. At a minimum, you should have the following dependencies and configuration parameters:

```
{
    "dependencies": {
        "metal-component": "^2.4.5",
        "metal-soy": "^2.4.5"
    },
    "devDependencies": {
        "liferay-module-config-generator": "^1.2.1",
        "metal-cli": "^4.0.1"
    },
    "name": "my-portlet-name",
    "version": "1.0.0"
}
```

This provides everything you need to create a Metal component based on Soy. Note that the `version` in your `package.json` should match the `Bundle-Version` in your `bnd.bnd` file.

Next you can specify your module's build dependencies.

Specifying Build Dependencies

Add the dependencies shown below to your `build.gradle` file:

```
dependencies {
    provided group: "com.liferay", name: "com.liferay.portal.portlet.bridge.soy", version: "3.1.0"
    provided group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    provided group: "com.liferay.portal", name: "com.liferay.util.java", version: "2.0.0"
    provided group: "javax.portlet", name: "portlet-api", version: "2.0"
    provided group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
    provided group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

Note: These are current at the time of this writing, but may change. Please check the Nexus Repository for the proper versions for your Liferay DXP instance.

Now that your module build is configured, you can learn how to create the Soy portlet component.

Creating a Soy Portlet Component

Create a Soy Portlet component that extends the `SoyPortlet` class. This requires an implementation of the `javax.portlet.portlet` service to run. Declare this using an `@Component` annotation in the portlet class:

```
@Component(
    immediate = true,
    service = Portlet.class
)
public class MySoyPortlet extends SoyPortlet {
    @Override
    public void render(RenderRequest renderRequest, RenderResponse renderResponse) {
        //do things here
    }
}
```

Liferay DXP's `SoyPortlet` class extends Liferay DXP's `MVCPortlet` class, which is an extension itself of `javax.portlet.Portlet`, so you've provided the right implementation.

The component requires some properties as well. A sample configuration is shown below:

```
@Component(
        immediate = true,
        property = {
          "com.liferay.portlet.add-default-resource=true",
          "com.liferay.portlet.application-type=full-page-application",
          "com.liferay.portlet.application-type=widget",
          "com.liferay.portlet.display-category=category.sample",
          "com.liferay.portlet.layout-cacheable=true",
          "com.liferay.portlet.preferences-owned-by-group=true",
          "com.liferay.portlet.private-request-attributes=false",
          "com.liferay.portlet.private-session-attributes=false",
          "com.liferay.portlet.render-weight=50",
          "com.liferay.portlet.scopeable=true",
          "com.liferay.portlet.use-default-template=true",
          "javax.portlet.display-name=Hello Soy Portlet",
          "javax.portlet.expiration-cache=0",
          "javax.portlet.init-param.copy-request-parameters=true",
          "javax.portlet.init-param.template-path=/",
          "javax.portlet.init-param.view-template=View",
          "javax.portlet.name=hello_soy_portlet",
          "javax.portlet.resource-bundle=content.Language",
            "javax.portlet.security-role-ref=guest,power-user,user",
            "javax.portlet.supports.mime-type=text/html"
        },
        service = Portlet.class
)
```

Some of these properties may seem familiar to you, as they are the same ones used to develop an MVC portlet. You can find a list of all the Liferay-specific attributes that are available for use as properties in your portlet components in the `liferay-portlet-app_7_0_0.dtd`.

The `javax.portlet...` properties are elements of the portlet.xml descriptor

Liferay's DTD files can be found here

Now that you've set your Soy portlet component's foundation, you can write the controller code.

Writing Controller Code

Soy portlets extend MVC portlets, so they use the same Model-View-Controller framework to operate. Your controller receives requests from the front-end, and it receives data from the back-end. It's responsible for sending that data to the right front-end view so it can be displayed to the user, and it's responsible for taking data the user entered in the front-end and passing it to the right back-end service. For this reason, it needs a way to process requests from the front-end and respond to them appropriately, and it needs a way to determine the appropriate front-end view to pass data back to the user.

Render Logic

The render logic is where all the magic happens. After all, what's the use of a portlet if you can't see it? Note the `init-param` properties you set in your Component class:

```
"javax.portlet.init-param.template-path=/",
"javax.portlet.init-param.view-template=View",
```

This directs the default rendering to View (`View.soy`). The `template-path` property tells the framework the location of your Soy templates. The / above means that the Soy files are located in your project's root `resources` folder. That's why it's important to follow Liferay DXP's standard folder structure, outlined above. Here's the path of a hypothetical web module's resource folder:

```
docs.liferaysoy.web/src/main/resources/META-INF/resources
```

In this case, the `View.soy` file is found at:

```
docs.liferaysoy.web/src/main/resources/META-INF/resources/View.soy
```

That's the default view of the application. When the `init` method is called, the initialization parameters you specify are read and used to direct rendering to the default template. Throughout this framework, you can render a different view (Soy template) by setting the `mvcRenderCommandName` parameter of the `javax.portlet.PortletURL` to the Soy template. The example below uses a portlet URL called `navigationURL` to render the view `View`:

```
navigationURL.setParameter("mvcRenderCommandName", "View");
```

Each view, excluding the default template view, **must have** an implementation of the `MVCRenderCommand` class. The `*MVCRenderCommand` implementation must declare itself as a component with the `MVCRenderCommand` service, and it must specify the portlet's name and MVC command name using the `javax.portlet.name` and `mvc.command.name` properties respectively. Below is an example `MVCRenderCommand` implementation for a `Navigation` Soy template:

```
@Component(
        immediate = true,
        property = {
                "javax.portlet.name=hello_soy_portlet",
                "mvc.command.name=Navigation"
        },
        service = MVCRenderCommand.class
)
public class HelloSoyNavigationExampleMVCRenderCommand
        implements MVCRenderCommand {

        @Override
        public String render(
                RenderRequest renderRequest, RenderResponse renderResponse) {

                Template template = (Template)renderRequest.getAttribute(
                        WebKeys.TEMPLATE);

                PortletURL navigationURL = renderResponse.createRenderURL();

                navigationURL.setParameter("mvcRenderCommandName", "View");

                template.put("navigationURL", navigationURL.toString());

                return "Navigation";
        }

}
```

The render logic provides the view layer with information to display the data properly to the user. In this case the MVC command name is set to `Navigation` (the Soy template with namespace `Navigation`). The MVC render command name for the `PortletURL` `navigationURL` is set to `View` (the Soy template with namespace `Navigation`), using the `mvcRenderCommandName` attribute. The `navigationURL` parameter is passed to the `Navigation` Soy template as the variable `navigationURL`, using the `template.put()` method. Finally, the `*MVCRenderCommand` class returns the MVC render command name as a `String`.

Note that Soy portlet parameters are scoped to the portlet class they're written in. For instance, you can have a `navigationURL` parameter in two different classes, each with a different value. Below is an example `HelloSoyPortlet` class that also defines a `navigationURL` parameter:

```
public class HelloSoyPortlet extends SoyPortlet {

    @Override
    public void render(
            RenderRequest renderRequest, RenderResponse renderResponse)
        throws IOException, PortletException {

        PortletURL navigationURL = renderResponse.createRenderURL();

        navigationURL.setParameter("mvcRenderCommandName", "Navigation");

        template.put("navigationURL", navigationURL.toString());

        template.put("releaseInfo", ReleaseInfo.getReleaseInfo());

        super.render(renderRequest, renderResponse);
    }

}
```

The `navigationURL` points to the `Navigation` Soy template this time. The `navigationURL` and `releaseInfo` parameters are passed to the `View` Soy template. Since this logic should be executed before the default `render` method, the method concludes by calling `super.render`.

Now that you understand the render logic, you can learn how the view layer works.

Configuring the View Layer

Your portlet also requires a view layer, and for that you'll use Soy templates, which is the whole point of developing a Soy portlet, isn't it? This section briefly covers how to get your view layer working, from including other Soy templates, to creating a MetalJS component for rendering your views.

Soy templates are defined in a file with the extension `.soy`. The filename is arbitrary. The Soy template's name is specified at the top of the template using the `namespace` declaration. For example, this template has the namespace `View`:

```
{namespace View}
```

It can be accessed in another Soy template by calling the `render` method on the namespace as shown below:

```
{call View.render data="all"}{/call}
```

Below is an example `View` Soy template that includes `Header` and `Footer` Soy templates:

```
{namespace View}

/**
 * Prints the portlet main view.
 */
{template .render}
  <div id="{$id}">
    {call Header.render data="all"}{/call}

    <p>{msg desc=""}here-is-a-message{/msg}</p>

    {call Footer.render data="all"}{/call}
  </div>
{/template}
```

Each view has a corresponding `*es.js` file (usually with the same name) that imports the Soy templates the view requires and registers the view as a MetalJS component. This file is also used for any additional JavaScript logic your view may have. For example, here is a `View.es.js` component for a `View.soy` template:

```
import Component from 'metal-component/src/Component';
import Footer from './Footer.es';
import Header from './Header.es';
import Soy from 'metal-soy/src/Soy';
import templates from './View.soy';

/**
 * View Component
 */
class View extends Component {}

// Register component
Soy.register(View, templates);

export default View;
```

Now that you understand how to configure a Soy template view, you can learn how to use portlet parameters in your Soy templates next.

Using Portlet Template Parameters in the Soy Template

As mentioned above, the `template.put()` method exposes portlet parameters to the Soy templates. Once a parameter is exposed, you can access it in the Soy template by defining it at the top with the `{@param name: type}` declaration. For instance, the `hello-soy-web` portlet's `View` Soy template defines the `navigationURL` parameter with the code below:

```
{@param navigationURL: string}
```

It is then used to navigate between portlet views:

```
<a href="{$navigationURL}">{msg desc=""}
    click-here-to-navigate-to-another-view
{/msg}</a>
```

Some Java theme object variables are available as well. For example, to access the `ThemeDisplay` object in a Soy template, use the following syntax:

```
{$themeDisplay}
```

You can also access the `Locale` object by using `{$locale}`. Here is the full `View.soy` template for the `com.liferay.hello.soy.web` portlet, which demonstrates the features covered in this section:

```
{namespace View}

/**
 * Prints the portlet main view.
 */
{template .render}
    {@param id: string}
    {@param layouts: list<[
        friendlyURL: string,
        nameCurrentValue: string
    ]>}
    {@param navigationURL: string}

    <div id="{$id}">
        {call Header.render data="all"}{/call}

        <p>{msg desc=""}here-you-will-find-how-easy-it-is-to-do-things-like{/msg}</p>

        <h3>{msg desc=""}listing-pages{/msg}</h3>

        <div class="list-group">
            <div class="list-group-heading">{msg desc=""}navigate-to{/msg}</div>

            {foreach $layout in $layouts}
                <a class="list-group-item" href="{$layout.friendlyURL}">{$layout.nameCurrentValue}</a>
            {/foreach}
        </div>

        <h3>{msg desc=""}navigating-between-views{/msg}</h3>

        <a href="{$navigationURL}">{msg desc=""}click-here-to-navigate-to-another-view{/msg}</a>

        {call Footer.render data="all"}{/call}
    </div>
{/template}
```

Now you know how to create a Soy Portlet!

CHAPTER 62

THE STATE OBJECT

MetalJS's `component` class, which your view component extends, extends MetalJS's `state` class. The `state` class provides a `STATE` object that contains state properties, as well as watches these properties for changes. Any template parameters defined in your portlet classes are automatically added as properties to the portlet's `STATE` object. The `component` class provides additional rendering logic, such as automatically re-rendering the component when the `state` class detects a change in a state property. This means that you can change a state property on the client-side and automatically see that change reflected in the component's UI!

This section of tutorials covers how to configure and use your Soy portlet's `STATE` object.

62.1 Understanding The State Object's Architecture

An example `STATE` object configuration appears below:

```
View.STATE {
  myStateProperty: {
    setter: 'setterFunction',
    validator: val => val === expected value,
    value: default value,
    valueFn: val => default value,
    writeOnce: true
  }
}
```

State properties have these configuration options:

setter: Normalizes the state key's value. The setter function receives the new value that was set and return the value that should be stored.

validator: Validates the state key's value. When it returns `false`, the new value is ignored.

value: The state key's default value. Alternatively, you can set the default value with the `valueFn` property. Setting this to an object causes all class instances to use the same reference to the object. To have each instance use a different reference for objects, use the `valueFn` option instead. Note that the portlet template parameter's value (if applicable) has priority over this value.

valueFn: A function that returns the state key's default value. Alternatively, you can set the default value with the `value` property. Note that the portlet template parameter's value (if applicable) has priority over this value.

writeOnce: Whether the state key is read-only, meaning the initial value is the final value.

Now you know the `STATE` object's architecture and how to configure it!

Related Topics

Configuring Portlet Template Parameter State Properties

Configuring Soy Portlet Template Parameters on the Client Side

62.2 Configuring Portlet Template Parameter State Properties

Portlet template parameters are added automatically as state properties to the view component's `STATE` object. Therefore, you can provide additional configuration options for them in the `STATE` object. The example below sets the default value for the portlet template parameter `color` in its `*MVCRenderCommand` class:

```
Template template = (Template)renderRequest.getAttribute(
            WebKeys.TEMPLATE);

String color = "red";

template.put("color", color);
```

The configuration above has the implicit state property configuration shown below in the view's component file (`View.es.js` for example):

```
   View.STATE {
     color: {
       value: 'red'
     }
   }
```

You can provide additional settings by configuring the state Property in the `View` component. The example below defines a `setter` function that transforms the color's string to upper case before adding it to the `STATE` object:

```
function setColor(color) {
  return color.toUpperCase();
}

View.STATE = {
  color: {
    setter: 'setColor'
  }
}
```

Now you know how to configure portlet template parameter state properties!

Understanding the State Object's Architecture

Configuring Soy Portlet Template Parameters on the Client Side

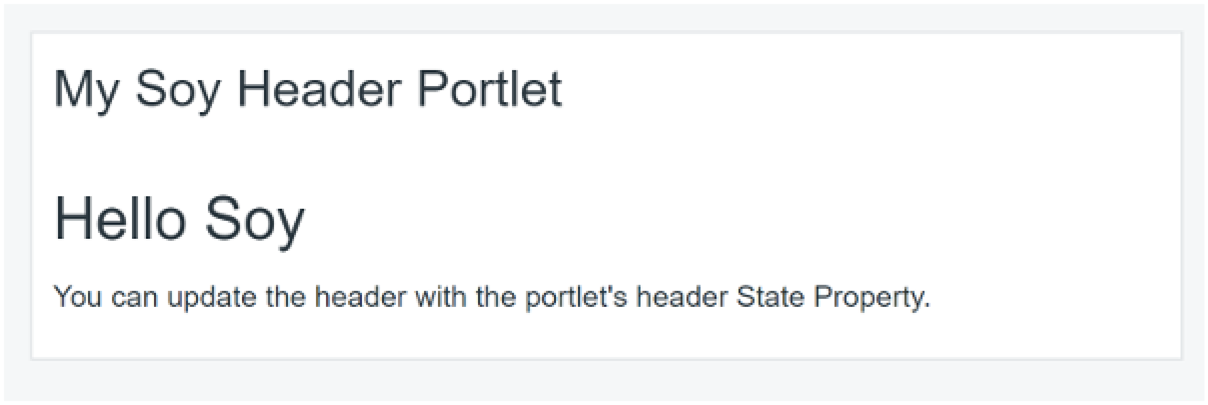
62.3 Configuring Soy Portlet Template Parameters on the Client Side

Portlet template parameters are set in the Soy Portlet's server-side code. MetalJS's `state` class provides a `STATE` object that exposes these parameters as properties so you can access them on the client side. This tutorial covers how to configure your view component's `STATE` object and its properties on the client side so you can update the UI.

This tutorial references the example below.

An Example Header State Portlet

This tutorial references the example portlet covered in this section. It includes one view with a header that reads *Hello Soy* by default.



My Soy Header Portlet
Hello Soy
You can update the header with the portlet's header State Property.

Figure 62.1: The example Soy portlet has a configurable header.

The text in the header following *Hello* is provided by the `header` state property defined in its `*mvcRenderCommand` class. Deploy the provided `com.liferay.docs.state.soy-1.0.0.jar` file to follow along with this tutorial. The example portlet's *MVCRenderCommand class and Soy template appear below for reference:

`*MVCRenderCommand` class:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=MyStateSoyPortlet", "mvc.command.name=View",
        "mvc.command.name=/"
    },
    service = MVCRenderCommand.class
)
public class MyStateSoyPortletViewMVCRenderCommand
    implements MVCRenderCommand {

    @Override
    public String render(
        RenderRequest renderRequest, RenderResponse renderResponse) {

        Template template = (Template)renderRequest.getAttribute(
            WebKeys.TEMPLATE);

        String header = "Soy";

        template.put("header", header);

        return "View";
    }

}
```

`View.soy`:

```
{namespace View}

/**
 * Prints the portlet main view.
 */
```

```
{template .render}
    {@param id: string}
    {@param header: string}

    <div id="{$id}">

        <h1>Hello {$header}</h1>

        <p>You can update the header with the portlet's header State properties.</p>
    </div>
{/template}
```

Configuring the State properties

Soy Portlets are registered automatically using the `Liferay.component` API, so you can use this API to retrieve your portlet and update its state properties. You can test this in your browser's developer console.

Follow these steps:

1. Open the console in your web browser.

2. Retrieve your portlet's component by passing the Soy portlet's ID in the method `Liferay.component()`. For example, you can access the example portlet's component with the code below:

   ```
   Liferay.component('_MyStateSoyPortlet_');
   ```

   This returns the Soy portlet's component Object containing the state properties along with properties inherited from the prototype. Alternatively, you can access the `STATE` object directly by calling the `getState()` method:

   ```
   Liferay.component("_MyStateSoyPortlet_").getState();
   ```

```
**Note:** The `Liferay.component()` method only returns the `STATE` object
information for components currently on the page. These are the state
properties defined for the current view.
```

---

3. Now that you retrieved your Soy portlet's component, you can access its state properties the same way you would access any object's properties: the dot notation or the bracket notation. For example, you can use the code below to retrieve the `com.liferay.docs.state.soy` portlet's header state property:

   ```
   Liferay.component("_MyStateSoyPortlet_").header;
   ```

   or

   ```
   Liferay.component("_MyStateSoyPortlet_")["header"]
   ```

4. Update the state property's value:

   ```
   Liferay.component("portletID").stateProperty = "new value";
   ```

or

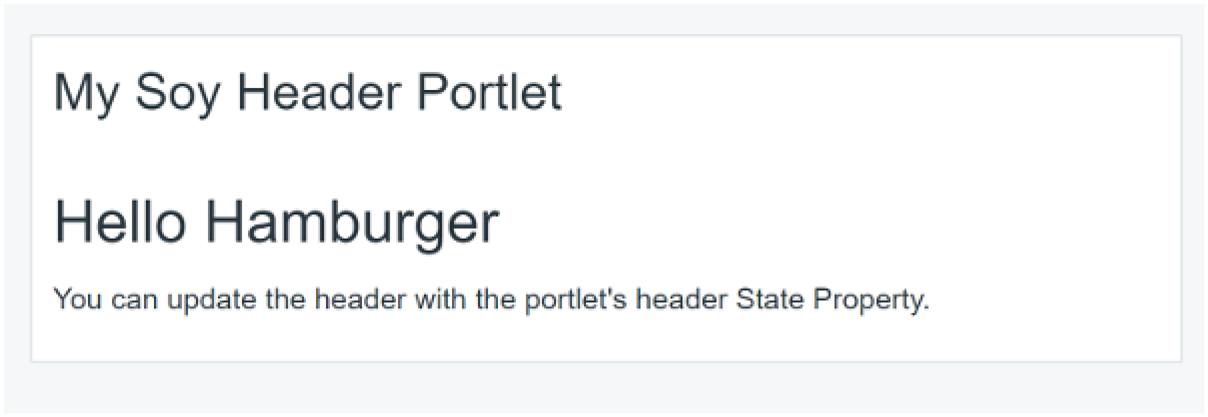
```
Liferay.component("portletID")["stateProperty"] = "new value";
```

or you can pass a configuration object with the `setState()` method:

```
Liferay.component("portletID").setState({stateProperty: new value});
```

For example, you can change the example portlet's header to read *Hello Hamburger* instead, if you don't like soy:

```
Liferay.component('_MyStateSoyPortlet_').setState({header: 'Hamburger'});
```



My Soy Header Portlet

Hello Hamburger

You can update the header with the portlet's header State Property.

Figure 62.2: You can change the example portlet's header state property on the client side.

Now you know how to configure Soy portlet state properties on the client side!

Chapter 63

Spring MVC

Liferay is an open platform in an ecosystem of open platforms. Just because Liferay has its own MVC framework, therefore, doesn't mean you have to use it. It is perfectly valid to bring the tools and experience you have from other development projects over to Liferay. In fact, we expect you to. Liferay's development platform is standards-based, making it an ideal choice for applications of almost any type.

If you're already a wizard with Spring MVC, you can use it instead of Liferay's `MVCPortlet` class with no limitations whatsoever. Since Spring MVC replaces only your application's web application layer, you can still use Service Builder for your service layer.

So what does it take to implement a Spring MVC application in Liferay? Start by considering how to package a Spring MVC application for 7.0.

63.1 Packaging a Spring MVC Portlet

Developers creating portlets for 7.0 can usually deploy their portlet as Java EE-style Web Application ARchive (WAR) artifacts or as Java ARchive (JAR) OSGi bundle artifacts. Spring MVC portlet developers don't have that flexibility. Spring MVC portlets must be packaged as WAR artifacts because the Spring MVC framework is designed for Java EE. Therefore, it expects a WAR layout and requires Java EE resources such as the `WEB-INF/web.xml` descriptor.

Because Liferay supports the OSGi WAB (Web Application Bundler) standard for deployment, you can deploy your WAR and it runs as expected in the OSGi runtime. Here are the high points on why that works in 7.0:

- The Liferay auto-deploy process runs, adding the `PortletServlet` and `PlugincontextListener` configurations to the `WEB-INF/web.xml` file.
- The Liferay WAB Generator automatically creates an OSGi-ready `META-INF/MANIFEST.MF` file. If you want to affect the content of the manifest file, you can place BND directives and OSGi headers directly into the `WEB-INF/liferay-plugin-package.properties` file.

You'll still need to provide the Liferay descriptor files `liferay-display.xml` and `liferay-portlet.xml`, and you'll need a `portlet.xml` descriptor.

Develop a Spring MVC portlet WAR file with the appropriate descriptor files.

Import class packages your portlet's descriptor files reference by adding the packages to an `Import-Package` header in your `liferay-plugin-package.properties` file.

Here's an example Import-Package header:

```
Import-Package:\
    org.springframework.beans.factory.xml,\
    org.springframework.context.config,\
    org.springframework.security.config,\
    org.springframework.web.servlet.config
```

The auto-deploy process and Liferay's WAB generator convert your project to a Liferay-ready WAB. The WAB generator detects your class's import statements and adds all external packages to the WAB's Import-Package header. The generator merges packages from your plugin's liferay-plugin-package.properties into the header also.

If you depend on a package from Java's rt.jar other than a java.* package, override portal property org.osgi.framework.bootdelegation and add it to the property's list. Go here for details.

Note: Spring MVC portlets whose embedded JARs contain properties files (e.g., spring.handlers, spring.schemas, spring.tooling) might be affected by issue LPS-75212. The last JAR that has properties files is the only JAR whose properties are added to the resulting WAB's classpath. Properties in other JARs aren't added.

For example, suppose that a portlet has several JARs containing these properties files:

- WEB-INF/src/META-INF/spring.handlers
- WEB-INF/src/META-INF/spring.schemas
- WEB-INF/src/META-INF/spring.tooling

The properties from the last JAR processed are the only ones added to the classpath. The properties files must be on the classpath in order for the module to use them.

To add all the properties files to the classpath, you can combine them into one of each type (e.g., one spring.handlers, one spring.schemas, and one spring.tooling) and add them to WEB-INF/src.

Here's a shell script that combines these files:

```
cat /dev/null > docroot/WEB-INF/src/META-INF/spring.handlers
cat /dev/null > docroot/WEB-INF/src/META-INF/spring.schemas
cat /dev/null > docroot/WEB-INF/src/META-INF/spring.tooling
for jar in $(find docroot/WEB-INF/lib/ -name '*.jar'); do
for file in $(unzip -l $jar | grep -F META-INF/spring. | awk '
{ print $4 }
'); do
if [ "META-INF/spring.tld" != "$file" ]; then
unzip -p $jar $file >> docroot/WEB-INF/src/$file
echo >> docroot/WEB-INF/src/$file
fi
done
done
```

You can modify and use the shell script to add your JAR's properties files to the classpath.

Note: If you want to use a Spring Framework version different from the version Liferay DXP provides, you must name your Spring Framework JARs differently from the ones portal property module.framework.web.generator.excluded.paths excludes. If you don't rename your Spring Framework JARs, the WAB generator assumes you're using Liferay DXP's Spring Framework JARs and excludes yours from the generated WAB. Understanding Excluded JARs explains how to detect Liferay DXP's Spring Framework version.

Now get into the details of configuring a Spring MVC portlet for Liferay.

63.2 Spring MVC Portlets in Liferay

This isn't a comprehensive guide to configuring a Spring MVC portlet. It covers the high points, assuming you already have familiarity with Spring MVC. If you don't, you should consider using Liferay's MVC framework.

What does a Liferay Spring MVC portlet look like? Almost identical to any other Spring MVC portlet. To configure a Spring MVC portlet, start with the `<portlet-class>` element in `portlet.xml`. In it you must declare Spring's `DispatcherPortlet`:

```
<portlet-class>org.springframework.web.portlet.DispatcherPortlet</portlet-class>
```

The Spring front controller needs to know where the application context file is, so specify it as an initialization parameter in `portlet.xml` (update the path as needed):

```
<init-param>
    <name>contextConfigLocation</name>
    <value>/WEB-INF/spring/portlet-context.xml</value>
</init-param>
```

Provide an application context file (`portlet-context.xml` in the example above), specified as you normally would for your Spring MVC portlet.

```
<bean id="viewResolver" class="org.springframework.web.servlet.view.InternalResourceViewResolver">
    <property name="prefix" value="/WEB-INF/views/" />
    <property name="suffix" value=".jsp" />
</bean>
```

If you're configuring a WAB yourself, the `web.xml` file in your Spring MVC project needs to be fully ready for deployment. In addition to any `web.xml` configuration for Spring MVC, you need to include a listener for `PluginContextListener` and a `servlet` and `servlet-mapping` for `PortletServlet`:

```
<listener>
    <listener-class>com.liferay.portal.kernel.servlet.PluginContextListener</listener-class>
</listener>
<servlet>
    <servlet-name>Portlet Servlet</servlet-name>
    <servlet-class>com.liferay.portal.kernel.servlet.PortletServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
    <servlet-name>Portlet Servlet</servlet-name>
    <url-pattern>/portlet-servlet/*</url-pattern>
</servlet-mapping>
```

If you're letting Liferay generate the WAB for you (this is the recommended approach), the above is not necessary, as it is added automatically during auto-deployment.

Your application must be able to convert `javax.portlet.PortletRequests` to `javax.servlet.ServletRequests` and back again. Add this to `web.xml`:

```
<servlet>
    <servlet-name>ViewRendererServlet</servlet-name>
    <servlet-class>org.springframework.web.servlet.ViewRendererServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
    <servlet-name>ViewRendererServlet</servlet-name>
    <url-pattern>/WEB-INF/servlet/view</url-pattern>
</servlet-mapping>
```

To configure the Spring view resolver, add a bean in your application context file:

```
<bean id="viewResolver" class="org.springframework.web.servlet.view.InternalResourceViewResolver">
    <property name="prefix" value="/WEB-INF/views/" />
    <property name="suffix" value=".jsp" />
</bean>
```

Now the front controller, `org.springframework.web.portlet.DispatcherPortlet`, can get a request from the view layer, but there are no actual controller classes to delegate the request handling to.

With Spring MVC, your controller is conveniently separated into classes that handle the portlet modes (View, Edit, Help).

You'll use Spring's annotations to configure the controller and tell `DispatcherPortlet` which mode the controller supports.

A simple controller class supporting View mode might look like this:

```
@Controller("myAppController")
@RequestMapping("VIEW")
public class MyAppController {

    @RenderMapping
    public String processRenderRequest(RenderRequest request,
            RenderResponse response) {

        return "defaultView";
    }
}
```

The return `defaultView` statement should be understood in terms of the view resolver bean in the application context file, which gives the String `defaultView` a prefix of `WEB-INF/views/`, and a suffix of `.jsp`. That maps to the path `WEB-INF/views/defaultView.jsp`, where you would place your default view for the application.

With Spring MVC, you can only support one portlet phase in each controller.

An edit mode controller might contain render methods and action methods.

```
@Controller("myAppEditController")
@RequestMapping("EDIT")
public class MyAppEditController {

    @RenderMapping
    public String processRenderRequest(RenderRequest request,
            RenderResponse response) {

        return "thisView";
    }

    @ActionMapping(params="action=doSomething")
    public void doSomething(Actionrequest request, ActionResponse response){

        // Do something here

    }
}
```

You need to define any controller classes in your application context file by adding a <bean> tag for each one:

```
<bean class="com.liferay.docs.springmvc.portlet.MyAppController" />
<bean class="com.liferay.docs.springmvc.portlet.MyAppEditController" />
```

Develop your controllers and your views as you normally would in a Spring MVC portlet. You'll also need to provide some necessary descriptors for Liferay.

Liferay Descriptors

Liferay portlet plugins that are packaged as WAR files should include some Liferay specific descriptors.

The descriptor `liferay-display.xml` controls the category in which your portlet appears in Liferay DXP's *Add* menu. Find the complete DTD here.

Here's a simple example that just specifies the category the application will go under in Liferay's menu for adding applications:

```
<display>
    <category name="New Category">
        <portlet id="example-portlet" />
    </category>
</display>
```

The descriptor `liferay-portlet.xml` is used for specifying additional information about the portlet (like the location of CSS and JavaScript files or the portlet's icon. A complete list of the attributes you can set can be found here

```
<liferay-portlet-app>
    <portlet>
        <portlet-name>example-portlet</portlet-name>
        <instanceable>true</instanceable>
        <render-weight>0</render-weight>
        <ajaxable>true</ajaxable>
        <header-portlet-css>/css/main.css</header-portlet-css>
        <footer-portlet-javascript>/js/main.js</footer-portlet-javascript>
        <footer-portlet-javascript>/js/jquery.foundation.orbit.js</footer-portlet-javascript>
    </portlet>
    <role-mapper>
        <role-name>administrator</role-name>
        <role-link>Administrator</role-link>
    </role-mapper>
    <role-mapper>
        <role-name>guest</role-name>
        <role-link>Guest</role-link>
    </role-mapper>
    <role-mapper>
        <role-name>power-user</role-name>
        <role-link>Power User</role-link>
    </role-mapper>
    <role-mapper>
        <role-name>user</role-name>
        <role-link>User</role-link>
    </role-mapper>
</liferay-portlet-app>
```

Important: Make your portlet name unique, considering how Liferay DXP uses the name to create the portlet's ID.

You'll also notice the `role-mapper` elements included above. They're for defining the Liferay roles used in the portlet.

Then there's the `liferay-plugin-package.properties`. These properties describe the Liferay plugin, declare its resources, and specify its security related parameters. The DTD is found here.

```
name=example-portlet
module-group-id=liferay
module-incremental-version=1
tags=
short-description=
change-log=
page-url=http://www.liferay.com
author=Liferay, Inc.
licenses=LGPL
version=1
```

In the `liferay-plugin-package.properties` file, you can also add OSGi metadata which the Liferay WAB Generator adds to the `MANIFEST.MF` file when you deploy your WAR file.

Find all of Liferay's DTDs here.

63.3 Calling Services from Spring MVC

To call OSGi-based Service Builder services from your Spring MVC portlet, you need a mechanism that gives you access to the OSGi service registry.

Note: If you don't already have one, create a service builder project using Blade CLI.

```
 springmvc-service-builder/
     build.gradle
     springmvc-service-builder-api/
         bnd.bnd
         build.gradle
     springmvc-service-builder-service/
         bnd.bnd
         build.gradle
         service.xml
```

Design your model entity and write your service layer as normal (see the tutorials on Service Builder here). After that, add your service's API JAR as a dependency in your Spring MVC project.

Since you're in the context of a Spring MVC portlet, you can't look up a reference to the services published to the OSGi runtime using Declarative Services. So how do you call Service Builder services, or other services published in the OSGi service registry? One way is by calling the static utility methods.

```
FooServiceUtil.getFoosByGroupId()
```

While very simple, that's not a good way to call OSGi services because of the dynamic nature of the OSGi runtime. Service implementations could be removed and added at any time, and your plugin needs to be able to account for that. Additionally, you need a mechanism that lets your portlet plugin react gracefully to the possibility of the service implementation becoming unavailable entirely. That's why you should open a Service Tracker when you want to call a service that's in the OSGi service registry.

Service Trackers

Since you don't have the luxury of using Declarative Services to manage your service dependencies, you have a little bit of work to do if you want to gain some of the benefits OSGi gives you:

- Accounting for multiple service implementations, using the best service implementation available (taking into account the service ranking property)
- Accounting for no service implementations

The static utility classes don't let you do that, and that's sad. But be happy, because with a little code, you can regain those benefits. For the details on implementing a service tracker, read the Service Trackers tutorial.

To summarize, you'll need to do these things:

- Instantiate a new `org.osgi.util.tracker.ServiceTracker` to track the service of the type you need.
- Open the service tracker in an `@PostConstruct` method.
- Make sure the service tracker has something in it.
- If there is indeed something in the service tracker, get the service.
- Now you're ready to call the service. Here's what the `if` block might look like:

```
if (!someServiceTracker.isEmpty()) {
    SomeService someService = someServiceTracker.getService();
    someService.doSomethingCool();
}
```

- Close the service tracker in an `@PreDestroy` method.

That's probably not enough detail, so refer to the tutorial on Service Trackers for the details. As you'll see in the tutorial, there's some boilerplate code involved, but leveraging service trackers lets you look up services in the OSGi runtime.

If you are not required to use a Spring MVC portlet, consider using Liferay's MVC framework to design your portlets instead. Then you can take advantage of the Declarative Services `@Component` and `@Reference` annotations, which let you avoid the boilerplate code associated with service trackers.

Chapter 64

JSF Portlets with Liferay Faces

Do you want to develop MVC-based portlets using the Java EE standard? Do you want to use a portlet development framework with a UI component model that makes it easy to develop sophisticated, rich UIs? Or have you been writing web apps using JSF that you'd like to use in Liferay DXP? If you answered *yes* to any of these questions, you're in luck! Liferay Faces provides all these capabilities and more.

Liferay Faces is an umbrella project that provides support for the JavaServer™ Faces (JSF) standard in Liferay DXP. It encompasses the following projects:

- **Liferay Faces Bridge** lets you deploy JSF web apps as portlets without writing portlet-specific Java code. It also contains innovative features that make it possible to leverage the power of JSF 2.x inside a portlet application. Liferay Faces Bridge implements the JSR 329/378 Portlet Bridge Standard.
- **Liferay Faces Alloy** lets you use AlloyUI components in a way that is consistent with JSF development.
- **Liferay Faces Portal** lets you leverage Liferay-specific utilities and UI components in JSF portlets.

For a comprehensive demo for the JSF component suite, visit the Liferay Faces Showcase.

If you're new to JSF, you may want to know its strengths, its weaknesses, and how it stacks up to developing portlets with CSS/JavaScript.

Here are some good reasons to use JSF and Liferay Faces:

- JSF is the Java EE standard for developing web applications that use the Model/View/Controller (MVC) design pattern. As a standard, the specification is actively maintained by the Java Community Process (JCP), and the Oracle reference implementation (Mojarra) has frequent releases. Software Architects often choose standards like JSF because they are supported by Java EE application server vendors and have a guaranteed service life according to Service Level Agreements (SLAs).
- JSF was first introduced in 2003 and is a mature technology for developing web applications that are (arguably) easy to maintain.
- JSF Portlet Bridges (like Liferay Faces Bridge) are also standardized by the JCP and make it possible to deploy JSF web applications as portlets without writing portlet-specific Java code.
- Support for JSF (via Liferay Faces) is included with Liferay DXP support.
- JSF is a unique framework in that it provides a UI component model that makes it easy to develop sophisticated, rich user interfaces.
- JSF has built-in Ajax functionality that provides automatic updates to the browser by replacing elements in the DOM.
- JSF is designed with many extension points that make a variety of integrations possible.
- There are several JSF component suites available including Liferay Faces Alloy, Primefaces, ICEfaces, and RichFaces. Each of these component suites fortify JSF with a variety of UI components and complimentary technologies such as Ajax Push.
- JSF is a good choice for server-side developers that need to build web user interfaces. This enables server-side developers to focus on their core competencies rather than being experts in HTML/CSS/JavaScript.
- JSF provides the Facelets templating engine which makes it possible to create reusable UI components that are encapsulated as markup.
- JSF provides good integration with HTML5 markup
- JSF provides the Faces Flows feature which makes it easy for developers to create wizard-like applications that flow from view-to-view.
- JSF has good integration with dependency injection frameworks such as CDI and Spring that make it easy for developers to create beans that are placed within a scope managed by a container: `@RequestScoped`, `@ViewScoped`, `@SessionScoped`, `@FlowScoped`
- Since JSF is a stateful technology, the framework encapsulates the complexities of managing application state so the developer doesn't have to write state management code. It is also possible to use JSF in a stateless manner, but some of the features of application state management become effectively disabled.

There are some reasons not to use JSF. For example, if you are a front-end developer who makes heavy use of HTML/CSS/JavaScript, you might find that JSF UI components render HTML in a manner that gives you less control over the overall HTML document. Sticking with JavaScript and leveraging AlloyUI or some other JavaScript framework may be better for you. Or, perhaps standards aren't a major consideration for you or you may simply prefer developing portlets using your current framework.

Whether you develop your next portlet application with JSF and Liferay Faces or with HTML/CSS/JavaScript is entirely up to you. But you probably want to learn more about Liferay Faces and try it out for yourself.

64.1 Generating a JSF Project from the Command Line

You can generate a Liferay Faces application without having to create your own folder structure, descriptor files, and such manually. If you really want to do that manually, you can examine the structure of a JSF application and create one from scratch in the Creating a JSF Project Manually tutorial.

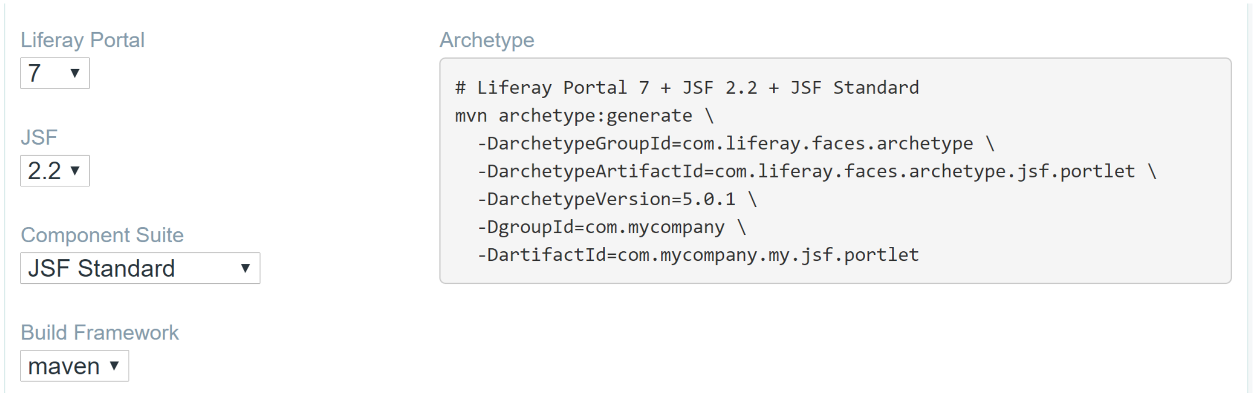
!PVideo Thumbnail

Before generating your JSF application, you should first visit liferayfaces.org, a great reference spot for JSF application development targeted for Liferay DXP. This site lets you choose the options for your JSF application and generates a Maven archetype command you can execute to generate an application with your chosen options. You can select the following archetype options:

- Liferay Portal Version
- JSF Version
- Component Suite

You can also choose a build framework (Gradle or Maven) and have a list of dependencies generated for you and displayed on the page. The dependencies are provided to you on the site page in a `pom.xml` or `build.gradle`, depending on the build type you selected. This is useful because it gives you an idea of what dependencies are required in your JSF application before generating it.

Note: Gradle developers can also use the `archetype:generate` command because it generates both a `build.gradle` and a `pom.xml` file for you to use.



Liferay Portal: 7
JSF: 2.2
Component Suite: JSF Standard
Build Framework: maven

Archetype

```
# Liferay Portal 7 + JSF 2.2 + JSF Standard
mvn archetype:generate \
  -DarchetypeGroupId=com.liferay.faces.archetype \
  -DarchetypeArtifactId=com.liferay.faces.archetype.jsf.portlet \
  -DarchetypeVersion=5.0.1 \
  -DgroupId=com.mycompany \
  -DartifactId=com.mycompany.my.jsf.portlet
```

Figure 64.1: You can select the Liferay Portal version, JSF version, and component suite for your archetype generation command.

Next you'll generate an example JSF application (e.g., Liferay Portal 7 + JSF 2.2 + JSF Standard) via command line using liferayfaces.org.

1. Navigate to liferayfaces.org and select the following options:

    - **Liferay Portal:** 7
    - **JSF:** 2.2
    - **Component Suite:** JSF Standard

2. Copy the archetype generation command and execute it. Make sure you've navigated to the folder where you want to generate your project.

That's it! Your JSF application is generated in the current folder!

You can also generate a Liferay JSF application using Maven's interactive archetype UI. To do this, execute `mvn archetype:generate -Dfilter=liferay` and select the JSF archetype you want to use. Then you'll step through each option and select the version, group ID, artifact ID, etc. To learn more about this, see the Generating New Projects Using Archetypes tutorial.

Once you have your JSF application generated, you can import it into Liferay @ide@ and develop it further. To deploy it to your Liferay DXP instance, drag and drop it onto the Liferay DXP server.

You can build the project and deploy it to Liferay DXP from the command line too! If you're using Gradle, run the following command to build your JSF application:

```
gradle build
```

For Maven, execute the following command:

```
mvn package
```

Then copy the generated WAR to Liferay DXP's `deploy` folder:

```
[cp|copy] ./com.mycompany.my.jsf.portlet.war LIFERAY_HOME/deploy
```

Awesome! You've generated your JSF application and deployed it using the command line.
!VVideo Tutorial

64.2 Generating a JSF Project Using @ide@

You can generate a Liferay Faces application without having to create your own folder structure and descriptor files manually using Liferay @ide@. If you're interested in creating the structure of a JSF application manually or if you want to examine a basic JSF application structure, visit the Creating a JSF Project Manually tutorial.

In this tutorial, you'll generate an example JSF project using Liferay @ide@. Open your @ide@ instance to get started.

1. Navigate to *File* → *New* → *Project...*. This opens a new project wizard.

2. Select the *Liferay* project and choose *Liferay JSF Project* from the listed subprojects. Then click *Next*.

3. Assign your JSF project a name, build framework (Gradle or Maven), and Component Suite. You have five component suites to choose from:

    - ICEFaces
    - JSF Standard
    - Liferay Faces Alloy
    - PrimeFaces
    - RichFaces

4. Click *Finish* to generate your Liferay JSF project.

You've generated a Liferay JSF project using @ide@! The project you generated contains a simple portlet that you can customize.

Note: There is another option in @ide@'s *File* → *New* menu named *Liferay JSF Portlet*. This is intended to add portlets to existing JSF projects. Currently, this is only configured to create Liferay Portal 6.2 JSF portlets. Do not use this option if you're developing for 7.0.

To deploy the new JSF project to your Liferay DXP instance, drag and drop it onto the Liferay server.
Fantastic! You're now able to quickly generate your Liferay JSF project using Liferay @ide@!

64.3 Creating a JSF Project Manually

Liferay DXP's modular architecture lends itself well to modular applications created using a multitude of different technologies. JSF applications are no different and can be developed to integrate seamlessly into the Liferay platform.

In this tutorial, you'll step through packaging and creating a JSF application that is deployable as an OSGi module at runtime. First, you'll learn how to package a JSF application as a module.

Packaging a JSF Application

Developers creating portlets for 7.0 can package their portlets as Java EE style Web Application ARchive (WAR) artifacts or as Java ARchive (JAR) OSGi bundle artifacts. JSF portlet developers, however, must package their portlets as WAR artifacts because the JSF framework expects a WAR layout and often requires the `WEB-INF/faces-config.xml` descriptor and other Java EE resources such as the `WEB-INF/web.xml` descriptor.

Liferay provides a way for these WAR-styled portlets to be deployed and treated like OSGi modules by Liferay's OSGi runtime. The WAB Generator does this automatically by converting your WAR artifact to a WAB at deployment time. You can learn more about WABs and the WAB Generator in the Using the WAB Generator tutorial.

This is how a JSF WAR artifact is structured:

- `jsf-portlet`
  - `src`

  - `views/`
  - XHTML views

  - `faces-config.xml`
  - `liferay-display.xml`
  - `liferay-plugin-package.properties`
  - `liferay-portlet.xml`
  - `portlet.xml`
  - `web.xml`

Next, you'll begin creating a simple JSF application that is deployable to Liferay DXP.

Creating a JSF Application

JSF portlets are supported on Liferay Portal by using Liferay Faces Bridge. Liferay Faces Bridge makes developing JSF portlets as similar as possible to JSF web app development.

You'll create a simple *Hello User* application that asks for the user's name and then greets him or her with the name. You'll begin by creating the WAR-style folder structure, and then you'll configure dependencies like Liferay Faces Bridge.

1. Create a WAR-style folder structure for your module. Maven archetypes are available to help you get started quickly. They set the default configuration for you and contain boilerplate code so you can skip the file creation steps and get started right away. For your JSF application, you'll set up the folder structure manually. Follow the folder structure outline below:

```
- hello-user-jsf-portlet
    - src
        - main
            - java
            - resources
            - webapp
                - WEB-INF
                    - resources
                    - views
```

2. Make sure your module specifies the dependencies necessary for a Liferay JSF application. For instance, you must always specify the Faces API, Faces Reference Implementation (Mojarra), and Liferay Faces Bridge as dependencies in a Liferay-compatible JSF application. Also, an important, but not required, dependency is the Log4j logging utility. This is highly recommended for development purposes because it logs DEBUG messages in the console. You'll configure the logging utility later.

   For an example build file, the `pom.xml` file used for the Maven based Hello User JSF application is below. All the dependencies described above are configured in the Hello User JSF application's `pom.xml` file.

```
<?xml version="1.0"?>

<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/maven-v4_0_0.xsd">
    <modelVersion>4.0.0</modelVersion>
    <groupId>com.liferay</groupId>
    <artifactId>com.liferay.hello.user.jsf.portlet</artifactId>
    <packaging>war</packaging>
    <name>hello-user-jsf-portlet</name>
    <version>1.0-SNAPSHOT</version>
    <properties>
        <faces.api.version>2.2</faces.api.version>
        <liferay.faces.bridge.ext.version>5.0.0</liferay.faces.bridge.ext.version>
        <liferay.faces.bridge.version>4.0.0</liferay.faces.bridge.version>
        <mojarra.version>2.2.13</mojarra.version>
    </properties>
    <build>
        <plugins>
            <plugin>
                <artifactId>maven-compiler-plugin</artifactId>
                <version>3.3</version>
                <configuration>
                    <encoding>UTF-8</encoding>
                    <source>1.8</source>

        </dependency>
        <dependency>
            <groupId>log4j</groupId>
            <artifactId>log4j</artifactId>
            <version>1.2.14</version>
        </dependency>
    </dependencies>
</project>
```

There are also two plugins the Hello User JSF application defined in its pom.xml: maven-compiler-plugin and maven-war-plugin. These two plugins are responsible for building and compiling the JSF application using Maven.

There are several UI component suites that a JSF application can use, which include *Liferay Faces Alloy*, *PrimeFaces*, *ICEfaces*, and *RichFaces*. Furthermore, you can take advantage of *Liferay Faces Portal* in order to use Liferay-specific utilities and UI components. These components can be used by specifying them as dependencies in your build file, as well.

Now that your build file is configured, you must define the JSF-specific configurations for your application. These fall into two convenient categories: general descriptors and Liferay descriptors. You'll start with creating the necessary general descriptors.

Defining JSF Portlet Descriptors

Since JSF portlets must follow a WAR-style folder structure, they must also have WAR-style portlet descriptors.

1. Create a portlet.xml file in the webapp/WEB-INF folder. All portlet WARs require this file. In this file, make sure to declare the following portlet class:

```
<portlet>
    ...
    <portlet-class>javax.portlet.faces.GenericFacesPortlet</portlet-class>
    ...
</portlet>
```

   The javax.portlet.faces.GenericFacesPortlet class handles invocations to your JSF portlet and makes your portlet, since it relies on Liferay Faces Bridge, easy to develop by acting as a turnkey implementation.

2. Define a default view file as an init-param in the portlet.xml. This ensures your portlet is visible when deployed to Liferay DXP.

```
<init-param>
    <name>javax.portlet.faces.defaultViewId.view</name>
    <value>/WEB-INF/views/view.xhtml</value>
</init-param>
```

   You'll create this view later.

   The portlet.xml file holds other important details too, like portlet info and security settings. Look at the portlet.xml file for the example Hello User JSF application.

```
<?xml version="1.0"?>

<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xsi:schemaLocation="http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd http://java.sun.com/xml/ns/portlet/portlet-
app_2_0.xsd" version="2.0">
    <portlet>
        <portlet-name>hello-user-jsf-portlet</portlet-name>
        <display-name>Hello User JSF Portlet</display-name>
        <portlet-class>javax.portlet.faces.GenericFacesPortlet</portlet-class>
        <init-param>
            <name>javax.portlet.faces.defaultViewId.view</name>
            <value>/WEB-INF/views/view.xhtml</value>
        </init-param>
        <expiration-cache>0</expiration-cache>
        <supports>
            <mime-type>text/html</mime-type>
        </supports>
        <portlet-info>
            <title>Hello User JSF Portlet</title>
            <short-title>Hello User</short-title>
            <keywords>com.liferay.hello.user.jsf.portlet</keywords>
        </portlet-info>
        <security-role-ref>
            <role-name>administrator</role-name>
        </security-role-ref>
        <security-role-ref>
            <role-name>guest</role-name>
        </security-role-ref>
        <security-role-ref>
            <role-name>power-user</role-name>
        </security-role-ref>
        <security-role-ref>
            <role-name>user</role-name>
        </security-role-ref>
    </portlet>
</portlet-app>
```

The above configuration sets your portlet's various names, MIME type, expiration cache, and security roles.

3. Create a `web.xml` file in your JSF application's `webapp/WEB-INF` folder. The `web.xml` file serves as a deployment descriptor that provides necessary configurations for your JSF portlet to deploy and function in Liferay DXP. Copy the XML code below into your Hello User JSF application.

```
<?xml version="1.0" encoding="UTF-8"?>

<web-app xmlns="http://java.sun.com/xml/ns/javaee" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/web-app_3_0.xsd" version="3.0">

    <context-param>
        <param-name>javax.faces.PROJECT_STAGE</param-name>
        <param-value>${project.stage}</param-value>
    </context-param>
    <context-param>
        <param-name>javax.faces.WEBAPP_RESOURCES_DIRECTORY</param-name>
        <param-value>/WEB-INF/resources</param-value>
    </context-param>
    <servlet>
        <servlet-name>Faces Servlet</servlet-name>
        <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
        <load-on-startup>1</load-on-startup>
    </servlet>
    <security-constraint>
        <display-name>Prevent direct access to Facelet XHTML</display-name>
        <web-resource-collection>
```

```
            <web-resource-name>Facelet XHTML</web-resource-name>
            <url-pattern>*.xhtml</url-pattern>
        </web-resource-collection>
        <auth-constraint/>
    </security-constraint>
</web-app>
```

First, you set the `javax.faces.PROJECT_STAGE` parameter to the `${project.stage}` variable, which is defined in your build file (e.g., `pom.xml`) as `Development`. When set to `Development`, the JSF implementation will perform the following steps at runtime:

1. Log more verbose messages.
2. Render tips and/or warnings in the view markup.
3. Cause the default `ExceptionHandler` to display a developer-friendly error page.

The `javax.faces.WEBAPP_RESOURCES_DIRECTORY` parameter sets the resources folder inside the `WEB-INF` folder. This setting makes the resources in that folder (e.g., CSS, JavaScript, XHTML) secure from non-JSF calls. You'll create resources for your app later.

The Faces Servlet configuration is required to initialize JSF and should be defined in all JSF portlets deployed to Liferay DXP.

Finally, a security restraint is set on Facelet XHTML, which prevents direct access to XHTML files in your JSF application.

4. Create a `faces-config.xml` file in your JSF application's `webapp/WEB-INF` folder. The `faces-config.xml` descriptor is a JSF portlet's application configuration file, which is used to register and configure objects and navigation rules. The Hello User portlet's `faces-config.xml` file has the following contents:

```
<?xml version="1.0"?>

<faces-config version="2.2"
    xmlns="http://xmlns.jcp.org/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://xmlns.jcp.org/xml/ns/javaee http://xmlns.jcp.org/xml/ns/javaee/web-facesconfig_2_2.xsd"
>
    <lifecycle>
        <phase-listener>com.liferay.faces.util.lifecycle.DebugPhaseListener</phase-listener>
    </lifecycle>
</faces-config>
```

Many auto-generated `faces-config.xml` files have the following configuration:

```
<lifecycle>
    <phase-listener>com.liferay.faces.util.lifecycle.DebugPhaseListener</phase-listener>
</lifecycle>
```

This configures your JSF portlet to log the before/after phases of the JSF lifecycle to your console in debug mode. Remove this declaration before deploying to production.

Great! You now have a good idea of how to specify and define general descriptor files for your JSF portlet. JSF portlets also use Liferay descriptors, which you can learn more about in the Liferay Descriptors sub-section.

Now that your portlet descriptors are defined, you should begin working on your JSF application's resources.

Defining Resources for a JSF Application

If you look back at the Hello User portlet's structure, you'll notice two `resources` folders defined. Why are there two of these folders for one portlet? These two folders have distinct differences in how they're used and what should be placed in them.

The `resources` folder in the application's `src/main` folder is intended for resources that need to be on the classpath. Files in this folder are usually properties files. For this portlet, you'll create two properties files to reside in this folder.

1. Create the `i18n.properties` file in the `src/main/resources` folder. Add the following property to this file:

   ```
   enter-your-name=Enter your name:
   ```

   This is a language key your JSF portlet displays in its view XHTML. The messages in the `i18n.properties` file can be accessed via the Expression Language using the implicit `i18n` object provided by the Liferay Faces Util class. The `i18n` object can access messages both from a resource bundle defined in the portlet's `portlet.xml` file, and from Liferay DXP's `Language.properties` file.

2. Create the `log4j.properties` file in the `src/main/resources` folder. This file sets properties for the Log4j logging utility defined in your JSF application (i.e., `faces-config.xml`). Insert the properties below into your JSF application's `log4j.properties` file.

   ```
   log4j.rootLogger=INFO, CONSOLE

   log4j.appender.CONSOLE=org.apache.log4j.ConsoleAppender
   log4j.appender.CONSOLE.layout=org.apache.log4j.PatternLayout
   log4j.appender.CONSOLE.layout.ConversionPattern=%d{ABSOLUTE} %-5p [%c{1}:%L] %m%n

   log4j.logger.com.liferay.faces.util.lifecycle.DebugPhaseListener=DEBUG
   ```

The second `resources` folder in your JSF application is located in the `src/main/webapp/WEB-INF` folder. This folder holds CSS/JS/XHTML resources that shouldn't be accessed directly by the browser. For the Hello User JSF application, create a `css` folder with a `main.css` file inside. In the `main.css` file, add the following style:

```
.com.liferay.hello.user.jsf.portlet {
    font-weight: bold;
}
```

This file gives your JSF portlet a bold font.

Now that your resources are defined, it's time to begin developing the Hello User application's behavior and UI.

Developing a JSF Application's Behavior and UI

Your current JSF application satisfies the requirements for portlet descriptors and WAR-style structure, but it doesn't do anything yet. You'll learn how to develop a JSF application's back-end and give it a simple UI next.

The first thing to do is create a Java class for your module. Your JSF portlet's behavior is defined here. In the case of the Hello User portlet, you should provide Java methods that can get/set a name and facilitate the submission process.

1. Create a unique package name in the module's `src/main/java` folder and create a new public Java class named `ExampleBacking.java` in that package. For example, the class's folder structure could be `src/main/java/com/liferay/example/ExampleBacking.java`. Make sure the class is annotated with @RequestScoped and @ManagedBean:

   ```
   @RequestScoped
   @ManagedBean
   public class ExampleBacking {
   ```

   Managed beans are Java beans that are managed by the JSF framework. Managed beans annotated with `@RequestScoped` are usually responsible for handling actions and listeners. JSF *manages* these beans by creating and removing the bean object from the server. Visit the linked annotations above for more details.

2. Add the following methods and field to your `ExampleBacking.java` class:

   ```
   public String getName() {
       return name;
   }

   public void setName(String name) {
       this.name = name;
   }

   public void submit(ActionEvent actionEvent) {
       FacesContextHelperUtil.addGlobalSuccessInfoMessage();
   }

   private String name;
   ```

   You've provided a getter and setter method for the private `name` field. You've also provided a `submit(...)` method, which is called when the *Submit* button is selected. A success info message is displayed once the method is invoked.

   You've defined your Hello User portlet's Java behavior; now create its UI!

3. Create a `view.xhtml` file in the `webapp/WEB-INF/views` folder. Add the following logic to that file:

   ```
   <?xml version="1.0"?>

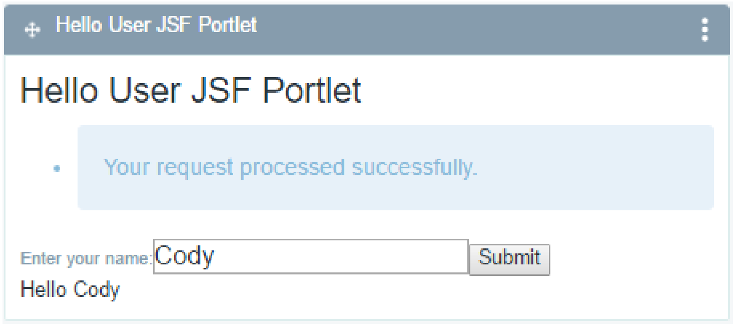
   <f:view
       xmlns="http://www.w3.org/1999/xhtml"
       xmlns:f="http://java.sun.com/jsf/core"
       xmlns:h="http://java.sun.com/jsf/html"
   >
       <h:head>
           <h:outputStylesheet library="css" name="main.css" />
       </h:head>
       <h:form>
           <h:messages globalOnly="true" />
           <h:outputLabel value="#{i18n['enter-your-name']}" />
           <h:inputText value="#{exampleBacking.name}" />
           <h:commandButton actionListener="#{exampleBacking.submit}" value="#{i18n['submit']}">
               <f:ajax execute="@form" render="@form" />
           </h:commandButton>
           <br />
           <h:outputText value="Hello #{exampleBacking.name}" />
       </h:form>
   </f:view>
   ```

The first thing to notice is the main.css file you created is specified here, which makes your portlet's heading typeface bold. Next, your form is defined within the <h:form> tags. The form asks the user to enter his or her name, and then sets that value to the name field in your Java class. The form uses the <h:commandButton> tag to execute the Submit button and render the form after submission.

Notice the i18n object call for the enter-your-name and submit properties. The enter-your-name property was set in the i18n.properties file you specified, but what about the submit property? This was not defined in your portlet's i18n.properties file, so how does your portlet know to use the string *Submit* for your button? If you recall, the i18n object can also access messages in Liferay DXP's Language.properties file. This is where the submit language key comes from.

Finally, the <h:outputText> tag prints the submitted name on the page, prefixed with *Hello*.

Awesome! Your Hello User JSF application is complete! Deploy your WAR to Liferay DXP. Remember, when your WAR-style portlet is deployed, it's converted to a WAB via the WAB Generator. Visit the Using the WAB Generator tutorial for more information on this process and your portlet's resulting folder structure.



Your request processed successfully.

Enter your name: Cody

Hello Cody

Figure 64.5: After submitting the user's name, it's displayed with a greeting.

To recap, you created your JSF application in the following steps:

- Construct the WAR-style folder structure.
- Specify the necessary dependencies in a build file of your choice.
- Create JSF portlet descriptors and Liferay descriptors.
- Add resource files in the two designated resources folders.
- Define the portlet's behavior using a Java class.
- Design a view XHTML form to let the user interact with the portlet.

You can view the finished version of the Hello User JSF application by downloading its ZIP file.
Now you have the knowledge to create your own JSF applications!

64.4 Services in JSF

Creating services works the same in a JSF portlet as it would in any other standard WAR-style MVC portlet; generate custom services as separate API and Impl JARs and deploy them as individual modules to Liferay

DXP. You can generate custom services for your JSF portlet using Service Builder. To learn more about how Service Builder works in Liferay DXP, visit the Service Builder tutorials.

The JSF WAR can then rely on the API module as a *provided* dependency. The main benefit for packaging your services this way is to allow multiple WARs to utilize the same custom service API without packaging it inside every WAR's `WEB-INF/lib` folder. This practice also enforces a separation of concerns, or *modularity*, between the UI layer and service layer of a system.

To call OSGi-based Service Builder services from your JSF portlet, you need a mechanism that gives you access to the OSGi service registry, because you can't look up services published to the OSGi runtime using Declarative Services. Instead, you should open a ServiceTracker when you want to call a service that's in the OSGi service registry.

To implement a service tracker in your JSF portlet, you can add a type-safe wrapper class that extends `org.osgi.util.tracker.ServiceTracker`. For example, this is done in a demo JSF portlet as follows

```
public class UserLocalServiceTracker extends ServiceTracker<UserLocalService, UserLocalService> {

    public UserLocalServiceTracker(BundleContext bundleContext) {
        super(bundleContext, UserLocalService.class, null);
    }
}
```

After extending the `ServiceTracker`, just call the constructor and the service tracker is ready to use in your managed bean.

In a managed bean, whenever you need to call a service, open the service tracker. For example, this is done in the same demo JSF portlet to open the service tracker, using the @PostContruct annotation:

```
@PostConstruct
public void postConstruct() {
    Bundle bundle = FrameworkUtil.getBundle(this.getClass());
    BundleContext bundleContext = bundle.getBundleContext();
    userLocalServiceTracker = new UserLocalServiceTracker(bundleContext);
    userLocalServiceTracker.open();
}
```

Then the service can be called:

```
UserLocalService userLocalService = userLocalServiceTracker.getService();
...

userLocalService.updateUser(user);
```

When it's time for the managed bean to go out of scope, you must close the service tracker using the @PreDestroy annotation:

```
@PreDestroy
public void preDestroy() {
    userLocalServiceTracker.close();
}
```

For more information on service trackers and how to use them in WAR-style portlets, see the Service Trackers tutorial.

Chapter 65

Making URLs Friendlier

This is a story of two URLs who couldn't be more different. One was full of himself, and always wanted to show everyone (users and SEO services alike) just how smart he was, by openly displaying all of the parameters he carried. He was happiest when he met new people and could tell they were intimidated and confused by him.

```
http://localhost:8080/group/guest/~/control_panel/manage?p_p_id=com_liferay_blogs_web_portlet_BlogsAdminPortlet&p_p_lifecycle=0&p_p_state=maximized&p_p_mode
```

The other was just, well, friendly. You knew only the important things about her, because she was less concerned about looking smart, and more concerned about those she interacted with. She didn't need to look fancy and complicated. She aspired to be simple and kind to all the users and SEO services she encountered.

```
http://localhost:8080/web/guest/home/-/blogs/lunar-scavenger-hunt
```

If you want your application to be friendly to your users and to SEO services, make your URLs friendlier. It only takes a couple steps, after all.

65.1 Creating Friendly URL Routes

1. First create a `routes.xml` file in your application's web module (if a multi-module build, in the pattern of Liferay's native Service Builder applications). It's recommended to put it in a `src/main/resources/META-INF/friendly-url-routes/` folder.

2. Add friendly URL routes, using as many <route> tags as you need friendly URLs, like this:

```
 <?xml version="1.0"?>
 <!DOCTYPE routes PUBLIC "-//Liferay//DTD Friendly URL Routes 7.0.0//EN" "http://www.liferay.com/dtd/liferay-friendly-url-
routes_7_0_0.dtd">

 <routes>
     <route>
         <pattern></pattern>
         <implicit-parameter name="mvcRenderCommandName">/blogs/view</implicit-parameter>
         <implicit-parameter name="p_p_lifecycle">0</implicit-parameter>
         <implicit-parameter name="p_p_state">normal</implicit-parameter>
     </route>
     <route>
         <pattern>/maximized</pattern>
         <implicit-parameter name="mvcRenderCommandName">/blogs/view</implicit-parameter>
         <implicit-parameter name="p_p_lifecycle">0</implicit-parameter>
```

```
            <implicit-parameter name="p_p_state">maximized</implicit-parameter>
        </route>
        <route>
            <pattern>/{entryId:\d+}</pattern>
            <implicit-parameter name="categoryId"></implicit-parameter>
            <implicit-parameter name="mvcRenderCommandName">/blogs/view_entry</implicit-parameter>
            <implicit-parameter name="p_p_lifecycle">0</implicit-parameter>
            <implicit-parameter name="p_p_state">normal</implicit-parameter>
            <implicit-parameter name="tag"></implicit-parameter>
        </route>
        ...
    </routes>
```

Use <pattern> tags to define placeholder values for the parameters that normally appear in the generated URL. This is just a mask. The beastly URL still lurks beneath it.

The pattern value /{entryId:\d+} matches a / followed by an entryId variable that matches the Java regular expression \d+—one or more numeric digits. For example, a URL /entryId, where the entryId value is 123 results in a URL value /123, which matches the pattern.

Warning: Make sure your pattern values don't end in a slash /. A trailing slash character prevents the request from identifying the correct route.

Important: If your portlet is instanceable, you must use a variant of the instanceId in the pattern value. If the starting value is render-it, for example, use one of these patterns:

```
<pattern>/{userIdAndInstanceId}/render-it</pattern>
```

or

```
<pattern>/{instanceId}/render-it</pattern>
```

or

```
<pattern>/{p_p_id}/render-it</pattern>
```

Use <implicit-parameter> tags to define parameters that will always be the same for the URL. For example, if you're dealing with a render URL, you can be certain that the p_p_lifecycle parameter will always be 0. There's no need for this to be generated. You don't have to define these type of implicit parameters, but it's a best practice. If you happen to forget one, or decide not to define any of them, they'll just be generated as usual.

The implicit parameters with the name mvcRenderCommandName are very important. If you're using an MVCPortlet with MVCRenderCommand classes, that parameter comes from the mvc.command.name property in the @Component of your MVCRenderCommand implementation. Basically, this determines what will be rendered (for example, view.jsp).

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS, "mvc.command.name=/",
        "mvc.command.name=/blogs/view"
    },
    service = MVCRenderCommand.class
)
```

65.2 Implementing a Friendly URL Mapper

Once you have your URLs mapped in a `routes.xml` file, you need to provide an implementation of the `FriendlyURLMapper` service. Just create a component that specifies a `FriendlyURLMapper` service, with two properties:

1. One that sets the path to your `routes.xml` file in the property `com.liferay.portlet.friendly-url-routes` property.

2. A `javax.portlet.name` property.

```
@Component(
    property = {
        "com.liferay.portlet.friendly-url-routes=META-INF/friendly-url-routes/routes.xml",
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS
    },
    service = FriendlyURLMapper.class
)
```

After that, implement the `FriendlyURLMapper` service. For your convenience, the `DefaultFriendlyURLMapper` class provides a default implementation. If you extend `DefaultFriendlyURLMapper` you only need to override one method, `getMapping()`. In this method you just need to return a String that defines the first part of your Friendly URLs. It's smart to name it after your application. Here's what it looks like for Liferay's Blogs application:

```
public class BlogsFriendlyURLMapper extends DefaultFriendlyURLMapper {

    @Override
    public String getMapping() {
        return _MAPPING;
    }

    private static final String _MAPPING = "blogs";

}
```

All of the Blogs application's friendly URLs begin with the String set here (`blogs`).

65.3 Friendly URLs in Action

Let's look at one of these Friendly URLs in action. If you add a blog entry in Liferay, and then add the Blogs application to a page, click on the title of the entry to see it. After that, look at the URL:

```
http://localhost:8080/web/guest/home/-/blogs/lunar-scavenger-hunt
```

As specified in the friendly URL mapper class, `blogs` is the first part of the friendly URL that comes after the Liferay part of the URL. The next part is determined by a specific URL route in `routes.xml`:

```
<route>
    <pattern>/{urlTitle}</pattern>
    <implicit-parameter name="categoryId"></implicit-parameter>
    <implicit-parameter name="mvcRenderCommandName">/blogs/view_entry</implicit-parameter>
    <implicit-parameter name="p_p_lifecycle">0</implicit-parameter>
    <implicit-parameter name="p_p_state">normal</implicit-parameter>
    <implicit-parameter name="tag"></implicit-parameter>
</route>
```

Here, the `urlTitle` is a database field that's generated from the title the author gives their blog post, and it's meant to be used in a URL. Since it's already a parameter in the URL (see below), it's available for use in the friendly URL.

```
<portlet:renderURL var="viewEntryURL">
    <portlet:param name="mvcRenderCommandName" value="/blogs/view_entry" />
    <portlet:param name="urlTitle" value="<%= entry.getUrlTitle() %>" />
</portlet:renderURL>
```

When a render URL for viewing a blog entry is invoked, the String defined in the friendly URL mapper teams up with the `pattern` tag in your friendly URL routes file, and you get a very friendly URL indeed, instead of some nasty, conceited, unfriendly URL that's despised by users and SEO services alike.

65.4 Automatic Single Page Applications

A good user experience is the measure of a well-designed site. A user's time is highly valuable. The last thing you want is for someone to grow frustrated with your site because of constant page reloads. A Single Page Application (SPA) is the solution. Single Page Applications drastically cut down on load times by loading only a single HTML page that is dynamically updated as the user interacts and navigates through the site. This provides a native-app experience by eliminating page loads. In Liferay DXP, **SPA is enabled by default in your apps and sites and requires no changes to your workflow or code!**

This tutorial covers these key topics:

- The benefits of SPAs
- What is SennaJS?
- How to enable SPA in Liferay DXP
- How to configure SPA settings
- How to listen to SPA lifecycle events

The Benefits of SPAs

Let's say you're surfing the web and you find a really rad site that happens to be SPA enabled. Alright! Page load times are blazin' fast. You're deep into the site, scrolling along, when you find this great post that just speaks to you. You copy the URL from the address bar and email it to all of your friends with the subject: 'Your Life Will Change Forever.' They must experience this awe-inspiring work!

You get a response back almost immediately. "This is a rad site, but what post are you talking about?" it reads.

"What!? Do my eyes deceive me?" you exclaim. You were in so much of a hurry to share this life-changing content that you neglected to notice that the URL never updated when you clicked the post. You click the back button, hoping to get back to the post, but it takes you to the site you were on before you ever visited this one.

What a bummer! "Why? Why have you failed me site?" you cry.

If only there was a way to have a Single Page Application, but also be able to link to the content you want. Well, don't despair my friend. You can have your cake and eat it too, thanks to SennaJS.

What is SennaJS?

SennaJS is Liferay DXP's SPA engine. SennaJS handles the client-side data, and AJAX loads the page's content dynamically. While there are other JavaScript frameworks out there that may provide some of the same features, Senna's only focus is SPA, ensuring that your site provides the best user experience possible.

SennaJS provides the following key enhancements to SPA:

SEO & Bookmarkability: Sharing or bookmarking a link displays the same content you are viewing. Search engines are able to index this content.

Hybrid rendering: Ajax + server-side rendering lets you disable pushState at any time, allowing progressive enhancement. You can use your preferred method to render the server side (e.g. HTML fragments or template views).

State retention: Scrolling, reloading, or navigating through the history of the page takes you back to where you were.

UI feedback: The UI indicates to the user when some content is requested.

Pending navigations: UI rendering is blocked until data is loaded, and the content is displayed all at once.

Timeout detection: If the request takes too long to load or the user tries to navigate to a different link while another request is pending, the request times out.

History navigation: The browser history is manipulated via the History API, so you can use the back and forward history buttons to navigate through the history of the page.

Cacheable screens: Once a surface is loaded, the content is cached in memory and is retrieved later without any additional request, speeding up your application.

Page resources management: Scripts and stylesheets are evaluated from dynamically loaded resources. Additional content can be appended to the DOM using XMLHttpRequest. For security reasons, some browsers won't evaluate `<script>` tags from content fragments. Therefore, SennaJS extracts scripts from the content and parses them to ensure that they meet the browser loading requirements.

You can read more about SennaJS as well as see examples at http://sennajs.com/.

Now that you have a better understanding of how SennaJS benefits SPA, you can learn how to enable and configure options for SPA within Liferay DXP next.

Enabling SPA

Enabling SPA is easy. Deploy `com.liferay.frontend.js.spa.web-[version]` module deployed and enabled, and you're all set to use SPA. Since this module is included with Liferay DXP by default, you shouldn't have to do anything.

SPA is enabled by default in your apps and sites, and requires no changes to your workflow or existing code!

Next you can learn how to customize SPA settings to meet your own needs.

Customizing SPA Settings

Depending on what behaviors you need to customize, you can configure SPA options in one of two places. SPA caching and SPA timeout settings can be configured in System Settings. If you wish to disable SPA for a certain link, page, or portlet in your site, you can do so within the corresponding element itself. All SPA configuration options are covered here.

Configuring SPA System Settings

To configure system settings for SPA, follow these steps:

1. In the Control Panel, navigate to *Configuration → System Settings*.

2. Select the *Foundation* tab at the top of the page.

3. Click *Frontend SPA Infrastructure*.

Note: In prior versions of Liferay, all SPA render requests that didn't belong to a portlet (no `p_p_id` in the URL) were cached indefinitely. This can confuse users, as the content they view is cached rather than the latest fresh content. Since Liferay Portal CE 7.0 GA2 and Liferay DXP 7.0 GA1, administrators can use the **Cache Expiration Time** property to set an expiration time for the Senna cache.

The following configuration options are available:

Cache Expiration Time: The time, in minutes, in which the SPA cache is cleared. A negative value means the cache should be disabled.

Request Timeout Time: The time, in milliseconds, in which a SPA request times out. A zero value means the request should never timeout.

User Notification Time: The time, in milliseconds, in which a notification is shown to the user stating that the request is taking longer than expected. A zero value means no notification should be shown.

Now that you know how to configure system settings for SPA, you can learn how to disable SPA for elements in your site next.

Disabling SPA

Certain elements of your page may require a regular navigation to work properly. For example, you may have downloadable content that you want to share with the user. In these cases, SPA must be disabled for those specific elements.

To disable SPA on a portal wide basis, you can add the following line to your `portal-ext.properties`:

```
javascript.single.page.application.enabled = false
```

If there is a portlet or element that you don't want to be part of the SPA, you have some options:

- Blacklist the portlet to disable SPA for the entire portlet
- Use the `data-senna-off` annotation to disable SPA for a specific form or link

To blacklist a portlet from SPA, follow these steps:

1. Open your portlet class.

2. Set the `com.liferay.portlet.single-page-application` property to false:

   ```
   com.liferay.portlet.single-page-application=false
   ```

   If you prefer, you can set this property to false in your `liferay-portlet.xml` instead by adding the following property to the `<portlet>` section:

   ```
   <single-page-application>false</single-page-application>
   ```

3. Alternatively, you can override the `isSinglePageApplication` method of the portlet to return `false`.

To disable SPA for a form or link follow these steps:

1. Add the `data-senna-off` attribute to the element.

2. Set the value to `true`.

For example `<a data-senna-off="true" href="/pages/page2.html">Page 2</a>`

That's all you need to do to disable SPA in your app.

Now that you know how to disable SPA, you can learn how to specify how resources are loaded during navigation.

Specifying How Resources Are Loaded During Navigation

By default, Liferay DXP unloads CSS resources from the `<head>` element on navigation. JavaScript resources in the `<head>`, however, are not removed on navigation. This functionality can be customized by setting the resource's `data-senna-track` attribute. Follow these steps to customize your resources:

1. Select the resource you want to modify the default behavior for.
2. Add the `data-senna-track` attribute to the resource.
3. Set the `data-senna-track` attribute to `permanent` to prevent a resource from unloading on navigation.

   Alternatively, set the `data-senna-track` attribute to `temporary` to unload the resource on navigation.

```
**Note:** the `data-senna-track` attribute can be added to resources loaded
outside of the `<head>` element as well to specify navigation behavior.
```

The example below ensures that the JS resource isn't unloaded during navigation:

```
<script src="myscript.js" data-senna-track="permanent" />
```

Next you can learn about the available SPA lifecycle events next.

Listening to SPA Lifecycle Events

During development, you may need to know when navigation has started or stopped in your SPA. SennaJS makes this easy by exposing lifecycle events that represent state changes in the application. The following events are available:

beforeNavigate: Fires before navigation starts. This event passes a JSON object with the path to the content being navigated to and whether to update the history. Below is an example event payload:

```
{ path: '/pages/page1.html', replaceHistory: false }
```

startNavigate: Fires when navigation begins. Below is an example event payload:

```
{ form: '<form name="form"></form>', path: '/pages/page1.html',
replaceHistory: false }
```

endNavigate: Fired after the content has been retrieved and inserted onto the page. This event passes the following JSON object:

```
{ form: '<form name="form"></form>', path: '/pages/page1.html' }
```

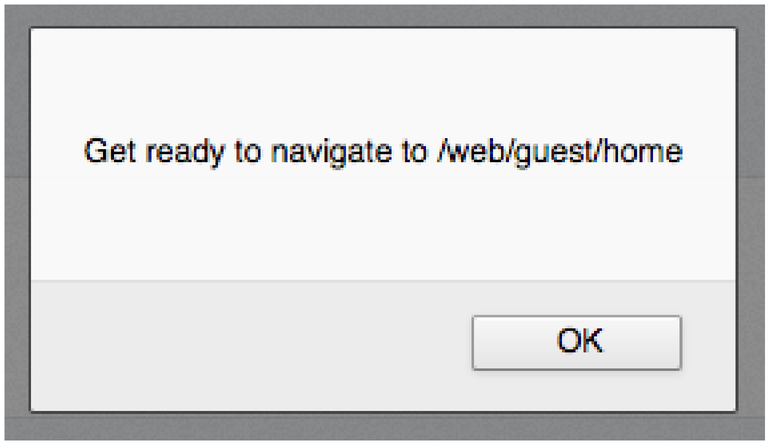
These events can be leveraged easily by listening for them on the Liferay global object.

For example, the JavaScript below alerts the user to "Get ready to navigate to" the URL that has been clicked, just before SPA navigation begins.

```
Liferay.on('beforeNavigate', function(event) {
    alert("Get ready to navigate to " + event.path);
});
```

The alert takes advantage of the payload for the `beforeNavigate` event, retrieving the URL from the `path` attribute of the JSON payload object.

The above code results in the behavior shown below:



Get ready to navigate to /web/guest/home

Figure 65.1: You can leverage SPA lifecycle events in your apps.

Due to the nature of SPA navigation, global listeners that you create can become problematic over time if not handled properly. You'll learn how to handle these listeners next.

Detaching Global Listeners

SPA provides several improvements that highly benefit your site and users, but there is potentially some additional maintenance as a consequence. In a traditional navigation scenario, every page refresh resets everything, so you don't have to worry about what's left behind. In a SPA scenario, however, global listeners such as `Liferay.on` or `Liferay.after` or body delegates can become problematic. Every time you execute these global listeners, you add yet another listener to the globally persisted `Liferay` object. The result is multiple invocations of those listeners. This can obviously cause problems if not handled.

To prevent this, you need to listen to the navigation event in order to detach your listeners. For example, you would use the following code to detach the event listeners of a global `category` event:

```
var onCategory = function(event) {...};

var clearPortletHandlers = function(event) {
    if (event.portletId === '<%= portletDisplay.getRootPortletId() %>') {
        Liferay.detach('onCategoryHandler', onCategory);
        Liferay.detach('destroyPortlet', clearPortletHandlers);
    }
};

Liferay.on('category', onCategory);
Liferay.on('destroyPortlet', clearPortletHandlers);
```

Now you know how to configure and use SPA in Liferay DXP!

Using ES2015 Modules in Your Portlet

65.5 Creating Layouts inside Custom Portlets

Page layout tags let you create layouts using Bootstrap 3 within your portlets.

This tutorial explains the `<aui:*>` tags that developers can use to create layouts.

AUI Container

The `<aui:container>` tag creates a container `<div>` tag to wrap `<aui:row>` components and offer additional styling.

It supports the following attributes:

Attribute	Type	Description
cssClass	String	A CSS class for styling the component
dynamicAttributes	Map<String, Object>	Map of `data-` attributes for your container
fluid	boolean	Whether to enable the container to span the entire width of the viewport. The default value is true
id	String	An ID for the component instance

AUI Row

The `<aui:row>` tag creates a row to hold `<aui:col>` components.

It supports the following attributes:

Attribute	Type	Description
cssClass	String	A CSS class for styling the component
id	String	An ID for the component instance

AUI Col

The `<aui:col>` tag creates a column to display content in an `<aui:row>` component.

It supports the following attributes:

Attribute	Type	Description
cssClass	String	A CSS class for styling the component.
id	String	An ID for the component instance.
lg	String	Comma separated string of numbers 1-12 to be used for Boostrap grid `col-lg-`
md	String	Comma separated string of numbers 1-12 to be used for Boostrap grid `col-md-`
sm	String	Comma separated string of numbers 1-12 to be used for Boostrap grid `col-sm-`
xs	String	Comma separated string of numbers 1-12 to be used for Boostrap grid `col-xs-`
span	int	The width of the column in the containing row as a fraction of 12. For example, a span of 4 would result in a column width 4/12 (or 1/3) of the total width of the containing row.
width	int	The width of the column in the containing row as a percentage, overriding the span attribute. The width is then converted to a span expressed as ((width/100) x 12), rounded to the nearest whole number. For example, a width of 33 would be converted to 3.96, which would be rounded up to a span value of 4.

Example JSP

Below is an example layout created in a portlet:

```
<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>

<aui:container cssClass='super-awesome-container'>
        <aui:row>
                <aui:col md="4" sm="6">
                        <h2>Some fun content using the 'md' and 'sm' attributes</h2>
                </aui:col>

                <aui:col md="8" sm="6">
                        <p>
                                Some text here.
                </p>
            </aui:col>
        </aui:row>

        <aui:row>
            <aui:col width="<%= 40 %>">
                <h2>Some fun content using the 'width' attribute</h2>
            </aui:col>

            <aui:col width="<%= 60 %>">
                <p>
                    Cool text here.
                </p>
            </aui:col>
        </aui:row>

        <aui:row>
            <aui:col span="<%= 4 %>">
                <h2>Some fun content using the 'span' attribute</h2>
            </aui:col>

            <aui:col span="<%= 8 %>">
                <p>
                    Nice text here.
                </p>
            </aui:col>
        </aui:row>
</aui:container>
```

Now you know how to create layouts inside your portlets!

Chapter 66

Using JavaScript in Your Portlets

Would you like to use the latest ECMAScript features in your JavaScript files and portlets? Do you wish you could use npm and npm packages in your portlets?

In this section of tutorials you'll learn how to prepare your JavaScript files to leverage these features in your portlets.

Chapter 67

Using ES2015 in Your Portlets

You can now write JavaScript that adheres to the new ECMAScript 2015 (ES2015) syntax, leverage ES2015 advanced features in your modules, and publish them. To do these things, you need make only minor adjustments to your JavaScript files and projects.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

This section of tutorials shows how to prepare modules for ES2015 and use them in your portlets.

67.1 Preparing Your JavaScript Files for ES2015

To use the ES2015 syntax in a JavaScript file, add the extension `.es` to its name. For example, you rename file `filename.js` to `filename.es.js`. The extension indicates it uses ES2015 syntax and must therefore be transpiled by Babel before deployment.

ES2015 advanced features, such as generators, are available to you if you import the `polyfillBabel` class from the `polyfill-babel` module found in 7.0:

```
import polyfillBabel from 'polyfill-babel'
```

The Babel Polyfill emulates a complete ES6 environment. Use it at your own discretion, as it loads a large amount of code. You can inspect https://github.com/zloirock/core-js#core-js to see what's polyfilled.

Once you've completed writing your module, you can expose it by creating a `package.json` file that specifies your bundle's name and version. Make sure to create this in your module's root folder. The js-logger module, for example, specifies the following values in its `package.json` file:

```
{
    "name": "js-logger",
    "version": "1.0.0"
}
```

The Module Config Generator creates the module based on this information. There you have it! In just a few steps you can prepare your module to leverage the latest JavaScript standard features and publish it.

OSGi and Modularity for Liferay Portal 6 Developers

67.2 Using ES2015 Modules in your Portlet

Once you've exposed your modules via your `package.json` file, you can use them in your portlets. The `aui:script` tag's `require` attribute makes it easy.

This tutorial covers how to access in your portlets the modules you've exposed. The example module `logger.es` was written inside the Console Logger Portlet. Once the portlet is deployed, and added to a page, you'll notice a printout in the console.

Follow the steps below to use your exposed modules in your portlets.

1. Declare the aui taglib in a JSP in your view:

   ```
    <%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
   ```

   Note: if you created the portlet using Blade, the aui taglib is already provided for you in the `init.jsp`.

2. Add an `aui:script` tag to the JSP and set the `require` attribute to the relative path for your module.

   Since 7.0, the `require` attribute allows you to include your exposed modules in your JSP. The AMD Loader fetches the specified module and its dependencies. For example, the Console Logger Portlet's `view.jsp` includes the module `logger.es`:

   ```
   <aui:script require="js-logger/logger.es">
       var Logger = jsLoggerLoggerEs.default;

       var loggerOne = new Logger('*** -> ');
       loggerOne.log('Hello');

       var loggerDefault = new Logger();
       loggerDefault.log('World');
   </aui:script>
   ```

   References to the module within the script tag are named after the `require` value, in camel-case and with all invalid characters removed. The `logger.es` module's reference `jsLoggerLoggerEs` is derived from the module's relative path value `js-logger/logger.es`. The value is stripped of its dash and slash characters and converted to camel case.

Thanks to the `aui:script` tag and its `require` attribute, using your modules in your portlet is a piece of cake!

Chapter 68

Using npm in Your Portlets

npm is a powerful tool, and almost a necessity for Front-End development. Since Liferay DXP 7.0 Fix Pack 30 and Liferay Portal 7.0 CE GA5, you can use npm as your JavaScript package manager tool—including npm and npm packages—while developing portlets in your normal, everyday workflow.

Deployed portlets leverage Liferay AMD Loader to share JavaScript modules and take advantage of semantic versioning when resolving modules among portlets on the same page. The liferay-npm-bundler helps prepare your npm modules for the Liferay AMD Loader.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

This section of tutorials covers how to set up npm-based portlet projects and how Liferay DXP supports them.

68.1 liferay-npm-bundler

The liferay-npm-bundler is a bundler (like Webpack or Browserify) that targets Liferay DXP as a platform and assumes you're using your npm packages from portlets (as opposed to typical web applications). It is just one of the pieces of the Liferay JS Bundle Toolkit. Liferay JS Bundle Toolkit is an abstract umbrella term that refers to the following tools:

- liferay-npm-bundler
- Babel plugins
- liferay-npm-bundler plugins
- frontend-js-loader-modules-extender
- Javascript AMD loader

Note: The Liferay JS Bundle Toolkit is supported for Liferay DXP 7.0 Fix Pack 39 and up.

The workflow for running npm packages inside portlets is slightly different from standard bundlers. Instead of bundling the JavaScript in a single file, you must *link* all packages together in the browser when the full web page is assembled. This lets portlets share common versions of modules instead of each one loading its own copy. The liferay-npm-bundler handles this for you. You can learn how it works next.

How it Works Internally

The liferay-npm-bundler takes a Liferay DXP portlet project and outputs its files (including npm packages) to a build folder, so the standard portlet build (Gradle) can produce an OSGi bundle. You can learn more about the build folder's structure in The Structure of OSGi Bundles Containing NPM Packages tutorial.

Here's what happens to produce the OSGi bundle:

1. Copy the project's `package.json` file to the output directory.
2. Traverse the project's dependency tree to determine its dependencies.
3. For each npm package dependency:

    a. Copy the npm package to the output folder and prefix the bundle's name to it. Note that the bundler stores packages in plain *bundle-name$package@version* format, rather than the standard node_modules tree format).

    b. Pre-process the npm package with any configured plugins.

    c. Run Babel with configured plugins for each `.js` file inside the npm package.

    d. Post-process the npm package with any configured plugins.

4. For the project:

    a. Pre-process the project's package with any configured plugins.

    b. Run Babel with configured plugins for each `.js` file inside the project.

    c. Post-process the project package with any configured plugins.

The only difference between the pre-process and post-process steps are when they are run (before or after Babel is run, respectively). During this workflow, liferay-npm-bundler calls all the configured plugins so they can perform transformations on the npm packages (for instance, modifying their `package.json` files, or deleting or moving files).

Now you understand how the liferay-npm-bundler works!

Related Topics

The Structure of OSGi Bundles Containing NPM Packages

How Liferay DXP Publishes NPM Packages

Liferay JavaScript APIs

68.2 Adding liferay-npm-bundler to Your Portlet

Adding liferay-npm-bundler to your portlet involves installing the package via npm and adding it to your npm build process.

Installing liferay-npm-bundler

Note: liferay-npm-bundler 1.x performs aggressive semantic version resolution, which can potentially lead to unstable results. To avoid issues, we recommend that you use the latest version of the bundler (2.x at the time of this writing).

Follow these steps to install liferay-npm-bundler:

1. Install NodeJS >= v6.11.0 if you don't have it installed.

2. Navigate to your portlet's `src/main/resources/META-INF/resources` folder.

   If you don't have a portlet already, create an empty MVC portlet. For convenience, you can use Blade CLI to create an empty portlet with the mvc portlet blade template.

3. Run the following command to install the liferay-npm-bundler:

   ```
   npm install --save-dev liferay-npm-bundler
   ```

Note: Use npm from within your portlet project's root folder (where the `package.json` file lives), as you normally do on a typical web project.

Now that you have the liferay-npm-bundler installed, you can add it to your npm build process.

Adding liferay-npm-bundler to Your Build Process

Once your source is transpiled (if necessary) to ECMAScript and converted to AMD format for the Liferay AMD Loader, you must run liferay-npm-bundler in `package.json` to pack the needed npm packages and transform them to AMD. This lets Liferay AMD Loader grab the packages from the Portal.

Add `liferay-npm-bundler` to your `package.json`'s build script:

```
"scripts": {
     "build": "[... && ] liferay-npm-bundler"
}
```

The `[...&&]` refers to any previous steps you need to perform (for example, transpiling your sources with Babel).

You can use any languages you like as long as they can be transpiled to Ecmascript 5 or higher (the only requirement is that Babel can process it and your browser can execute it). When you deploy your portlet using Gradle, the build script is called as part of the process.

Now you know how to add the liferay-npm-bundler to your portlet!

Related Topics

Configuring liferay-npm-bundler

Understanding How liferay-npm-bundler Formats JavaScript Modules for AMD

68.3 Configuring liferay-npm-bundler

The liferay-npm-bundler is configured via a `.npmbundlerrc` file placed in the portlet project's root folder. You can create a complete configuration manually or extend a configuration preset (via Babel).

This tutorial explains the `.npmbundlerrc` file's structure and shows how the default preset configures the liferay-npm-bundler.

Understanding the .npmbundlerrc File's Structure

The `.npmbundlerrc` file has four possible phase definitions: *copy-process*, *pre-process*, *post-process*, and *babel*. These phase definitions are explained in more detail below:

Copy-Process: Defined with the `copy-plugins` property (only available for dependency packages). Specifies which files should be copied or excluded from each given package.

Pre-Process: Defined with the `plugins` property. Specifies plugins to run before the Babel phase is run.

Babel: Defined with the `.babelrc` definition. Specifies the `.babelrc` file to use when running Babel through the package's `.js` files.

Note: During this phase, Babel transforms package files (for example, to convert them to AMD format, if necessary), but doesn't transpile them. In theory, you could also transpile them by configuring the proper plugins. We recommend transpiling before running the bundler, to avoid mixing both unrelated processes.

Post-Process: Defined with the `post-plugins` property. An alternative to using the *pre-process* phase, this specifies plugins to run after the Babel phase has completed.

Here's an example of a `.npmbundlerrc` configuration:

```
{
    "exclude": {
        "*": [
            "test/**/*"
        ],
        "some-package-name": [
            "test/**/*",
            "bin/**/*"
        ],
        "another-package-name@1.0.10": [
            "test/**/*",
            "bin/**/*",
            "lib/extras-1.0.10.js"
        ]
    },
    "include-dependencies": [
        "isobject", "isarray"
    ],
    "output": "build",
    "process-serially": false,
    "verbose": false,
    "dump-report": true,
    "config": {
        "imports": {
            "npm-angular5-provider": {
                "@angular/common": "^5.0.0",
                "@angular/core": "^5.0.0"
            }
        }
    },
    "/": {
        "plugins": ["resolve-linked-dependencies"],
        ".babelrc": {
            "presets": ["liferay-standard"]
        },
        "post-plugins": [
            "namespace-packages",
            "inject-imports-dependencies"
        ]
    },
    "*": {
        "copy-plugins": ["exclude-imports"],
        "plugins": ["replace-browser-modules"],
        ".babelrc": {
            "presets": ["liferay-standard"]
        },
        "post-plugins": [
            "namespace-packages",
            "inject-imports-dependencies",
            "inject-peer-dependencies"
        ]
    }
    "packages": {
        "a-package-name": [
        "copy-plugins": ["exclude-imports"],
            "plugins": ["replace-browser-modules"],
            ".babelrc": {
                "presets": ["liferay-standard"]
            },
            "post-plugins": [
                "namespace-packages",
                "inject-imports-dependencies",
                "inject-peer-dependencies"
            ]
        ],
        "other-package-name@1.0.10": [
          "copy-plugins": ["exclude-imports"],
            "plugins": ["replace-browser-modules"],
            ".babelrc": {
                "presets": ["liferay-standard"]
            },
            "post-plugins": [
                "namespace-packages",
                "inject-imports-dependencies",
                "inject-peer-dependencies"
            ]
        ]
    }
```

Note: Not all definition formats (*, `some-package-name`, and `some-package-name@version`) shown above are required. In most cases, the wildcard definition (*) is enough. The non-wildcard formats (`some-package-name` and `some-package-name@version`) are rare exceptions for packages that require a more specific configuration than the wildcard definition provides.

Below are the configuration options for the `.npmbundlerrc` file:

exclude: defines glob expressions of files to exclude from bundling from all or specific packages.

include-dependencies: defines packages to include in bundling, even if they are not listed under the `dependencies` section of `package.json`. These packages must be available in the `node_modules` folder (i.e. installed manually, without saving them to `package.json`, or listed in the `devDependencies` section).

output: by default the bundler writes packages to the standard Gradle resources folder: `build/resources/main/META-INF/resources`. Set this value to override the default output folder.

process-serially: Process packages in parallel, leveraging Node.js asynchronous model, or one by one. The default value is `false`, (parallel), but if you get EMFILE errors, you can disable this.

verbose: Sets whether to output detailed information about what the tool is doing to the commandline.

dump-report: Sets whether to generate a debugging report. If `true`, an HTML file is generated in the project directory with information such as what the liferay-npm-bundler is doing with each package.

config: global configuration which is passed to all bundler and Babel plugins. Please refer to each plugin's documentation to find the available options for each specific plugin.

"/": plugins' configuration for the project's package.

"": plugins' configuration for dependency packages.

Note: Plugins' configuration specifies the options for configuring plugins in all the possible phases, as well as the `.babelrc` file to use when running Babel (see Babel's documentation for more information on that file format).

Note: Prior to version 1.4.0 of the liferay-npm-bundler, package configurations were placed next to the tools options (*, `output`, `exclude`, etc.) To prevent package name collisions, package configurations are now namespaced and placed under the `packages` section. To maintain backwards compatibility, the liferay-npm-bundler falls back to the root section outside `packages` for package configuration, if no package configurations (`package-name@version`, `package-name`, or *) are found in the `packages` section.

Now that you know the structure of the `.npmbundlerrc` file, you can learn about the default configuration preset.

How the Default Preset Configures the liferay-npm-bundler

The liferay-npm-bundler comes with a default configuration preset: `liferay-npm-bundler-preset-standard` in your `.npmbundlerrc` file. This preset configures several plugins for the build process and is automatically used (even if the `.npmbundlerrc` is missing), unless you override it with one of your own. Running the liferay-npm-bundler with this preset applies the config file from `liferay-npm-bundler-preset-standard`:

```
{
    "/": {
        "plugins": ["resolve-linked-dependencies"],
        ".babelrc": {
            "presets": ["liferay-standard"]
        },
        "post-plugins": ["namespace-packages", "inject-imports-dependencies"]
    },
    "*": {
        "copy-plugins": ["exclude-imports"],
        "plugins": ["replace-browser-modules"],
        ".babelrc": {
            "presets": ["liferay-standard"]
        },
        "post-plugins": [
            "namespace-packages",
            "inject-imports-dependencies",
            "inject-peer-dependencies"
        ]
    }
}
```

Note: You can override configuration preset values by adding your own configuration to your project's `.npmbundlerrc` file. For instance, using the configuration preset example above, you can define your own `.babelrc` value in `.npmbundlerrc` file to override the defined "liferay-standard" babelrc preset.

The `liferay-standard` preset applies the following plugins to packages:

- exclude-imports: Exclude packages declared in the `imports` section from the build.
- inject-imports-dependencies: Inject dependencies declared in the `imports` section in the dependencies' `package.json` files.
- inject-peer-dependencies: Inject declared peer dependencies (as they are resolved in the project's `node_modules` folder) in the dependencies' `package.json` files.
- namespace-packages: Namespace package names based on the root project's package name to isolate packages per project and avoid collisions. This prepends `<project-package-name>$` to each package name appearance in `package.json` files.
- replace-browser-modules: Replace modules listed under `browser/unpkg/jsdelivr` section of `package.json` files.
- resolve-linked-dependencies: Replace linked dependencies versions appearing in `package.json` files (those obtained from local file system or GitHub, for example) by their real version number, as resolved in the project's `node_modules` directory.

In addition, the bundler runs Babel with the babel-preset-liferay-standard preset, that invokes the following plugins:

- babel-plugin-name-amd-modules: Name AMD modules based on package name, version, and module path.
- babel-plugin-namespace-amd-define: Add a prefix to AMD `define()` calls (by default `Liferay.Loader.`).
- babel-plugin-namespace-modules: Namespace modules based on the root project's package name, prepending `<project-package-name>$`. Wrap modules inside an AMD `define()` module for each module name appearance (in `define()` or `require()` calls) so that the packages are localized per project and don't clash.
- babel-plugin-normalize-requires: Normalize AMD `require()` calls.
- babel-plugin-wrap-modules-amd: Wrap modules inside an AMD `define()` module.
- babel-plugin-transform-node-env-inline: Inline the `NODE_ENV` environment variable, and if it's part of a binary expression (eg. `process.env.NODE_ENV === "development"`), then statically evaluate and replace it.

Now you know how to configure the liferay-npm-bundler!

The Structure of OSGi Bundles Containing NPM Packages

68.4 The Structure of OSGi Bundles Containing npm Packages

To deploy JavaScript modules, you must create an OSGi bundle with the npm dependencies extracted from the project's `node_modules` folder and modify them to work with the Liferay AMD Loader. The liferay-npm-bundler automates this process for you, creating a bundle similar to the one below:

- `my-bundle/`
  - `META-INF/`
    - `resources/`
      - `package.json`
      - name: my-bundle-package
      - version: 1.0.0
      - main: lib/index
      - dependencies:
      - my-bundle-package$isarray: 2.0.0
      - my-bundle-package$isobject: 2.1.0

      - ...

      - `lib/`
      - `index.js`
      - ...

      - ...
      - `node_modules/`
      - `my-bundle-package$isobject@2.1.0/`
      - `package.json`
      - name: my-bundle-package$isobject
      - version: 2.1.0
      - main: lib/index
      - dependencies:
      - my-bundle-package$isarray: 1.0.0

      - ...

      - ...

      - `my-bundle-package$isarray@1.0.0/`
      - `package.json`
      - name: my-bundle-package$isarray
      - version: 1.0.0
      - ...

      - ...

      - `my-bundle-package$isarray@2.0.0/`
      - `package.json`

            · name: my-bundle-package$isarray
            · version: 2.0.0
            · ...

            · ...

The packages inside `node_modules` are the same format as the npm tool and can be copied (after a little processing for things like converting to AMD, for example) from a standard `node_modules` folder. The `node_modules` folder can hold any number of npm packages (even different versions of the same package), or no npm packages at all.

Now that you know the structure for OSGi bundles containing npm packages, you can learn how the liferay-npm-bundler handles inline JavaScript packages.

Inline JavaScript packages

The resulting OSGi bundle that the liferay-npm-bundler creates lets you deploy one inline JavaScript package (named `my-bundle-package` in the example) with several npm packages that are placed inside the `node_modules` folder, one package per folder.

The inline package is nested in the OSGi standard `META-INF/resources` folder and is defined by a standard npm `package.json` file.

The inline package is optional, but only one inline package is allowed per OSGi bundle. The inline package usually provides the JavaScript code for a portlet, when the OSGi bundle contains one. Note that the architecture does not differentiate between inline and npm packages once they are published. The inline package is only used for organizational purposes.

Now you know the liferay-npm-bundler creates OSGi bundles for npm packages!

liferay-npm-bundler

Adding liferay-npm-bundler to Your Portlet

68.5 Understanding How liferay-npm-bundler Formats JavaScript Modules for AMD

Liferay AMD Loader is based on the AMD specification. All modules inside an npm OSGi bundle must be in AMD format. This is done for CommonJS modules by wrapping the module code inside a `define` call. The liferay-npm-bundler helps automate this process by wrapping the module for you. This tutorial references the OSGi structure below as an example. You can learn more about this structure in The Structure of OSGi Bundles Containing NPM Packages tutorial.

- `my-bundle/`
    - `META-INF/`
        * `resources/`
            · `package.json`
            · name: my-bundle-package

- version: 1.0.0
- main: lib/index
- dependencies:
- my-bundle-package$isarray: 2.0.0
- my-bundle-package$isobject: 2.1.0

- ...

- `lib/`
- `index.js`
- ...

- ...
- `node_modules/`
- `my-bundle-package$isobject@2.1.0/`
- `package.json`
- name: my-bundle-package$isobject
- version: 2.1.0
- main: lib/index
- dependencies:
- my-bundle-package$isarray: 1.0.0

- ...

- ...

- `my-bundle-package$isarray@1.0.0/`
- `package.json`
- name: my-bundle-package$isarray
- version: 1.0.0
- ...

- ...

- `my-bundle-package$isarray@2.0.0/`
- `package.json`
- name: my-bundle-package$isarray
- version: 2.0.0
- ...

- ...

For example, the `my-bundle-package$isobject@2.1.0` package's `index.js` file contains the following code:

```
'use strict';

var isArray = require('my-bundle-package$isarray');

module.exports = function isObject(val) {
    return val ≠ null && typeof val === 'object' && isArray(val) === false;
};
```

The updated module code configured for AMD format is shown below:

```
define(
    'my-bundle-package$isobject@2.1.0/index',
    ['module', 'require', 'my-bundle-package$isarray'],
    function (module, require) {
        'use strict';

        var define = undefined;

        var isArray = require('my-bundle-package$isarray');

        module.exports = function isObject(val) {
            return val != null && typeof val === 'object'
            && isArray(val) === false;
        };
    }
);
```

Note: The module's name must be based on its package, version, and file path (for example `my-bundle-package$isobject@2.1.0/index`), otherwise Liferay AMD Loader can't find it.

Note the module's dependencies: `['module', 'require', 'my-bundle-package$isarray']`.

`module` and `require` must be used to get a reference to the `module.exports` object and the local `require` function, as defined in the AMD specification.

The subsequent dependencies state the modules on which this module depends. Note that `my-bundle-package$isarray` in the example is not a package but rather an alias of the `my-bundle-package$isarray` package's main module (thus, it is equivalent to `my-bundle-package$isarray/index`).

Also note that there is enough information in the `package.json` files to know that `my-bundle-package$isarray` refers to `my-bundle-package$isarray/index`, but also that it must be resolved to version `1.0.0` of such package, i.e., that `my-bundle-package$isarray/index` in this case refers to `my-bundle-package$isarray@1.0.0/index`.

You may also have noted the `var define = undefined;` addition to the top of the file. This is introduced by `liferay-npm-bundler` to make the module think that it is inside a CommonJS environment (instead of an AMD one). This is because some npm packages are written in UMD format and, because we are wrapping it inside our AMD `define()` call, we don't want them to execute their own `define()` but prefer them to take the CommonJS path, where the exports are done through the `module.exports` global.

You can leverage liferay-npm-bundler with the correct presets to process your npm modules for AMD. All liferay-npm-bundler presets (*liferay-npm-bundler-preset-*) found in the liferay-npm-build-tools repository include some or all of the following Babel plugins to accomplish the AMD conversion:

- babel-plugin-wrap-modules-amd
- babel-plugin-name-amd-modules
- Babel-plugin-namespace-amd-define

Now you have a better understanding of how liferay-npm-bundler formats JavaScript modules for AMD!

How Liferay DXP Publishes NPM Packages

Configuring liferay-npm-bundler

68.6 How Liferay DXP Publishes npm Packages

When you deploy an OSGi bundle with the specified structure, as explained in The Structure of OSGi Bundles Containing NPM Packages tutorial, its modules are made available for consumption through canonical URLs. To better illustrate resolved modules, the example structure below is the standard structure that the liferay-npm-bundler 1.x generates, and therefore doesn't have the namespaced packages that the 2.x version generates. Please refer to the last sections of this tutorial to know how liferay-npm-bundler 2.0 overrides this de-duplication mechanism to implement isolated dependencies and imports.

- `my-bundle/`
  - `META-INF/`
    - `resources/`
      - `package.json`
      - name: my-bundle-package
      - version: 1.0.0
      - main: lib/index
      - dependencies:
      - isarray: 2.0.0
      - isobject: 2.1.0

      - …

      - `lib/`
      - `index.js`
      - …

      - …
      - `node_modules/`
      - `isobject@2.1.0/`
      - `package.json`
      - name: isobject
      - version: 2.1.0
      - main: lib/index
      - dependencies:
      - isarray: 1.0.0

      - …

      - …

      - `isarray@1.0.0/`
      - `package.json`
      - name: isarray
      - version: 1.0.0
      - …

      - …

- `isarray@2.0.0/`
- `package.json`
- name: isarray
- version: 2.0.0
- …

- …

If you deploy the example OSGi bundle shown above, the following URLs are made available (one for each module):

- http://localhost/o/js/module/598/my-bundle-package@1.0.0/lib/index.js
- http://localhost/o/js/module/598/isobject@2.1.0/index.js
- http://localhost/o/js/module/598/isarray@1.0.0/index.js
- http://localhost/o/js/module/598/isarray@2.0.0/index.js

NOTE: The OSGi bundle ID (598) may vary.

You can learn about package de-duplication next.

Package De-duplication

Since two or more OSGi modules may export multiple copies of the same package and version, Liferay Portal must de-duplicate such collisions. To accomplish de-duplication, a new concept called resolved module was created.

A resolved module is the reference package exported to Liferay Portal's front-end, when multiple copies of the same package and version exist. It's randomly referenced from one of the several bundles exporting the same copies of the package.

Using the example from the previous section, for each group of canonical URLs referring to the same module inside different OSGi bundles, there's another canonical URL for the resolved module. The example structure has the resolved module URLs shown below:

- http://localhost/o/js/resolved-module/my-bundle-package@1.0.0/lib/index.js
- [http://localhost/o/js/resolved-module/my-bundle-package$isobject@2.1.0/index.js](http: //localhost/o/js/resolved - module/my - bundle - package$isobject@2.1.0/index.js)
- [http://localhost/o/js/resolved-module/my-bundle-package$isarray@1.0.0/index.js](http: //localhost/o/js/resolved - module/my - bundle - package$isarray@1.0.0/index.js)
- [http://localhost/o/js/resolved-module/my-bundle-package$isarray@2.0.0/index.js](http: //localhost/o/js/resolved - module/my - bundle - package$isarray@2.0.0/index.js)

NOTE: The OSGi bundle ID (598 in the example) is removed and module is replaced by `resolved-module`.

Next you can learn how the bundler (since version 2.0.0) isolates package dependencies. See What Changed Between liferay-npm-bundler 1.x and 2.x for more information on why this change was made.

Isolated Package Dependencies

A typical OSGi bundle structure generated with liferay-npm-bundler 2.x is shown below:

- `my-bundle/`
  - `META-INF/`
    - `resources/`
      - `package.json`
      - name: my-bundle-package
      - version: 1.0.0
      - main: lib/index
      - dependencies:
      - my-bundle-package$isarray: 2.0.0
      - my-bundle-package$isobject: 2.1.0

      - ...

      - `lib/`
      - `index.js`
      - ...

      - ...
      - `node_modules/`
      - `my-bundle-package$isobject@2.1.0/`
      - `package.json`
      - name: my-bundle-package$isobject
      - version: 2.1.0
      - main: lib/index
      - dependencies:
      - my-bundle-package$isarray: 1.0.0

      - ...

      - ...

      - `my-bundle-package$isarray@1.0.0/`
      - `package.json`
      - name: my-bundle-package$isarray
      - version: 1.0.0
      - ...

      - ...

      - `my-bundle-package$isarray@2.0.0/`
      - `package.json`
      - name: my-bundle-package$isarray
      - version: 2.0.0

- ...
- ...

Note that each package dependency is namespaced with the bundle's name (`my-bundle-package$` in the example structure). This lets each project load its own dependencies and avoid potential collisions with projects that export the same package. For example, consider the two portlet projects below:

```
- `my-portlet`
    - package.json
        - dependencies:
            - a-library 1.0.0
            - a-helper 1.0.0
    - node_modules
        - a-library
            - version: 1.0.0
            - dependencies:
                - a-helper ^1.0.0
        - a-helper
            - version: 1.0.0

- `another-portlet`
    - package.json
        - dependencies:
            - a-library 1.0.0
            - a-helper 1.2.0
    - node_modules
        - a-library
            - version: 1.0.0
            - dependencies:
                - a-helper ^1.0.0
        - a-helper
            - version: 1.2.0
```

In this example, `a-library` depends on `a-helper` at version 1.0.0 or higher (note the caret ^ expression in the dependencies). The bundler implements isolated dependencies by prefixing the name of the bundle to the modules, so that `my-portlet` gets its `a-helper` at 1.0.0, while `another-portlet` gets its `a-helper` at 1.2.0.

The dependencies isolation not only avoids collisions between bundles, but also makes peer dependencies behave deterministically as each portlet gets what it had in its `node_modules` folder when it was developed.

Now that you understand how namespacing modules isolates bundle dependencies, avoiding collisions, you can learn about de-duplication next.

De-duplication through Importing

Isolated dependencies are very useful, but there are times when sharing the same package between modules would be more beneficial. To do this, the liferay-npm-bundler lets you import packages from an external OSGi bundle, instead of using your own. This lets you put shared dependencies in one project and reference them from the rest.

Imagine that you have three portlets that compose the homepage of your site: `my-toolbar`, `my-menu`, and `my-content`. These portlets depend on the fake, but awesome, Wonderful UI Components (WUI) framework. This quite limited framework is composed of only three packages:

1. `component-core`
2. `button`
3. `textfield`

Since the bundler namespaces each dependency package with the portlet's name by default, you would end up with three namespaced copies of the WUI package on the page. This is not what you want. Since they share the same package, instead you can create a fourth bundle that contains the WUI package, and import the WUI package in the three portlets. This results in the structure below:

- `my-toolbar/`
  - `.npmbundlerrc`
    - config:
      - imports:
      - wui-provider:
      - component-core: ^1.0.0
      - button: ^1.0.0
      - textfield: ^1.0.0
- `my-menu/`
  - `.npmbundlerrc`
    - config:
      - imports:
      - wui-provider:
      - component-core: ^1.0.0
      - button: ^1.0.0
      - textfield: ^1.0.0
- `my-content/`
  - `.npmbundlerrc`
    - config:
      - imports:
      - wui-provider:
      - component-core: ^1.0.0
      - button: ^1.0.0
      - textfield: ^1.0.0
- `wui-provider/`
  - `.package.json`
    - name: wui-provider
    - dependencies:
      - component-core: 1.0.0
      - button: 1.0.0

- textfield: 1.0.0

The bundler switches the namespace of certain packages, thus pointing them to an external bundle. Say that you have the following code in `my-toolbar` portlet:

```
var Button = require('button');
```

By default, the bundler 2.x transforms this into the following when not imported from another bundle:

```
var Button = require('my-toolbar$button');
```

But, because `button` is imported from `wui-provider`, it is instead changed to the value below:

```
var Button = require('wui-provider$button');
```

Also, a dependency on `wui-provider$button` at version `^1.0.0` is included in `my-toolbar`'s `package.json` file so that the loader finds the correct version. That's all you need. Once `wui-provider$button` is required at runtime, it jumps to `wui-provider`'s context and loads the subdependencies from there on, even if code is executed from `my-toolbar`. This works because, as you can imagine, `wui-provider`'s modules are namespaced too, and once you load a module from it, it keeps requiring `wui-provider$` prefixed modules all the way down.

Next, you will learn possible strategies for importing.

Strategies When Importing Packages

De-duplication by importing is a powerful tool, but you must design a versioning strategy suitable for you so that you don't run into errors.

First of all, you must decide if you want to declare imported dependencies only in the `.npmbundlerrc` file or in the `package.json` too. Listing an imported dependency in `.npmbundlerrc` is enough, even if it isn't present in your `node_modules` folder because during runtime the loader will find it. Listing an imported dependency in `.npmbundlerrc` is enough, even if it isn't present in your `node_modules` folder, because during runtime the loader finds it. If you have previous experience with dynamic linking support in standard operating systems, think of it as a DLL or shared object.

You may need to install your dependencies in `node_modules` too if you use them for tests, or if they contain types needed to compile (like in Typescript), etc. If that is the case, then you can place them in the `dependencies` or `devDependencies` section of your `package.json`. If you list them under the latter, they are automatically excluded from the output bundle by the liferay-npm-bundler. Otherwise, you need to exclude them in the `.npmbundlerrc` file so they don't redundantly appear in the output.

If you list dependencies both in `package.json` and `.npmbundlerrc`, decide how to keep versions in sync. The best advice is to use the same version constraints in both files, but you may decide not to do so if it is necessary. For example, imagine that you import one of your dependencies from another bundle during runtime to run tests. Say you are using version constraint ^1.5.1. It would be desirable that if you have tested your code with a version >=1.5.1 and <2.0.0 (that's what ^1.5.1 means), you get a compatible version during runtime. Thus, you would declare the dependency with ^1.5.1 in `.npmbundlerrc` too.

However, there are times when you may want to be more lenient, and you may need to get a lower version (1.4.0 for example) during runtime, even if you are developing against ^1.5.1. In that case, you can declare ^1.5.1 in your `package.json` and ^1.0.0 in `.npmbundlerrc`.

In the end, it's up to you to decide how you want to handle your dependencies:

1. `package.json` (While developing)
2. `.npmbundlerrc` (During runtime)

we recommend that you choose a versioning strategy and stick to it, to ensure dependencies are satisfied at runtime.

Now you know how Liferay DXP publishes npm packages!

Understanding How liferay-npm-bundler Formats JavaScript Modules for AMD

Understanding How Liferay DXP Exposes Configuration for Liferay AMD Loader

68.7 Understanding How Liferay DXP Exposes Configuration For Liferay AMD Loader

NOTE: This tutorial is for users who know how Liferay AMD Loader works under the hood. You can learn more about Liferay AMD Loader in the Liferay AMD Module Loader tutorial.

With de-duplication in place, JavaScript modules are made available to Liferay AMD Loader through the configuration returned by the `/o/js_loaded_modules` URL.

The OSGi bundle shown below is used for reference in this tutorial:

- `my-bundle/`
  - `META-INF/`
    - `resources/`
      - `package.json`
      - name: my-bundle-package
      - version: 1.0.0
      - main: lib/index
      - dependencies:
      - isarray: 2.0.0
      - isobject: 2.1.0

      - ...

      - `lib/`
      - `index.js`
      - ...

      - ...
      - `node_modules/`
      - `isobject@2.1.0/`
      - `package.json`
      - name: isobject
      - version: 2.1.0
      - main: lib/index
      - dependencies:
      - isarray: 1.0.0

      - ...

- ...

- isarray@1.0.0/
- package.json
- name: isarray
- version: 1.0.0
- ...

- ...

- isarray@2.0.0/
- package.json
- name: isarray
- version: 2.0.0
- ...

- ...

For example, for the specified structure (shown above), as explained in The Structure of OSGi Bundles Containing npm Packages tutorial, the following configuration is published for Liferay AMD loader to consume:

```
Liferay.PATHS = {
  ...
  'my-bundle-package@1.0.0/lib/index': '/o/js/resolved-module/my-bundle-package@1.0.0/lib/index',
  'isobject@2.1.0/index': '/o/js/resolved-module/isobject@2.1.0/index',
  'isarray@1.0.0/index': '/o/js/resolved-module/isarray@1.0.0/index',
  'isarray@2.0.0/index': '/o/js/resolved-module/isarray@2.0.0/index',
  ...
}
Liferay.MODULES = {
  ...
  "my-bundle-package@1.0.0/lib/index.es": {
    "dependencies": ["exports", "isarray", "isobject"],
    "map": {
      "isarray": "isarray@2.0.0",
      "isobject": "isobject@2.1.0"
    }
  },
  "isobject@2.1.0/index": {
    "dependencies": ["module", "require", "isarray"],
    "map": {
      "isarray": "isarray@1.0.0"
    }
  },
  "isarray@1.0.0/index": {
    "dependencies": ["module", "require"],
    "map": {}
  },
  "isarray@2.0.0/index": {
    "dependencies": ["module", "require"],
    "map": {}
  },
  ...
}
Liferay.MAPS = {
  ...
  'my-bundle-package@1.0.0': { value: 'my-bundle-package@1.0.0/lib/index', exactMatch: true}
  'isobject@2.1.0': { value: 'isobject@2.1.0/index', exactMatch: true},
  'isarray@2.0.0': { value: 'isarray@2.0.0/index', exactMatch: true},
  'isarray@1.0.0': { value: 'isarray@1.0.0/index', exactMatch: true},
  ...
}
```

Note:

- The `Liferay.PATHS` property describes paths to the JavaScript module files.
- The `Liferay.MODULES` property describes the dependency names and versions of each module.
- The `Liferay.MAPS` property describes the aliases of the package's main modules.

Chapter 69

Using the NPMResolver API in Your Portlets

If you're developing an npm-based portlet, your OSGi bundle's `package.json` is a treasure-trove of information. It contains everything that's stored in the npm registry about your bundle: default entry point, dependencies, modules, package names, versions, and more. Since Liferay DXP 7.0 Fix Pack 37 and Liferay Portal 7.0 CE GA6, Liferay DXP's `NPMResolver` APIs expose this information so you can access it in your portlet. If it's defined in the OSGi bundle's `package.json`, you can retrieve the information in your portlet with the `NPMResolver` API. For instance, you can use this API to reference an npm package's static resources (such as CSS files) and even to make your code more maintainable.

To enable the `NPMResolver` in your portlet, use the `@Reference` annotation to inject the `NPMResolver` OSGi component into your portlet's Component class, as shown below:

```
import com.liferay.frontend.js.loader.modules.extender.npm.NPMResolver;

public class MyPortlet extends MVCPortlet {

  @Reference
  private NPMResolver `_npmResolver`;

}
```

Note: Because the `NPMResolver` reference is tied directly to the OSGi bundle's `package.json` file, it can only be used to retrieve npm module and package information from that file. You can't use the `NPMResolver` to retrieve npm package information for other OSGi bundles.

Now that the `NPMResolver` is added to your portlet, the tutorials in this section describe retrieving your OSGi bundle's npm package and module information.

69.1 Referencing an npm Module's Package to Improve Code Maintenance

Once you've exposed your modules, you can use them in your portlet via the `aui:script` tag's `require` attribute. By default, Liferay DXP automatically composes an npm module's JavaScript variable based on its name. For example, the module `my-package@1.0.0` translates to the variable `myPackage100` for the `<aui:script>` tag's `require` attribute. This means that each time a new version of the OSGi bundle's npm package is released, you must update your code's variable to reflect the new version. You can use the JSPackage interface to obtain the module's package name and create an alias to reference it, so the variable name always reflects the latest version number!

Follow these steps:

1. Retrieve a reference to the OSGi bundle's npm package using the `getJSPackage()` method:

```
JSPackage jsPackage = _npmResolver.getJSPackage();
```

2. Grab the npm package's resolved ID (the current package version, in the format `<package name>@<version>`, defined in the OSGi module's `package.json`) using the `getResolvedId()` method and alias it with the `as myVariableName` pattern. The example below retrieves the npm module's resolved ID, sets it to the `bootstrapRequire` variable, and assigns the entire value to the attribute `bootstrapRequire`. This ensures that the package version is always up to date:

```
renderRequest.setAttribute(
  "bootstrapRequire",
  jsPackage.getResolvedId() + " as bootstrapRequire");
```

3. Include the reference to the `NPMResolver`:

```
@Reference
private NPMResolver _npmResolver;
```

4. Resolve the `JSPackage` and `NPMResolver` imports:

```
import com.liferay.frontend.js.loader.modules.extender.npm.JSPackage;
import com.liferay.frontend.js.loader.modules.extender.npm.NPMResolver;
```

5. In the portlet's JSP, retrieve the aliased attribute (`bootstrapRequire` in the example):

```
<%
String bootstrapRequire =
    (String)renderRequest.getAttribute("bootstrapRequire");
%>
```

6. Finally, use the attribute as the `<aui:script>` require attribute's value:

```
<aui:script require="<%= bootstrapRequire %>">
    bootstrapRequire.default();
</aui:script>
```

Below is the full example `*Portlet` class:

```
public class MyPortlet extends MVCPortlet {

    @Override
    public void doView(
            RenderRequest renderRequest, RenderResponse renderResponse)
        throws IOException, PortletException {

        JSPackage jsPackage = _npmResolver.getJSPackage();

        renderRequest.setAttribute(
            "bootstrapRequire",
            jsPackage.getResolvedId() + " as bootstrapRequire");

        super.doView(renderRequest, renderResponse);
    }

    @Reference
    private NPMResolver _npmResolver;

}
```

And here is the corresponding example `view.jsp`:

```
<%
String bootstrapRequire =
  (String)renderRequest.getAttribute("bootstrapRequire");
%>

<aui:script require="<%= bootstrapRequire %>">
  bootstrapRequire.default();
</aui:script>
```

Now you know how to reference an npm module's package!

Obtaining an OSGi bundle's Dependency npm Package Descriptors

liferay-npm-bundler

How Liferay DXP Publishes npm Packages

69.2 Obtaining an OSGi bundle's Dependency npm Package Descriptors

While writing your npm portlet, you may need to reference a dependency package or its modules. For instance, you can retrieve an npm dependency package module's CSS file and use it in your portlet. The `NPMResolver` OSGi component provides two methods for retrieving an OSGi bundle's dependency npm package descriptors: `getDependencyJSPackage()` to retrieve dependency npm packages and `resolveModuleName()` to retrieve dependency npm modules. This tutorial references the `package.json` below to help demonstrate these methods:

```
{
    "dependencies": {
        "react": "15.6.2",
        "react-dom": "15.6.2"
    },
    .
    .
    .
}
```

To obtain an OSGi bundle's npm dependency package, pass the package's name in as the `getDependencyJSPackage()` method's argument. The example below resolves the `react` dependency package:

```
String reactResolvedId = npmResolver.getDependencyJSPackage("react");
```

`reactResolvedId`'s resulting value is `react@15.6.2`.

You can use the `resolveModuleName()` method To obtain a module in an npm dependency package. To do this, pass the module's relative path in as the `resolveModuleName()` method's argument. The example below resolves a module named `react-with-addons` for the `react` dependency package:

```
String resolvedModule =
npmResolver.resolveModuleName("react/dist/react-with-addons");
```

The `resolvedModule` variable evaluates to `react@15.6.2/dist/react-with-addons`. You can also use this to reference static resources inside npm packages (like CSS or image files), as shown in the example below:

```
String cssPath = npmResolver.resolveModuleName(
      "react/lib/css/main.css");
```

Now you know how to obtain an OSGi bundle's dependency npm packages descriptors!

Chapter 70

Applying Lexicon Styles to your App

It's important to have a consistent user experience across your apps. Liferay DXP's built-in apps achieve this through Liferay's Lexicon Experience Language and its web implementation, Lexicon.

Lexicon provides a consistent, user-friendly UI for Liferay DXP apps, and is included in all themes that are based on the `_styled` base theme, making all the components documented on the Lexicon site accessible.

This means you can use Lexicon markup and components in your Liferay DXP apps. These tutorials explain how to apply Lexicon's design patterns to achieve the same look and feel as Liferay DXP's built-in apps.

The tutorials in this section cover the following topics:

- Configuring your portlet title and back link
- Applying Lexicon patterns to your forms, navigation, and more
- Using the Add Button pattern
- Implementing the Management Bar
- Configuring your admin app's actions menu
- Setting search container animations
- Using Lexicon icons in your app

70.1 Configuring Your Application's Title and Back Link

For 7.0 administration applications, the title should be moved to the inner views of the app and the associated back link should be moved to the portlet titles.

If you open the Blogs Admin application in the Control Panel and add a new blog entry, you'll see this behavior in action:

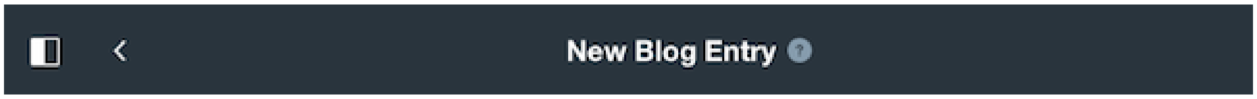

Figure 70.1: Adding a new blog entry displays the portlet title at the top, along with a back link.

This tutorial uses the Blogs Admin application's `edit_entry.jsp` as an example.

Follow these steps to configure your app's title and back URL:

1. Use `ParamUtil` to retrieve the redirect for the URL:

   ```
   String redirect = ParamUtil.getString(request, "redirect");
   ```

2. Display the back icon and set the back URL to the `redirect`:

   ```
   portletDisplay.setShowBackIcon(true);
   portletDisplay.setURLBack(redirect);
   ```

3. Finally, set the title using the `renderResponse.setTitle()` method, as shown in the example configuration below:

   ```
   renderResponse.setTitle((entry ≠ null) ? entry.getTitle() :
   LanguageUtil.get(request, "new-blog-entry"));
   %>
   ```

The example above provides a title for two scenarios:

- If an existing blog entry is being updated, the blog's title is displayed.
- Otherwise it defaults to *New Blog Entry* since a new blog entry is being created.

You should also update any back links in the view to use the `redirect`. For example the `edit_entry.jsp` form's cancel button redirects the user:

```
<aui:button cssClass="btn-lg" href="<%= redirect %>" name="cancelButton"
type="cancel" />
```

Now you know how to configure your app's title and back URL!

Applying Lexicon Patterns to your Forms, Navigation, and Search
Setting Search Container Animations

70.2 Applying Lexicon Patterns to Your Forms, Navigation, and Search

This tutorial covers how to leverage Lexicon patterns in your app's forms, navigation, and search results to make them more user-friendly.

You can learn how to update your navigation next.

Applying Lexicon to the Navigation Bar

All administration apps in 7.0 have a navigation bar. Applying Lexicon to your existing navigation bar takes only one additional attribute.

If your app already has a navigation bar implemented with the `aui:nav-bar` tag, you can reuse it by adding the attribute `markupView="lexicon"`.

For example, Liferay's Trash app has the configuration below:

```
<aui:nav-bar cssClass="collapse-basic-search" markupView="lexicon">
```

Note: The `markupView="lexicon"` attribute ensures that the Lexicon markup is used for the UI components, rather than the standard markup. This attribute tells the app to use the `lexicon` folder in the taglib to render the HTML, rather than the default rendering. For example, `<aui:fieldset markupView="lexicon" />` renders the HTML using `/portal/portal-web/docroot/html/taglib/aui/fieldset/lexicon/` instead of the `end.jsp` and `start.jsp` files in `/portal/portal-web/docroot/html/taglib/aui/fieldset/`.

Alternatively, you can use non-bordered tabs with the `liferay-ui:tabs` taglib as the Lexicon Guidelines state.

Sweet! Now you know how to style a navigation bar with Lexicon. Next, you'll learn how to apply Lexicon to your forms.

Applying Lexicon Patterns to the Application Body

To ensure that your application uses all available screen real state from left to right, make the application body fluid in all portlet views. This helps provide a consistent user-experience across all app views.

To make your app's content fluid, add the `container-fluid-1280` class in a `<div>` (or equivalent) element that contains all the portlet's content (excluding the Nav Bar and Management Bar).

If your app's view (or views) are already contained within a `<div>` element, add the `container-fluid-1280` class to it. Otherwise add an uppermost `<div>` element for this purpose:

```
<div class="container-fluid-1280">
...
</div>
```

Next, you can learn how to apply Lexicon to your forms.

Improving your Forms with Lexicon

Follow these steps to apply Lexicon to your forms:

1. Encapsulate your `fieldsets` with the following taglib:

   ```
   <aui:fieldset-group markupView="lexicon">

   </aui:fieldset-group>
   ```

2. The `fieldset` inside `fieldset-group` should be collapsible, so you can hide it when it's not being used. Add the `collapsed` and `collapsible` attributes to your `aui:fieldset` taglib:

```
<aui:fieldset collapsed="<%= true %>" collapsible="<%= true %>"
label="permissions">
      ...
</aui:fieldset>
```

3. Finally, add the `btn-lg` CSS class to your form's buttons to increase the click area:

```
<aui:button-row>

    <aui:button cssClass="btn-lg" type="submit" />

    <aui:button cssClass="btn-lg" href="<%= redirect %>"
    type="cancel" />

</aui:button-row>
```

Your forms are now configured to use Lexicon! Next, you can learn how to apply Lexicon to the Actions menu for your entities.

Applying Lexicon to Your Entity's Actions Menus

Your Actions menus can also benefit from Lexicon patterns. Learn how to apply Lexicon patterns to your Admin app's actions in the Configuring Your Admin app's Actions Menu tutorial. For regular apps, follow these steps:

1. Open your module's actions JSP (`guestbook_actions.jsp` for example) and update the `<liferay-ui:icon-menu>` to use Lexicon's markup with the `markupView` attribute:

```
<liferay-ui:icon-menu
    direction="left-side"
    icon="<%= StringPool.BLANK %>"
    markupView="lexicon"
    message="<%= StringPool.BLANK %>"
    showWhenSingleIcon="<%= true %>"
>
```

2. To follow the Lexicon guidelines, the Actions menu should only display an icon if it is one action. If the Actions menu contains multiple actions, remove the icon's `image` attribute and replace it with the `message` attribute displaying the action's title. Below is an example configuration:

```
<liferay-ui:icon
    message="Edit"
    url="<%= editURL.toString() %>"
/>
```

Next you can update your search iterator.

Applying Lexicon to your Search iterator

To apply Lexicon to your search iterator, add the `markupView="lexicon"` attribute:

```
<liferay-ui:search-iterator

    displayStyle="<%= displayStyle %>"
    markupView="lexicon"
    searchContainer="<%= searchContainer %>"
/>
```

The `displayStyle` attribute specifies which display style is set for the management bar. You can learn how to configure display styles in the Implementing Management Bar Display Styles tutorial.

If the results contain different sets of entries (folders and documents, categories and threads, etc.), you must use a class that implements `*ResultRowSplitter` to divide the results. This is covered next.

Creating a Result Row Splitter

Classes that implement the `*ResultRowSplitter` class divide and categorize the results based on the different entry types. Follow these steps to create a result row splitter:

1. Create a Java class that implements the `ResultRowSplitter` interface. For example, the `com.liferay.bookmarks.web` module has the following `BookmarksResultRowSplitter` class to split its folder and bookmark results:

   public class BookmarksResultRowSplitter implements ResultRowSplitter {

2. Override the `split()` method:

```
    @Override
    public List<ResultRowSplitterEntry> split(List<ResultRow> resultRows) {
        List<ResultRowSplitterEntry> resultRowSplitterEntries =
            new ArrayList<>();
```

3. Create an `ArrayList` for each type of entity, as shown in the example below:

```
        List<ResultRow> entryResultRows = new ArrayList<>();
        List<ResultRow> folderResultRows = new ArrayList<>();
```

4. Loop through the results and add your entities to the proper `ArrayList`:

```
        for (ResultRow resultRow : resultRows) {
            Object object = resultRow.getObject();

            if (object instanceof BookmarksFolder) {
                folderResultRows.add(resultRow);
            }
            else {
                entryResultRows.add(resultRow);
            }
    }
```

5. Create a new `ResultRowSplitterEntry` for each entity, passing the name of the entity and the ArrayList:

```
    if (!folderResultRows.isEmpty()) {
        resultRowSplitterEntries.add(
            new ResultRowSplitterEntry("folders", folderResultRows));
    }

    if (!entryResultRows.isEmpty()) {
        resultRowSplitterEntries.add(
            new ResultRowSplitterEntry("bookmarks", entryResultRows));
    }
```

6. Return the List of `resultRowSplitter` Entries.

7. Use the `resultRowSplitter` attribute in your `liferay-ui:search-iterator` taglib to create a new instance of your `*ResultRowSplitter` as shown in the example below:

```
<liferay-ui:search-iterator
    displayStyle="<%= displayStyle %>"
    markupView="lexicon"
    resultRowSplitter="<%= new BookmarksResultRowSplitter() %>"
    searchContainer="<%= bookmarksSearchContainer %>"
/>
```

Now you know how to apply Lexicon patterns to your app's forms, navigation, and search results!

Related topics

Configuring Your Application's Title and Back Link
Using Lexicon Icons in Your App

70.3 Applying the Add Button Pattern

Lexicon's add button pattern is for actions that add entities (for example a new blog entry button): it gives you a clean, minimal UI. You can use it in any of your app's screens. The add button pattern consists of an `add-menu` tag and at least one `add-menu-item` tag.

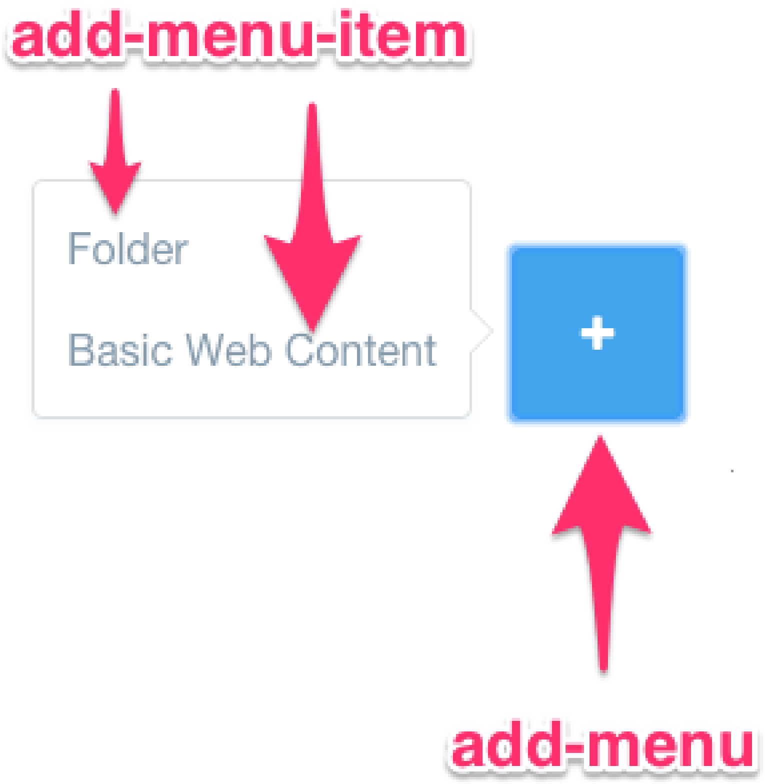

Figure 70.2: The add button pattern consists of an `add-menu` tag and at least one `add-menu-item` tag.

If there's only one item, the plus icon acts as a button that triggers the item. If there's more than one item, clicking the plus icon displays a menu containing them.

Add a `<liferay-frontend:add-menu-item>` tag for every menu item you have. Here's an example of the add button pattern with a single item:

```
<liferay-frontend:add-menu>
    <liferay-frontend:add-menu-item title='<%= LanguageUtil.get(request,
    "titleName") %>' url="<%= nameURL.toString() %>" />
</liferay-frontend:add-menu>
```

You can also find the add button pattern in Liferay DXP's built-in apps. For example, the Message Boards Admin application uses the following add button pattern:

```
<liferay-frontend:add-menu>
    ...
    <liferay-frontend:add-menu-item title='<%= LanguageUtil.get(request,
    "thread") %>' url="<%= addMessageURL.toString() %>" />
    ...
    <liferay-frontend:add-menu-item title='<%= LanguageUtil.get(request,
    (categoryId == MBCategoryConstants.DEFAULT_PARENT_CATEGORY_ID) ?
    "category[message-board]" : "subcategory[message-board]") %>'
    url="<%= addCategoryURL.toString() %>" />
    ...
</liferay-frontend:add-menu>
```

There you have it! Now you know how to use the add button pattern.

Setting Search Container Animations

Adding the Management Bar

Chapter 71

Adding the Management Bar

The Management Bar controls display options for search container results. You can use it to display content in a list or a grid, or to display a specific type of content. You can also customize your app's Management Bar.

The Management Bar is divided into a few key sections. Each section is grouped and configured using different taglibs:

The `<liferay-frontend:management-bar-buttons>` tag wraps the Management Bar's button elements:

The `<liferay-frontend:management-bar-sidenav-toggler-button>` tag implements slide-out navigation for the info button.

The `<liferay-frontend:management-bar-display-buttons>` tag renders the app's display style options:

The `<liferay-frontend:management-bar-filters>` tag wraps the app's filtering options. This filter should be included in all control panel applications. Filtering options can include sort criteria, sort ordering, and more:

Finally, the `<liferay-frontend:management-bar-action-buttons>` tag wraps the actions that you can execute over selected items. In 7.0, you can select multiple items between pages. The management bar keeps track of the number of selected items for you:

For example, here's the Management Bar configuration in Liferay's Trash app:

```
    <liferay-portlet:actionURL name="changeDisplayStyle"
    varImpl="changeDisplayStyleURL">
        <portlet:param name="redirect" value="<%= currentURL %>" />
    </liferay-portlet:actionURL>

    <liferay-frontend:management-bar-display-buttons
        displayViews='<%= new String[] {"descriptive", "icon",
        "list"} %>'
        portletURL="<%= changeDisplayStyleURL %>"
        selectedDisplayStyle="<%= trashDisplayContext.getDisplayStyle()
        %>"
    />
</liferay-frontend:management-bar-buttons>

<liferay-frontend:management-bar-filters>
    <liferay-frontend:management-bar-navigation
        navigationKeys='<%= new String[] {"all"} %>'
        portletURL="<%= trashDisplayContext.getPortletURL() %>"
    />

    <liferay-frontend:management-bar-sort
        orderByCol="<%= trashDisplayContext.getOrderByCol() %>"
        orderByType="<%= trashDisplayContext.getOrderByType() %>"
```

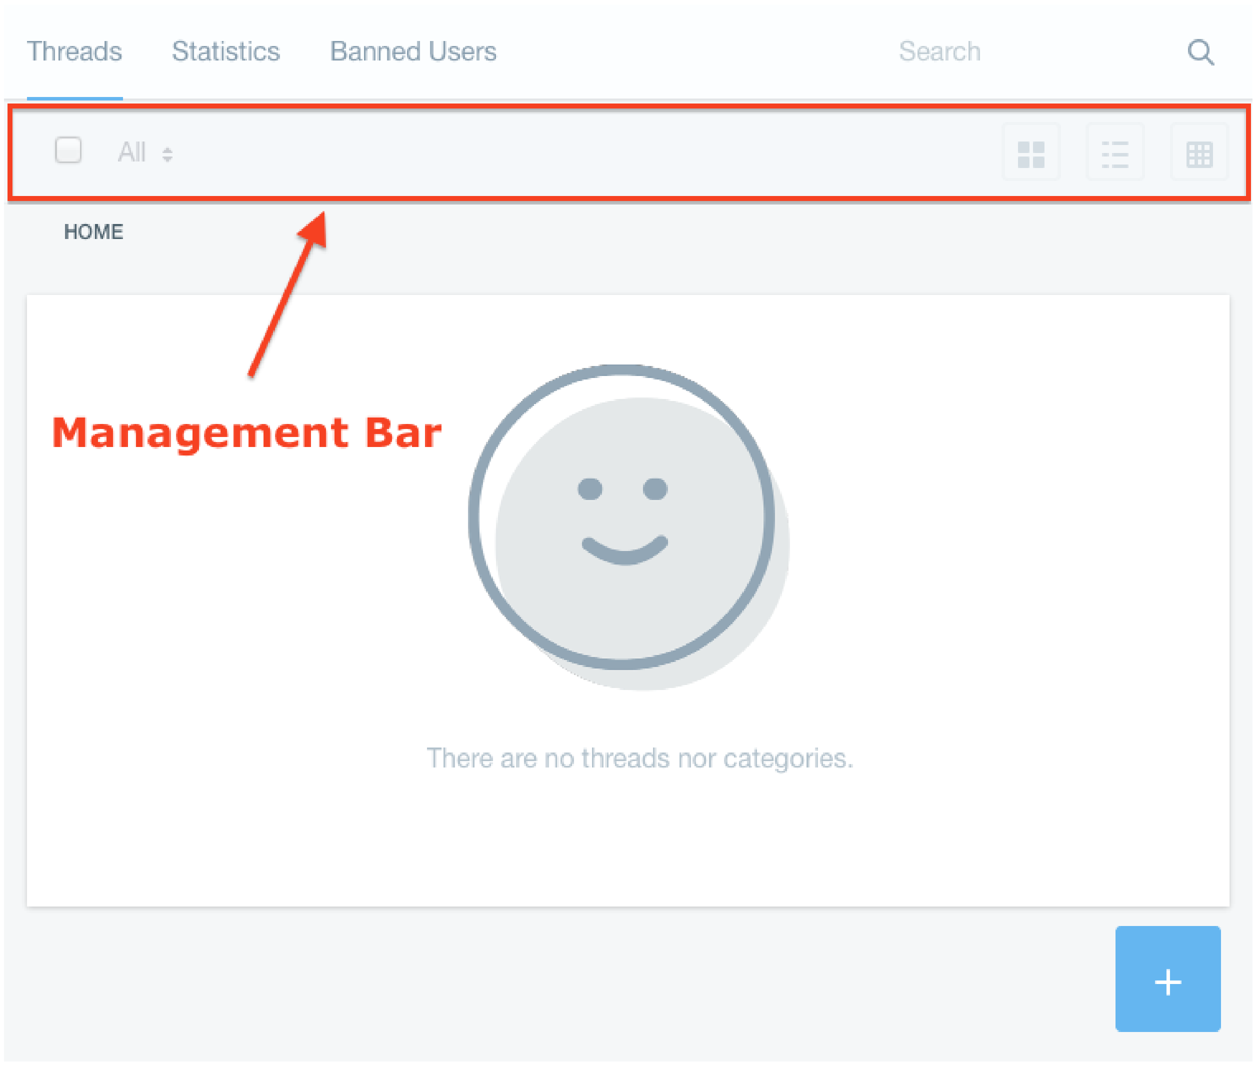

Figure 71.1: The Management Bar lets the user customize how the app displays content.

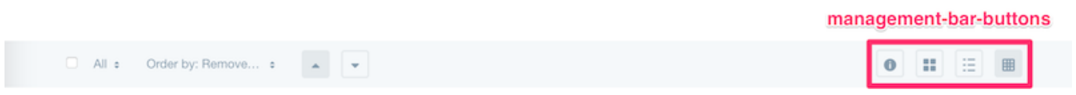

Figure 71.2: The `management-bar-buttons` tag contains the Management Bar's main buttons.

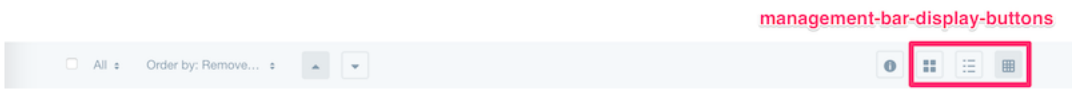

Figure 71.3: The `management-bar-display-buttons` tag contains the content's display options.

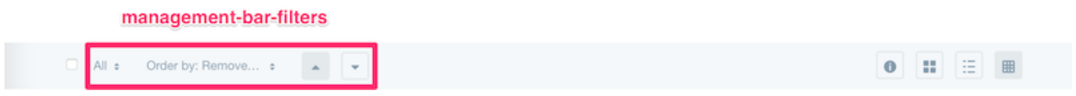

Figure 71.4: The `management-bar-filters` tag contains the content filtering options.

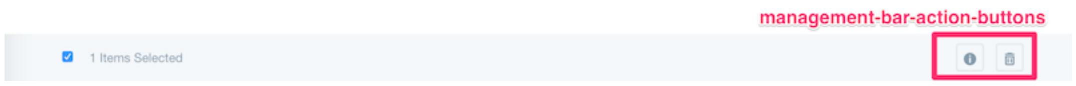

Figure 71.5: The management bar keeps track of the items selected and displays the actions to execute on them.

```
        orderColumns='<%= new String[] {"removed-date"} %>'
        portletURL="<%= trashDisplayContext.getPortletURL() %>"
    />
</liferay-frontend:management-bar-filters>

<liferay-frontend:management-bar-action-buttons>
    <liferay-frontend:management-bar-sidenav-toggler-button />

    <liferay-frontend:management-bar-button href="javascript:;"
    icon="trash" id="deleteSelectedEntries" label="delete" />
</liferay-frontend:management-bar-action-buttons>
```

In this section of tutorials, you'll learn how to add a management bar to your application.

71.1 Implementing the Management Bar Display Styles

The Management Bar offers a few display styles for your app's search container contents: descriptive, icon, and list. These views are standard in Liferay DXP's control panel apps. While you are not required to implement all these display styles in your app's management bar, they provide some additional control over how your app's information is displayed.

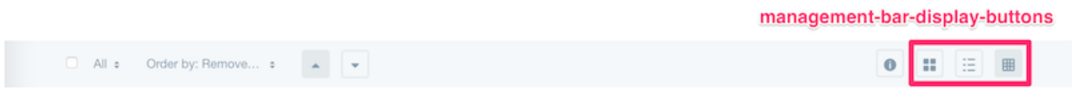

Figure 71.6: The `management-bar-display-buttons` tag contains the content's display options.

To provide these views in your app, you must make some updates to your search result columns. Follow the patterns covered in this tutorial to configure your app.

Note: You are not required to implement all the display views in your app. You must just at least have one display style implemented (`list` is the default). Views that are disabled in your app will render as greyed out buttons.

Start by configuring the Management Bar Display Buttons tag next.

Configuring the Management Bar Display Buttons Tag

Follow these steps to configure the management bar display button tags:

1. Add the `<liferay-frontend:management-bar>` taglib to your app's main view (`view.jsp` for example). If the management bar has a checkbox that needs to stay selected while the navigation is used, you can optionally provide a search container ID with the `searchContainerId` attribute and set the `includeCheckBox` attribute to `true`.

2. Add the management bar buttons using the `<liferay-frontend:management-bar-buttons>` and `<liferay-frontend:management-bar-display-buttons>` tags. The `<liferay-frontend:management-bar-display-buttons>` tag requires three attributes: `displayViews`, the display style views that are available;

`portletURL`, the URL to redirect to after an option is chosen; and `selectedDisplayStyle`, the view to display. Below is an example configuration that implements all three display views:

```
<liferay-frontend:management-bar>
    <liferay-frontend:management-bar-buttons>
      <liferay-frontend:management-bar-display-buttons
        displayViews='<%= new String[] {"icon", "descriptive", "list"} %>'
        portletURL="<%= myViewURL %>"
        selectedDisplayStyle="<%= displayStyle %>"
      />
    </liferay-frontend:management-bar-buttons>
</liferay-frontend:management-bar>
```

Your taglibs are configured for your display styles, but at the moment they don't do anything. You'll configure the views next.

Configuring the Display Views

Note that your management bar may not contain all three views. You only need to implement the views that you defined in your `<liferay-frontend:management-bar-display-buttons>` tag's `displayViews` attribute. Follow these steps to set the display views for the management bar:

1. Define a default display style. For example, the configuration below sets the default display style to list:

```
<%
String displayStyle = ParamUtil.getString(request, "displayStyle", "list");
%>
```

2. Wrap each display style configuration with the proper check:

```
<c:choose>
                <c:when test='<%= Objects.equals(displayStyle, "icon") %>'>
            <%-- icon display style configuration goes here --%>
        </c:when>
        ...
        <c:when test='<%= Objects.equals(displayStyle, "descriptive") %>'>
            <%-- descriptive display style configuration goes here --%>
        </c:when>
        ...
        <c:when test='<%= Objects.equals(displayStyle, "list") %>'>
            <%-- list display style configuration goes here --%>
        </c:when>
</c:choose>
```

Use cards to display the information. Use a vertical card to display assets like files or web content. Use horizontal cards to display folders or directories. You can add the display style configurations for each view next.

Implementing the Icon View

The icon view prominently displays an icon for the content, along with its name, status, and a condensed description.

Follow the steps below to create your icon view:

1. First, make your icon view responsive to different devices.

   For vertical cards use the following pattern:

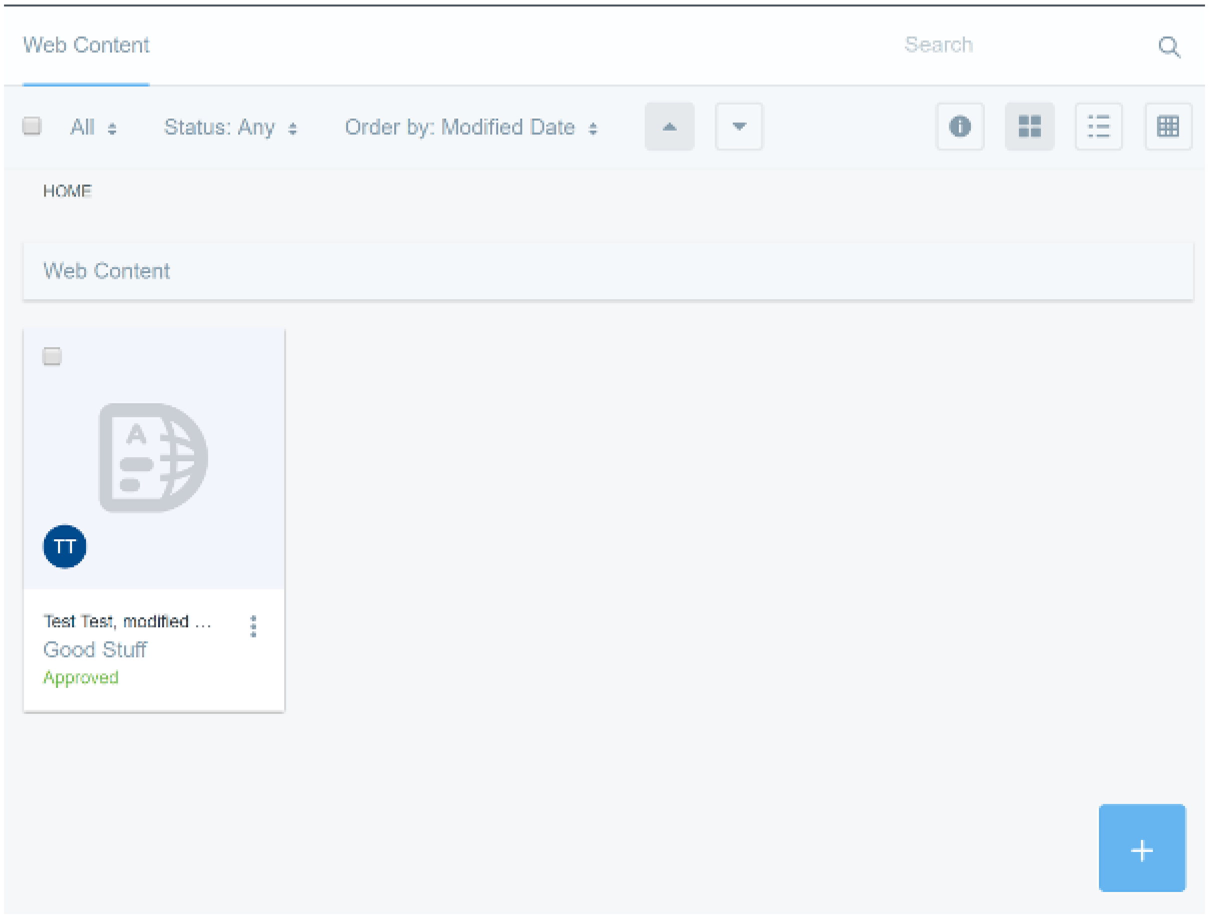

Figure 71.7: The Management Bar's icon display view gives a quick summary of the content's description and status.

```
<%
row.setCssClass("col-md-2 col-sm-4 col-xs-6");
%>
```

For horizontal cards use the following pattern:

```
<%
row.setCssClass("col-md-3 col-sm-4 col-xs-12");
%>
```

2. Once your cards are responsive, you must add search container column text using the pattern below:

```
<liferay-ui:search-container-column-text>
    <%-- include your vertical card or horizontal card here --%>
</liferay-ui:search-container-column-text>
```

3. Add the card to the `<liferay-ui:search-container-column-text>`:

   Use one of the following tags for your vertical card:

```
<liferay-frontend:vertical-card/>
```

```
<liferay-frontend:user-vertical-card/>

<liferay-frontend:icon-vertical-card/>
```

Below is an example from the `com.liferay.journal.web` module's `view_comments.jsp`:

```
<liferay-ui:search-container-column-text>
  <liferay-frontend:vertical-card
    cssClass="entry-display-style"
    imageUrl="<%= (userDisplay ≠ null) ? userDisplay.getPortraitURL(themeDisplay) : UserConstants.getPortraitURL(themeDisplay.getPathImage(), true,
    resultRow="<%= row %>"
  >
    <liferay-frontend:vertical-card-header>
      <liferay-ui:message arguments="<%= new String[] {LanguageUtil.getTimeDescription(locale, System.currentTimeMillis() - mbMessage.getModifiedDat
ago-by-x" translateArguments="<%= false %>" />
    </liferay-frontend:vertical-card-header>

    <liferay-frontend:vertical-card-footer>
      <%= HtmlUtil.extractText(content) %>
    </liferay-frontend:vertical-card-footer>
  </liferay-frontend:vertical-card>
</liferay-ui:search-container-column-text>
```

For horizontal cards you can use the tag below:

```
<liferay-frontend:horizontal-card/>
```

Now that your icon view is configured, you can move onto your descriptive view next.

Implementing the Descriptive View

The descriptive view displays the complete description, along with a small icon for the content, and its name. Your descriptive view should have three columns.

1. The first column usually contains an icon, image, or user portrait:

   For an icon use the following tag:

   ```
   <liferay-ui:search-container-column-icon/>
   ```

   For an image use the following tag:

   ```
   <liferay-ui:search-container-column-image/>
   ```

   For a user portrait use the following pattern:

   ```
   <liferay-ui:search-container-column-text>
       <liferay-ui:user-portrait/>
   </liferay-ui:search-container-column-text>
   ```

2. The second column should contain the descriptions. For example, the site teams application is configured with the settings below:

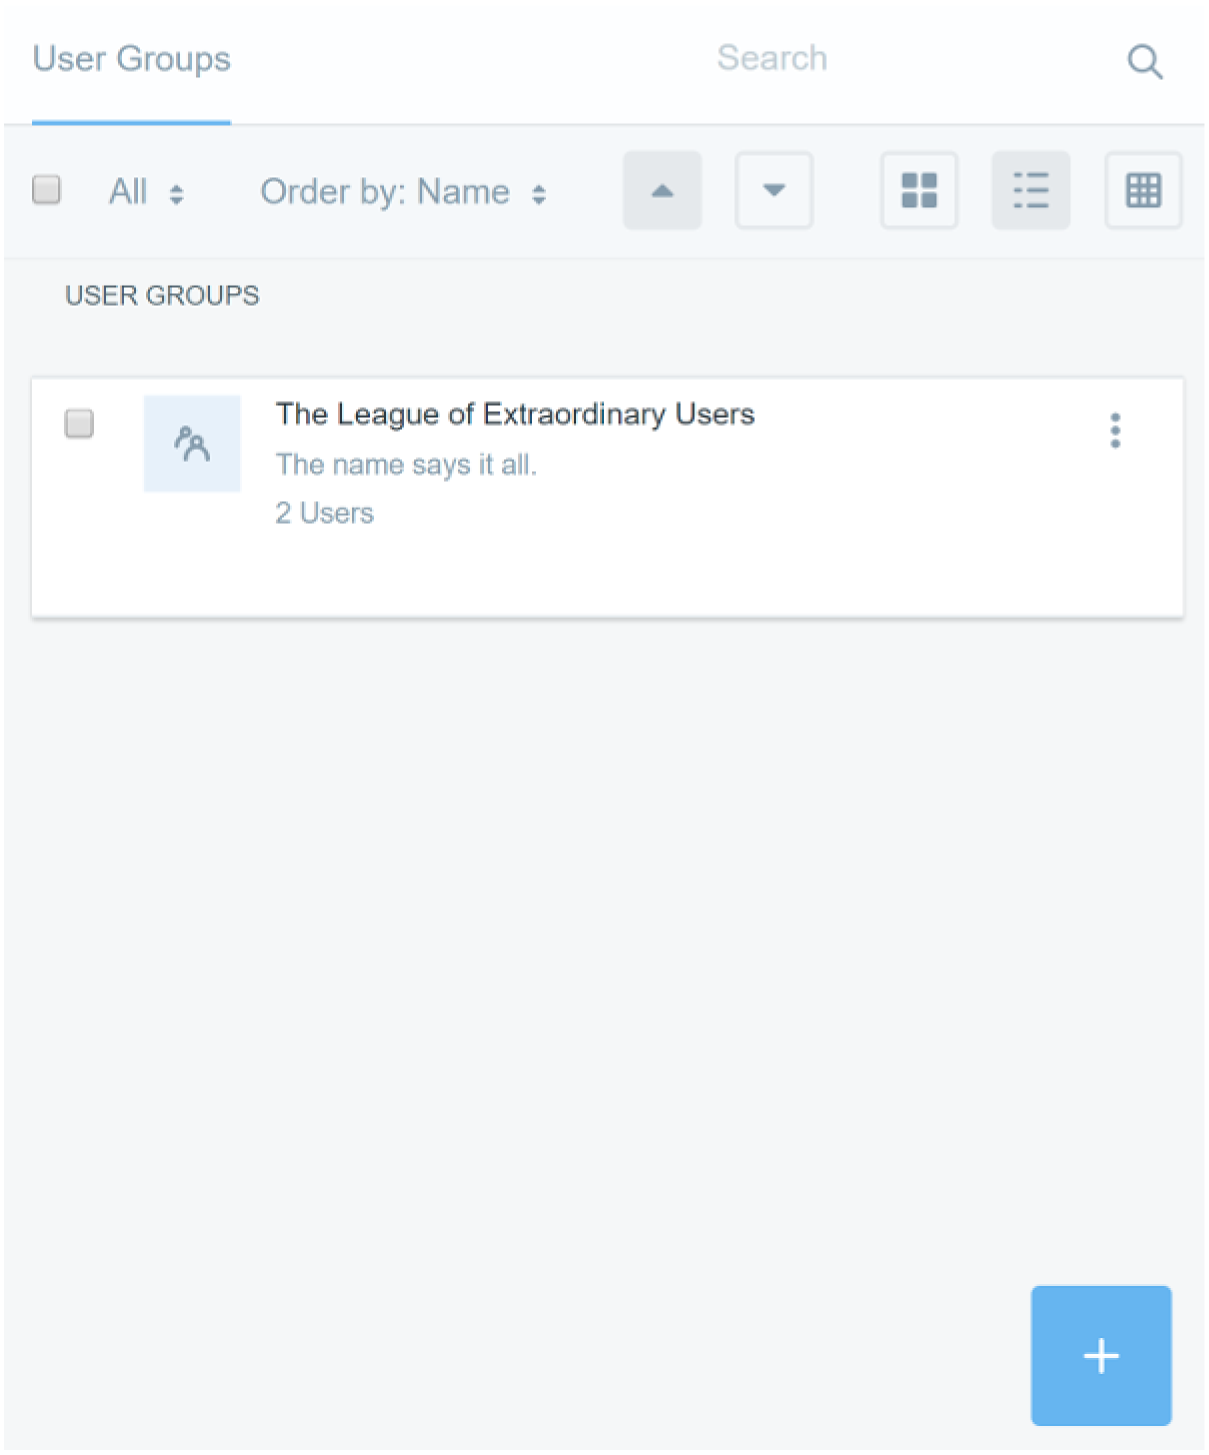

Figure 71.8: The Management Bar's descriptive display view gives the content's full description.

```
<liferay-ui:search-container-column-text
    colspan="<%=2%>"
>
    <h5><%= userGroup.getName() %></h5>

    <h6 class="text-default">
        <span><%= userGroup.getDescription() %></span>
    </h6>

    <h6 class="text-default">
        <span><liferay-ui:message arguments="<%= usersCount%>" key="x-users"
        /></span>
    </h6>

</liferay-ui:search-container-column-text>
```

3. Finally, the third column contains the actions. For example, the site teams application uses the configuration below:

```
<liferay-ui:search-container-column-jsp
    path="/edit_team_assignments_user_groups_action.jsp"
/>
```

Now that your descriptive view is configured you can implement your list view next.

Implementing the List View

The list view is the default view that is shown for most applications. This view lists the content's information in individual columns.

For example, the mobile device rules application configures its list view using the pattern below:

```
<liferay-ui:search-container-column-text
        cssClass="content-column name-column title-column"
        name="name"
        truncate="<%= true %>"
        value="<%= rule.getName(locale) %>"
/>

<liferay-ui:search-container-column-text
        cssClass="content-column description-column"
        name="description"
        truncate="<%= true %>"
        value="<%= rule.getDescription(locale) %>"
/>

<liferay-ui:search-container-column-date
        cssClass="create-date-column text-column"
        name="create-date"
        property="createDate"
/>

<liferay-ui:search-container-column-text
        cssClass="text-column type-column"
        name="type"
        translate="<%= true %>"
        value="<%= rule.getType() %>"
/>

<liferay-ui:search-container-column-jsp
        cssClass="entry-action-column"
        path="/rule_actions.jsp"
/>
```

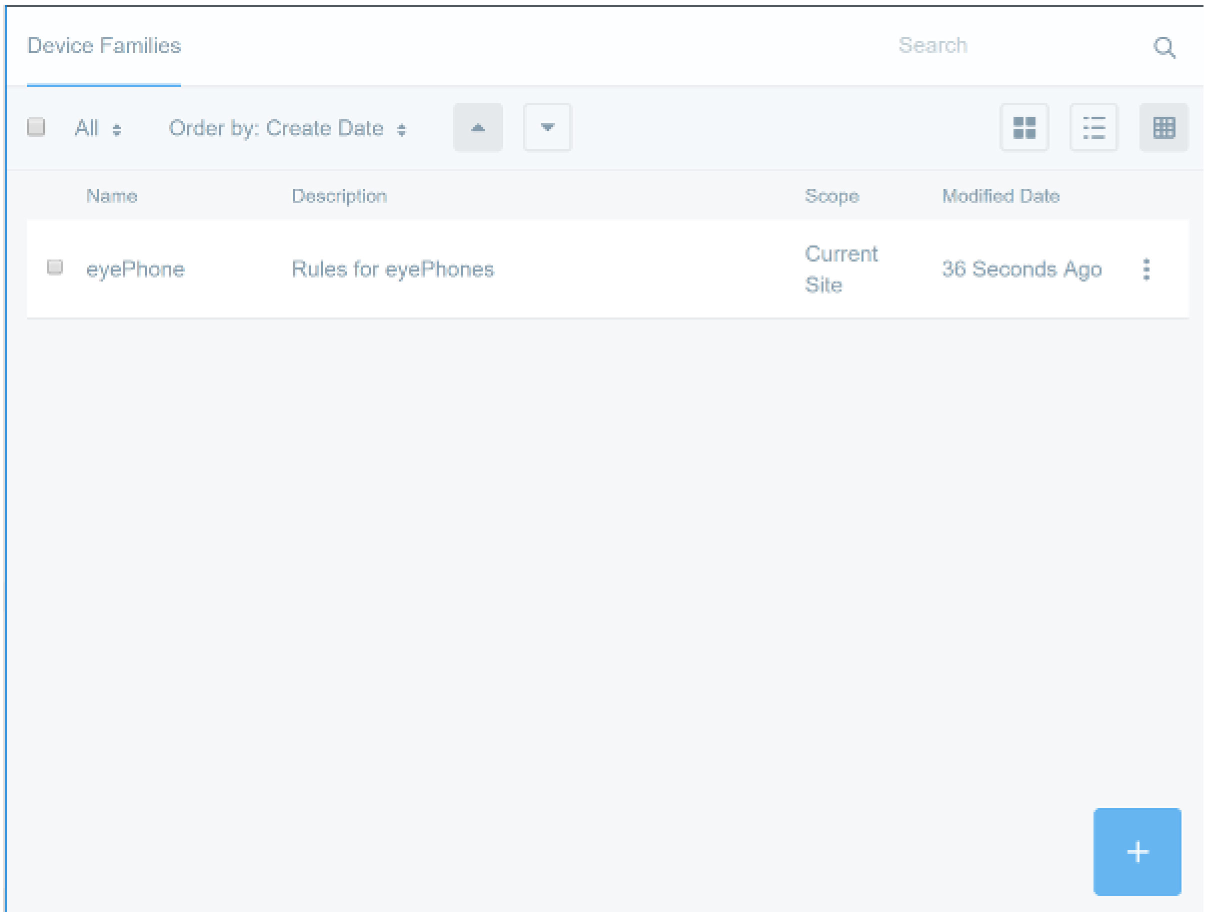

Figure 71.9: The Management Bar's list display view list the content's information in individual columns.

Finally, set the display style in your `liferay-ui:search-iterator` tag with the `displayStyle` attribute:

```
<liferay-ui:search-iterator

    displayStyle="<%= displayStyle %>"
    markupView="lexicon"
    searchContainer="<%= searchContainer %>"
/>
```

The `displayStyle` attribute is set to the `displayStyle` var which is set by the management bar display style buttons.

Your display views are configured!

Implementing a Management Bar Navigation Filter

71.2 Implementing a Management Bar Navigation Filter

Navigation filters are used to create navigation menus in the Management Bar. You can add as many navigation filters to the Management Bar as your app requires.

You can learn how to configure the navigation filter next.

Configuring the Navigation Filter

Follow these steps to configure the navigation filter:

1. Add the `<liferay-frontend:management-bar-filters>` tag below the `<liferay-frontend:management-bar-buttons>` tags, to contain your management bar filters.

2. Use the `<liferay-frontend:management-bar-navigation>` tag to add as many navigation menus as your app requires. Use the `navigationKeys` attribute to set the navigation menu options. The `navigationParam` attribute identifies the parameter to use for the navigation filter value. The default value is `navigation`. If you have more than one navigation menu, you can specify a unique variable with the `navigationParam` to identify each menu. Finally, use the `portletURL` attribute to set the URL for the page. Below is an example configuration with one navigation menu:

   ```
   <liferay-frontend:management-bar-filters>

       <liferay-frontend:management-bar-navigation
       navigationKeys='<%= new String[] {"all", ["navigation-title"]...} %>'
       navigationParam="myCustomNavigationVariable"
       portletURL="<%= portletURL %>"
       />
   </liferay-frontend:management-bar-filters>
   ```

   If your app doesn't require any navigation filters, you can just provide the *all* filter to display everything. If, however, you need to let the user navigate between pages (JSPs) of your app , you can add additional strings to the `navigationKeys` attribute for each page you need.

3. Set the navigation filter's default value with `paramUtil`. For example, the configuration below sets the default navigation filter to *all*:

   ```
   String navigation = ParamUtil.getString(request, "navigation", "all");
   ```

4. If your app has multiple options in a navigation menu, use the `navigationParam` to check the current value. Below is an example code snippet from `com.liferay.wiki.web` module's `page_iterator.jsp` that checks the navigation menu's value to render the proper JSP content. Note that it uses the `navigationParam`'s default value `navigation` to check the current value:

   ```
   if (navigation.equals("all-pages")) {
       portletURL.setParameter("mvcRenderCommandName", "/wiki/view_pages");

       PortalUtil.addPortletBreadcrumbEntry(request, LanguageUtil.get(request,
     "all-pages"), portletURL.toString());
   }
   else if (navigation.equals("categorized-pages")) {
       portletURL.setParameter("mvcRenderCommandName",
     "/wiki/view_categorized_pages");

       portletURL.setParameter("categoryId", String.valueOf(categoryId));
   }
   else if (navigation.equals("draft-pages")) {
       portletURL.setParameter("mvcRenderCommandName", "/wiki/view_draft_pages");

       PortalUtil.addPortletBreadcrumbEntry(request, LanguageUtil.get(request,
     "draft-pages"), portletURL.toString());
   }
   ```

Now you know how to add navigation filters to a management bar!

Implementing a Management Bar Sort Filter

Implementing the Management Bar Display Styles

71.3 Implementing a Management Bar Sort Filter

The Management Bar Sort Filters let you compare entries for a search container field, and sort them by ascending or descending. To do this, you must create a comparator class for each field that you want to sort.

The sort filters are an implementation of the standard `Comparator` Interface, with some additional methods provided by the `OrderByComparator` class.

Once the class is created you can use it in your view to add the sort filters to the UI.

Go ahead and get started by creating the Comparator class next.

Creating the Comparator Class

The `OrderByComparator` class is a `Comparator` implementation that you can extend to create sort filters. Follow these steps to create the *`OrderByComparator` class:

1. Right-click on your API module's folder in the package explorer and select *New→Package* to create a new package.

2. Right-click the package you just created and select *New→Class*. Enter *EntryNameComparator* for the class Name, check the *Constructors from superclass* option, and click *Finish*.

3. Update the class declaration to extend the `OrderByComparator` class and use a proper asset type, <Entry> for example>. Below is an example configuration for an entry name field comparator:

```
 public class EntryNameComparator extends OrderByComparator<Entry>{
   ...
 }
```

4. Add variables for the ascending, descending, and column name field (name for example) sorters:

```
public static final String ORDER_BY_ASC = "[asset].[column name] ASC";

public static final String ORDER_BY_DESC = "[asset].[column name] DESC";

public static final String[] ORDER_BY_FIELDS = {"[field name]"};
```

Below is an example configuration for an Entry asset's name field:

```
public static final String ORDER_BY_ASC = "Entry.name ASC";

public static final String ORDER_BY_DESC = "Entry.name DESC";

public static final String[] ORDER_BY_FIELDS = {"name"};
```

5. Replace the public constructor with the following constructors:

```
public *Comparator() {
    this(false);
}

public *Comparator(boolean ascending) {
    _ascending = ascending;
}
```

Below is an example configuration for an EntryNameComparator:

```
public EntryNameComparator() {
  this(false);
}

public EntryNameComparator(boolean ascending) {
  _ascending = ascending;
}
```

6. Add the `compare()` method to compare search container asset entries. Below is an example configuration for entry assets:

```
@Override
public int compare(Entry entry1, Entry entry2) {
  String name1 = entry1.getName();
  String name2 = entry2.getName();

  int value = name1.compareTo(name2);

  if (_ascending) {
    return value;
  }
  else {
    return -value;
  }
}
```

7. Add the following code to return the order fields and check whether the order is ascending or descending:

```
@Override
public String getOrderBy() {
    if (_ascending) {
        return ORDER_BY_ASC;
    }
    else {
        return ORDER_BY_DESC;
    }
}

@Override
public String[] getOrderByFields() {
    return ORDER_BY_FIELDS;
}

@Override
public boolean isAscending() {
    return _ascending;
}

private final boolean _ascending;
```

8. Finally, resolve imports for the class:

```
import com.liferay.docs.guestbook.model.Entry;
import com.liferay.portal.kernel.util.OrderByComparator;
```

Now that your *Comparator class is written you must update the service layer to use it.

Updating the Service Layer

Follow these steps to update services:

1. Open your *EntryLocalServiceImpl class in your service module and import the OrderByComparator class:

```
import com.liferay.portal.kernel.util.OrderByComparator;
```

2. Update the getEntries() method with the start and end integers to include the OrderByComparator parameter. Below is an example configuraiton:

```
public List<Entry> getEntries(
    long groupId, long guestbookId, int start, int end,
    OrderByComparator<Entry> obc) {

    return entryPersistence.findByG_G(
        groupId, guestbookId, start, end, obc);
}
```

3. Rebuild services for your App. Right-click the service module in the Project Explorer and select *Liferay → build-service*.

4. Export the comparator package in the API module's BND.

Now that the services are updated and your exports are in order, you can configure the view to use the comparator next.

Configuring the View

Follow these steps to configure the view to use the Comparator:

1. Import the EntryNameComparator and Comparator classes into the web module project's init.jsp:

```
page import="com.liferay.docs.guestbook.util.comparator.EntryNameComparator"

page import="com.liferay.portal.kernel.util.OrderByComparator"
```

2. Open the view and add the comparator code below the displayStyle variable in the java scriplet at the top. Below is an example configuration that uses the EntryNameComparator class:

```
String orderByCol = ParamUtil.getString(request, "orderByCol", "name");

boolean orderByAsc = false;

String orderByType = ParamUtil.getString(request, "orderByType", "asc");

if (orderByType.equals("asc")) {
    orderByAsc = true;
}

OrderByComparator orderByComparator = null;

if (orderByCol.equals("name")) {
    orderByComparator = new EntryNameComparator(orderByAsc);
}
```

This sets up the configuration for the comparators.

3. Add `orderByCol` and `orderByType` portlet parameters for your order comparator to the view's render URL. The `orderByCol` parameter specifies the column to order by and the `orderByType` column specifies whether the order is ascending or descending. Below is the configuration for the EntryNameComparator:

```
<liferay-portlet:renderURL varImpl="viewPageURL">
    <portlet:param name="mvcPath" value="/html/guestbookmvcportlet/view.jsp" />
    <portlet:param name="guestbookId" value="<%= String.valueOf(guestbookId) %>" />
    <portlet:param name="displayStyle" value="<%= displayStyle %>" />
    <portlet:param name="orderByCol" value="<%= orderByCol %>" />
    <portlet:param name="orderByType" value="<%= orderByType %>" />
</liferay-portlet:renderURL>
```

4. Add the sort filters below the navigation filters, using the `<liferay-frontend:management-bar-sort />` taglib. Pass the name of the column you specified in the *Comparator class. Below is the example configuration for the EntryNameComparator class:

```
<liferay-frontend:management-bar-sort
  orderByCol="<%= orderByCol %>"
  orderByType="<%= orderByType %>"
  orderColumns='<%= new String[] {"name"} %>'
  portletURL="<%= viewPageURL %>"
/>
```

5. Finally, pass the `orderByComparator` in as an argument in the search container results to match the updated method signature you modified. Below is the configuration for the example EntryNameComparator:

```
<liferay-ui:search-container-results
    results="<%= EntryLocalServiceUtil.getEntries(scopeGroupId,
  guestbookId, searchContainer.getStart(), searchContainer.getEnd(),
  orderByComparator) %>"
/>
```

The Management Bar Sort Filters are finished!

Implementing a Management Bar Navigation Filter
Disabling the Management Bar

71.4 Disabling the Management Bar

When there's no content in the app, you should disable all the Management Bar's buttons, except the info button.

You can disable the Management Bar by adding the `disabled` attribute to the `liferay-frontend:management-bar` tag:

```
<liferay-frontend:management-bar
        disabled="<%= total == 0 %>"
        includeCheckBox="<%= true %>"
        searchContainerId="<%= searchContainerId %>"
>
```

You can also disable individual buttons by adding the `disabled` attribute to the corresponding tag. The example configuration below disables the display buttons when the search container displays 0 results:

```
<liferay-frontend:management-bar-display-buttons
        disabled="<%= total == 0 %>"
        displayViews='<%= new String[] {"descriptive", "icon", "list"} %>'
        portletURL="<%= changeDisplayStyleURL %>"
        selectedDisplayStyle="<%= trashDisplayContext.getDisplayStyle() %>"
/>
```

Now you know how to disable the Management Bar!

71.5 Configuring Your Admin App's Actions Menu

In versions prior to 7.0, it was common to have a series of buttons or menus with actions in the different views of the app. In 7.0 the proposed pattern is to move all of these actions to the upper right menu of the administrative portlet, leaving the primary action (often an "Add" operation) visible in the add menu, using the Add Button pattern. For example, the web content application has the actions menu shown below:

The changes covered in this tutorial do not refer to actions menus associated with entities. For those, see Applying Lexicon Patterns to Your Forms, Navigation, and Search.

This tutorial shows how to configure the actions menu in your admin app. The first step is to create the `PortletConfigurationIconFactory` class.

Creating the Icon Factory Class

To add an action to the upper right menu of the Admin portlet you must first create a `PortletConfigurationIcon` Component class. This class specifies the portlet for the action, the screen to show it on, and the order (by specifying a weight).

In this example, the action appears on the System Settings portlet. To make it appear in a secondary screen, you can use the `path` property as shown below:

```
@Component(
  immediate = true,
  property = {
     "javax.portlet.name=" +
        ConfigurationAdminPortletKeys.SYSTEM_SETTINGS,
```

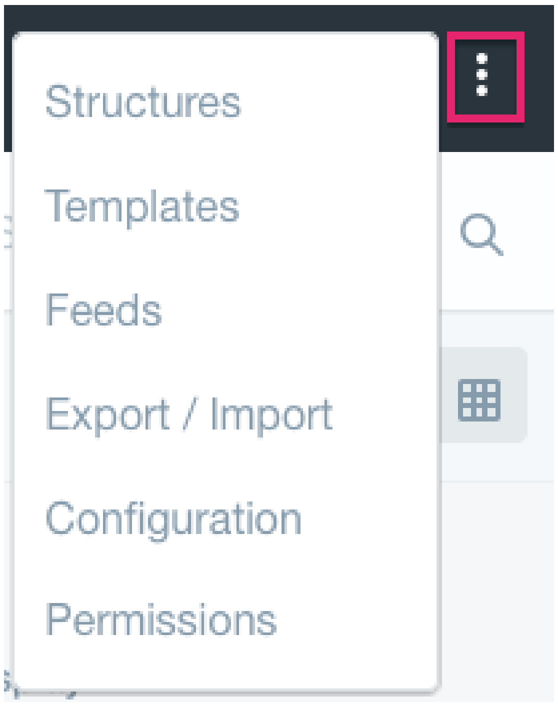

Figure 71.10: The upper right ellipsis menu contains most of the actions for the app.

```
        "path=/view_factory_instances"
    },
    service = PortletConfigurationIconFactory.class
)
public class ExportFactoryInstancesIconFactory
    extends BasePortletConfigurationIconFactory {

    @Override
    public PortletConfigurationIcon create(PortletRequest portletRequest) {
        return new ExportFactoryInstancesIcon(portletRequest);
    }

    @Override
    public double getWeight() {
        return 1;
    }

}
```

The value of the path property depends on the MVC framework used to develop the app.

For the MVCPortlet framework, provide the path (often a JSP) from the `mvcPath` parameter.

For MVCPortlet with MVC Commands, the path should contain the `mvcRenderCommandName` where the actions should be displayed (such as `/document_library/edit_folder` for example).

Now that your `PortletConfigurationIconFactory` class is written, you can write the `PortletConfigurationIcon` class next.

Writing the Configuration Icon Class

The second class that you must write is a class that extends the `BasePortletConfigurationIcon` class. This class specifies the action's label, whether it's invoked with a GET or POST method, and the URL (or `onClick` JavaScript method) to invoke when the action is clicked. It can also implement some custom code to determine whether the action should display for the current request. For example the class below creates a export-all-settings label and specifies the GET method for the action:

```
public class ExportAllConfigurationIcon extends BasePortletConfigurationIcon {

  public ExportAllConfigurationIcon(PortletRequest portletRequest) {
     super(portletRequest);
  }

  @Override
  public String getMessage() {
     return "export-all-settings";
  }

  @Override
  public String getMethod() {
     return "GET";
  }

  @Override
  public String getURL() {
     LiferayPortletURL liferayPortletURL =
        (LiferayPortletURL)PortalUtil.getControlPanelPortletURL(
           portletRequest, ConfigurationAdminPortletKeys.SYSTEM_SETTINGS,
           PortletRequest.RESOURCE_PHASE);

     liferayPortletURL.setResourceID("export");

     return liferayPortletURL.toString();
  }

  @Override
  public boolean isShow() {
     return true;
  }

}
```

By default, if the portlet uses mvcPath, the global actions (such as configuration, export/import, maximized, etc.) are displayed for the JSP indicated in the initialization parameter of the portlet javax.portlet.init-param.view-template=/view.jsp. The value indicates the JSP where the global actions should be displayed.

However, if the portlet uses MVC Command, the views for the global actions must be indicated with the initialization parameter javax.portlet.init-param.mvc-command-names-default-views=/wiki_admin/view and the value must contain the mvcRenderCommandName where the global actions should be displayed.

For portlets that can be added to a page, if the desired behavior is to always include the configuration options, the following initialization parameter should be added to the portlet:

```
javax.portlet.init-param.always-display-default-configuration-icons=true
```

Now you know how to configure your admin app's actions!

Configuring Your Application's Title and Back Link

71.6 Setting Search Container Animations

If you've toured 7.0's UI, you've probably noticed animations in the search containers. These animations show the user when there is no available content.

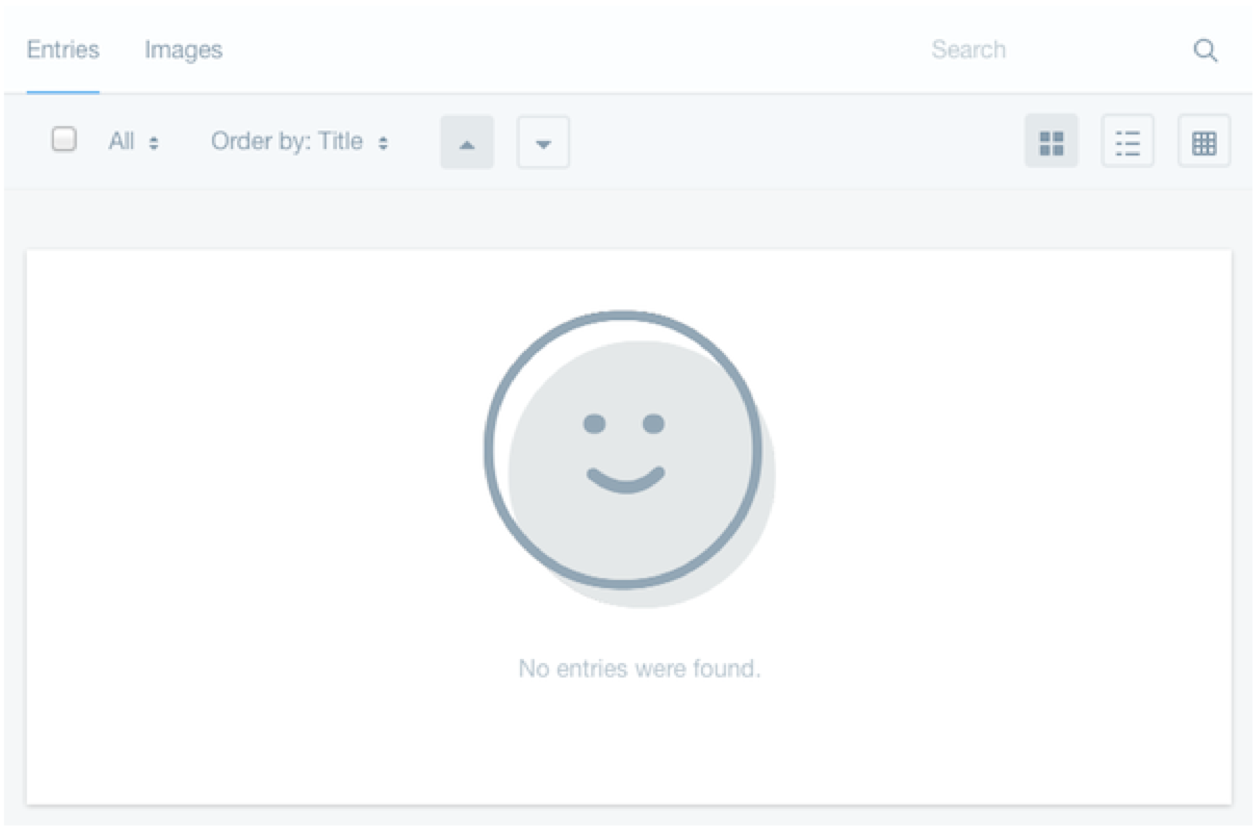

Figure 71.11: This is a still frame from the Blogs portlet's empty results animation.

This tutorial covers the following topics:

- Using the default animations in your search container
- Using custom animations in your search container

First, you'll learn how to use the default animations in your search container.

Using the Default Animations in Your Search Container

There are three built-in classes for the search container animation:

1. The default class is *taglib-empty-result-message-header*. This is used for most cases.
2. *taglib-empty-search-result-message-header* is used when there are no search results.
3. *taglib-empty-result-message-header-has-plus-btn* is used when there is no content, but you can use the add button to add an entity.

To use these animations, use the following method:

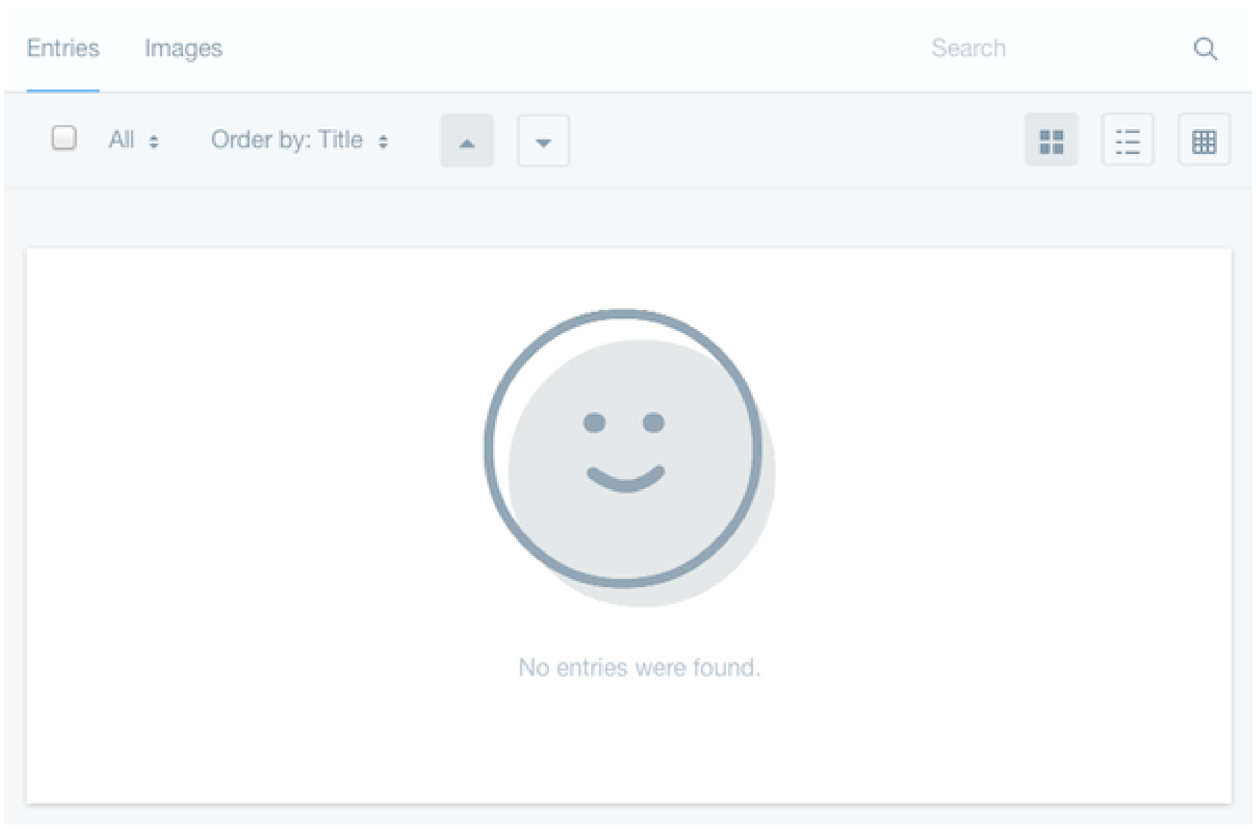

Figure 71.12: When no content is found, the default animation is usually shown.

```
SearchContainer.setEmptyResultsMessageCssClass()
```

For example, the Roles Admin application uses this code to set its animation in its `edit_role_assignments_sites.jsp` file:

```
if (!searchTerms.isSearch()) {
        searchContainer.setEmptyResultsMessageCssClass(
        "taglib-empty-result-message-header-has-plus-btn"
        );
}
```

Alternatively you can use the `emptyResultsMessageCssClass` attribute of the `liferay-ui:search-container` tag to set the animation. For example,

```
<liferay-ui:search-container
  emptyResultsMessage="no-results-were-found"
  emptyResultsMessageCssClass="taglib-empty-result-message-header-has-plus-btn"
  ...
>
```

If you don't want to use the default animations packaged with 7.0, you can use custom animations instead. This is covered next.

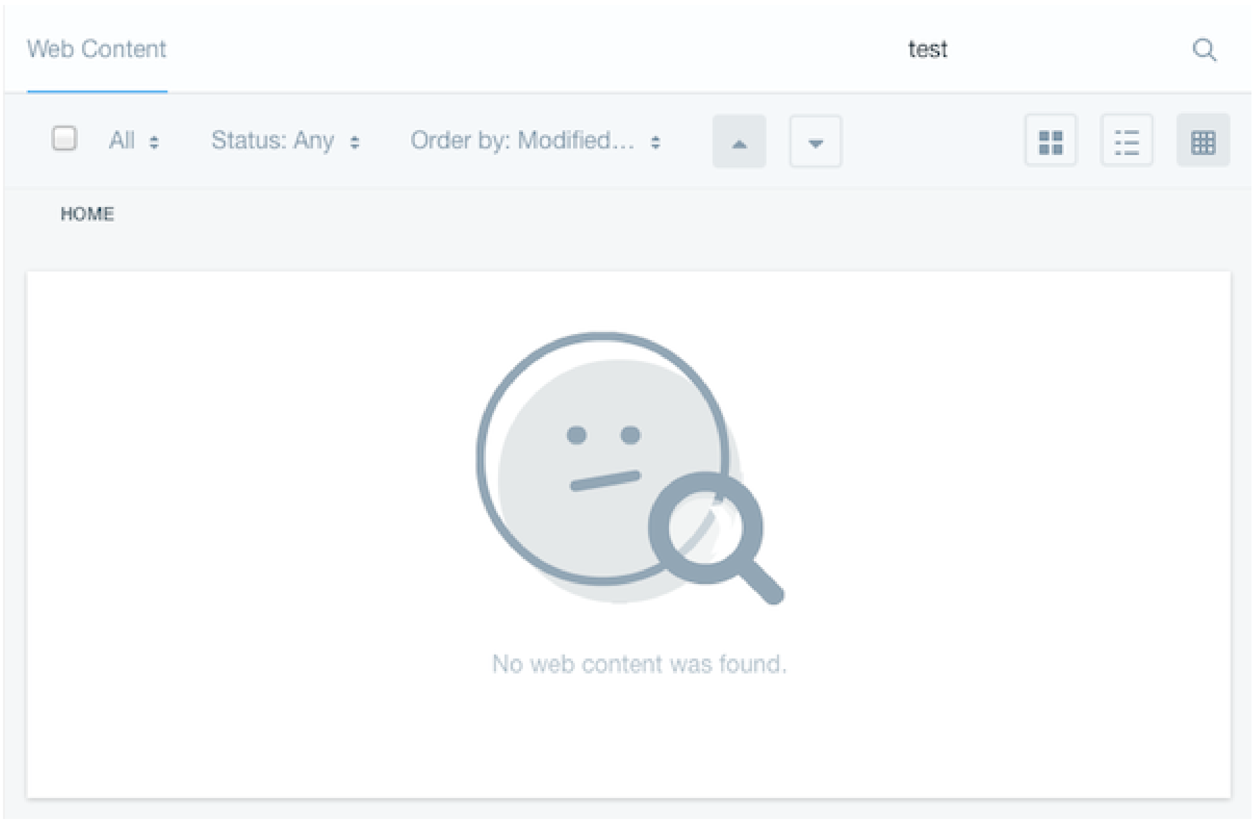

Figure 71.13: You can use the empty search result animation to show that no search results were found.

Using Custom Animations

As stated earlier, each animation has a matching CSS class that the search container uses. To use a custom animation, therefore, you must modify the existing styles.

There are two approaches you can take:

- Overwrite the existing styles to replace the default animations
- Create new styles to make the animation available to the search container

Regardless of the approach you choose, you must provide the CSS styles in a Theme, Themelet, or Theme Contributor. These styles point to the animation's source. You can provide the animation however you like: as long as you have a valid URL (relative or absolute) that points to the animation, you can use it.

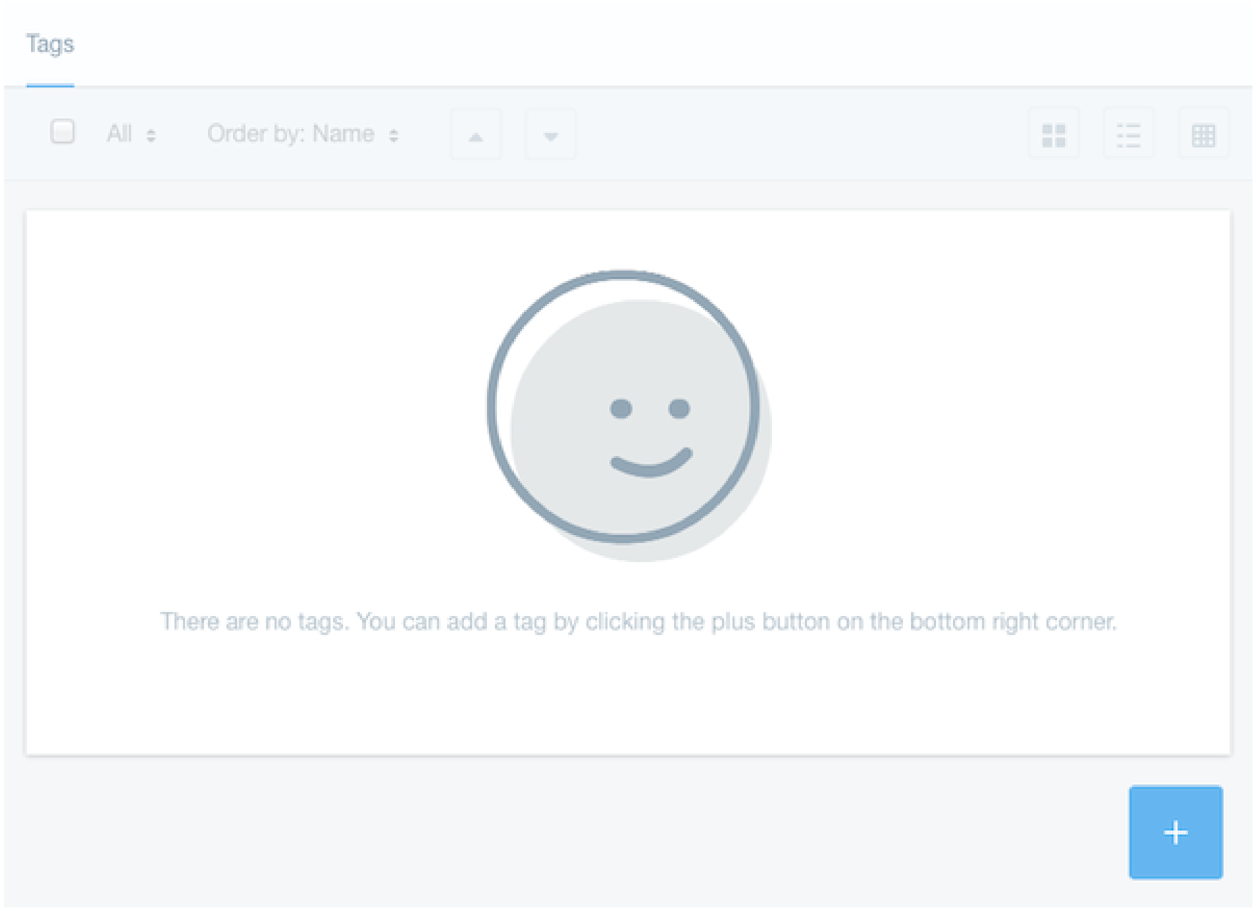
The default search container animation styles are provided by the _empty_result_message.scss file.

Note: Search containers can also contain static images for the no results message if you prefer. Just use a valid image type instead. All animations must be of type `GIF` though.

You can learn how to replace the default animations next.

Replacing Default Empty Results Message Animations

Follow these steps to replace the existing animations with your own:



There are no tags. You can add a tag by clicking the plus button on the bottom right corner.

Figure 71.14: If you can use the add button to add entities to the app, use the has plus button animation.

1. Make your custom animation available in your theme, themelet, Documents and Media repository, etc. For example, place the `.gif` in your theme's `images` folder.

2. Inside your CSS file (`_custom.scss` for example), override the animation styles that you want to replace. For example, to replace the default animation, include the following styles for a custom animation located in the `images/emoticons` folder of a theme:

```
.taglib-empty-result-message {
    .taglib-empty-result-message-header {
        background-image:
        url(@theme_image_path@/emoticons/[your_custom_animation].gif);
    }
}
```

3. Inside your app's search container, use the `emptyResultsMessageCssClass` attribute, or use the `SearchContainer.setEmptyResultsMessageCssClass()` method. Below is an example configuration that uses the `emptyResultsMessageCssClass` attribute:

```
<liferay-ui:search-container
    emptyResultsMessage="no-results-were-found"
    emptyResultsMessageCssClass="taglib-empty-result-message-header"
    total="<%= total %>"
>
```

Here is an example configuration that uses the `SearchContainer.setEmptyResultsMessageCssClass()` method:

```
SearchContainer.setEmptyResultsMessageCssClass("taglib-empty-result-message-header")
```

Your custom animation now appears in the search container instead of the default animation. If instead you want to add your custom animation to the default ones available, follow the steps in the next section.

Adding A New Empty Results Message Animation

Adding an animation to the empty results message involves the same steps as replacing a default animation. The only difference is you must add a new CSS class. Follow these steps to create a new style for your custom search container animation:

1. Make your custom animation available in your theme, themelet, Documents and Media repository, etc. For example, place the GIF in your theme's `images` folder.

2. Inside your CSS file (`_custom.scss` for example), add the styles for your new class, wrapped with `.taglib-empty-result-message`. For example, the styles below add a custom animation for a class called `my-custom-message-header`:

```
.taglib-empty-result-message {
    .my-custom-message-header {
        background-image:
        url(@theme_image_path@/emoticons/[my_custom_animation].gif);
    }
}
```

3. Use the `emptyResultsMessageCssClass` attribute in the Search Container, or use the `SearchContainer.setEmptyResultsMess` method to use the new CSS class you just added. Below is an example configuration that uses the `emptyResultsMessageCssClass` attribute:

```
<liferay-ui:search-container
    emptyResultsMessage="no-results-were-found"
    emptyResultsMessageCssClass="my-custom-message-header"
    total="<%= total %>"
>
```

Here is an example configuration that uses the `SearchContainer.setEmptyResultsMessageCssClass()` method:

```
SearchContainer.setEmptyResultsMessageCssClass("my-custom-message-header")
```

Now you know how to set search container animations in your app!

Using the Liferay UI Taglib

Introduction to Liferay Search

71.7 Using Lexicon Icons in Your App

Whether you're updating your app to 7.0 or writing a new 7.0 app, follow the process here to use Lexicon's icons. You can find the list of available Lexicon icons on the Lexicon site.

Lexicon icons are defined with the `icon` attribute. For example, you define the icon in the management bar, inside the `liferay-frontend:management-bar-sidenav-toggler-button` taglib:

```
<liferay-frontend:management-bar-sidenav-toggler-button
        disabled="<%= false %>"
        href="javascript:;"
        icon="info-circle"
        label="info"
        sidenavId='<%= liferayPortletResponse.getNamespace() + "infoPanelId" %>'
/>
```

To use Lexicon icons outside the management bar, you have two options:

1. You can use the `liferay-ui:icon` taglib. For example:

    ```
    <liferay-ui:icon

        icon="icon-name"

        markupView="lexicon"

        message="message-goes-here"

    />
    ```

2. You can use the `aui:icon` taglib. For example:

    ```
    <aui:icon

         cssClass="icon-monospaced"

         image="times"

         markupView="lexicon"

    />
    ```

Note the addition of the `markupView="lexicon"` attribute. This ensures that the HTML is rendered with Lexicon markup.

That's it! Now you know how to use Lexicon icons in your apps.

Setting Search Container Animations

Creating Layouts inside Custom Portlets

Chapter 72

Customizing

In Liferay DXP, portlets let you add functionality and themes let you style your sites. But how do you modify and add to existing functionality in Liferay DXP and portlets? How do you change their content? The *Customizing* tutorials answer these questions and demonstrate how to affect your site in the following ways:

- Add, modify, or remove content from Liferay DXP and portlets
- Modify behavior
- Perform actions that respond to events

CHAPTER 73

CUSTOMIZING JSPS

There are several different ways to customize JSPs in portlets and the core. Liferay DXP's API provides the safest ways to customize them. If you customize a JSP by other means, new versions of the JSP can render your customization invalid and leave you with runtime errors. It's highly recommended to use one of the API-based ways.

73.1 Using Liferay's API to Override a JSP

Here are API-based approaches to overriding JSPs in Liferay DXP:

Approach	Description	Cons/Limitations
Dynamic includes	Adds content at dynamic include tags.	Limited to JSPs that have `dynamic-include` tags (or tags whose classes inherit from `IncludeTag`). Only inserts content in the JSPs at the dynamic include tags.
Portlet filters	Modifies portlet requests and/or responses to simulate a JSP customization.	Although this approach doesn't directly customize a JSP, it achieves the effect of a JSP customization.

73.2 Overriding a JSP Without Using Liferay's API

It's strongly recommended to customize JSPs using Liferay DXP's API, as the previous section describes. As of Liferay 7.0, overriding a JSP using an OSGi fragment or a Custom JSP Bag are both deprecated. Since these approaches are not based on APIs there's no way to guarantee that they'll fail gracefully. Instead, if your customization is buggy (because of your code or because of a change in Liferay), you are most likely to find out at runtime, where functionality breaks and nasty log errors greet you.

If you're maintaining a JSP customization that uses one of these approaches, you should know how they work. This section describes them and links to their tutorials.

Here are ways to customize JSPs without using Liferay DXP's API:

Approach	Description	Cons/Limitations
OSGi fragment (deprecated as of Liferay 7.0)	Completely overrides a module's JSP using an OSGi fragment	Changes to the original JSP or module can cause runtime errors.
Custom JSP bag (deprecated as of Liferay 7.0)	Completely override a Liferay DXP core JSP or one of its corresponding `-ext.jsp` files.	For Liferay DXP core JSPs only. Changes to the original JSP or module can cause runtime errors.

All the JSP customization approaches are available to you. It's time to customize some JSPs!

73.3 Customizing JSPs with Dynamic Includes

The `liferay-util:dynamic-include` tag is an extension point for inserting content (e.g., JavaScript code, HTML, and more). To do this, create a module that has content you want to insert, register that content with the dynamic include tag, and deploy your module.

Note: If the JSP you want to customize has no `liferay-util:dynamic-include` tags (or tags whose classes inherit from `IncludeTag`), you must use a different customization approach, such as portlet filters.

We'll demonstrate how dynamic includes work using the Blogs entries. For reference, you can download the example module.

1. Find the `liferay-util:dynamic-include` tag where you want to insert content and note the tag's key.

   The Blogs app's `view_entry.jsp` has a dynamic include tag at the top and another at the very bottom.

   ```
   <%@ include file="/blogs/init.jsp" %>

   <liferay-util:dynamic-include key="com.liferay.blogs.web#/blogs/view_entry.jsp#pre" />

       ... JSP content is here

   <liferay-util:dynamic-include key="com.liferay.blogs.web#/blogs/view_entry.jsp#post" />
   ```

   Here are the Blogs view entry dynamic include keys:

   - `key="com.liferay.blogs.web#/blogs/view_entry.jsp#pre"`
   - `key="com.liferay.blogs.web#/blogs/view_entry.jsp#post"`

2. Create a module (e.g., `blade create my-dynamic-include`). The module will hold your dynamic include implementation.

3. Specify compile-only dependencies, like these Gradle dependencies, in your module build file:

   ```
   dependencies {
       compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
       compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
       compileOnly group: "com.liferay", name: "com.liferay.petra.string", version: "1.0.0"
       compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
       compileOnly group: "org.osgi", name: "osgi.cmpn", version: "6.0.0"
   }
   ```

4. Create an OSGi component class that implements the `DynamicInclude` interface.

   Here's an example dynamic include implementation for Blogs:

```
import java.io.IOException;
import java.io.PrintWriter;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;

import com.liferay.portal.kernel.servlet.taglib.DynamicInclude;

@Component(
    immediate = true,
    service = DynamicInclude.class
)
public class BlogsDynamicInclude implements DynamicInclude {

    @Override
    public void include(
            HttpServletRequest request, HttpServletResponse response,
            String key)
        throws IOException {

        PrintWriter printWriter = response.getWriter();

        printWriter.println(
            "<h2>Added by Blogs Dynamic Include!</h2><br />");
    }

    @Override
    public void register(DynamicIncludeRegistry dynamicIncludeRegistry) {
        dynamicIncludeRegistry.register(
            "com.liferay.blogs.web#/blogs/view_entry.jsp#pre");
    }

}
```

   Giving the class a `@Component` annotation that has the service attribute `service = DynamicInclude.class` makes the class a `DynamicInclude` service component.

```
@Component(
    immediate = true,
    service = DynamicInclude.class
)
```

   In the `include` method, add your content. The example `include` method writes a heading.

```
@Override
public void include(
        HttpServletRequest request, HttpServletResponse response,
        String key)
    throws IOException {

    PrintWriter printWriter = response.getWriter();

    printWriter.println(
    "<h2>Added by Blogs Dynamic Include!</h2><br />");
}
```

In the register method, specify the dynamic include tag you want to use. The example register method targets the dynamic include at the top of the Blogs view_entry.jsp.

```
@Override
public void register(DynamicIncludeRegistry dynamicIncludeRegistry) {
    dynamicIncludeRegistry.register(
        "com.liferay.blogs.web#/blogs/view_entry.jsp#pre");
}
```

Once you've deployed your module, the overridden JSP dynamically includes your content. Congratulations on injecting dynamic content into a JSP!

73.4 JSP Overrides Using Portlet Filters

Portlet filters let you intercept portlet requests before they're processed and portlet responses after they're processed but before they're sent back to the client. You can operate on the request and / or response to modify the JSP content. Unlike dynamic includes, portlet filters give you access to all of the content sent back to the client.

We'll demonstrate using a portlet filter to modify content in Liferay's Blogs portlet. For reference, you can download the example module.

Create a new module and make sure it specifies these compile-only dependencies, shown here in Gradle format:

```
dependencies {
    compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
    compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "org.osgi", name: "osgi.cmpn", version: "6.0.0"
}
```

Create an OSGi component class that implements the javax.portlet.filter.RenderFilter interface.

Here's an example portlet filter implementation for Blogs:

```
import java.io.IOException;

import javax.portlet.PortletException;
import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;
import javax.portlet.filter.FilterChain;
import javax.portlet.filter.FilterConfig;
import javax.portlet.filter.PortletFilter;
import javax.portlet.filter.RenderFilter;
import javax.portlet.filter.RenderResponseWrapper;

import org.osgi.service.component.annotations.Component;

import com.liferay.portal.kernel.util.PortletKeys;

@Component(
    immediate = true,
    property = {
            "javax.portlet.name=" + PortletKeys.BLOGS
    },
    service = PortletFilter.class
)
public class BlogsRenderFilter implements RenderFilter {

    @Override
    public void init(FilterConfig config) throws PortletException {
    }

    @Override
    public void destroy() {

    }

    @Override
    public void doFilter(RenderRequest request, RenderResponse response, FilterChain chain)
            throws IOException, PortletException {

        RenderResponseWrapper renderResponseWrapper = new BufferedRenderResponseWrapper(response);

        chain.doFilter(request, renderResponseWrapper);

        String text = renderResponseWrapper.toString();

        if (text ≠ null) {
            String interestingText = "<input  class=\"field form-control\"";

            int index = text.lastIndexOf(interestingText);

            if (index ≥ 0) {
                String newText1 = text.substring(0, index);
                String newText2 = "\n<p>Added by Blogs Render Filter!</p>\n";
                String newText3 = text.substring(index);

                String newText = newText1 + newText2 + newText3;

                response.getWriter().write(newText);
            }
        }
    }

}
```

Make your class a `PortletFilter` service component by giving it the `@Component` annotation that has the service attribute `service = PortletFilter.class`. Target the portlet whose content you're overriding by assigning it a javax.portlet.name property that's the same as your portlet's key. Here's the example `@Component` annotation:

```
@Component(
   immediate = true,
   property = {
           "javax.portlet.name=" + PortletKeys.BLOGS
   },
   service = PortletFilter.class
)
```

Override the `doFilterMethod` to operate on the request or response to produce the content you want. The example appends a paragraph stating `Added by Blogs Render Filter!` to the portlet content:

```
@Override
public void doFilter(RenderRequest request, RenderResponse response, FilterChain chain)
        throws IOException, PortletException {

    RenderResponseWrapper renderResponseWrapper = new BufferedRenderResponseWrapper(response);

    chain.doFilter(request, renderResponseWrapper);

    String text = renderResponseWrapper.toString();

    if (text ≠ null) {
        String interestingText = "<input  class=\"field form-control\"";
        int index = text.lastIndexOf(interestingText);

        if (index ≥ 0) {
            String newText1 = text.substring(0, index);
            String newText2 = "\n<p>Added by Blogs Render Filter!</p>\n";
            String newText3 = text.substring(index);

            String newText = newText1 + newText2 + newText3;

            response.getWriter().write(newText);
        }
    }
}
```

The example uses a `RenderResponseWrapper` extension class called `BufferedRenderResponseWrapper`. `BufferedRenderResponseWrapper` is a helper class whose `toString` method returns the current response text and whose `getWriter` method lets you write data to the response before it's sent back to the client.

```
import java.io.CharArrayWriter;
import java.io.IOException;
import java.io.OutputStream;
import java.io.PrintWriter;

import javax.portlet.RenderResponse;
import javax.portlet.filter.RenderResponseWrapper;

public class BufferedRenderResponseWrapper extends RenderResponseWrapper {

    public BufferedRenderResponseWrapper(RenderResponse response) {
        super(response);

        charWriter = new CharArrayWriter();
    }

    public OutputStream getOutputStream() throws IOException {
        if (getWriterCalled) {
            throw new IllegalStateException("getWriter already called");
        }

        getOutputStreamCalled = true;

        return super.getPortletOutputStream();
    }

    public PrintWriter getWriter() throws IOException {
        if (writer ≠ null) {
            return writer;
        }

        if (getOutputStreamCalled) {
            throw new IllegalStateException("getOutputStream already called");
        }

        getWriterCalled = true;

        writer = new PrintWriter(charWriter);

        return writer;
    }

    public String toString() {
        String s = null;

        if (writer ≠ null) {
            s = charWriter.toString();
        }

        return s;
    }

    protected CharArrayWriter charWriter;
    protected PrintWriter writer;
    protected boolean getOutputStreamCalled;
    protected boolean getWriterCalled;

}
```

Once you've deployed your module, the portlet's JSP shows your custom content.

Your portlet filter operates directly on portlet response content. Unlike dynamic includes, portlet filters allow you to work with all of a JSP's content.

73.5 JSP Overrides Using OSGi Fragments

You can completely override JSPs using OSGi fragments. This approach is powerful but can make things unstable when the host module is upgraded:

1. By overriding an entire JSP, you might not account for new content or new widgets that are essential to new host module versions.
2. Fragments are tied to a specific host module version. If the host module is upgraded, the fragment detaches from it. In this scenario, the original JSPs are still available and the module is functional (but lacks your JSP enhancements).

Liferay's API based approaches to overriding JSPs, on the other hand, provide more stability as they let you customize specific parts of the JSP that are safe to override. Also, the API based approaches don't limit your override to a specific host module version. In case you're maintaining existing JSP overrides that use OSGi fragments, however, this tutorial explains how they work.

An OSGi fragment that overrides a JSP requires these two things:

- Specifies a host module's symbolic name and version in the OSGi header `Fragment-Host` declaration.
- includes the original JSP with any modifications you need to make.

For more information about fragment modules, you can refer to section 3.14 of the OSGi Alliance's core specification document.

Declaring a Fragment Host

There are two players in this game: the fragment and the host. The fragment is a parasitic module that attaches itself to a host. That sounds harsh, so let's compare the fragment-host relationship to the relationship between a pilot fish and a huge, scary shark. It's symbiotic, really. Your fragment module benefits by not doing much work (like the pilot fish who benefits from the shark's hunting prowess). In return, the host module gets whatever benefits you've conjured up in your fragment's JSPs (for the shark, it gets free dental cleanings!). To the OSGi runtime, your fragment is part of the host module.

Your fragment must declare two things to the OSGi runtime regarding the host module:

1. The Bundle Symbolic Name of the host module.

   This is the module containing the original JSP.

2. The exact version of the host module to which the fragment belongs.

Both are declared using the OSGi header `Fragment-Host`.

```
Fragment-Host: com.liferay.login.web;bundle-version="[1.0.0,1.0.1)"
```

Supplying a specific host module version is important. If that version of the module isn't present, your fragment won't attach itself to a host, and that's a good thing. A new version of the host module might have changed its JSPs, so if your now-incompatible version of the JSP is applied to the host module, you'll break the functionality of the host. It's better to detach your fragment and leave it lonely in the OSGi runtime than it is to break the functionality of an entire application.

Provide the Overridden JSP

There are two possible naming conventions for targeting the host original JSP: `portal` or `original`. For example, if the original JSP is in the folder `/META-INF/resources/login.jsp`, then the fragment bundle should contain a JSP with the same path, using the following pattern:

```
<liferay-util:include
    page="/login.original.jsp" (or login.portal.jsp)
    servletContext="<%= application %>"
/>
```

After that, make your modifications. Just make sure you mimic the host module's folder structure when overriding its JAR. If you're overriding Liferay's login application's `login.jsp` for example, you'd put your own `login.jsp` in

```
my-jsp-fragment/src/main/resources/META-INF/resources/login.jsp
```

If you need to post-process the output, you can update the pattern to include Liferay DXP's buffering mechanism. Below is an example that overrides the original `create_account.jsp`:

```
<%@ include file="/init.jsp" %>

<liferay-util:buffer var="html">
    <liferay-util:include page="/create_account.portal.jsp"
    servletContext="<%= application %>"/>
</liferay-util:buffer>

<liferay-util:buffer var="openIdFieldHtml"><aui:input name="openId"
type="hidden" value="<%= ParamUtil.getString(request, "openId") %>" />
</liferay-util:buffer>

<liferay-util:buffer var="userNameFieldsHtml"><liferay-ui:user-name-fields />
</liferay-util:buffer>

<liferay-util:buffer var="errorMessageHtml">
    <liferay-ui:error
    exception="<%= com.liferay.portal.kernel.exception.NoSuchOrganizationException.class %>" message="no-such-registration-code" />
</liferay-util:buffer>

<liferay-util:buffer var="registrationCodeFieldHtml">
            <aui:input name="registrationCode" type="text" value="">
                    <aui:validator name="required" />
            </aui:input>
</liferay-util:buffer>

<%
    html = com.liferay.portal.kernel.util.StringUtil.replace(html,
      openIdFieldHtml, openIdFieldHtml + errorMessageHtml);
    html = com.liferay.portal.kernel.util.StringUtil.replace(html,
      userNameFieldsHtml, userNameFieldsHtml + registrationCodeFieldHtml);
%>

<%=html %>
```

Note: An OSGi fragment can access all of the fragment host's packages—it doesn't need to import them from another bundle. bnd adds external packages the fragment uses (even ones in the fragment host) to the fragment's `Import-Package: [package],...` OSGi manifest header. That's fine for packages exported to the OSGi runtime. The problem is, however, when bnd tries to import a host's internal package (a package the host doesn't export). The OSGi runtime can't activate the fragment because the internal package remains an `Unresolved requirement`—a fragment shouldn't import a fragment host's packages.

If your fragment uses an internal package from the fragment host, continue using it but explicitly exclude the package from your bundle's `Import-Package` OSGi manifest header. This `Import-Package` header, for example, excludes packages that match `com.liferay.portal.search.web.internal.*`.

```
Import-Package: !com.liferay.portal.search.web.internal.*,*
```

Now you can easily modify the JSPs of any application in Liferay.

To see a sample JSP-modifying fragment in action, look at the BLADE project named `module-jsp-override`.

Upgrading App JSP Hooks

73.6 JSP Overrides Using Custom JSP Bag

Liferay's API based approaches to overriding JSPs are the best way to override JSPs in apps and in the core. You can also use Custom JSP Bags to override core JSPs. But the approach is not as stable as the API based approaches. If your Custom JSP Bag's JSP is buggy (because of your code or because of a change in Liferay), you are most likely to find out at runtime, where functionality breaks and nasty log errors greet you. In the case that you're maintaining existing Custom JSP Bags, however, this tutorial explains how they work.

A Custom JSP Bag module must satisfy these criteria:

- Includes a class that implements the `CustomJspBag` interface.
- Registers the service in the OSGi runtime.
- Provides the JSP you're extending.

The module provides transportation for this code into Liferay's OSGi runtime. When configuring it to build a proper JAR, map the path of the JSPs in the JAR to their path in your module. In a `bnd.bnd` file you could specify

```
-includeresource: META-INF/jsps=src/META-INF/custom_jsps
```

If you're using the Maven Standard Directory Layout and placing your JSPs under `src/main/resources`, you can ignore the `-includeresource` directive.

Any core JSPs you're customizing should be put into this folder, and the rest of their path and their name must match exactly the path and name of the JSP that's nested underneath `portal-web/docroot/html`. For example, if you're overriding

```
portal-web/docroot/html/common/themes/bottom-ext.jsp
```

and you used the `includeresource` directive above, put the overridden JSP in this folder of your module:

```
my-module/src/META-INF/custom_jsps/html/common/themes/bottom-ext.jsp
```

Implement a Custom JSP Bag

Create a class that implements `CustomJspBag`. The overall goal is to make sure that Liferay (specifically the `CustomJspBagRegistryUtil` class) loads the JSPs from your module upon activation.

```
public class MyCustomJspBag implements CustomJspBag {
```

When the Component is activated, you need to add the URL path for all your custom core JSPs (by directory path) to a `List`.

```
    @Activate
    protected void activate(BundleContext bundleContext) {
        bundle = bundleContext.getBundle();

        _customJsps = new ArrayList<>();

        Enumeration<URL> entries = bundle.findEntries(
            getCustomJspDir(), "*.jsp", true);

        while (entries.hasMoreElements()) {
            URL url = entries.nextElement();

            _customJsps.add(url.getPath());
        }
    }

    ...

    private List<String> _customJsps;

    private Bundle bundle;
```

In the custom JSP bag you'll need to override the following methods:

- **`getCustomJspDir`:** Return the directory path in your module's JAR where the JSPs are placed (for example, `META-INF/jsps`).
- **`getCustomJsps`:** Return a List of the custom JSP URL paths.
- **`getURLContainer`:** Return a new `com.liferay.portal.kernel.url.URLContainer`. Instantiate the URL container and override its `getResources` and `getResource` methods. The `getResources` method is for looking up all of the paths to resources in the container by a given path. It should return a `HashSet` of `Strings` for the matching custom JSP paths. The `getResource` method returns one specific resource by its name (the path included).
- **`isCustomJspGlobal`:** Return `true`.

For an example of a full class that provides a working implementation of a custom JSP bag, refer to the core-jsp-override BLADE project.

Register the Custom JSP Bag

Register the custom JSP bag implementation from your module in the OSGi runtime with three properties:

- **`context.id`:** Specify your custom JSP bag class name. For example, `MyCustomJspBag`.
- **`contex.name`:** This should be a more human readable name, like `My Custom JSP Bag`.
- **`service.ranking:integer`:** This will determine the priority of your implementation. If you specify `100` here, and one of your coworkers develops a separate custom JSP bag implementation and gives theirs a ranking of `101`, you're out of luck. Theirs will take precedence. Logically then, you should use `102`.

Extend a JSP

If you want to add something to a core JSP, see if it has an empty `-ext.jsp` and override that instead of the whole JSP. It'll keep things simpler and more stable, since the full JSP might change significantly, breaking your customization in the process. By overriding the `-ext.jsp`, you're only relying on the original JSP including the `-ext.jsp`. For an example, open `portal-web/docroot/html/common/themes/bottom.jsp`, and scroll to the end. You'll see this:

```
<liferay-util:include page="/html/common/themes/bottom-ext.jsp" />
```

If you need to add something to `bottom.jsp`, override `bottom-ext.jsp`.

As of 7.0, the content from the following JSP files formerly in `html/common/themes` are inlined to improve performance. - `body_bottom-ext.jsp` - `body_top-ext.jsp` - `bottom-ext.jsp` - `bottom-test.jsp`

They're no longer explicit files in the code base. But you can still create them in your module to add functionality and content.

Remember, this type of customization should be seen as a last resort. There's a risk that your override will break due to the nature of this implementation, and core functionality in Liferay can go down with it. If the JSP you want to override is in another module, refer to the section on API based approaches to overriding JSPs.

Site Scoped JSP Customization

In Liferay Portal 6.2, you could use Application Adapters to scope your core JSP customizations to a specific site. Since the majority of JSPs were moved into modules for 7.0, the use case for this has shrunk considerably. If you need to scope a core JSP customization to a site, prepare an application adapter as you would have for Liferay Portal 6.2, and deploy it to 7.0. It will still work. However, note that this approach is deprecated in 7.0 and won't be supported at all in Liferay 8.0.

73.7 Overriding Liferay DXP's Default YUI and AUI Modules

Liferay DXP contains several default YUI/AUI modules. You may need to override functionality provided by these module's scripts. It's possible to override JSPs using fragments, but you can't with JavaScript files. Instead, you create a custom AUI module containing three things:

- A copy of the original module's JavaScript file containing your modifications
- A `config.js` file that specifies the modified JavaScript file's path and the module it overrides
- A `bnd.bnd` file that tells the OSGi container to override the original

Follow these steps:

1. Create an OSGi module to override the original one. For example, you can create a module named `session-js-override-web` to override Liferay DXP's `session.js` file.

2. Create a `src/main/resources/META-INF/resources/js` folder in your module, copy the original JavaScript file into it, and rename it. For example, create a copy of the `session.js` module and rename it `session-override.js`. Make sure you also rename the module definition inside the `session-override.js`, e.g. `AUI().add('liferay-session-override', ....`

3. Apply your modifications and save the file.

4. Next, you'll write your module's configuration file (`config.js`) to apply your override. Add the `config.js` file to the module's `src/main/resources/META-INF/resources/js` folder. The example `config.js` file below specifies the `condition` that the YUI/AUI Loader should load the custom AUI module (`liferay-session-override`) `instead` (indicated with the `when` property) of the `trigger` module (`liferay-session`). You can follow this same pattern to create your module's `config.js` file:

```
;(function() {

    var base = MODULE_PATH + '/js/';

    AUI().applyConfig(
        {
            groups: {
                mymodulesoverride: { //mymodulesoverride
                    base: base,
                    combine: Liferay.AUI.getCombine(),
                    filter: Liferay.AUI.getFilterConfig(),
                    modules: {
                        'liferay-session-override': { //my-module-override
                            path: 'session-override.js', //my-module.js
                            condition: {
                                name: 'liferay-session-override', //my-module-override
                                trigger: 'liferay-session', //original module
                                when: 'instead'
                            }
                        }
                    },
                    root: base
                }
            }
        }
    );
})();
```

5. Finally, you must configure your `bnd.bnd` file. For the system to apply the changes, you must specify the `config.js`'s location with the `Liferay-JS-Config` BND header. The `liferay-session-override` module from the previous example has the configuration below in its `bnd.bnd` file:

```
Bundle-Name: session-js-override
Bundle-SymbolicName: session.js.override.web
Bundle-Version: 1.0.0
Liferay-JS-Config:/META-INF/resources/js/config.js
Web-ContextPath: /liferay-session-override-web
```

Now you know how to override Liferay DXP's default YUI/AUI modules!

73.8 Overriding Liferay Services (Service Wrappers)

Why might you need to customize Liferay services? Perhaps you've added a custom field to Liferay's `User` object and you want its value to be saved whenever the `addUser` or `updateUser` methods of Liferay's API are called. Or maybe you want to add some additional logging functionality to some of Liferay's APIs. Whatever your case may be, Liferay's service wrappers provide easy-to-use extension points for customizing Liferay's services.

To create a module that overrides one of Liferay's services, follow the Service Wrapper Template reference article to create a `servicewrapper` project type.

As an example, here's the `UserLocalServiceOverride` class that's generated in the Service Wrapper Template tutorial:

```
package com.liferay.docs.serviceoverride;

import com.liferay.portal.kernel.service.UserLocalServiceWrapper;
import com.liferay.portal.kernel.service.ServiceWrapper;
import org.osgi.service.component.annotations.Component;

@Component(
    immediate = true,
    property = {
    },
    service = ServiceWrapper.class
)
public class UserLocalServiceOverride extends UserLocalServiceWrapper {

    public UserLocalServiceOverride() {
        super(null);
    }

}
```

Notice that you must specify the fully qualified class name of the service wrapper class that you want to extend. The service argument was used in full in this import statement:

```
import com.liferay.portal.service.UserLocalServiceWrapper
```

This import statement, in turn, allowed the short form of the service wrapper class name to be used in the class declaration of your component class:

```
public class UserLocalServiceOverride extends UserLocalServiceWrapper
```

The bottom line is that when using `blade create` to create a service wrapper project, you must specify a fully qualified class name as the `service` argument. (This is also true when using `blade create` to create a service project.) For information about creating service projects, please see the Service Builder tutorial.

The generated `UserLocalServiceOverride` class does not actually customize any Liferay service. Before you can test that your service wrapper module actually works, you need to override at least one service method.

Open your `UserLocalServiceOverride` class and add the following methods:

```
@Override
public int authenticateByEmailAddress(long companyId, String emailAddress,
        String password, Map<String, String[]> headerMap,
        Map<String, String[]> parameterMap, Map<String, Object> resultsMap)
    throws PortalException {

    System.out.println(
        "Authenticating user by email address " + emailAddress);
    return super.authenticateByEmailAddress(companyId, emailAddress, password,
        headerMap, parameterMap, resultsMap);
}

@Override
public User getUser(long userId) throws PortalException {
    System.out.println("Getting user by id " + userId);
    return super.getUser(userId);
}
```

Each of these methods overrides a Liferay service method. These implementations merely add a few print statements that are executed before the original service implementations are invoked.

Lastly, you must add the following method to the bottom of your service wrapper so it can find the appropriate service it's overriding on deployment.

```
@Reference(unbind = "-")
private void serviceSetter(UserLocalService userLocalService) {
    setWrappedService(userLocalService);
}
```

Now you're ready to build your project. Navigate to your project's root folder and run `../../gradlew build`. The JAR file representing your portlet module is produced in your project's `build/libs` directory.

To deploy your project, run this command from your project's root directory:

```
blade deploy
```

Blade CLI detects your locally running Liferay instance and deploys the specified module to Liferay's module framework. After running the `blade deploy` command, you should see a message like this:

```
Installed or updated bundle 334
```

Use the Gogo shell to confirm that your module was installed: Run `blade sh lb` at the prompt. If your module was installed, you'll see an entry like this:

```
335|Active     |    1|com.liferay.docs.serviceoverride (1.0.0.201502122109)
```

Finally, log into your portal as an administrator. Navigate to the Users section of the Control Panel. Confirm that your customizations of Liferay's user service methods have taken effect by checking Liferay's log for the print statements that you added. Congratulations! You've created and deployed a 7.0 service wrapper module!

73.9 Overriding Language Keys

Liferay DXP Core and portlet module `language*.properties` files implement site internationalization. They're fully customizable, too. This tutorial demonstrates this in the following topics:

- Overriding Global Language Keys
- Overriding a Module's Language Keys

Modifying Global Language Keys

Language files contain translations of your application's user interface messages. But you can also override the default language keys globally and in other applications (including your own). Here are the steps for overriding language keys:

1. Determine the language keys to override
2. Override the keys in a new language properties file
3. Create a Resource Bundle service component

Note: Many applications that were once part of Liferay Portal 6.2 are now modularized. Their language keys might have been moved out of Liferay's language properties files and into one of the application modules. The process for overriding a module's language keys is different from the process for overriding global language keys.

Determine the language keys to override

So how do you find global language keys? They're in the `Language[xx_XX].properties` files in the source code or your Liferay DXP bundle.

- From the source:

  `/portal-impl/src/content/Language[_xx_XX].properties`

- From a bundle:

  `portal-impl.jar`

All language properties files contain properties you can override, like the language settings properties:

```
##
## Language settings
##

...
lang.user.name.field.names=prefix,first-name,middle-name,last-name,suffix
lang.user.name.prefix.values=Dr,Mr,Ms,Mrs
lang.user.name.required.field.names=last-name
lang.user.name.suffix.values=II,III,IV,Jr,Phd,Sr
...
```

There are also many simple keys you can override to update default messages and labels.

```
##
## Category titles
##

category.admin=Admin
category.alfresco=Alfresco
category.christianity=Christianity
category.cms=Content Management
...
```

For example, Figure 1 shows a button that uses Liferay's `publish` default language key.

```
publish=Publish
```

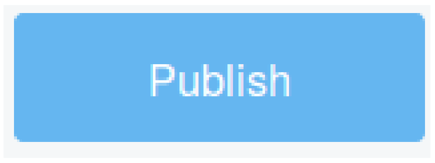

Figure 73.1: Messages displayed in Liferay's user interface can be customized.

Next, you'll learn how to override this key.

Override the keys in a new language properties file

Once you know the keys to override, create a language properties file for the locale you want (or the default `Language.properties` file) in your module's `src/main/resources/content` folder. In your file, define the keys your way. For example, you could override the `publish` key.

```
publish=Publish Override
```

To enable your change, you must create a resource bundle service component to reference your language file.

Create a Resource Bundle service component

In your module, create a class that extends `java.util.ResourceBundle` for the locale you're overriding. Here's an example resource bundle class for the `en_US` locale:

```
@Component(
    property = { "language.id=en_US" },
    service = ResourceBundle.class
)
public class MyEnUsResourceBundle extends ResourceBundle {

    @Override
    protected Object handleGetObject(String key) {
        return _resourceBundle.getObject(key);
    }

    @Override
    public Enumeration<String> getKeys() {
        return _resourceBundle.getKeys();
    }

    private final ResourceBundle _resourceBundle = ResourceBundle.getBundle(
        "content.Language_en_US", UTF8Control.INSTANCE);

}
```

The class's `_resourceBundle` field is assigned a `ResourceBundle`. The call to `ResourceBundle.getBundle` needs two parameters. The `content.Language_en_US` parameter is the language file's qualified name with respect to the module's `src/main/resources` folder. The second parameter is a `control` that sets the language syntax of the resource bundle. To use language syntax identical to Liferay's syntax, import Liferay's `com.liferay.portal.kernel.language.UTF8Control` class and set the second parameter to `UTF8Control.INSTANCE`.

The class's `@Component` annotation declares it an OSGi `ResourceBundle` service component. It's `language.id` property designates it for the `en_US` locale.

```
@Component(
    property = { "language.id=en_US" },
    service = ResourceBundle.class
)
```

The class overrides these methods:

- **`handleGetObject`:** Looks up the key in the module's resource bundle (which is based on the module's language properties file) and returns the key's value as an `Object`.

- **`getKeys`:** Returns an `Enumeration` of the resource bundle's keys.

Your resource bundle service component redirects the default language keys to your module's language key overrides.

Note: Global language key overrides for multiple locales require a separate module for each locale. Each module's ResourceBundle extension class (like the MyEnUsResourceBundle class above) must specify its locale in the language.id component property definition and in the language file qualified name parameter. For example, here is what they look like for the Spanish locale.

Component definition:

```
@Component(
    property = { "language.id=es_ES" },
    service = ResourceBundle.class
)
```

Resource bundle assignment:

```
private final ResourceBundle _resourceBundle = ResourceBundle.getBundle(
    "content.Language_es_ES", UTF8Control.INSTANCE);
```

Important: If your module uses language keys from another module and overrides any of that other module's keys, make sure to use OSGi headers to specify the capabilities your module requires and provides. This lets you prioritize resource bundles from the modules.

To see your Liferay language key overrides in action, deploy your module and visit the portlets and pages that use the keys.

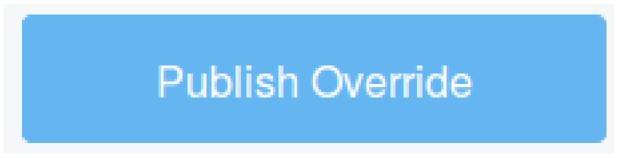

Figure 73.2: This button uses the overridden publish key.

That's all there is to overriding global language keys.

Overriding a Module's Language Keys

What do you do if the language keys you want to modify are in one of Liferay's applications or another module whose source code you don't control? Since module language keys are in the respective module, the process for overriding a module's language keys is different from the process of overriding global language keys.

Here is the process:

1. Find the module and its metadata and language keys
2. Write your custom language key values
3. Prioritize your module's resource bundle

Find the module and its metadata and language keys

In Gogo shell, list the bundles and grep for keyword(s) that match the portlet's display name. Language keys are in the portlet's web module (bundle). When you find the bundle, note its ID number.

To find the Blogs portlet, for example, your Gogo commands and output might look like this:

```
g! lb | grep Blogs
  152|Active     |    1|Liferay Blogs Service (1.0.2)
  184|Active     |    1|Liferay Blogs Editor Config (2.0.1)
  202|Active     |    1|Liferay Blogs Layout Prototype (2.0.2)
  288|Active     |    1|Liferay Blogs Recent Bloggers Web (1.0.2)
  297|Active     |    1|Liferay Blogs Item Selector Web (1.0.2)
  374|Active     |    1|Liferay Blogs Item Selector API (2.0.1)
  448|Active     |    1|Liferay Blogs API (3.0.1)
  465|Active     |    1|Liferay Blogs Web (1.0.6)
true
```

List the bundle's headers by passing its ID to the headers command.

```
g! headers 465

Liferay Blogs Web (465)
-----------------------
Manifest-Version = 1.0
Bnd-LastModified = 1459866186018
Bundle-ManifestVersion = 2
Bundle-Name = Liferay Blogs Web
Bundle-SymbolicName = com.liferay.blogs.web
Bundle-Version: 1.0.6
...
Web-ContextPath = /blogs-web
g!
```

Note the `Bundle-SymbolicName`, `Bundle-Version`, and `Web-ContextPath`. The `Web-ContextPath` value, following the `/`, is the servlet context name.

Important: Record the servlet context name, bundle symbolic name and version, as you'll use them to create the resource bundle loader later in the process.

For example, here are those values for Liferay Blogs Web module:

- Bundle symbolic name: `com.liferay.blogs.web`
- Bundle version: `1.0.6`
- Servlet context name: `blogs-web`

Next find the module's JAR file so you can examine its language keys. Liferay follows this module JAR file naming convention:

```
[bundle symbolic name]-[version].jar
```

For example, the Blogs Web version 1.0.6 module is in `com.liferay.blogs.web-1.0.6.jar`.

Here's where to find the module JAR:

- Liferay's Nexus repository
- `[Liferay Home]/osgi/modules`
- Embedded in an application's or application suite's LPKG file in `[Liferay Home]/osgi/marketplace`.

The language property files are in the module's `src/main/resources/content` folder. Identify the language keys you want to override in the `Language[_xx].properties` files.

Checkpoint: Make sure you have the required information for overriding the module's language keys:

- Language keys
- Bundle symbolic name
- Servlet context name

Next you'll write new values for the language keys.

Write custom language key values

Create a new module to hold a resource bundle loader and your custom language keys.

In your module's `src/main/resources/content` folder, create language properties files for each locale whose keys you want to override. In each language properties file, specify your language key overrides.

Next you'll prioritize your module's language keys as a resource bundle for the target module.

Prioritize Your Module's Resource Bundle

Now that your language keys are in place, use OSGi manifest headers to specify the language keys are for the target module. To compliment the target module's resource bundle, you'll aggregate your resource bundle with the target module's resource bundle. You'll list your module first to prioritize its resource bundle over the target module resource bundle. Here's an example of module `com.liferay.docs.l10n.myapp.lang` prioritizing its resource bundle over target module `com.liferay.blogs.web`'s resource bundle:

```
Provide-Capability:\
liferay.resource.bundle;resource.bundle.base.name="content.Language",\
liferay.resource.bundle;resource.bundle.aggregate:String="(bundle.symbolic.name=com.liferay.docs.l10n.myapp.lang),(bundle.symbolic.name=com.liferay.blogs.we
servlet.context.name=blogs-web
```

Let's examine the example `Provide-Capability` header.

1. `liferay.resource.bundle;resource.bundle.base.name="content.Language"` declares that the module provides a resource bundle whose base name is `content.language`.
2. The `liferay.resource.bundle;resource.bundle.aggregate:String=...` directive specifies the list of bundles whose resource bundles are aggregated, the target bundle, the target bundle's resource bundle name, and this service's ranking:

    - `"(bundle.symbolic.name=com.liferay.docs.l10n.myapp.lang),(bundle.symbolic.name=com.liferay.blogs.web)"`: The service aggregates resource bundles from bundles `com.liferay.docs.l10n.myapp.lang` and `com.liferay.blogs.web`. Aggregate as many bundles as desired. Listed bundles are prioritized in descending order.
    - `bundle.symbolic.name=com.liferay.blogs.web;resource.bundle.base.name="content.Language"`: Override the `com.liferay.blogs.web` bundle's resource bundle named `content.Language`.
    - `service.ranking:Long="2"`: The resource bundle's service ranking is `2`. The OSGi framework applies this service if it outranks all other resource bundle services that target `com.liferay.blogs.web`'s `content.Language` resource bundle.
    - `servlet.context.name=blogs-web`: The target resource bundle is in servlet context `blogs-web`.

Deploy your module to see the language keys you've overridden.

Tip: If your override isn't showing, use Gogo Shell to check for competing resource bundle services. It may be that another service outranks yours. To check for competing resource bundle services whose aggregates include `com.liferay.blogs.web`'s resource bundle, for example, execute this Gogo Shell command:

```
 services "(bundle.symbolic.name=com.liferay.login.web)"
```

Search the results for resource bundle aggregate services whose ranking is higher.

Now you can modify the language keys of modules in Liferay's OSGi runtime. Remember, language keys you want to override might actually be in Liferay's core. You can override global language keys too.

73.10 Overriding Portal Properties using a Hook

A portal properties hook plugin lets you override a subset of portal properties dynamically. These properties define event actions, model listeners, validators, generators, and content sanitizers. The `liferay-hook-7.0.dtd` file lists this subset of properties.

Note: To customize a property that's not in the `liferay-hook-7.0.dtd` file, you must use an Ext plugin.

Some portal properties accept *multiple* values. For example, the `login.event.pre` property defines action classes to invoke before login. Deploying multiple hooks for properties like this appends the values to the property's current value. For example, multiple hooks that add login event actions append their action classes to the portal instance's `login.event.pre` property. The portal property reference documentation shows whether a property accepts multiple values by stating it or showing value lists assigned to a default or example property setting.

Some portal properties accept a *single* value only. For example, the `terms.of.use.required` property is either `true` or `false`. Override a single value property from one hook only–there's no telling which value is assigned if multiple hooks override it.

Here's how to override a portal property using a Hook:

1. Create a Hook plugin using Liferay @ide@ or Maven.

2. In the plugin's `WEB-INF/src` folder, create a `portal.properties` file and override properties with the values you want.

3. In the plugin's `WEB-INF/liferay-hook.xml` file, add the following `portal-properties` element as a child of the `hook` element. Refer to the `liferay-hook-7.0.dtd` file for details.

   ```
   <portal-properties>portal.properties</portal-properties>
   ```

4. Deploy the plugin.

You've modified the portal property. The *Server Administration* page's *Properties* screen in the Control Panel shows your new property setting.

73.11 Overriding MVC Commands

MVC Commands are used to break up the controller layer of a Liferay MVC application into smaller, more digestible code chunks.

Sometimes you'll want to override an MVC command, whether it's in a Liferay application or another Liferay MVC application whose source code you don't own. Since MVC commands are components registered in the OSGi runtime, you can simply publish your own component, and give it a higher service ranking. Your MVC command will then be invoked instead of the original one.

The logical way of breaking up the controller layer is to do it by portlet phase. The three MVC command classes you can override are

- **`MVCActionCommand`:** An interface that allows the portlet to process a particular action request.
- **`MVCRenderCommand`:** An interface that handles the render phase of the portlet.
- **`MVCResourceCommand`:** An interface that allows the portlet to serve a resource.

Find more information about implementing each of these MVC command classes in the tutorials on Liferay MVC Portlets. Here we're going to focus on overriding the logic contained in existing MVC commands.

Note: While it's possible to copy the logic from an existing MVC command into your override class, then customize it to your liking, it's strongly recommended to decouple the original logic from your override logic. Keeping the override logic separate form the original logic will keep the code clean, maintainable, and easy to understand.

To do this, use the `@Reference` method to fetch a reference to the original MVC command component. If there are no additional customizations on the same command, this reference will be the original MVC command.

```
@Reference(
    target = "(component.name=com.liferay.blogs.web.internal.portlet.action.EditEntryMVCRenderCommand)")
protected MVCRenderCommand mvcRenderCommand;
```

Set the `component.name` target to the MVC command class name. If you use this approach, your extension will continue to work with new versions of the original portlet, because no coupling exists between the original portlet logic and your customization. The command implementation class can change. Make sure to keep your reference updated to the name of the current implementation class.

Note: In 7.0 GA1, there's a bug that occurs when modules with override MVC commands are removed from the OSGi runtime. Instead of looking for an MVC command with a lower service ranking (the original MVC command in most cases) to replace the removed one, the reference to the command is removed entirely. This bug is documented and fixed here

---

Start by learning to override `MVCRenderCommand`. The process will be similar for the other MVC commands.

Overriding MVCRenderCommand

You can override `MVCRenderCommand` for any portlet that uses Liferay's MVC framework and publishes an `MVCRenderCommand` component.

For example, Liferay's Blogs application has a class called `EditEntryMVCRenderCommand`, with this component:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS,
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS_ADMIN,
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS_AGGREGATOR,
        "mvc.command.name=/blogs/edit_entry"
    },
    service = MVCRenderCommand.class
)
```

This MVC render command can be invoked from any of the portlets specified by the `javax.portlet.name` parameter, by calling a render URL that names the MVC command.

```
<portlet:renderURL var="addEntryURL">
    <portlet:param name="mvcRenderCommandName" value="/blogs/edit_entry" />
    <portlet:param name="redirect" value="<%= viewEntriesURL %>" />
</portlet:renderURL>
```

What if you want to override the command, but not for all of the portlets listed in the original component? In your override component, just list the `javax.portlet.name` of the portlets where you want the override to take effect. For example, if you want to override the `/blogs/edit_entry` MVC render command just for the Blogs Admin portlet (the Blogs Application accessed in the site administration section of Liferay), your component could look like this:

```
@Component(
  immediate = true,
  property = {
     "javax.portlet.name=" + BlogsPortletKeys.BLOGS_ADMIN,
     "mvc.command.name=/blogs/edit_entry",
     "service.ranking:Integer=100"
  },
  service = MVCRenderCommand.class
)
```

Note the last property listed, `service.ranking`. It's used to tell the OSGi runtime which service to use, in cases where there are multiple components registering the same service, with the same properties. The higher the integer you specify here, the more weight your component carries. In this case, the override component will be used instead of the original one, since the default value for this property is `0`.

After that, it's up to you to do whatever you'd like. You can add logic to the existing `render` method or redirect to an entirely new JSP.

Adding Logic to an Existing MVC Render Command

Don't copy the existing logic from the MVC render command into your override command class. This unnecessary duplication of code that makes maintenance more difficult. If you want to do something new (like set a request attribute) and then execute the logic in the original MVC render command, obtain a reference to the original command and call its `render` method like this:

```
@Override
public String render(RenderRequest renderRequest,
                 RenderResponse renderResponse) throws PortletException {

    //Do something here

    return mvcRenderCommand.render(renderRequest, renderResponse);
}

@Reference(target =
      "(component.name=com.liferay.blogs.web.internal.portlet.action.EditEntryMVCRenderCommand)")
  protected MVCRenderCommand mvcRenderCommand;
}
```

Sometimes, you might need to redirect the request to an entirely new JSP that you'll place in your command override module.

Redirecting to a New JSP

If you want to render an entirely new JSP, the process is different.

The render method of MVCRenderCommand returns the path to a JSP as a String. The JSP must live in the original module, so you cannot simply specify a path to a custom JSP in your override module. You need to make the method skip dispatching to the original JSP altogether, by using the MVC_PATH_VALUE_SKIP_DISPATCH constant from the MVCRenderConstants class. Then you need to initiate your own dispatching process, directing the request to your JSP path. Here's how that might look in practice:

```
public class CustomEditEntryMVCRenderCommand implements MVCRenderCommand {

    @Override
    public String render
        (RenderRequest renderRequest, RenderResponse renderResponse) throws
        PortletException {

        System.out.println("Rendering custom_edit_entry.jsp");

        RequestDispatcher requestDispatcher =
            servletContext.getRequestDispatcher("/custom_edit_entry.jsp");

        try {
            HttpServletRequest httpServletRequest =
                PortalUtil.getHttpServletRequest(renderRequest);
            HttpServletResponse httpServletResponse =
                PortalUtil.getHttpServletResponse(renderResponse);

            requestDispatcher.include
                (httpServletRequest, httpServletResponse);
        } catch (Exception e) {
            throw new PortletException
                ("Unable to include custom_edit_entry.jsp", e);
        }

        return MVCRenderConstants.MVC_PATH_VALUE_SKIP_DISPATCH;
    }

    @Reference(target = "(osgi.web.symbolicname=com.custom.code.web)")
    protected ServletContext servletContext;

}
```

In this approach, there's no reference to the original MVC render command because the original logic isn't reused. Instead, there's a reference to the servlet context of your module, which is needed to use the request dispatcher.

A servlet context is automatically created for portlets. It can be created for other modules by including the following line in your bnd.bnd file:

```
Web-ContextPath: /custom-code-web
```

Once we have the servlet context we just need to dispatch to the specific JSP in our own module.

Overriding MVCActionCommand

You can override MVC action commands using a similar process to the one presented above for MVC render commands. Again, you'll register a new OSGi component with the same properties, but with a higher service ranking. This time the service you're publishing is `MVCActionCommand.class`.

For MVC action command overrides, extend the `BaseMVCActionCommand` class, and the only method you'll need to override is `doProcessAction`, which must return `void`.

As with MVC render commands, you can add your logic to the original behavior of the action method by getting a reference to the original service, and calling it after your own logic. Here's an example of an `MVCActionCommand` override that checks whether the `delete` action is invoked on a blog entry, and prints a message to the log, before continuing with the original processing:

```
@Component(
    property = {
        "javax.portlet.name=" + BlogsPortletKeys.BLOGS_ADMIN,
        "mvc.command.name=/blogs/edit_entry",
        "service.ranking:Integer=100"
    },
    service = MVCActionCommand.class)
public class CustomBlogsMVCActionCommand extends BaseMVCActionCommand {

    @Override
    protected void doProcessAction
        (ActionRequest actionRequest, ActionResponse actionResponse)
        throws Exception {

        String cmd = ParamUtil.getString(actionRequest, Constants.CMD);

        if (cmd.equals(Constants.DELETE)) {
            System.out.println("Deleting a Blog Entry");
        }

        mvcActionCommand.processAction(actionRequest, actionResponse);
    }

    @Reference(
        target = "(component.name=com.liferay.blogs.web.internal.portlet.action.EditEntryMVCActionCommand)")

    protected MVCActionCommand mvcActionCommand;

}
```

It's straightforward to override MVC action commands while keeping your code decoupled from the original action methods. You can also override MVC resource commands.

Overriding MVCResourceCommand

There are fewer uses for overriding MVC resource commands, but it can also be done.

The process is similar to the one described for `MVCRenderCommand` and `MVCActionCommand`. There's a couple things to keep in mind:

- The service to specify in your component is `MVCResourceCommand.class`
- As with overriding `MVCRenderCommand`, there's no base implementation class to extend. You'll implement the interface yourself.
- Keep your code decoupled from the original code by adding your logic to the original `MVCResourceCommand`'s logic by getting a reference to the original and returning a call to its `serveResource` method:

```
        return mvcResourceCommand.serveResource(resourceRequest, resourceResponse);
```

The following example overrides the behavior of `com.liferay.login.web.portlet.action.CaptchaMVCResourceCommand`, from the `login-web` module of the Login portlet. It simply prints a line in the console then executes the original logic: returning the Captcha image for the account creation screen.

```
@Component(
    property = {
        "javax.portlet.name=" + LoginPortletKeys.LOGIN,
        "mvc.command.name=/login/captcha" },
    service = MVCResourceCommand.class)
public class CustomCaptchaMVCResourceCommand implements MVCResourceCommand {

    @Override
    public boolean serveResource
        (ResourceRequest resourceRequest, ResourceResponse resourceResponse) {

        System.out.println("Serving login captcha image");

        return mvcResourceCommand.serveResource(resourceRequest, resourceResponse);
    }

    @Reference(target = "(component.name=com.liferay.login.web.internal.portlet.action.CaptchaMVCResourceCommand)")
    protected MVCResourceCommand mvcResourceCommand;

}
```

And that, as they say, is that. Even if you don't own the source code of an application, you can override its MVC commands just by knowing the component class name.

73.12 Overriding lpkg files

Applications are delivered through Liferay Marketplace as *lpkg* files. This is a simple compressed file format that contains .jar files to be deployed to Liferay DXP. If you want to examine an application from Marketplace, all you have to do is unzip it to reveal the .jar files it contains.

After examining them, you may want to customize one of these applications. Make your customization, but don't deploy it the way you'd normally deploy an application. Instead, Liferay DXP provides a way to update application modules without modifying the original .lpkg file they're packaged in, by overriding the .lpkg file. This only takes a few steps:

1. Shut down Liferay DXP.
2. Create a folder called `override` in the Liferay DXP instance's `osgi/marketplace` folder.
3. Name your updated .jar the same as the .jar in the original .lpkg, minus the version information. For example, if you're overriding the `com.liferay.amazon.rankings.web-1.0.5.jar` from the `Liferay CE Amazon Rankings.lpkg`, you'd name your .jar `com.liferay.amazon.rankings.web.jar`.
4. Copy this .jar into the `override` folder you created in step one.

This works for applications from Marketplace, but there's also the static .lpkg that contains core Liferay technology and third-party utilities (such as the servlet API, Apache utilities, etc.). If you find you need to customize or patch any of these .jar files, deploying these customizations is a similar process:

1. Make your customization and package your .jar file.

2. Name your updated .jar the same as the original .jar, minus the version information. For example, a customized `com.liferay.portal.profile-1.0.4.jar` should be `com.liferay.portal.profile.jar`.

3. Place this .jar in the `osgi/static` folder.

Now start @product. Note that any time you add and remove .jars this way, Liferay DXP must be shut down and then restarted to make the changes take effect.

If you must roll back your customizations, delete the overriding .jar files: Liferay DXP uses the original .jar on its next startup.

73.13 Creating Model Listeners

Model Listeners implement the `ModelListener` interface. They are used to listen for persistence events on models and do something in response (either before or after the event).

Model listeners were designed to perform lightweight actions in response to a `create`, `remove`, or `update` attempt on an entity's database table or a mapping table (for example, `users_roles`). Here are some supported use cases:

- Audit Listener: In a separate database, record information about updates to an entity's database table.
- Cache Clearing Listener: Clear caches that you've added to improve the performance of custom code.
- Validation Listener: Perform additional validation on a model's attribute values before they are persisted to the database.
- Entity Update Listener: Do some additional processing when an entity table is updated. For example, notify users when changes are made to their account.

There are also use cases that are not recommended, since they're likely to break unpredictably and give you headaches:

- Setting a model's attributes in an `onBeforeUpdate` call. If some other database table has already been updated with the values before your model listener is invoked, your database will get out of sync. To change how an entity's attributes are set, consider using a service wrapper instead.
- Wrapping a model. Model listeners are not called when fetching records from the database.
- Creating worker threads to do parallel processing and querying data you updated via your listener. Model listeners are called *before* the database transaction is complete (even the `onAfter...` methods), so the queries could be executed before the database transaction is completed.

If there is no existing listener on the model, your model listener is the only one that runs. However, there can be multiple listeners on a single model, and the order in which the listeners run cannot be controlled.

You can create a model listener in a module by doing two simple things:

- Implement `ModelListener`
- Register the service in Liferay's OSGi runtime

Creating a Model Listener Class

Create a `-ModelListener` class that extends `BaseModelListener`.

```
package ...;

import ...;

public class CustomEntityListener extends BaseModelListener<CustomEntity> {

    /* Override one or more methods from the ModelListener
        interface.
    */

}
```

In the body of the class override any methods from the `ModelListener` interface. The available methods are listed and described at the end of this article.

In your model listener class, the parameterized type (for example, `CustomEntity` in the snippet above) is used to tell the listener's `ServiceTrackerCustomizer` which model class the listener should be registered against.

Register the Model Listener Service

Register the service with Liferay's OSGi runtime. If using Declarative Services, set `service= ModelListener.class` and `immediate=true` in the Component.

```
@Component(
    immediate = true,
    service = ModelListener.class
)
```

That's all there is to preparing a model listener. Now learn what model events you can respond to.

Listening For Persistence Events

The `ModelListener` interface provides lots of opportunity to listen for model events:

- **`onAfterAddAssociation`:** If there's an association between two models (if they have a mapping table), use this method to do something after an association record is added.
- **`onAfterCreate`:** Use this method to do something after the persistence layer's `create` method is called.
- **`onAfterRemove`:** Use this method to do something after the persistence layer's `remove` method is called.
- **`onAfterRemoveAssociation`:** If there's an association between two models (if they have a mapping table), do something after an association record is removed.
- **`onAfterUpdate`:** Use this method to do something after the persistence layer's `update` method is called.
- **`onBeforeAddAssociation`:** If there's an association between two models (if they have a mapping table), do something before an addition to the mapping table.
- **`onBeforeCreate`:** Use this method to do something before the persistence layer's `create` method is called.
- **`onBeforeRemove`:** Use this method to do something before the persistence layer's `remove` method is called.
- **`onBeforeRemoveAssociation`:** If there's an association between two models (if they have a mapping table), do something before a removal from the mapping table.
- **`onBeforeUpdate`:** Use this method to do something before the persistence layer's `update` method is called.

Look in Liferay's `BasePersistenceImpl`, particularly the `remove` and `update` methods, and you'll see how model listeners are accounted for before (for the `onBefore...` case) and after (for the `onAfter...` case) the model persistence event.

Now that you know how to create model listeners, keep in mind that they're useful as standalone projects or inside of your application. If your application needs to do something (like add a custom entity) every time a User is added in Liferay, you can include the model listener inside your application.

Chapter 74

Application Display Templates

The application display template (ADT) framework allows portal administrators to override the default display templates, removing limitations to the way your site's content is displayed. With ADTs, you can define custom display templates used to render asset-centric applications.

Usually, when you need to modify the UI of a Liferay portlet, you can do so using a hook (e.g., HTML-related change) or a theme (e.g., CSS-related change). It'd be nice, however, if you could apply particular display changes to specific portlet instances without having to redeploy any plugins. Ideally, you should be able to provide authorized portal users the ability to apply custom display interfaces to portlets.

Be of good cheer! That's precisely what Application Display Templates (ADTs) provide–the ability to add custom display templates to your portlets from the portal. This isn't actually a new concept in Liferay; some applications already had templating capabilities (e.g., *Web Content* and *Dynamic Data Lists*), in which you can already add as many display options (or templates) as you want. Now you can add them to your custom portlets, too.

Some portlets that already support Application Display Templates in 7.0 are *Asset Catgories Navigation*, *Asset Publisher*, *Asset Tags Navigation*, *Blogs*, *Media Gallery*, *RSS*, *Breadcrumb*, *Language*, *Navigation Menu*, *SiteMap*, and *Wiki*.

74.1 Implementing Application Display Templates

Application Display Templates (ADTs) provide–the ability to add custom display templates to your portlets from the portal. The figure below shows what the Display Template option looks like in a portlet Configuration menu.

In this tutorial, you'll learn how to use the Application Display Templates API to add an ADT to a portlet.

Using the Application Display Templates API

To leverage the ADT API, there are several steps you need to follow. These steps involve registering your portlet to use ADTs, defining permissions, and exposing the ADT functionality to users. You'll walk through these steps now:

1. Create and register a custom `*PortletDisplayTemplateHandler` component. Liferay provides the BasePortletDisplayTemplateHandler as a base implementation for you to extend. You can check the TemplateHandler interface Javadoc to learn about each template handler method.

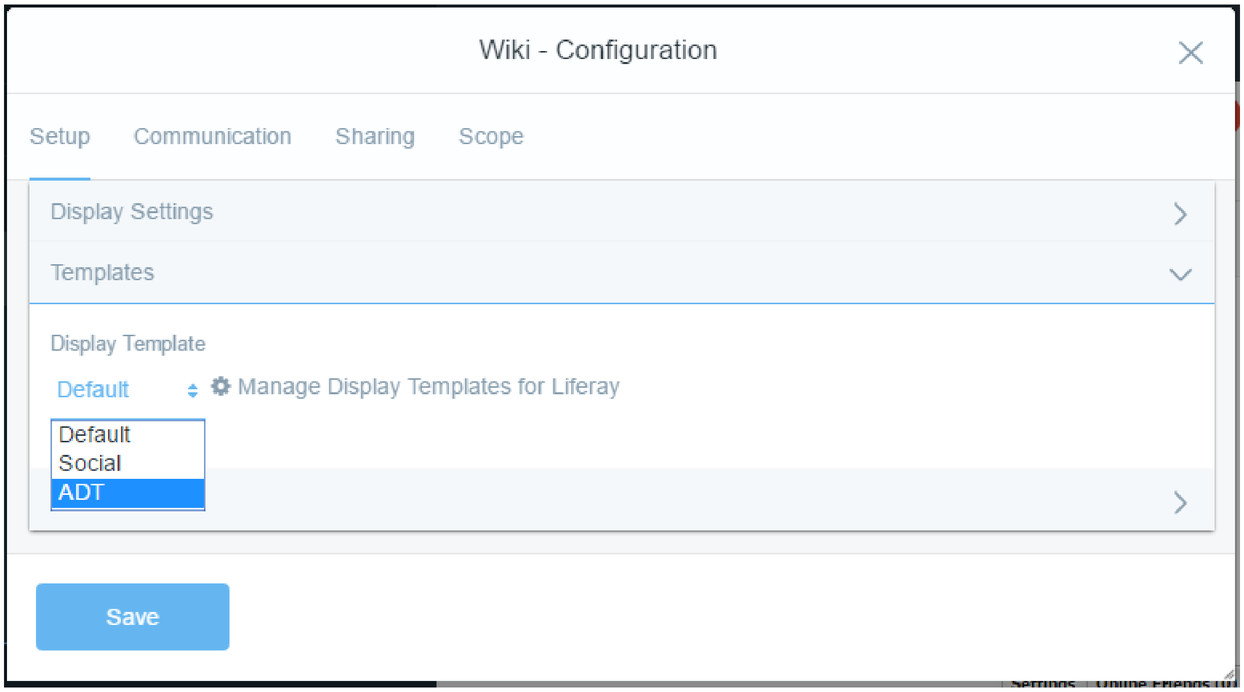

Figure 74.1: By using a custom display template, your portlet's display can be customized.

The Component annotation ties your handler to a specific portlet setting the property `javax.portlet.name` as the portlet name of your portlet. The same property should be found in your portlet class. For example:

```
@Component(
    immediate = true,
    property = {
        "javax.portlet.name="+ AssetCategoriesNavigationPortletKeys.ASSET_CATEGORIES_NAVIGATION
    },
    service = TemplateHandler.class
)
```

Each of the methods in this class have a significant role in defining and implementing ADTs for your custom portlet. View the list below for a detailed explanation for each method defined specifically for ADTs:

- **getClassName():** Defines the type of entry your portlet is rendering.
- **getName():** Declares the name of your ADT type (typically, the name of the portlet).
- **getResourceName():** Specifies which resource is using the ADT (e.g., a portlet) for permission checking. This method must return the portlet's Fully Qualified Portlet ID (FQPI).
- **getTemplateVariableGroups():** Defines the variables exposed in the template editor.

As an example `*PortletDisplayTemplateHandler` implementation, you can look at WikiPortletDisplayTemplateHandler.java.

2. Since the ability to add ADTs is new to your portlet, you must configure permissions so that administrative users can grant permissions to the roles that will be allowed to create and manage display templates.

Add the action key `ADD_PORTLET_DISPLAY_TEMPLATE` to your portlet's `/src/main/resources/resource-actions/default.xml` file:

```
<?xml version="1.0"?>
<!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-
resource-action-mapping_7_0_0.dtd">
<resource-action-mapping>

    ...

    <portlet-resource>
        <portlet-name>yourportlet</portlet-name>
        <permissions>
            <supports>
                <action-key>ADD_PORTLET_DISPLAY_TEMPLATE</action-key>
                <action-key>ADD_TO_PAGE</action-key>
                <action-key>CONFIGURATION</action-key>
                <action-key>VIEW</action-key>
            </supports>

            ...

        </permissions>
    </portlet-resource>

    ...

</resource-action-mapping>
```

3. Next, you need to make sure that Liferay can find the updated `default.xml` with the new resource action when you deploy the module. Create a file named `portlet.prtoperies` in the `/resources` folder and add the following contents providing the path to your `default.xml`:

```
include-and-override=portlet-ext.properties
resource.actions.configs=resource-actions/default.xml
```

4. Now that your portlet officially supports ADTs, you'll want to expose the ADT option to your users. Just include the `<liferay-ui:ddm-template-selector>` tag in the JSP file you're using to control your portlet's configuration.

   For example, it may be helpful for you to insert an `<aui:fieldset>` in your configuration JSP file, like the following:

```
<aui:fieldset>
    <div class="display-template">
        <liferay-ddm:template-selector
            classNameId="<%= YourEntity.class.getName() %>"
            displayStyle="<%= displayStyle %>"
            displayStyleGroupId="<%= displayStyleGroupId %>"
            refreshURL="<%= PortalUtil.getCurrentURL(request) %>"
            showEmptyOption="<%= true %>"
        />
    </div>
</aui:fieldset>
```

   In this JSP, the `<liferay-ddm:template-selector>` tag specifies the Display Template drop-down menu to be used in the portlet's Configuration menu. The variables `displayStyle` and `displayStyleGroupId` are preferences that your portlet stores when you use this taglib and your portlet uses the BaseJSPSettingsConfigurationAction or DefaultConfigurationAction. Otherwise, you would need to obtain the value of those parameters and store them manually in your configuration class.

As an example JSP, see the Wiki application's configuration.jsp.

5. You must now extend your view code to render your portlet with the selected ADT. This allows you to decide which part of your view will be rendered by the ADT and what will be available in the template context.

   First, initialize the Java variables needed for the ADT:

```
<%
String displayStyle = GetterUtil.getString(portletPreferences.getValue("displayStyle", StringPool.BLANK));
long displayStyleGroupId = GetterUtil.getLong(portletPreferences.getValue("displayStyleGroupId", null), scopeGroupId);
%>
```

   Next, you can test if the ADT is configured, grab the entities to be rendered, and render them using the ADT. The tag `<liferay-ddm:template-renderer>` aids with this process. It will automatically use the selected template or render its body if no template is selected.

   Here's some example code that demonstrates implementing this:

```
<liferay-ddm:template-renderer
    className="<%= YourEntity.class.getName() %>"
    contextObjects="<%= contextObjects %>"
    displayStyle="<%= displayStyle %>"
    displayStyleGroupId="<%= displayStyleGroupId %>"
    entries="<%= yourEntities %>"
>

    <%-- The code that will be rendered by default when there is no
    template available should be inserted here. --%>

</liferay-ddm:template-renderer>
```

   In this step, you initialized variables dealing with the display settings (`displayStyle` and `displayStyleGroupId`) and passed them to the tag along with other parameterers listed below:

   - `className`: your entity's class name.
   - `contextObjects`: accepts a `Map<String, Object>` with any object you want to the template context.
   - `entries`: accepts a list of your entities (e.g., `List<YourEntity>`).

   For an example that demonstrates implementing this, see configuration.jsp.

Now that your portlet supports ADTs, you can create your own scripts to change the display of your portlet. You can experiment by adding your own custom ADT.

1. Navigate to Site Admin* → *Configuration* → *Application Display Templates*. Then select *Add* (+) → *Your Template*. Give your ADT a name and insert FreeMarker (like the following code) or Velocity code into the template editor, and click *Save*:

```
<#if entries?has_content>
    Quick List:
    <ul>
    <#list entries as curEntry>
        <li>${curEntry.name} - ${curEntry.streetAddress}, ${curEntry.city}, ${curEntry.stateOrProvince}</li>
    </#list>
    </ul>
</#if>
```

2. Go back to your portlet and select *Options* (⋮) → *Configuration* and click the *Display Template* drop-down. Select the ADT you created, and click *Save*.

This is a wiki article! Lorem Ipsum doobsum boom!

Figure 74.2: The example Social template for the Wiki application provides extended social functionalities.

Once your script is uploaded into the portal and saved, users with the specified roles can select the template when they're configuring the display settings of your portlet on a page. You can visit the Styling Apps with Application Display Templates section for more details on using ADTs.

Next, we'll provide some recommendations for using ADTs in Liferay Portal.

Recommendations for Using ADTs

You've harnessed a lot of power by learning to leverage the ADT API. Be careful, for with great power, comes great responsibility! To that end, you'll learn about some practices you can use to optimize your portlet's performance and security.

First let's talk about security. You may want to hide some classes or packages from the template context, to limit the operations that ADTs can perform on your portal. Liferay provides some portal system settings, which can be accessed by navigating to *Control Panel* → *Configuration* → *System Settings* → *Foundation* → *FreeMarker/Velocity Engine*, to define the restricted classes, packages, and variables. In particular, you may want to add `serviceLocator` to the list of default values assigned to the FreeMarker and Velocity Engine Restricted variables.

Application Display Templates introduce additional processing tasks when your portlet is rendered. To minimize negative effects on performance, make your templates as minimal as possible by focusing on the presentation, while using the existing API for complex operations. The best way to make Application Display Templates efficient is to know your template context well, and understand what you can use from it. Fortunately, you don't need to memorize the context information, thanks to Liferay's advanced template editor!

To navigate to the template editor for ADTs, go to the Site Admin menu and select *Configuration* → *Application Display Templates* and then click *Add* and select the specific portlet on which you decide to create an ADT.

The template editor provides fields, general variables, and util variables customized for the portlet you chose. These variable references can be found on the left-side panel of the template editor. You can use them by simply placing your cursor where you'd like the variable placed, and clicking the desired variable to place it there. You can learn more about the template editor in the Styling Apps with Application Display Templates section.

Finally, don't forget to run performance tests and tune the template cache options by modifying the *Resource modification check* field in *System Settings* → *Foundation* → *FreeMarker/Velocity Engine*.

The cool thing about ADTs is the power they provide to your Liferay portlets, providing infinite ways of editing your portlet to provide new interfaces for your portal users. You stepped through how to configure ADTs for a custom portlet, tried out a sample template, and ran through important recommendations for using ADTs, which included security and performance.

Mobile

Liferay provides two ways to create native Android and iOS apps that work with your Liferay instances: Liferay Screens and the Liferay Mobile SDK. Liferay Screens does this via ready-to-use components called *Screenlets*. Since Screenlets already contain the code required to call your Liferay instance–and a complete UI–all you need to do is insert and configure them in your Android or iOS app. Screens provides Screenlets for common tasks such as logging in, viewing web content, adding DDL records, and more. You can also customize each Screenlet to fit your specific needs, or write your own Screenlet. Behind the scenes, Screenlets use the Liferay Mobile SDK to call Liferay's remote services.

The Liferay Mobile SDK is a lower-level tool that lets you manually invoke Liferay's remote services. You'll need to use the Mobile SDK to write your own Screenlets, or call Liferay's remote services independent of Screens. In most cases, you'll find that using Screens saves you time and effort. For example, although you can use the Mobile SDK to implement login in your app, Screens already provides this via Login Screenlet. There are certain cases, however, where using the Mobile SDK makes sense. For example, if you need to call one or more Liferay remote services but your app's UI doesn't need to reflect this, then it doesn't make sense to use Screenlets for this purpose. Each Screenlet must contain a UI.

Regardless of your specific needs, Liferay has you covered with Liferay Screens and the Liferay Mobile SDK. This section of tutorials contains the following sections that show you how to use both:

- Android Apps with Liferay Screens
- iOS Apps with Liferay Screens
- Using Xamarin with Liferay Screens
- Liferay Mobile SDK

Venture forth to become a mobile guru!

Chapter 76

Android Apps with Liferay Screens

Liferay Screens speeds up and simplifies developing native mobile apps that use Liferay. Its power lies in its *Screenlets*. A Screenlet is a visual component that you insert into your native app to leverage Liferay Portal's content and services. On Android, Screenlets are available to log in to your portal, create accounts, submit forms, display content, and more. You can use any number of Screenlets in your app; they're independent, so you can use them in modular fashion. Screenlets on Android also deliver UI flexibility with pluggable *Views* that implement elegant user interfaces. Liferay's reference documentation for Android Screenlets describes each Screenlet's features and Views.

You might be thinking, "These Screenlets sound like the greatest thing since taco Tuesdays, but what if they don't fit in with my app's UI? What if they don't behave exactly how I want them to? What if there's no Screenlet for what I want to do?" Fret not! You can customize Screenlets to fit your needs by changing or extending their UI and behavior. You can even write your own Screenlets! What's more, Screens seamlessly integrates with your existing Android projects.

Screenlets leverage the Liferay Mobile SDK to make server calls. The Mobile SDK is a low-level layer on top of the Liferay JSON API. To write your own Screenlets, you must familiarize yourself with Liferay's remote services. If no existing Screenlet meets your needs, consider customizing an existing Screenlet, creating a Screenlet, or directly using the Mobile SDK. Creating a Screenlet involves writing Mobile SDK calls and constructing the Screenlet; if you don't plan to reuse or distribute the implementation then you may want to forgo writing a Screenlet and, instead, work with the Mobile SDK. A benefit of integrating an existing Screenlet into your app, however, is that the Mobile SDK's details are abstracted from you.

These tutorials show you how to use, customize, create, and distribute Screenlets for Android. They show you how to create Views too. There's even a tutorial that explains the nitty-gritty details of the Liferay Screens architecture. No matter how deep you want to go, you'll use Screenlets in no time. Start by preparing your Android project to use Liferay Screens.

76.1 Preparing Android Projects for Liferay Screens

To use Liferay Screens, you must install it in your Android project and then configure it to communicate with your Liferay DXP instance. Note that Screens is released as an AAR file hosted in jCenter.

There are three different ways to install Screens. This tutorial shows you each:

1. With Gradle: Gradle is the build system Android Studio uses to build Android projects. We therefore recommend that you use it to install Screens.

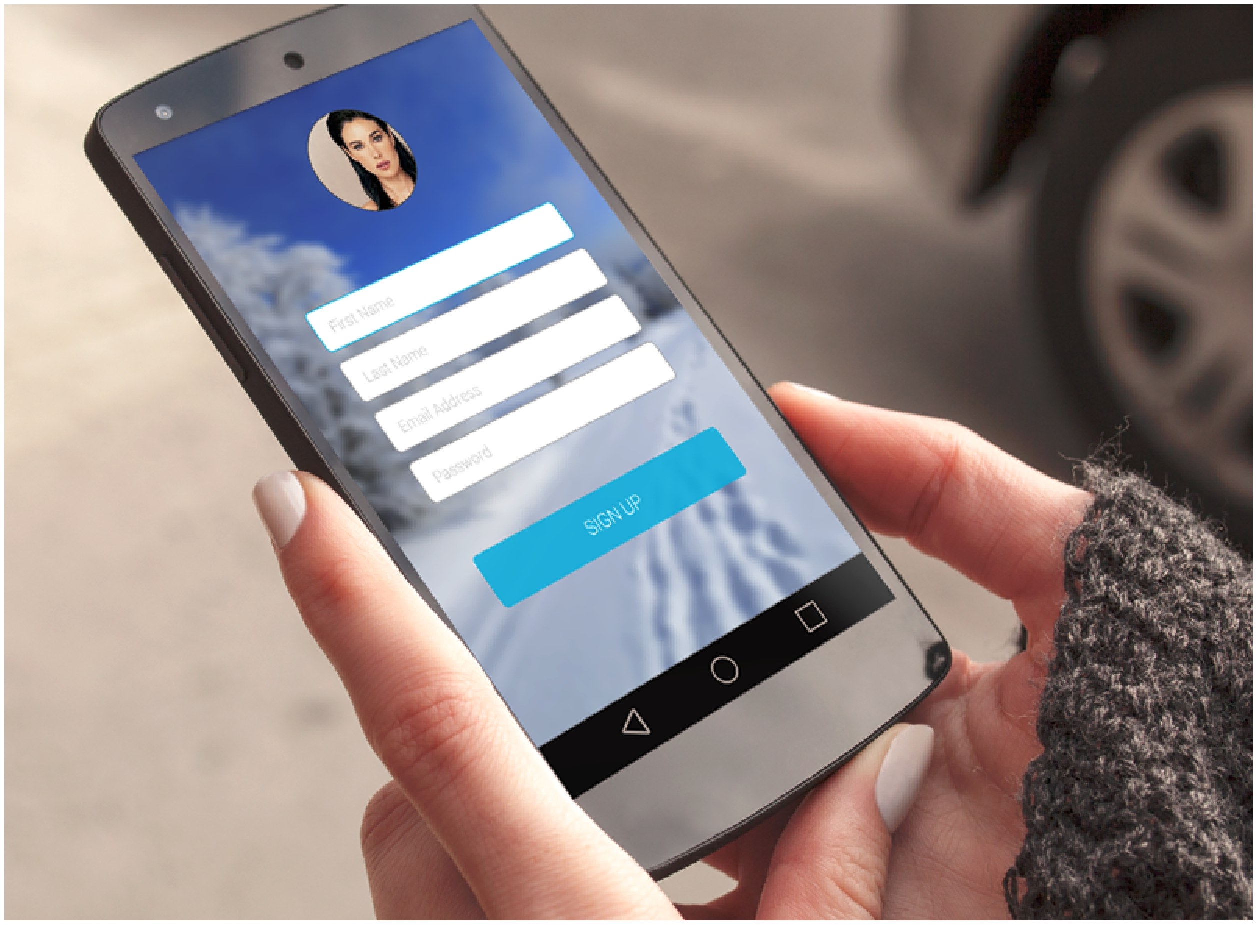

Figure 76.1: Here's an app that uses a Liferay Screens Sign Up Screenlet.

2. With Maven
3. Manually

Note: After installation, you must configure Liferay Screens to communicate with your Liferay DXP instance. The last section in this tutorial shows you how to do this.

Requirements

Liferay Screens for Android includes the Component Library (the Screenlets) and a sample project. It requires the following software:

- Android Studio 3.0 or above.
- Android SDK 4.1 (API Level 16) or above.
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, or Liferay DXP 7.0
- Liferay Screens Compatibility Plugin (CE or DXP/EE, depending on your portal edition). This app is preinstalled in Liferay CE Portal 7.0/7.1 CE and Liferay DXP 7.0.
- Liferay Screens source code.

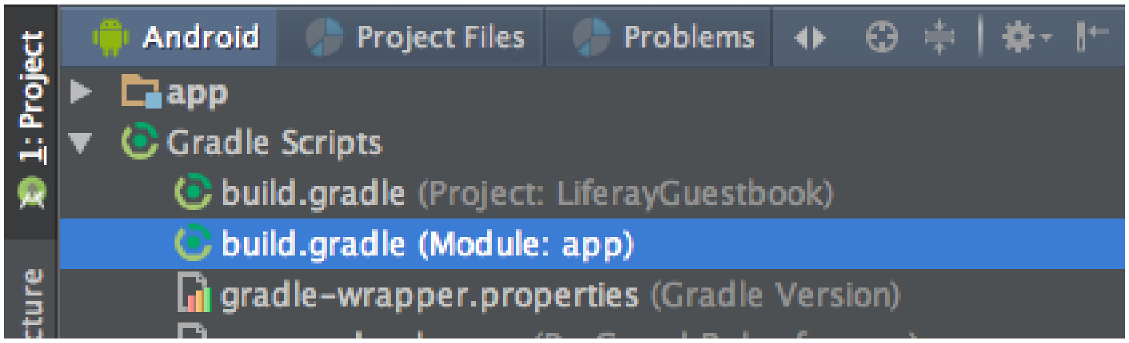
Liferay Screens for Android uses EventBus internally.

Securing JSON Web Services

Each Screenlet in Liferay Screens calls one or more of Liferay DXP's JSON web services, which are enabled by default. The Screenlet reference documentation lists the web services that each Screenlet calls. To use a Screenlet, its web services must be enabled in the portal. It's possible, however, to disable the web services needed by Screenlets you're not using. For instructions on this, see the tutorial Configuring JSON Web Services. You can also use Service Access Policies for more fine-grained control over accessible services.

Using Gradle to Install Liferay Screens

To use Gradle to install Liferay Screens in your Android Studio project, you must edit your app's `build.gradle` file. Note that your project has two `build.gradle` files: one for the project and another for the app module. You can find them under Gradle Scripts in your Android Studio project. This screenshot highlights the app module's `build.gradle` file:



1: Project
Android
Project Files
Problems
app
Gradle Scripts
build.gradle (Project: LiferayGuestbook)
build.gradle (Module: app)
gradle-wrapper.properties (Gradle Version)

Figure 76.2: The app module's `build.gradle` file.

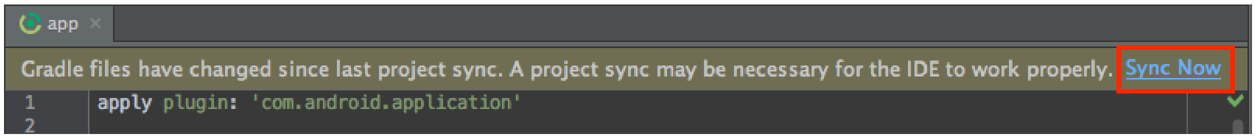
In the app module's `build.gradle` file, add the following line of code inside the `dependencies` element:

```
implementation 'com.liferay.mobile:liferay-screens:+'
```

Note that the `+` symbol tells Gradle to install the newest version of Screens. If your app relies on a specific version of Screens, you can replace the `+` symbol with that version.

If you're not sure where to add the above lines, see the below screenshot.

Once you edit `build.gradle`, a message appears at the top of the file that asks you to *sync* your app with its Gradle files. Syncing the Gradle files incorporates the changes you make to them. Syncing also downloads and installs any new dependencies, like the Liferay Screens dependency that you just added. Sync the Gradle files now by clicking the *Sync Now* link in the message. The following screenshot shows the top of an edited `build.gradle` file with the Sync Now link highlighted by a red box:



Gradle files have changed since last project sync. A project sync may be necessary for the IDE to work properly.

```
apply plugin: 'com.android.application'
```

Figure 76.3: After editing the app module's `build.gradle` file, click *Sync Now* to incorporate the changes in your app.

In the case of conflict with the `appcompat-v7` or other support libraries (`com.android.support:appcompat-v7`, `com.android.support:support-v4`), you have several options:

- Explicitly add the versions of the conflicting libraries you want to use. For example:

  ```
  implementation 'com.android.support:design:27.0.2'
  implementation 'com.android.support:support-media-compat:27.0.2'
  implementation 'com.android.support:exifinterface:27.0.2'
  ```

- Remove the `com.android.support:appcompat-v7` dependency from your project and use the one embedded in Liferay Screens.
- Exclude the problematic library from Liferay Screens. For example:

  ```
  implementation ('com.liferay.mobile:liferay-screens:+') {
      exclude group: 'com.android.support:', module: 'design'
  }
  ```

- Ignore the inspection, adding a comment like this:

  ```
  //noinspection GradleCompatible
  ```

- Ignore the warning–Liferay Screens will work without problems.

Although we strongly recommend that you use Gradle to install Screens, the following section shows you how to install Screens with Maven.

Using Maven to Install Liferay Screens

Note that we strongly recommend that you use Gradle to install Screens. It's possible though to use Maven to install Screens. Follow these steps to configure Liferay Screens in a Maven project:

1. Add the following dependency to your `pom.xml`:

   ```
   <dependency>
       <groupId>com.liferay.mobile</groupId>
       <artifactId>liferay-screens</artifactId>
       <version>LATEST</version>
   </dependency>
   ```

2. Force a Maven update to download all the dependencies.

If Maven doesn't automatically locate the artifact, you must add jCenter as a new repository in your maven settings (e.g., `.m2/settings.xml` file):

```
<profiles>
    <profile>
        <repositories>
            <repository>
                <id>bintray-liferay-liferay-mobile</id>
                <name>bintray</name>
                <url>http://dl.bintray.com/liferay/liferay-mobile</url>
            </repository>
        </repositories>
        <pluginRepositories>
```

```
            <pluginRepository>
                <id>bintray-liferay-liferay-mobile</id>
                <name>bintray-plugins</name>
                <url>http://dl.bintray.com/liferay/liferay-mobile</url>
            </pluginRepository>
        </pluginRepositories>
        <id>bintray</id>
    </profile>
</profiles>
<activeProfiles>
    <activeProfile>bintray</activeProfile>
</activeProfiles>
```

Nice work!

Manual Configuration in Gradle

Although we strongly recommend that you use Gradle to install Screens automatically, it's possible to use Gradle to install Screens manually. Follow these steps to use Gradle to install Screens and its dependencies manually in your Android project:

1. Download the latest version of Liferay Screens for Android.

2. Copy the contents of `Android/library` into a folder outside your project.

3. In your project, configure a `settings.gradle` file with the paths to the library folders:

   ```
   include ':core'
   project(':core').projectDir = new File(settingsDir, '../../library/core')
   project(':core').name = 'liferay-screens'
   ```

4. Include the required dependencies in your `build.gradle` file:

   ```
   implementation project(':liferay-screens')
   ```

You can also configure the `.aar` binary files (in `Android/dist`) as local `.aar` file dependencies. You can download all necessary files from jCenter.

To check your configuration, you can compile and execute a blank activity and import a Liferay Screens class (like Login Screenlet).

Next, you'll set up communication with Liferay DXP.

Configuring Communication with Liferay DXP

Before using Liferay Screens, you must configure it to communicate with your Liferay DXP instance. To do this, you must provide Screens the following information:

- Your Liferay DXP instance's ID

- The ID of the site your app needs to communicate with

- Your Liferay DXP instance's version

- Any other information required by specific Screenlets

Fortunately, this is straightforward. In your Android project's res/values folder, create a new file called `server_context.xml`. Add the following code to the new file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <!-- Change these values for your Liferay DXP installation -->

    <string name="liferay_server">http://10.0.2.2:8080</string>

    <string name="liferay_company_id">10155</string>
    <string name="liferay_group_id">10182</string>

    <integer name="liferay_portal_version">70</integer>

</resources>
```

As the above comment indicates, make sure to change these values to match your Liferay DXP instance. The server address `http://10.0.2.2:8080` is suitable for testing with Android Studio's emulator, because it corresponds to `localhost:8080` through the emulator. If you're using the Genymotion emulator, you should, however, use address `192.168.56.1` instead of `localhost`.

The `liferay_company_id` value is your Liferay DXP instance's ID. You can find it in your Liferay DXP instance at *Control Panel* → *Configuration* → *Virtual Instances*. The instance's ID is in the *Instance ID* column. Copy and paste this value into the `liferay_company_id` value in `server_context.xml`.

The `liferay_group_id` value is the ID of the site your app needs to communicate with. To find this value, first go to the site in your Liferay DXP instance that you want your app to communicate with. In the *Site Administration* menu, select *Configuration* → *Site Settings*. The site ID is listed at the top of the *General* tab. Copy and paste this value into the `liferay_group_id` value in `server_context.xml`.

The `liferay_portal_version` value `70` tells Screens that it's communicating with a Liferay CE Portal 7.0 or Liferay DXP 7.0 instance. Here are the supported `liferay_portal_version` values and the portal versions they correspond to:

- `71`: Liferay CE Portal 7.1 or Liferay DXP 7.1
- `70`: Liferay CE Portal 7.0 or Liferay DXP 7.0
- `62`: Liferay Portal 6.2 CE/EE

You can also configure Screenlet properties in your `server_context.xml` file. The example properties listed below, `liferay_recordset_id` and `liferay_recordset_fields`, enable DDL Form Screenlet and DDL List Screenlet to interact with a Liferay DXP instance's DDLs. You can see an additional example `server_context.xml` file here.

```
<!-- Change these values for your Liferay DXP installation -->

<string name="liferay_recordset_id">20935</string>
<string name="liferay_recordset_fields">Title</string>
```

Super! Your Android project's ready for Liferay Screens.

Example Apps

As you use Screens to develop your apps, you may want to refer to some example apps that also use it. There are two demo applications available:

- test-app: A showcase app containing all the currently available Screenlets.

- Westeros Bank: An example app that uses Screenlets to manage technical issues for the *Westeros Bank*. It's also available in Google Play.

Great! Now you're ready to put Screens to use. The following tutorials show you how to do this.

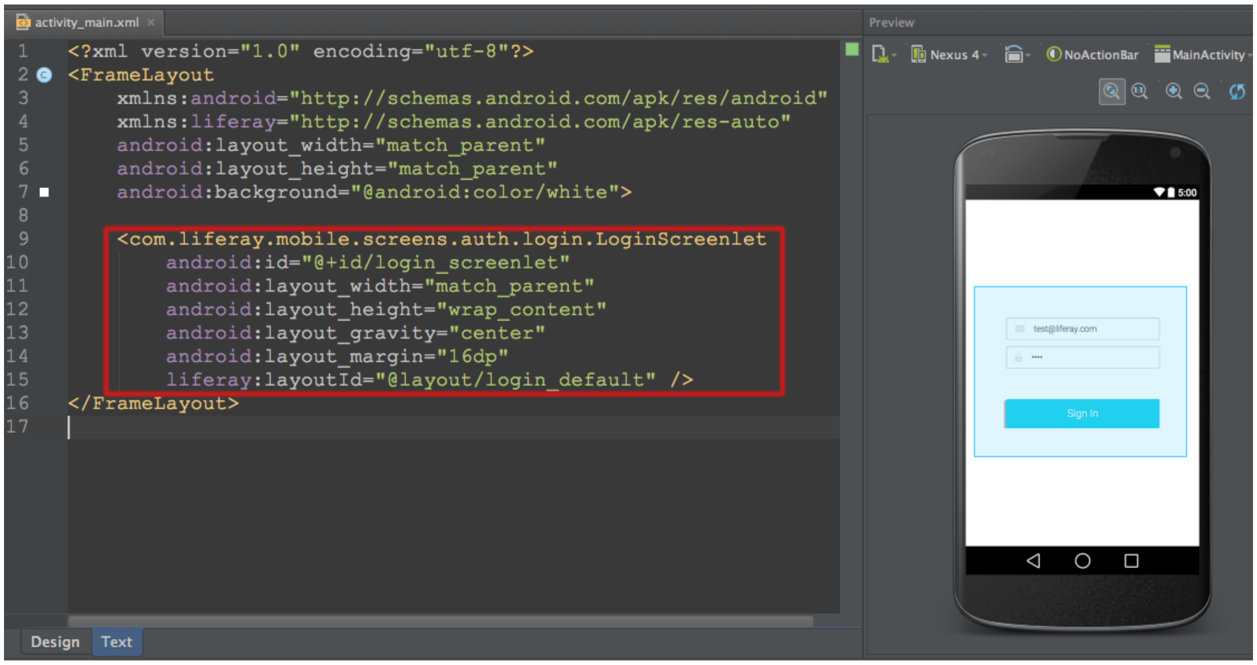
76.2 Using Screenlets in Android Apps

You can start using Screenlets once you've prepared your project to use Liferay Screens. There are plenty of Liferay Screenlets available and they're described in the Screenlet reference documentation. It is very straightforward to use Screenlets. This tutorial shows you how to insert Screenlets into your android app and configure them. You'll be a Screenlet master in no time!

First, in Android Studio's visual layout editor or your favorite editor, open your app's layout XML file and insert the Screenlet in your activity or fragment layout. The following screenshot, for example, shows the Login Screenlet inserted in an activity's `FrameLayout`.



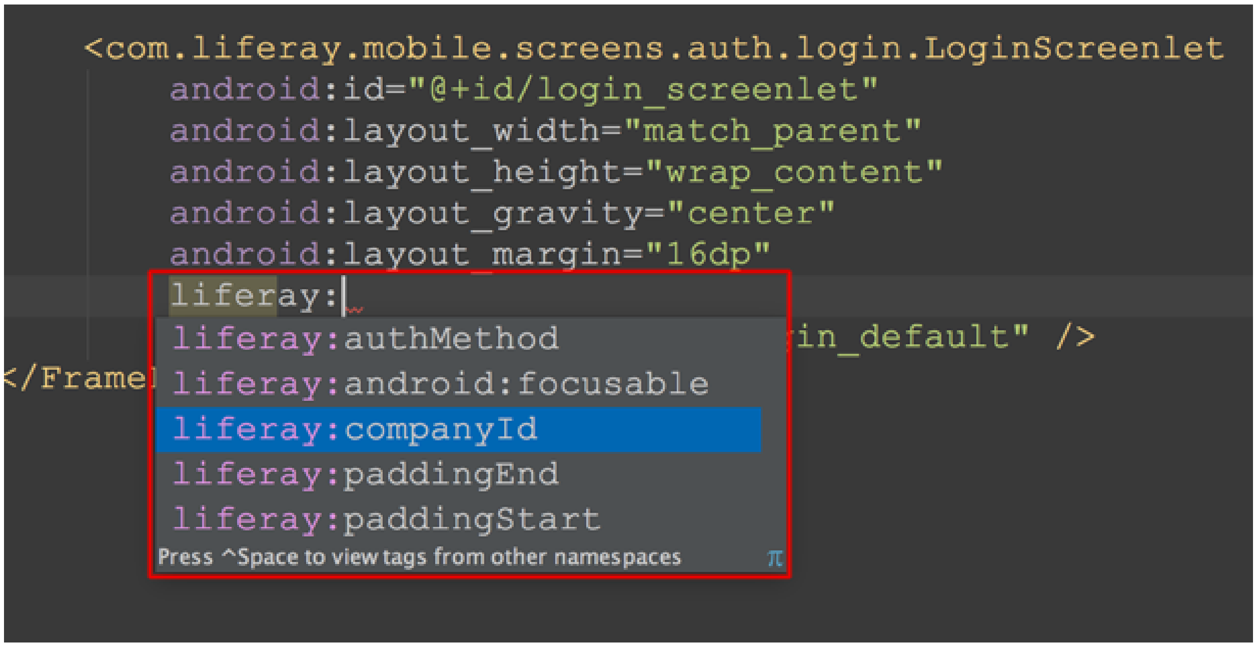
```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout
    xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:liferay="http://schemas.android.com/apk/res-auto"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    android:background="@android:color/white">

    <com.liferay.mobile.screens.auth.login.LoginScreenlet
        android:id="@+id/login_screenlet"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:layout_margin="16dp"
        liferay:layoutId="@layout/login_default" />
</FrameLayout>
```

Figure 76.4: Here's the Login Screenlet in an activity's layout in Android Studio.

Next, set the Screenlet's attributes. If it's a Liferay Screenlet, refer to the Screenlet reference documentation to learn the Screenlet's required and supported attributes. This screenshot shows the attributes of the Login Screenlet being set:

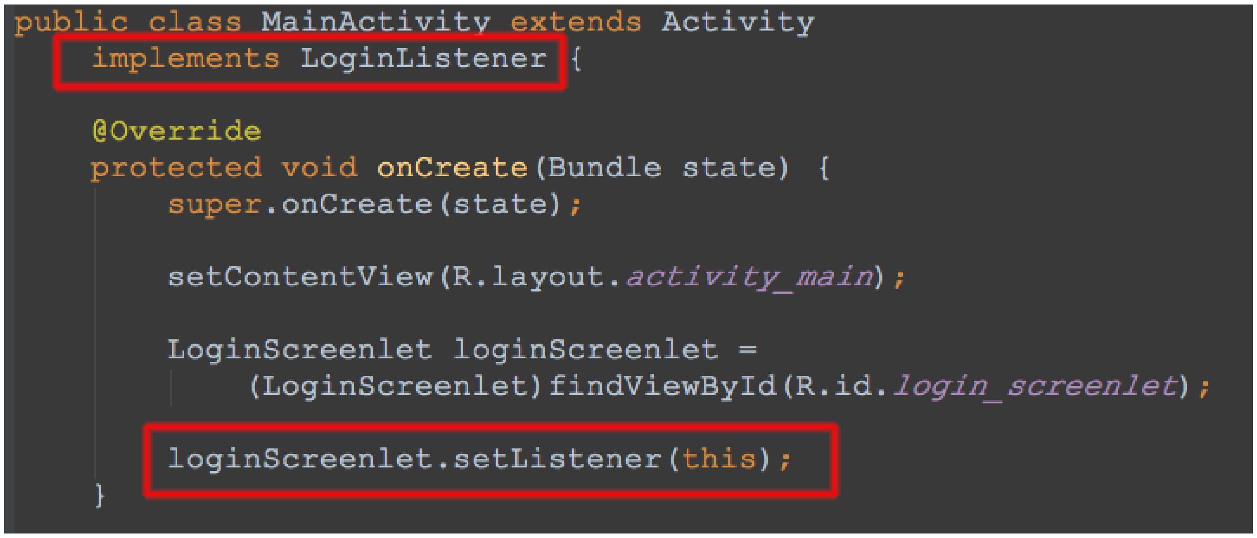
To configure your app to listen for events the Screenlet triggers, implement the Screenlet's listener interface in your activity or fragment class. Refer to the Screenlet's documentation to learn its listener



```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:layout_gravity="center"
    android:layout_margin="16dp"
    liferay:
    liferay:authMethod                      in_default" />
</Frame liferay:android:focusable
    liferay:companyId
    liferay:paddingEnd
    liferay:paddingStart
    Press ^Space to view tags from other namespaces
```

Figure 76.5: You can set a Screenlet's attributes via the app's layout XML file.

interface. Then register your activity or fragment as the Screenlet's listener. The activity class, for example, in the screenshot below, declares that it implements the Login Screenlet's `LoginListener` interface, and it registers itself to listen for the Screenlet's events.



```
public class MainActivity extends Activity
    implements LoginListener {

    @Override
    protected void onCreate(Bundle state) {
        super.onCreate(state);

        setContentView(R.layout.activity_main);

        LoginScreenlet loginScreenlet =
            (LoginScreenlet)findViewById(R.id.login_screenlet);

        loginScreenlet.setListener(this);
    }
```

Figure 76.6: Implement the Screenlet's listener in your activity or fragment class.

Make sure to implement all methods required by the Screenlet's listener interface. For Liferay's Screenlets, the listener methods are listed in each Screenlet's reference documentation. That's all there is to it! Awesome! Now you know how to use Screenlets in your Android apps.

Using Views in Android Screenlets
Creating Android Screenlets
Using Screenlets in iOS apps

76.3 Using Views in Android Screenlets

You can use a Liferay Screens *View* to set a Screenlet's look and feel independent of the Screenlet's core functionality. Liferay's Screenlets come with several Views, and more are being developed by Liferay and the community. The Screenlet reference documentation lists the Views available for each Screenlet included with Screens. This tutorial shows you how to use Views in Android Screenlets. It's straightforward; you'll master using Views in no time!

Views and View Sets

Before using Views, you should know what components make them up. Note that what follows is a simple description, sufficient for learning how to use different Views. For a detailed description of the View layer in Liferay Screens, see the tutorial Architecture of Liferay Screens for Android.

A View consists of the following items:

Screenlet class: A Java class that coordinates and implements the Screenlet's functionality. The Screenlet class contains attributes for configuring the Screenlet's behavior, a reference to the Screenlet's View class, methods for invoking server operations, and more.

View class: A Java class that implements a View's behavior. This class usually listens for the UI components' events.

Layout: An XML file that defines a View's UI components. The View class is usually this file's root element. To use a View, you must specify its layout in the Screenlet XML (you'll see an example of this shortly).

Note that because it contains a Screenlet class and a specific set of UI components, a View can only be used with one particular Screenlet. For example, the Default View for Login Screenlet can only be used with Login Screenlet. Multiple Views for several Screenlets can be combined into a *View Set*. A View Set typically implements a similar look and feel for several Screenlets. This lets an app use a View Set to present a cohesive look and feel. For example, the Bank of Westeros sample app uses the Westeros View Set's Views with several Screenlets to present the red and white motif you can see here on Google Play. Liferay Screens for Android comes with the Default View Set, but Liferay makes additional View Sets, like Material and Westeros, available in jCenter. Anyone can create View Sets and publish them in public repositories like Maven Central and jCenter.

To install View Sets besides Default, add them as dependencies in your project. The `build.gradle` file code snippet below specifies the Material and Westeros View Sets as dependencies:

```
dependencies {
    ...
    implementation 'com.liferay.mobile:liferay-material-viewset:+'
    implementation 'com.liferay.mobile:liferay-westeros-viewset:+'
    ...
}
```

Here are the View Sets that Liferay currently provides for Screens:

Default: Comes standard with a Screenlet. It's used by a Screenlet if no layout ID is specified or if no View is found with the layout ID. The Default Views can be used as parent Views for your custom Views. Refer to the architecture tutorial for more details.

Material: Demonstrates Views built from scratch. It follows Google's Material Design guidelines. Refer to the View creation tutorial for instructions on creating your own Views.

Westeros: Customizes the behavior and appearance of the Westeros Bank demo app.

Now that you know about Views and View Sets, you're ready to put them to use!

Using Views

To use a View in a Screenlet, specify the View's layout as the `liferay:layoutId` attribute's value when inserting the Screenlet XML in an activity or fragment layout. For example, to use Login Screenlet with its Material View, insert the Screenlet's XML with `liferay:layoutId` set to `@layout/login_material`:

```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    liferay:layoutId="@layout/login_material"
    />
```

The following links list the View layouts available in each View Set:

- Default
- Material
- Westeros

If the View you want to use is part of a View Set, your app or activity's theme must also inherit the theme that defines that View Set's styles. For example, the following code in an app's `res/values/styles.xml` tells `AppTheme.NoActionBar` to use the Material View Set as its parent theme:

```
<resources>

    <style name="AppTheme.NoActionBar" parent="material_theme">
        <item name="colorPrimary">@color/colorPrimary</item>
        <item name="colorPrimaryDark">@color/colorPrimaryDark</item>
        <item name="colorAccent">@color/colorAccent</item>

        <item name="windowActionBar">false</item>
        <item name="windowNoTitle">true</item>
    </style>
    ...
</resources>
```

To use the Default or Westeros View Set, inherit `default_theme` or `westeros_theme`, respectively.

That's it! Great! Now you know how to use Views to spruce up your Android Screenlets. This opens up a world of possibilities, like writing your own Views.

Creating Android Views

Architecture of Liferay Screens for Android

Using Themes in iOS Screenlets

76.4 Using Offline Mode in Android

Offline mode in Liferay Screens lets your apps function when connectivity is unavailable or intermittent. Even though the steady march of technology makes connections more stable and prevalent, there are still plenty of places the Internet has trouble reaching. Areas with complex terrain, including cities with large buildings, often lack stable connections. Remote areas typically don't have connections at all. Using Screens's offline mode in your apps gives your users flexibility in these situations.

This tutorial shows you how to use offline mode in Screenlets. For an explanation of how offline mode works, see the tutorial Architecture of Offline Mode in Liferay Screens. Offline mode's architecture is the same on iOS and Android, although its use on these platforms differs.

Configuring Screenlets for Offline Mode

If you want to enable offline mode in any of your screenlets, you must configure the `offlinePolicy` attribute when inserting the Screenlet's XML in a layout. This attribute can take four possible values:

- `REMOTE_ONLY`
- `CACHE_ONLY`
- `REMOTE_FIRST`
- `CACHE_FIRST`

For a description of these values, see the section Using Policies with Offline Mode in the offline mode architecture tutorial. Note that each Screenlet behaves a bit differently with offline mode. For specific details, see the Screenlet reference documentation.

Handling Synchronization

Under some scenarios, values stored in the local cache need to be synchronized with the portal. To do this, you need to use the `CacheSyncService` class. This class sends information from the local cache to the portal. To register `CacheSyncService` with your app, you must add the following code to your `AndroidManifest.xml` file:

```
<receiver android:name=".CacheReceiver">
    <intent-filter>
        <action android:name="com.liferay.mobile.screens.auth.login.success"/>
        <action android:name="com.liferay.mobile.screens.cache.resync"/>
        <action android:name="android.net.conn.CONNECTIVITY_CHANGE"/>
    </intent-filter>
</receiver>

<service
    android:name=".CacheSyncService"
    android:exported="false"/>
```

This code registers the `CacheReceiver` and `CacheSyncService` components. The `CacheReceiver` is invoked in the following scenarios:

- When a connectivity change occurs (for example, when the network connection is restored).
- When Login Screenlet successfully completes the login.
- When a specific resync intent is broadcasted. In this case, use `context.sendBroadcast(new Intent("com.liferay.mobile.screens.cache.resync"));`.

The `CacheSyncService` performs the synchronization process when invoked from the above receiver. This is currently an unassisted process. Future versions will include some kind of control mechanism.

76.5 Architecture of Liferay Screens for Android

Liferay Screens applies architectural ideas from Model View Presenter, Model View ViewModel, and VIPER. Screens isn't considered a canonical implementation of these architectures, because it isn't an app, but it borrows from them to separate presentation layers from business-logic. This tutorial explains Screen's high-level architecture, its components' low-level architecture, and the Android Screenlet lifecycle. Now go ahead and get started examining Screens's building blocks!

High-Level Architecture

Liferay Screens for Android is composed of a Core, a Screenlet layer, a View layer, Interactors, and Server Connectors. Interactors are technically part of the core, but are worth covering separately. They facilitate interaction with both local and remote data sources, as well as communication between the Screenlet layer and the Liferay Mobile SDK.

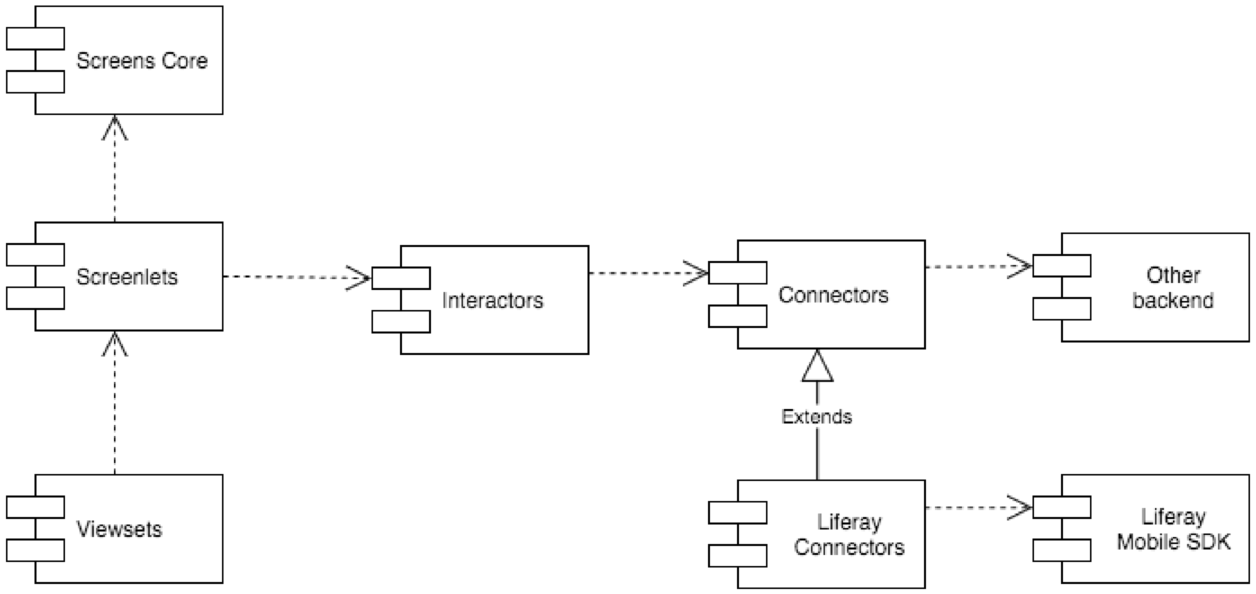

Figure 76.7: Here are the high-level components of Liferay Screens for Android. The dashed arrow connectors represent a "uses" relationship, in which a component uses the component its pointing to.

Each component is described below.

Core: includes all the base classes for developing other Screens components. It's a micro-framework that lets developers write their own Screenlets, Views, and Interactors.

Screenlets: Java view classes for inserting into any activity or fragment view hierarchy. They render a selected layout in the runtime and in Android Studio's visual editor and react to UI events, sending any necessary server requests. You can set a Screenlet's properties from its layout XML file and Java classes. The Screenlets bundled with Liferay Screens are known collectively as the Screenlet Library.

Server Connectors: a collection of classes that interact with different Liferay DXP versions. These classes abstract away the complexity of communicating with different versions. This allows the developer to call API methods and the correct Interactor without worrying about the specific Liferay DXP version.

Interactors: implement specific use cases for communicating with servers. They can use local and remote data sources. Most Interactors use the Liferay Mobile SDK to exchange data with a Liferay instance. If a user action or use case needs to execute more than one query on a local or remote store, the sequence is done in the corresponding Interactor. If a Screenlet supports more than one user action or use case, an Interactor must be created for each. Interactors are typically bound to one specific Liferay version, and instantiated by a Server Connector. Interactors run in a background thread and can therefore perform intensive operations without blocking the UI thread.

Views: a set of layouts and accompanying custom view classes that present Screenlets to the user.

Next, the core layer is described in detail.

Core Layer

The core layer is the micro-framework that lets developers write Screenlets in a structured and isolated way. All Screenlets share a common structure based on the core classes, but each Screenlet can have a unique purpose and communication API.

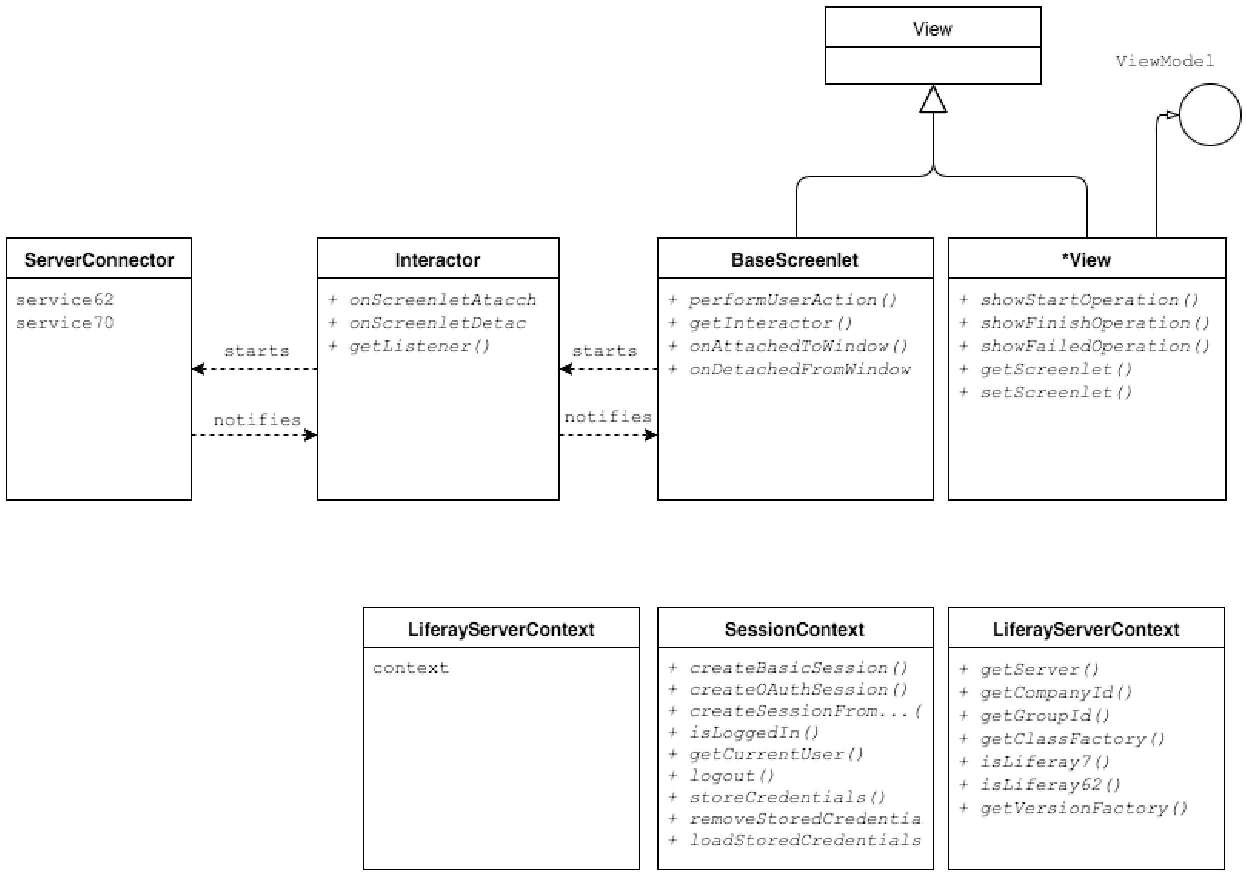

Figure 76.8: Here's the core layer of Liferay Screens for Android.

Here are the core's main components:

Interactor: the base class for all Liferay Portal interactions and use cases that a Screenlet supports. Interactors call services through the Liferay Mobile SDK and receive responses asynchronously through the EventBus, eventually changing a View's state. Their actions can vary in complexity, from performing simple algorithms to requesting data asynchronously from a server or database. A Screenlet can have multiple Interactors, each dedicated to supporting a specific operation.

BaseScreenlet: the base class for all Screenlet classes. It receives user events from a Screenlet's View, instantiates and calls the Interactors, and then updates the View with operation results. Classes that extend it can override its template methods:

- *createScreenletView:* typically inflates the Screenlet's View and gets the attribute values from the XML definition.
- *createInteractor:* instantiates an Interactor for the specified action. If a Screenlet only supports one Interactor type then that type of Interactor is always instantiated.
- *onUserAction:* runs the Interactor associated with the specified action.

Screenlet View: implements the Screenlet's UI. It's instantiated by the Screenlet's `createScreenletView` method. It renders a specific UI using standard layout files and updates the UI with data changes. When developing your own Views that extend a parent View, you can read the parent Screenlet's properties or call its methods from this class.

EventBus: notifies the Interactor when asynchronous operations complete. It decouples the `AsyncTask` class instance from the activity life cycle, to avoid problems typically associated with `AsyncTask` instances.

Liferay Mobile SDK: calls a Liferay instance's remote services in a type-safe and transparent way.

SessionContext: a singleton class that holds the logged in user's session. Apps can use an implicit login, invisible to the user, or a login that relies on explicit user input to create the session. User logins can be implemented with the Login Screenlet. This is explained in detail here.

LiferayServerContext: a singleton object that holds server configuration parameters. It's loaded from the `server_context.xml` file, or from any other XML file that overrides the keys defined in the `server_context.xml`.

server_context.xml: specifies the default server, `companyId` (Liferay instance ID) and `groupId` (site ID). You can also configure other Screens parameters in this file, such as the current Liferay version (with the attribute `liferay_portal_version`) or an alternative `ServiceVersionFactory` to access custom backends.

LiferayScreensContext: a singleton object that holds a reference to the application context. It's used internally where necessary.

ServiceVersionFactory: an interface that defines all the server operations supported in Liferay Screens. This is created and accessed through a `ServiceProvider` that creates the Server Connectors needed to interact with a specific Liferay version. The `ServiceVersionFactory` is an implementation of an Abstract Factory pattern.

Now that you know what makes up the core layer, you're ready to learn the Screenlet layer's details.

Screenlet Layer

The Screenlet layer contains the Screenlets available in Liferay Screens for Android. The following diagram uses Screenlet classes prefixed with *MyScreenlet* to show the Screenlet layer's relationship with the core, View, and Interactor components.

Screenlets are comprised of several Java classes and an XML descriptor file:

MyScreenletViewModel: an interface that defines the attributes shown in the UI. It typically accounts for all the input and output values presented to the user. For instance, `LoginViewModel` includes attributes like the user name and password. The Screenlet can read the attribute values, invoke Interactor operations, and change these values based on operation results.

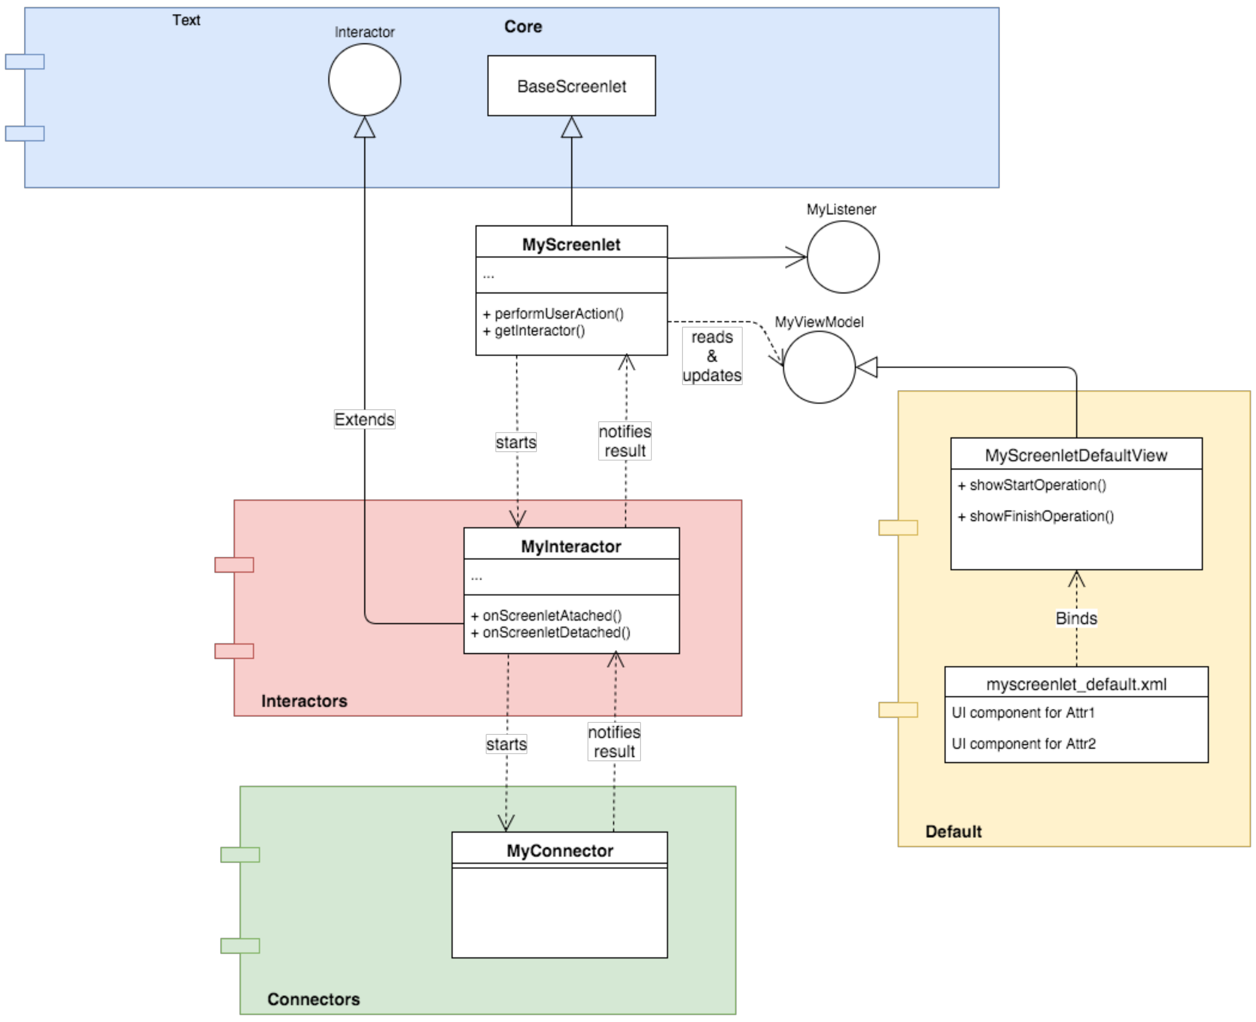

Figure 76.9: This diagram illustrates the Android Screenlet layer's relationship to other Screens components.

MyScreenlet: a class that represents the Screenlet component the app developer interacts with. It includes the following things:

- Attribute fields for configuring the Screenlet's behavior. They are read in the Screenlet's `createScreenletView` method and their default values can optionally be set there too.
- A reference to the Screenlet's View, specified by the `liferay:layoutId` attribute's value. Note: a View must implement the Screenlet's `ViewModel` interface.
- Any number of methods for invoking Interactor operations. You can optionally make them public for app developers to call. They can also handle UI events received in the view class through a regular listener (such as Android's `OnClickListener`) or events forwarded to the Screenlet via the `performUserAction` method.
- An optional (but recommended) listener object for the Screenlet to call on a particular event.

MyScreenletInteractor: implements an end-to-end use case that communicates with a server or consumes a Liferay service. It might perform several intermediate steps. For example, it might send a request to a server, compute a local value based on the response, and then send this value to a different server. On completing an interaction, the Interactor must notify its listeners, one of which is typically the Screenlet class instance. The number of Interactors a Screenlet requires depends on the number of server use cases it supports. For example, the Login Screenlet class only supports one use case (log in the user), so it has only one Interactor. The DDL Forms Screenlet class, however, supports several use cases (load the form, load a record, submit the form, etc.), so it uses a different Interactor class for each use case.

MyScreenletConnector62 and **MyScreenletConnector70**: the classes that create the Interactors required to communicate with a specific Liferay version. The `ServiceProvider` creates a singleton `ServiceVersionFactory` that returns the right Connector.

MyScreenletDefaultView: a class that renders the Screenlet's UI with the default layout. The class in Figure 3, for example, belongs to the Default View set. The View object and the layout file communicate using standard mechanisms, like a `findViewById` method or a listener object. User actions are received by a specified listener (for example, `OnClickListener`) and then passed to the Screenlet object via the `performUserAction` method.

myscreenlet_default.xml: an XML file that specifies how to render the Screenlet's View. Here's a skeleton of a Screenlet's layout XML file:

```
<?xml version="1.0" encoding="utf-8"?>
<com.your.package.MyScreenletView
    xmlns:android="http://schemas.android.com/apk/res/android">

    <!-- Put your regular components here: EditText, Button, etc. -->

</com.your.package.MyScreenletView>
```

Refer to the tutorial Creating Android Screenlets for more Screenlet details. Next, the View layer's details are described.

View Layer

The View layer lets developers set a Screenlet's look and feel. Each Screenlet's `liferay:layoutId` attribute specifies its View. A View consists of a Screenlet class, view class, and layout XML file. The layout XML file specifies the UI components, while the Screenlet class and view class control the View's behavior. By inheriting one or more of these View layer components from another View, the different View *types* allow varying levels of control over a Screenlet's UI design and behavior.

There are several different View types:

Themed: presents the same structure as the current View, but alters the theme colors and tints of the View's resources. All existing Views can be themed with different styles. The View's colors reflect the current value of the Android color palette. If you want to use one View Set with another View Set's colors, you can use those colors in your app's theme (e.g. `colorPrimary_default`, `colorPrimary_material`, `colorPrimary_westeros`).

Child: presents the same behavior and UI components as its parent, but can change the UI components' appearance and position. A Child View specifies visual changes in its own layout XML file; it inherits the parent's view class and Screenlet class. It can't add or remove any UI components. The parent must be a Full View. Creating a Child View is ideal when you only need to make visual changes to an existing View. For example, you might create a Child View for Login Screenlet's Default View to set new positions and sizes for the standard text boxes.

Extended: inherits the parent View's behavior and appearance, but lets you change and add to both. You can do so by creating a custom view class and a new layout XML file. An Extended View inherits all the parent View's other classes, including its Screenlet, listeners, and Interactors; if you need to customize any of them, you must create a Full View to do so. An Extended View's parent must be a Full View. Creating an Extended View is ideal for adding, removing, or changing an existing View's UI components. For example, you can extend the Login Screenlet's Default View to present different UI components for the user name and password fields.

Full: provides a complete standalone View. It doesn't inherit another View's UI components or behavior. When creating a Full View, you must therefore create its Screenlet class, view class, and layout XML file. You should create a Full View when you don't need to inherit another View or when you need to alter the core behavior of a Screenlet by customizing its listeners or calling custom Interactors. For example, you could implement a Full View with a new Interactor for calling a different Liferay Portal instance. Default Views are Full Views.

Liferay Screens Views are organized into *View sets* that contain Views for several Screenlets. Liferay's available View sets are listed here:

- *Default:* a mandatory View Set supplied by Liferay. It's used by a Screenlet if no layout ID is specified or if no View is found with the layout ID. The Default View Set uses a neutral, flat white and blue design with standard UI components. In the Login Screenlet, for example, the Default View uses standard text boxes for the user name and password, but the text boxes are styled with the Default View's flat white and blue design. You can customize this View Set's properties, such as its components' colors, positions, and sizes. See the Default View Set's `styles.xml` file for specific values. Since the Default View Set contains Full Views, you can use them to create your own custom Child and Extended Views.

- *Material:* the View Set containing Views that conform to Android's Material design guidelines.

- *Westeros:* the View Set containing Views for the Bank of Westeros sample app.

For information on creating or customizing Views, see the tutorial Creating Android Views.

Great! Now you know how Liferay Screens for Android is composed. However, there's something you should know before moving on: how Screenlets interact with the Android life cycle.

Screenlet Lifecycle

Liferay Screens automatically saves and restores Screenlets' states using the Android SDK methods `onSaveInstanceState` and `onRestoreInstanceState`. Each Screenlet uses a uniquely generated identifier (`screenletId`) to assign action results to action sources.

The Screenlets' states are restored after the `onCreate` and `onStart` methods, as specified by the standard Android lifecycle. It's a best practice to execute Screenlet methods inside the activity's `onResume` method; this helps assure that actions and tasks find their destinations.

Awesome! Now you know the nitty gritty architectural details of Liferay Screens for Android. Let this tutorial be a resource for you as you work with Liferay Screens.

76.6 Architecture of Offline Mode in Liferay Screens

Mobile users may encounter difficulty getting or maintaining a network connection at certain locations or times of day. Using offline mode with Screenlets ensures that your app still functions in these situations.

You should note, however, that some difficulties may arise when using an app offline. For example, allowing users to edit data in an app when they're offline may cause synchronization conflicts with the portal when they reconnect. By detailing how offline mode is implemented in Liferay Screens, this tutorial helps you be aware of such difficulties and know how to handle them.

Understanding Offline Mode's Basics

Screenlets in Liferay Screens support the following phases:

1. Get information from the portal.
2. Show information to the user.
3. Collect the user's input (if necessary).
4. Send input to the portal (if necessary).

The following diagram summarizes these phases:

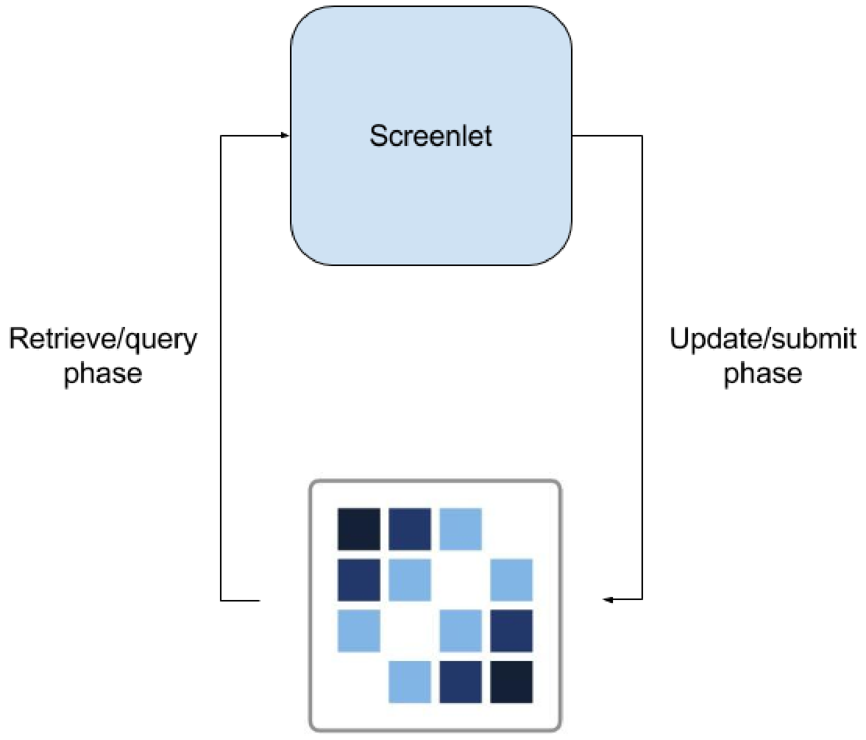

Figure 76.10: A Screenlet's basic phases when requesting and submitting data to the portal.

Note that not all Screenlets need to execute each phase. For example, the Web Content Display Screenlet only needs to retrieve and display portal content. Conversely, Login Screenlet and Sign Up Screenlet only need to handle user input. Only the most complex Screenlets, like the DDL Form Screenlet and the User Portrait Screenlet, need to do both.

So what does all this have to do with offline mode? Liferay Screens's offline infrastructure is a small layer of code that intercepts information going to and coming from the portal. It stores this information in a local data store for use when there's no Internet connection. The following diagram illustrates this, with *Local cache* representing the local data store:

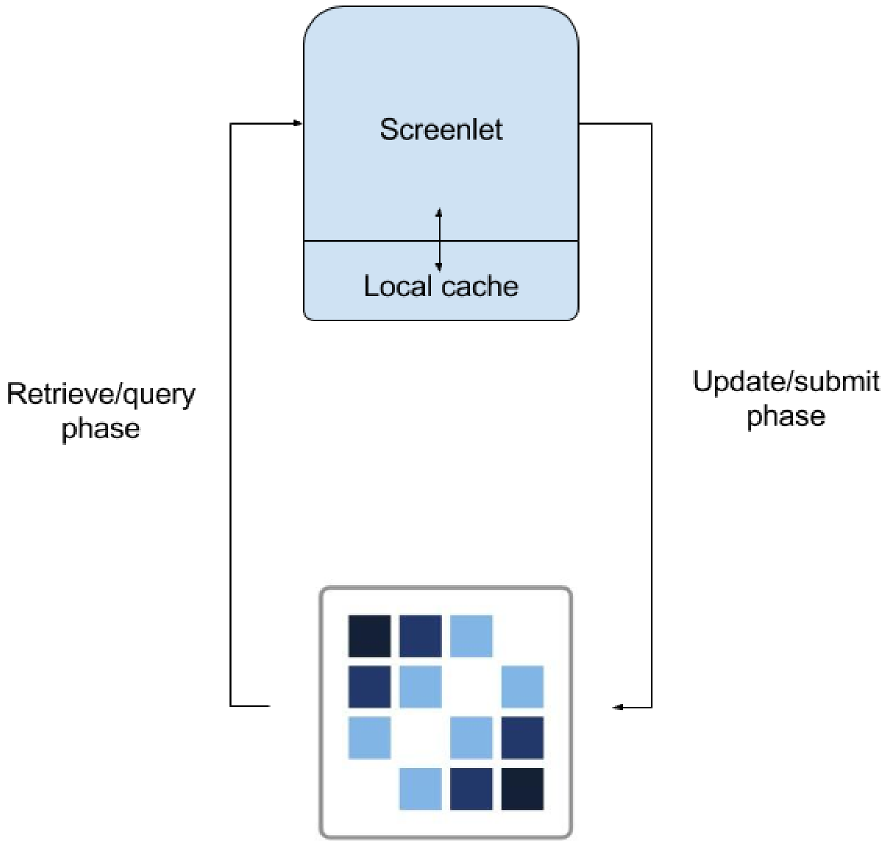

Figure 76.11: This is the same diagram as before, with the addition of the local cache for offline mode.

With offline mode enabled, any Screenlet can persist information exchanged with the portal. You can also configure exactly how offline mode works with the Screenlet you're using. You do this through *policies*.

Using Policies with Offline Mode

Policies configure how a Screenlet behaves with offline mode when it sends or receives data. The Screenlet adheres to the policy even if the data operation fails. Screenlets support the following policies:

remote-only: The Screenlet only uses network connections to load data. Screenlets functioned this way prior to the introduction of offline mode. Use this policy when you want the Screenlet always to use remote content. Your app won't work, however, if a network connection is unavailable. Also, apps using this policy tend to be slower due to network lag. Note that if the request succeeds, the Screenlet stores the data in the local cache for later use.

cache-only: The Screenlet only uses local storage to load data (it doesn't use the network connection). Use this policy when you want the Screenlet to always use offline content. Note that in the app's local cache, some portal data may not exist or may be outdated.

remote-first: The Screenlet first tries to use the network connection to load data. If this fails, it then tries to load data from local storage. Use this policy when you want the Screenlet to use the latest portal data when there's a connection, but also want to support a fallback mechanism when the connection is gone. Note that the Screenlet may use outdated information when there's no connection. In many cases, however, this is better than showing your users no information at all.

cache-first: The Screenlet first tries to load data from local storage. If this fails, it then tries to use the network connection. Use this policy when you want the Screenlet to optimize performance and network efficiency. You can update data in a background process, or let the user update on-demand (via an option, for example). Note that while the information retrieved from local storage may be outdated, loading times and bandwidth consumption are typically lower.

These policies behave a bit differently depending on the data's direction. In other words, when a Screenlet set to a specific policy retrieves information from the portal, it may behave differently than when it submits information to the portal. As an example, consider the possible scenarios for User Portrait Screenlet:

- When loading the portrait:
  - **remote-only:** The Screenlet always attempts to load the portrait from the portal. If the request fails, the operation also fails.
  - **cache-only**: The Screenlet always attempts to load the portrait from the local cache. The operation fails if the portrait doesn't exist there.
  - **remote-first:** The Screenlet first attempts to load the portrait from the portal. If the request succeeds, the Screenlet stores the portrait locally for later use. If the request fails, the Screenlet tries to load the portrait from the local cache. If the local cache doesn't contain the portrait, the Screenlet can't load it, and calls the standard error handling code (call the delegate, use the default placeholder, etc...).
  - **cache-first:** The Screenlet first attempts to load the portrait from the local cache. If the portrait doesn't exist there, it's then requested from the server.
- When submitting the portrait:
  - **remote-only:** The Screenlet first sends the new portrait to the portal. If the submission succeeds, the Screenlet also stores the portrait in the local cache. If the submission fails, the operation also fails.
  - **cache-only**: The Screenlet only stores the portrait locally. The portrait may be loaded from the cache later, or synchronized with the portal.
  - **remote-first:** The Screenlet first tries to send the new portrait to the portal. If this fails due to lack of network connectivity, the Screenlet stores the portrait in the local cache for later synchronization with the portal.
  - **cache-first:** The screenlet first stores the new portrait locally, then sends it to the portal. If the submission fails, the Screenlet still stores the portrait locally, but the send operation fails.

Understanding Synchronization

Synchronization can be a tricky problem to solve. What initially seems straightforward quickly evolves into scenarios where you're not sure which version of the data to use. Having offline users complicates things further. The following diagram illustrates how the Screenlet retrieves and stores portal data.

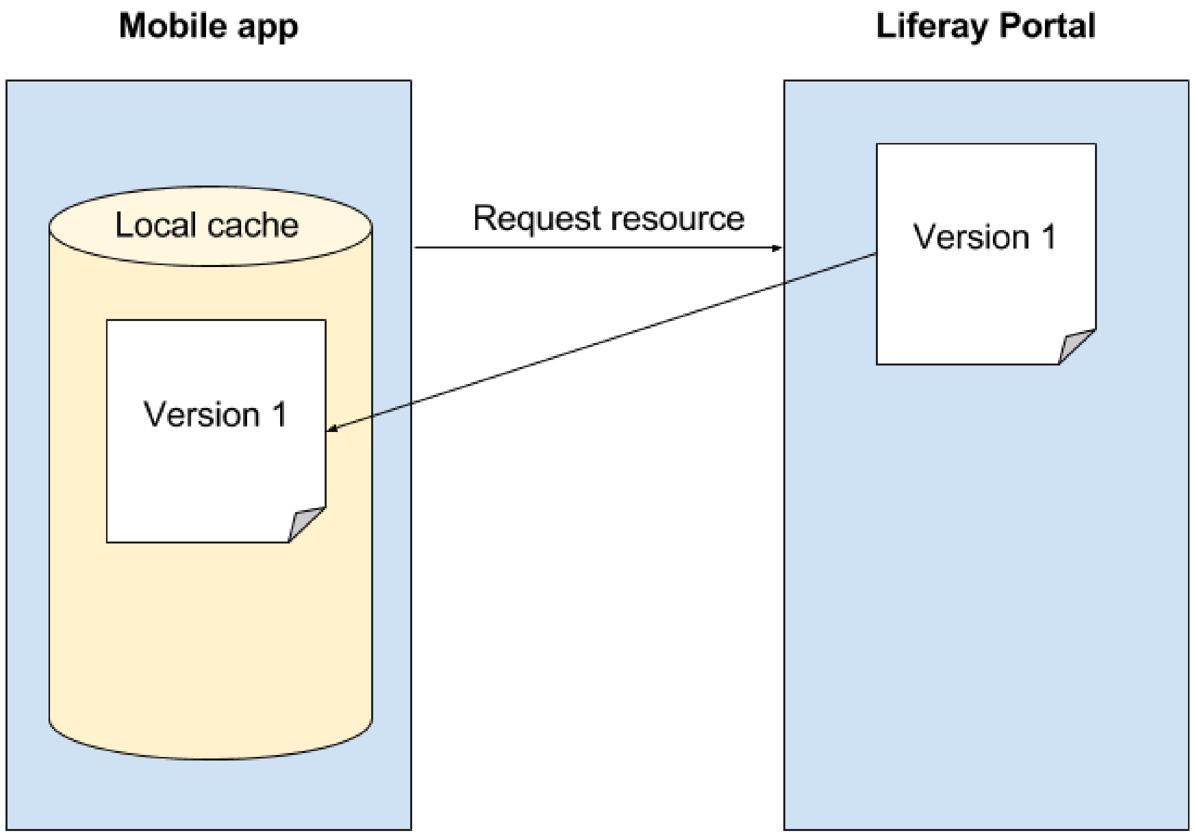

Figure 76.12: The Screenlet requests the resource from the portal and stores it in the app's local cache.

When a user edits the data in the app, the Screenlet needs to send the new data to the portal. But what happens if the user is offline? In this case, the new data can't reach the portal and the local and portal data are out-of-sync. In this scenario, the app has the new data while the portal has the old data. The app's data in this synchronization state is called the *dirty version*. Put away your soap and washcloth. We don't recommend giving your mobile device a bath. In this context, dirty means that the data should be synchronized with the portal as soon as possible. When the Screenlet synchronizes the dirty version, it removes the dirty flag from the local data.

There are other complicated synchronization states. For example, portal data may change while out-of-sync with a Screenlet's local data. To avoid data loss, the local data can't overwrite the portal data, and vice versa. In this situation, the synchronization process produces a conflict when it runs. The following diagram illustrates this.

The developer needs to resolve the conflict by choosing the local data or portal data. Synchronization conflicts have four possible resolutions:

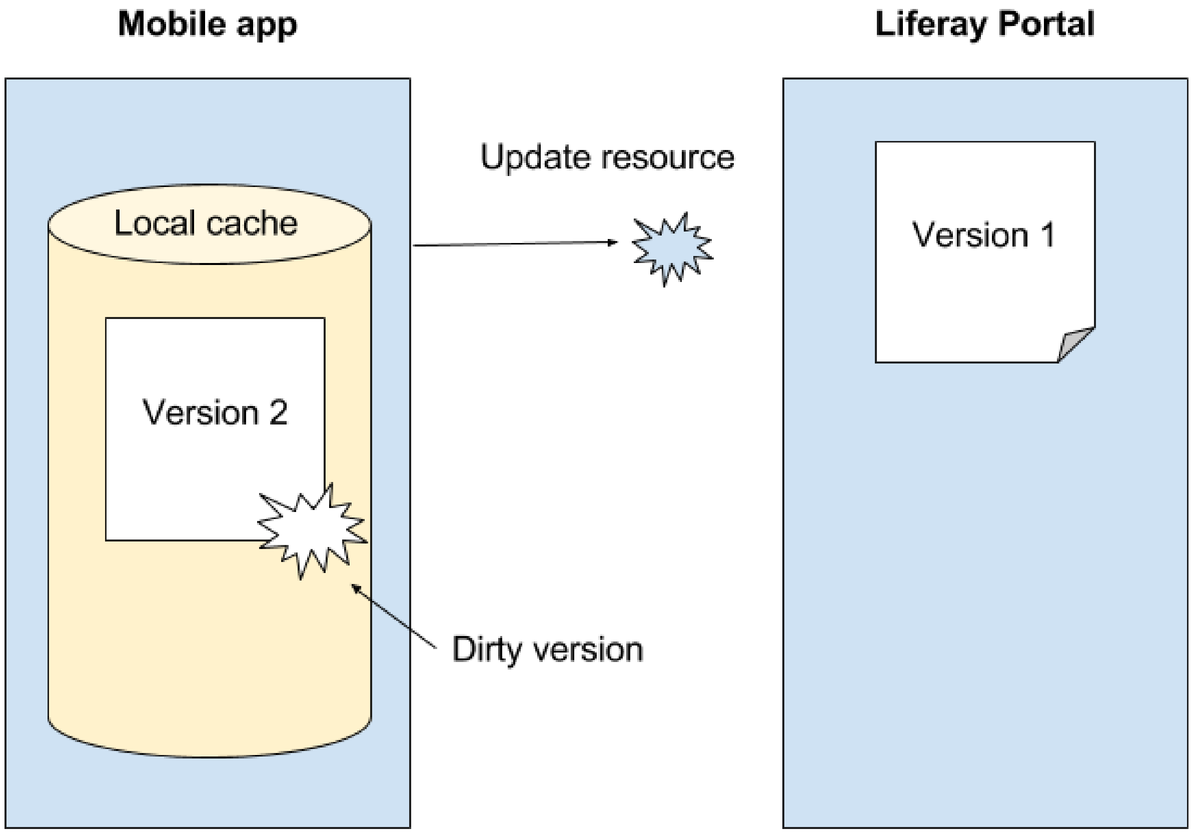

Figure 76.13: The updated data is said to be dirty when the Screenlet can't send it to the portal.

1. **Keep the local version:** The Screenlet overwrites the portal data with the local data. This results in the local cache and the portal having the same version of the data (Version 2 in the above diagram).

2. **Keep remote version:** The Screenlet overwrites the local data with the portal data. This results in the local cache and the portal having the same version of the data (Version 3 in the above diagram).

3. **Discard:** The Screenlet removes the local data, and the portal data isn't overwritten.

4. **Ignore:** The Screenlet doesn't change any data. The next synchronization event reproduces the conflict.

Great! Now that you know how offline mode works, you're ready to put it to use.

76.7 Creating Android Screenlets

The Screenlets that come with Liferay Screens cover common use cases for mobile apps that use Liferay. They authenticate users, interact with Dynamic Data Lists, view assets, and more. However, what if there's no Screenlet for *your* specific use case? No sweat! You can create your own. Extensibility is a key strength of Liferay Screens.

This tutorial explains how to create your own Screenlets. As an example, it references code from the sample Add Bookmark Screenlet, that saves bookmarks to Liferay's Bookmarks portlet.

In general, you use the following steps to create Screenlets:

1. Determine your Screenlet's location. Where you create your Screenlet depends on how you'll use it.

2. Create the Screenlet's UI (its View). Although this tutorial presents all the information you need to create a View for your Screenlet, you may first want to learn how to create a View. For more information on Views in general, see the tutorial on using Views with Screenlets.

3. Create the Screenlet's Interactor. Interactors are Screenlet components that make server calls.

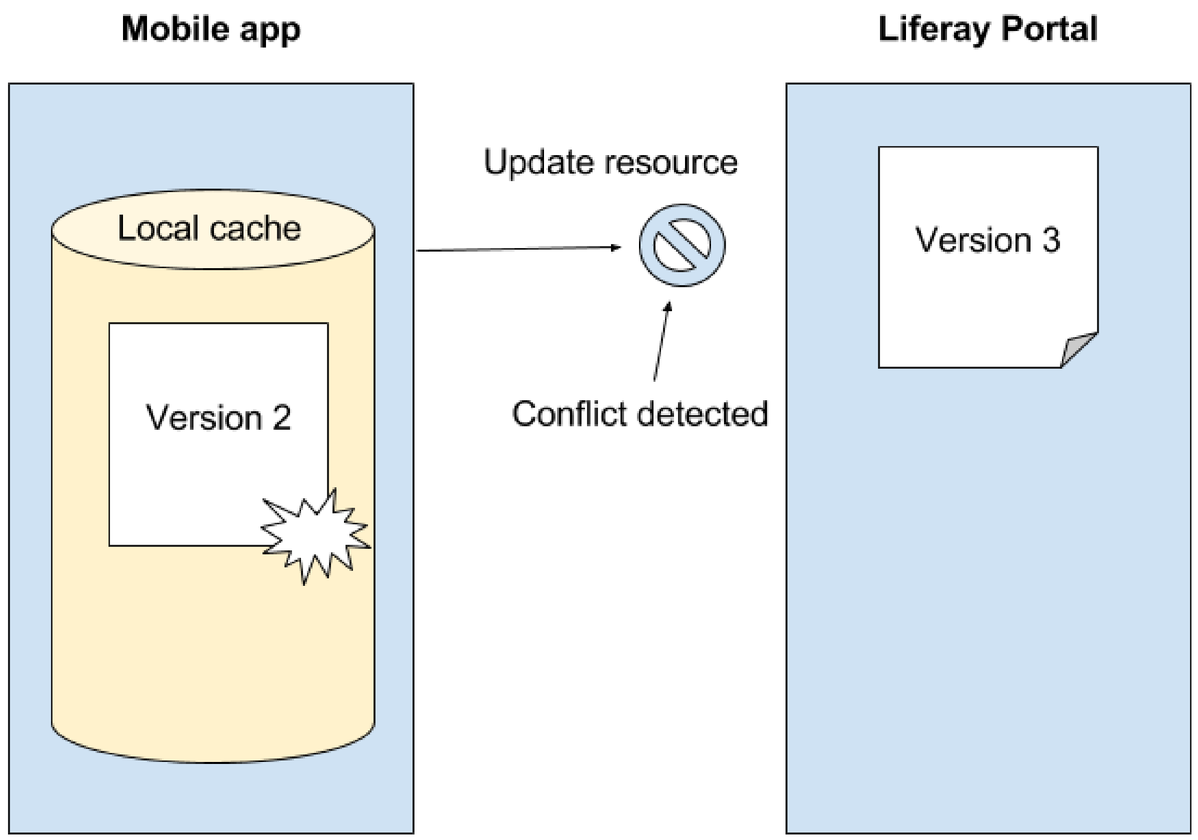

Figure 76.15: Users have changed the data independently in the app and in the portal, causing a synchronization conflict.

4. Define the Screenlet's attributes. These are the XML attributes the app developer can set when inserting the Screenlet's XML. These attributes control aspects of the Screenlet's behavior. You'll add functionality to these attributes in the Screenlet class.
5. Create the Screenlet class. The Screenlet class is the Screenlet's central component. It controls the Screenlet's behavior and is the component the app developer interacts with when inserting a Screenlet.

To understand the components that make up a Screenlet, you should first learn the architecture of Liferay Screens for Android.

Without further ado, let the Screenlet creation begin!

Determining Your Screenlet's Location

Where you should create your Screenlet depends on how you plan to use it. If you don't plan to reuse your Screenlet in another app or don't want to redistribute it, create it in a new package inside your Android app project. This lets you reference and access Liferay Screens's core, in addition to all the View Sets you may have imported.

If you want to reuse your Screenlet in another app, create it in a new Android application module. The tutorial Packaging Android Screenlets explains how to do this. When your Screenlet's project is in place, you can start by creating the Screenlet's UI.

Creating the Screenlet's UI

In Liferay Screens for Android, Screenlet UIs are called Views. Every Screenlet must have at least one View. A View consists of the following components:

- The View Model interface: defines the methods the View needs to update the UI.
- A layout XML file: defines the UI components that the View presents to the end user.
- A View class: renders the UI, handles user interactions, and communicates with the Screenlet class. The View class implements the View Model interface.
- The Screenlet class: Although technically part of a View, the Screenlet class depends on all the other Screenlet components. You therefore won't create the Screenlet class until the end of this tutorial.

The first items to create for a Screenlet's View are its View Model interface and layout. The following steps explain how:

1. To define the methods that every Screenlet's View class must implement, Screens provides the `BaseViewModel` interface. Your View Model interface should extend `BaseViewModel` to define any additional methods needed by your Screenlet. This includes any getters and setters for the attributes you want to use.

   For example, Add Bookmark Screenlet needs attributes for each bookmark's URL and title. Its View Model interface, `AddBookmarkViewModel`, therefore, defines getters and setters for these attributes:

   ```
   public interface AddBookmarkViewModel extends BaseViewModel {
       String getURL();

       void setURL(String value);

       String getTitle();

       void setTitle(String value);
   }
   ```

2. Define your Screenlet's UI by writing a standard Android layout XML file. The layout's root element should be the fully qualified class name of your Screenlet's View class. You'll create that class in the next step, but determine its name now and name the layout's root element after it. Finally, add any UI elements your View needs.

   For example, Add Bookmark Screenlet's layout needs two text fields: one for entering a bookmark's URL and one for entering its title. The layout also needs a button for saving the bookmark. The Screenlet defines this UI in its `bookmark_default.xml` layout file:

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <com.your.package.AddBookmarkView
       xmlns:android="http://schemas.android.com/apk/res/android"
       style="@style/default_screenlet">

       <EditText
           android:id="@+id/url"
           android:layout_width="match_parent"
           android:layout_height="wrap_content"
           android:layout_marginBottom="15dp"
           android:hint="URL Address"
           android:inputType="textUri"/>
   ```

```
    <EditText
        android:id="@+id/title"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="15dp"
        android:hint="Title"/>

    <Button
        android:id="@+id/add_button"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="Add Bookmark"/>

</com.your.package.AddBookmarkView>
```

Next, you'll create your Screenlet's View class.

Creating the Screenlet's View Class

Your Screenlet needs a View class to support the layout you just created. This class must extend an Android layout class (e.g. `LinearLayout`, `ListView`), implement your View Model interface, and implement a separate listener interface to handle user actions. Follow these steps to create this View class:

1. Create a View class that extends the Android layout class appropriate for your Screenlet's UI. For example, Add Bookmark Screenlet renders its UI components in a single column, so its View class (`AddBookmarkView`) extends Android's `LinearLayout`. Your View class's constructors should call the parent layout class's constructors. For example, `AddBookmarkView`'s constructors call those of `LinearLayout`:

```
public AddBookmarkView(Context context) {
    super(context);
}

public AddBookmarkView(Context context, AttributeSet attributes) {
    super(context, attributes);
}

public AddBookmarkView(Context context, AttributeSet attributes, int defaultStyle) {
    super(context, attributes, defaultStyle);
}
```

2. Add instance variables for your View Model's attributes and `BaseScreenlet`. For example, Add Bookmark Screenlet needs instance variables for a bookmark's URL and title. Because all Screenlet classes extend the `BaseScreenlet` class, a `BaseScreenlet` variable in your View class ensures that your View always has a reference to the Screenlet. For example, here are `AddBookmarkView`'s instance variables:

```
private EditText urlText;
private EditText titleText;
private BaseScreenlet screenlet;
```

3. Implement your View Model interface. Implement your View Model's getter and setter methods to get and set the inner value of each component, respectively. For example, here's `AddBookmarkView`'s implementation of `AddBookmarkViewModel`:

```
public String getURL() {
    return urlText.getText().toString();
}

public void setURL(String value) {
    urlText.setText(value);
}

public String getTitle() {
    return titleText.getText().toString();
}

public void setTitle(String value) {
    titleText.setText(value);
}
```

4. Implement a listener interface to handle user actions in the Screenlet. For example, Add Bookmark Screenlet must detect when the user presses the save button. The `AddBookmarkView` class enables this by implementing Android's `View.OnClickListener` interface, which defines a single method: `onClick`. The Screenlet's `onClick` implementation gets a reference to the Screenlet and calls its `performUserAction()` method (you'll create `performUserAction()` in the Screenlet class shortly):

```
public void onClick(View v) {
    AddBookmarkScreenlet screenlet = (AddBookmarkScreenlet) getParent();

    screenlet.performUserAction();
}
```

You can set the listener to the appropriate UI element by implementing an `onFinishInflate()` method. This method should also retrieve and assign any other UI elements from your layout. For example, the `onFinishInflate()` implementation in `AddBookmarkView` retrieves the URL and title attributes from the layout, and sets them to the `urlText` and `titleText` variables, respectively. This method then retrieves the button from the layout and sets this View class as the button's click listener:

```
protected void onFinishInflate() {
    super.onFinishInflate();

    urlText = (EditText) findViewById(R.id.url);
    titleText = (EditText) findViewById(R.id.title_bookmark);

    Button addButton = (Button) findViewById(R.id.add_button);
    addButton.setOnClickListener(this);
}
```

5. Implement the `BaseViewModel` interface's methods: `showStartOperation`, `showFinishOperation`, `showFailedOperation`, `getScreenlet`, and `setScreenlet`. In the `show*Operation` methods, you can log what happens in your Screenlet when the server operation starts, finishes successfully, or fails, respectively. In the `getScreenlet` and `setScreenlet` methods, you must get and set the `BaseScreenlet` variable, respectively. This ensures that the View always has a Screenlet reference. For example, Add Bookmark Screenlet implements these methods as follows:

```
@Override
public void showStartOperation(String actionName) {

}

@Override
```

```
public void showFinishOperation(String actionName) {
    LiferayLogger.i("Add bookmark successful");
}

@Override
public void showFailedOperation(String actionName, Exception e) {
    LiferayLogger.e("Could not add bookmark", e);
}

@Override
public BaseScreenlet getScreenlet() {
    return screenlet;
}

@Override
public void setScreenlet(BaseScreenlet screenlet) {
    this.screenlet = screenlet;
}
```

Note that although you must implement the `show[something]Operation` methods, you can leave their implementations empty if you don't need to take any specific action.

Click here to see the complete example `AddBookmarkView` class.
Great! Your View class is finished. Now you're ready to create your Screenlet's Interactor class.

Creating the Screenlet's Interactor

A Screenlet's Interactor makes the service call to retrieve the data you need from a Liferay instance. An Interactor is made up of several components:

1. The event class. This class lets you handle communication between the Screenlet's components via event objects that contain the server call's results. Screens uses the EventBus library for this. Screens supplies the `BasicEvent` class and `BaseListEvent` class for communicating `JSONObject` and `JSONArray` results within Screenlets, respectively. You can create your own event classes by extending `BasicEvent`. You should create your own event classes when you must communicate objects other than `JSONObject` or `JSONArray`. The example Add Bookmark Screenlet only needs to communicate `JSONObject` instances, so it uses `BasicEvent`.

2. The listener interface. This defines the methods the app developer needs to respond to the Screenlet's behavior. For example, Login Screenlet's listener defines the `onLoginSuccess` and `onLoginFailure` methods. Screens calls these methods when login succeeds or fails, respectively. By implementing these methods in the activity or fragment class that contains the Screenlet, the app developer can respond to login success and failure. Similarly, the example Add Bookmark Screenlet's listener interface defines two methods: one for responding to the Screenlet's failure to add a bookmark and one for responding to its success to add a bookmark:

   ```
    public interface AddBookmarkListener {

        void onAddBookmarkFailure(Exception exception);

        void onAddBookmarkSuccess();
    }
   ```

3. The Interactor class. This class must extend Screens's `BaseRemoteInteractor` with your listener and event as type arguments. The listener lets the Interactor class send the server call's results to any

classes that implement the listener. In the implementation of the method that makes the server call, the execute method, you must use the Mobile SDK to make an asynchronous service call. This means you must get a session and then make the server call. You make the server call by creating an instance of the Mobile SDK service (e.g., BookmarksEntryService) that can call the Liferay service you need and then making the call. The Interactor class must also process the event object that contains the call's results and then notify the listener of those results. You do this by implementing the onSuccess and onFailure methods to invoke the corresponding getListener() methods.

For example, the AddBookmarkInteractor class is Add Bookmark Screenlet's Interactor class. This class implements the execute method, which adds a bookmark to a folder in a Liferay instance's Bookmarks portlet. This method first validates the bookmark's URL and folder. It then calls the getJSONObject method to add the bookmark, and concludes by returning a new BasicEvent object created from the JSONObject. The if statement in the getJSONObject method checks the Liferay version so it can create the appropriate BookmarksEntryService instance needed to make the server call. Regardless of the Liferay version, the getSession() method retrieves the existing session created by Login Screenlet upon successful login. The session's addEntry method makes the server call. The Screenlet calls the onSuccess or onFailure method to notify the listener of the server call's success or failure, respectively. In either case, the BasicEvent object contains the server call's results. Since this Screenlet doesn't retrieve anything from the server, however, there's no need to process the BasicEvent object in the onSuccess method; calling the listener's onAddBookmarkSuccess method is sufficient. Here's the complete code for AddBookmarkInteractor:

```
public class AddBookmarkInteractor extends BaseRemoteInteractor<AddBookmarkListener, BasicEvent> {

    @Override
    public BasicEvent execute(Object[] args) throws Exception {
        String url = (String) args[0];
        String title = (String) args[1];
        long folderId = (long) args[2];

        validate(url, folderId);

        JSONObject jsonObject = getJSONObject(url, title, folderId);
        return new BasicEvent(jsonObject);
    }

    @Override
    public void onSuccess(BasicEvent event) throws Exception {
        getListener().onAddBookmarkSuccess();
    }

    @Override
    public void onFailure(BasicEvent event) {
        getListener().onAddBookmarkFailure(event.getException());
    }

    private void validate(String url, long folderId) {
        if (url == null || url.isEmpty() || !URLUtil.isValidUrl(url)) {
            throw new IllegalArgumentException("Invalid url");
        } else if (folderId == 0) {
            throw new IllegalArgumentException("folderId not set");
        }
    }

    @NonNull
    private JSONObject getJSONObject(String url, String title, long folderId) throws Exception {
        if (LiferayServerContext.isLiferay7()) {
            return new BookmarksEntryService(getSession()).addEntry(LiferayServerContext.getGroupId(),
                folderId, title, url, "", null);
        } else {
            return new com.liferay.mobile.android.v62.bookmarksentry.BookmarksEntryService(
                getSession()).addEntry(LiferayServerContext.getGroupId(), folderId, title, url, "", null);
        }
    }
}
```

Sweetness! Your Screenlet's Interactor is done. Next, you'll create the Screenlet class.

Defining Screenlet Attributes in Your App

Before creating the Screenlet class, you should define its attributes. These are the attributes the app developer can set when inserting the Screenlet's XML in an activity or fragment layout. For example, to use Login Screenlet, the app developer could insert the following Login Screenlet XML in an activity or fragment layout:

```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:basicAuthMethod="email"
    app:layoutId="@layout/login_default"
    />
```

The app developer can set the `liferay` attributes `basicAuthMethod` and `layoutId` to set Login Screenlet's authentication method and View, respectively. The Screenlet class reads these settings to enable the appropriate functionality.

When creating a Screenlet, you can define the attributes you want to make available to app developers. You do this in an XML file inside your Android project's `res/values` directory. For example, Add Bookmark Screenlet's attributes are defined in the Screenlet's `bookmark_attrs.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <declare-styleable name="AddBookmarkScreenlet">
        <attr name="layoutId"/>
        <attr name="folderId"/>
        <attr name="defaultTitle" format="string"/>
    </declare-styleable>
</resources>
```

This defines the attributes `layoutId`, `folderId`, and `defaultTitle`. Add Bookmark Screenlet's Screenlet class adds functionality to these attributes. Here's a brief description of what each does:

- `layoutId`: Sets the View that displays the Screenlet. This functions the same as the `layoutId` attribute in Liferay's existing Screenlets.
- `folderId`: Sets the folder ID in the Bookmarks portlet where the Screenlet adds bookmarks.
- `defaultTitle`: Sets each Bookmark's default title.

Now that you've defined your Screenlet's attributes, you're ready to create the Screenlet class.

Creating the Screenlet Class

The Screenlet class is the central hub of a Screenlet. It contains attributes for configuring the Screenlet's behavior, a reference to the Screenlet's View, methods for invoking Interactor operations, and more. When using a Screenlet, app developers primarily interact with its Screenlet class. In other words, if a Screenlet were to become self-aware, it would happen in its Screenlet class (though we're reasonably confident this won't happen).

To make all this possible, your Screenlet class must implement the Interactor's listener interface and extend Screens's `BaseScreenlet` class with the View Model interface and Interactor class as type arguments. Your Screenlet class should also contain instance variables and accompanying getters and setters for the listener and any other attributes that the app developer needs to access. For constructors, you can call `BaseScreenlet`'s constructors.

For example, Add Bookmark Screenlet's Screenlet class extends `BaseScreenlet<AddBookmarkViewModel, AddBookmarkInteractor>` and implements `AddBookmarkListener`. It also contains instance variables for `AddBookmarkListener` and the bookmark's folder ID, and getters and setters for these variables. Also note the constructors call `BaseScreenlet`'s constructors:

```
public class AddBookmarkScreenlet extends
    BaseScreenlet<AddBookmarkViewModel, AddBookmarkInteractor>
    implements AddBookmarkListener {

    private long folderId;
    private AddBookmarkListener listener;

    public AddBookmarkScreenlet(Context context) {
        super(context);
    }

    public AddBookmarkScreenlet(Context context, AttributeSet attributes) {
        super(context, attributes);
    }

    public AddBookmarkScreenlet(Context context, AttributeSet attributes, int defaultStyle) {
        super(context, attributes, defaultStyle);
    }

    public long getFolderId() {
        return folderId;
    }

    public void setFolderId(long folderId) {
        this.folderId = folderId;
    }

    public AddBookmarkListener getListener() {
        return listener;
    }

    public void setListener(AddBookmarkListener listener) {
        this.listener = listener;
    }

    ...
```

Next, implement the Screenlet's listener methods. This lets the Screenlet class receive the server call's results and thus act as the listener. These methods should communicate the server call's results to the View (via the View Model) and any other listener instances (via the Screenlet class's listener instance). For example, here are Add Bookmark Screenlet's listener method implementations:

```
public void onAddBookmarkSuccess() {
    getViewModel().showFinishOperation(null);

    if (listener ≠ null) {
        listener.onAddBookmarkSuccess();
    }
}

public void onAddBookmarkFailure(Exception e) {
    getViewModel().showFailedOperation(null, e);

    if (listener ≠ null) {
        listener.onAddBookmarkFailure(e);
    }
}
```

These methods are called when the server call succeeds or fails, respectively. They first use `getViewModel()` to get a View Model instance and then call the `BaseViewModel` methods `showFinishOperation` and `showFailedOperation` to send the server call's results to the View. The `showFinishOperation` call sends `null` because a successful server call to add a bookmark doesn't return any objects. If a successful server call in your Screenlet returns any objects you need to display, then you should send them in this `showFinishOperation` call. The `showFailedOperation` call sends the `Exception` that results from a failed server call to the View. This lets you display an informative error to the user. The `onAddBookmarkSuccess` and `onAddBookmarkFailure` implementations then call the listener instance's method of the same name. This sends the server call's results to any other classes that implement the listener interface, such as the activity or fragment that uses the Screenlet.

Next, you must implement `BaseScreenlet`'s abstract methods:

- `createScreenletView`: Reads the app developer's Screenlet attribute settings, and inflates the View. You'll use an Android `TypedArray` to retrieve the attribute settings. You should set the attribute values to the appropriate variables, and set any default values you need to display via a View Model reference.

  For example, Add Bookmark Screenlet's `createScreenletView` method gets the app developer's attribute settings via a `TypedArray`. This includes the `layoutId`, `defaultTitle`, and `folderId` attributes. The `layoutId` is used to inflate a View reference (`view`), which is then cast to a View Model instance (`viewModel`). The View Model instance's `setTitle` method is then called with `defaultTitle` to set the bookmark's default title. The method concludes by returning the View reference.

  ```
  @Override
  protected View createScreenletView(Context context, AttributeSet attributes) {
      TypedArray typedArray = context.getTheme()
          .obtainStyledAttributes(attributes, R.styleable.AddBookmarkScreenlet, 0, 0);

      int layoutId = typedArray.getResourceId(R.styleable.AddBookmarkScreenlet_layoutId, 0);

      View view = LayoutInflater.from(context).inflate(layoutId, null);

      String defaultTitle = typedArray.getString(R.styleable.AddBookmarkScreenlet_defaultTitle);

      folderId = castToLong(typedArray.getString(R.styleable.AddBookmarkScreenlet_folderId));

      typedArray.recycle();

      AddBookmarkViewModel viewModel = (AddBookmarkViewModel) view;
      viewModel.setTitle(defaultTitle);

      return view;
  }
  ```

- createInteractor: Instantiates the Screenlet's Interactor. For example, Add Bookmark Screenlet's createInteractor method calls the AddBookmarkInteractor constructor to create a new instance of this Interactor:

  ```
  @Override
  protected AddBookmarkInteractor createInteractor(String actionName) {
      return new AddBookmarkInteractor(getScreenletId());
  }
  ```

- onUserAction: Retrieves any data the user has entered in the View, and starts the Screenlet's server operation via an Interactor instance. If your Screenlet doesn't take user input, this method only needs to do the latter.

  The example Add Bookmark Screenlet takes user input (the bookmark's URL and title), so its onUserAction method must retrieve this data. This method does so via a View Model instance it retrieves with the getViewModel() method. The onUserAction method starts the server operation by calling the Interactor's start method with the user input. Note that the Interactor inherits the start method from the BaseInteractor class. Invoking the start method causes the Interactor's execute method to run in a background thread:

  ```
  @Override
  protected void onUserAction(String userActionName, AddBookmarkInteractor interactor, Object... args) {
      AddBookmarkViewModel viewModel = getViewModel();
      String url = viewModel.getURL();
      String title = viewModel.getTitle();

      interactor.start(url, title, folderId);
  }
  ```

Nice! Your Screenlet is finished! You can now use it the same way you would any other. If you created your Screenlet in its own project, you can also package and distribute it via the Screens project, JCenter, or Maven Central.

To finish the Add Bookmark Screenlet example, the following section shows you how to use this Screenlet. It also shows how you can set default attribute values in an app's server_context.xml file. Although you may not need to do this when using your Screenlets, it might come in handy on your way to becoming a master of Screenlets.

Using Your Screenlet

To use any Screenlet, you must follow these general steps:

1. Insert the Screenlet's XML in the activity or fragment layout you want the Screenlet to appear in. You can fine-tune the Screenlet's behavior by setting the Screenlet XML's attributes.

2. Implement the Screenlet's listener in the activity or fragment class.

As an example of this, the Liferay Screens Test App uses Add Bookmark Screenlet. You can find the following Add Bookmark Screenlet XML in the Test App's add_bookmark.xml layout:

```
<com.liferay.mobile.screens.bookmark.AddBookmarkScreenlet
    android:id="@+id/bookmark_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:folderId="@string/bookmark_folder"
    app:layoutId="@layout/bookmark_default" />
```

Note that the layout specified by `app:layoutId` (`bookmark_default`) matches the layout file of the Screenlet's View (`bookmark_default.xml`). This is how you specify the View that displays your Screenlet. For example, if Add Bookmark Screenlet had another View defined in a layout file named `bookmark_awesome.xml`, you could use that layout by specifying `@layout/bookmark_awesome` as the `app:layoutId` attribute's value.

Also note that the `app:folderId` attribute specifies `@string/bookmark_folder` as the bookmark folder's ID. This is an alternative way of specifying an attribute's value. Instead of specifying the value directly, the Test App specifies the value in its `server_context.xml` file:

```
...
<string name="bookmark_folder">20622</string>
...
```

This `name` attribute's value, `bookmark_folder` is then used in the Screenlet XML to set the `app:folderId` attribute to `20622`.

Great! Now you know how to use the Screenlets you create. You also know a convenient way to specify default values for a Screenlet's attributes.

76.8 Creating Android List Screenlets

It's very common for mobile apps to display lists. Liferay Screens lets you display asset lists and DDL lists in your Android app by using Asset List Screenlet and DDL List Screenlet, respectively. Screens also includes list Screenlets for displaying lists of other Liferay entities like web content articles, images, and more. The Screenlet reference documentation lists all the Screenlets included with Liferay Screens. If there's not a list Screenlet for the entity you want to display in a list, you must create your own. A list Screenlet can display any entity from a Liferay instance. For example, you can create a list Screenlet that displays standard Liferay entities like `User`, or custom entities from custom Liferay apps.

This tutorial uses code from the sample Bookmark List Screenlet to show you how to create your own list Screenlet. This Screenlet displays a list of bookmarks from Liferay's Bookmarks portlet. You can find this Screenlet's complete code here in GitHub.

Note that because this tutorial focuses on creating a list Screenlet, it doesn't explain general Screenlet concepts and components. Before beginning, you should therefore read the following tutorials:

- Screens architecture tutorial
- Basic Screenlet creation tutorial

You'll create the list Screenlet by following these steps:

1. Creating the Model Class
2. Creating the View
3. Creating the Interactor
4. Creating the Screenlet Class

First though, you should understand how pagination works with list Screenlets.

Pagination

To ensure that users can scroll smoothly through large lists of items, list Screenlets support fluent pagination. Support for this is built into the list Screenlet framework. You'll see this as you construct your list Screenlet.

Now you're ready to begin!

Creating the Model Class

Entities come back from Liferay in JSON. To work with these results efficiently in your app, you must convert them to model objects that represent the entity in Liferay. Although Screens's `BaseListInteractor` transforms the JSON entities into `Map` objects for you, you still must convert these into proper entity objects for use in your app. You'll do this via a model class.

For example, Bookmark List Screenlet's model class (`Bookmark`) creates `Bookmark` objects that contain a bookmark's URL and other data. To ensure quick access to the URL, the constructor that takes a `Map<String, Object>` extracts it from the `Map` and sets it to the `url` variable. To allow access to any other data, the same constructor sets the entire `Map` to the `values` variable. Besides the getters and setter, the rest of this class implements Android's `Parcelable` interface:

```
import android.os.Parcel;
import android.os.Parcelable;

import java.util.Map;

public class Bookmark implements Parcelable {

    private String url;
    private Map values;

    public static final Creator<Bookmark> CREATOR = new Creator<Bookmark>() {
        @Override
        public Bookmark createFromParcel(Parcel in) {
            return new Bookmark(in);
        }

        @Override
        public Bookmark[] newArray(int size) {
            return new Bookmark[size];
        }
    };

    public Bookmark() {
        super();
    }

    protected Bookmark(Parcel in) {
        url = in.readString();
    }

    public Bookmark(Map<String, Object> stringObjectMap) {
        url = (String) stringObjectMap.get("url");
        values = stringObjectMap;
    }

    @Override
    public void writeToParcel(Parcel dest, int flags) {
        dest.writeString(url);
    }

    @Override
    public int describeContents() {
        return 0;
    }
    public String getUrl() {
        return url;
    }

    public Map getValues() {
        return values;
    }

    public void setValues(Map values) {
        this.values = values;
    }

}
```

Now that you have your model class, you can create your Screenlet's View.

Creating the Screenlet's View

Recall from the basic Screenlet creation tutorial that a View defines a Screenlet's UI. To accommodate its list, a list Screenlet's View is constructed a bit differently than that of a non-list Screenlet. To create a List Screenlet's View, you'll create the following components:

1. Row Layout: the layout for each list row.
2. Adapter Class: an Android adapter class that populates each list row with data.
3. View Class: the class that controls the View. This class serves the same purpose in list Screenlets as it does in non-list Screenlets.
4. Main Layout: the layout for the list as a whole. Note this is different from the row layout, which defines the UI for individual rows.

First, you'll create the row layout.

Creating the Row Layout

Before constructing the rest of the View, you should first define the layout to use for each row in the list. For example, Bookmark List Screenlet needs to display a bookmark in each row. Its row layout (`res/layout/bookmark_row.xml`) is therefore a `LinearLayout` containing a single `TextView` that displays the bookmark's URL:

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <TextView
        android:id="@+id/bookmark_url"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"/>

</LinearLayout>
```

As you can see, this example is very simple. Row layouts, however, can be as simple or complex as you need them to be to display your content.

Next, you'll create the adapter class.

Creating the Adapter Class

Android adapters fill a layout with content. In the example Bookmark List Screenlet, the layout is the row layout (`bookmark_row.xml`) and the content is each list item (a URL). To make list scrolling smooth, the adapter class should use an Android view holder. To make this easier, you can extend the list Screenlet framework's `BaseListAdapter` class with your model class and view holder as type arguments. By extending `BaseListAdapter`, your adapter needs only two methods:

- `createViewHolder`: instantiates the view holder
- `fillHolder`: fills in the view holder for each row

Your view holder should also contain variables for any data each row needs to display. The view holder must assign these variables to the corresponding row layout elements, and set the appropriate data to them.

For example, Bookmark List Screenlet's adapter class (`BookmarkAdapter`) extends `BaseListAdapter` with `Bookmark` and `BookmarkAdapter.BookmarkViewHolder` as type arguments. This class's view holder is an inner class that extends `BaseListAdapter`'s view holder. Since Bookmark List Screenlet only needs to display a URL in each row, the view holder only needs one variable: `url`. The view holder's constructor assigns the `TextView` from `bookmark_row.xml` to this variable. The `bind` method then sets the bookmark's URL as the `TextView`'s text. The other methods in `BookmarkAdapter` leverage the view holder. The `createViewHolder` method instantiates `BookmarkViewHolder`. The `fillHolder` method calls the view holder's `bind` method to set the bookmark's URL as the `url` variable's text:

```
public class BookmarkAdapter extends BaseListAdapter<Bookmark, BookmarkAdapter.BookmarkViewHolder> {

    public BookmarkAdapter(int layoutId, int progressLayoutId, BaseListAdapterListener listener) {
        super(layoutId, progressLayoutId, listener);
    }

    @NonNull
    @Override
    public BookmarkViewHolder createViewHolder(View view, BaseListAdapterListener listener) {
        return new BookmarkAdapter.BookmarkViewHolder(view, listener);
    }

    @Override
    protected void fillHolder(Bookmark entry, BookmarkViewHolder holder) {
        holder.bind(entry);
    }

    public class BookmarkViewHolder extends BaseListAdapter.ViewHolder {

        private final TextView url;

        public BookmarkViewHolder(View view, BaseListAdapterListener listener) {
            super(view, listener);

            url = (TextView) view.findViewById(R.id.bookmark_url);
        }

        public void bind(Bookmark entry) {
            url.setText(entry.getUrl());
        }
    }
}
```

Great! Your adapter class is finished. Next, you'll create the View class.

Creating the View Class

Now that your adapter exists, you can create your list Screenlet's View class. Recall from the basic Screenlet creation tutorial that the View class is the central hub of any Screenlet's UI. It renders the UI, handles user interactions, and communicates with the Screenlet class. The list Screenlet framework provides most of this functionality for you via the `BaseListScreenletView` class. Your View class must extend this class to provide your row layout ID and an instance of your adapter. You'll do this by overriding `BaseListScreenletView`'s `getItemLayoutId` and `createListAdapter` methods. Note that in many cases this is the only custom functionality your View class needs. If it needs more, you can provide it by creating new methods or overriding other `BaseListScreenletView` methods.

Create your View class by extending `BaseListScreenletView` with your model class, view holder, and adapter as type arguments. This is required for your View class to represent your model objects in a view holder, inside an adapter. For example, Bookmark List Screenlet's View class (`BookmarkListView`) must represent `Bookmark` instances in a `BookmarkViewHolder` inside a `BookmarkAdapter`. The `BookmarkListView` class must therefore extend `BaseListScreenletView` parameterized with `Bookmark`, `BookmarkAdapter.BookmarkViewHolder`, and `BookmarkAdapter`. Besides overriding `createListAdapter` to return a `BookmarkAdapter` instance, the only other functionality that this View class needs to support is to get the layout for each row in the list. The overridden `getItemLayoutId` method does this by returning the row layout `bookmark_row`:

```
import android.content.Context;
import android.util.AttributeSet;

import com.liferay.mobile.screens.base.list.BaseListScreenletView;

public class BookmarkListView
    extends BaseListScreenletView<Bookmark, BookmarkAdapter.BookmarkViewHolder, BookmarkAdapter> {

    public BookmarkListView(Context context) {
        super(context);
    }

    public BookmarkListView(Context context, AttributeSet attributes) {
        super(context, attributes);
    }

    public BookmarkListView(Context context, AttributeSet attributes, int defaultStyle) {
        super(context, attributes, defaultStyle);
    }

    @Override
    protected BookmarkAdapter createListAdapter(int itemLayoutId, int itemProgressLayoutId) {
        return new BookmarkAdapter(itemLayoutId, itemProgressLayoutId, this);
    }

    @Override
    protected int getItemLayoutId() {
        return R.layout.bookmark_row;
    }
}
```

Next, you'll create your View's main layout.

Creating the View's Main Layout

Although you already created a layout for your list rows, you must still create a layout to define the list as a whole. This layout must contain:

- The View class's fully qualified name as the layout's first element.

- An Android `RecyclerView` to let your app efficiently scroll through a potentially large list of items.
- An Android `ProgressBar` to indicate progress when loading the list.

Apart from the View class and styling, this layout's code is the same for all list Screenlets. For example, here's Bookmark List Screenlet's layout `res/layout/list_bookmarks.xml`:

```
<com.liferay.mobile.screens.listbookmark.BookmarkListView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:id="@+id/liferay_list_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <ProgressBar
        android:id="@+id/liferay_progress"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:layout_gravity="center"
        android:visibility="gone"/>

    <android.support.v7.widget.RecyclerView
        android:id="@+id/liferay_recycler_list"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:visibility="gone"/>
</com.liferay.mobile.screens.listbookmark.BookmarkListView>
```

Warning: The `android:id` values in your View's layout XML must **exactly** match the ones shown here. These values are hardcoded into the Screens framework and changing them will cause your app to crash.

Great job! Your View is finished. Next, you'll create your Screenlet's Interactor.

Creating the Screenlet's Interactor

Recall from the basic Screenlet creation tutorial that Interactors retrieve and process a server call's results. Also recall that the following components make up an Interactor:

1. Event
2. Listener
3. Interactor Class

These components perform the same basic functions in list Screenlets as they do in non-list Screenlets. Creating them, however, is a bit different. Each of the following sections show you how to create one of these components. First, you'll create the event.

Creating the Event

Screens uses the EventBus library to handle communication within Screenlets. Screenlet components therefore communicate with each other by using event classes that contain the server call's results. Your list Screenlet's event class must extend the `ListEvent` class parameterized with your model class. Your event class should also contain a private instance variable for the model class, a constructor that sets this variable, and a no-argument constructor that calls the superclass constructor. For example, Bookmark List Screenlet's event class (`BookmarkEvent`) communicates `Bookmark` objects. It therefore extends `ListEvent` with `Bookmark` as a type argument, and defines a private `Bookmark` variable that its `BookmarkEvent(Bookmark bookmark)` constructor sets:

```
public class BookmarkEvent extends ListEvent<Bookmark> {

     private Bookmark bookmark;

     public BookmarkEvent() {
          super();
     }

     public BookmarkEvent(Bookmark bookmark) {
         this.bookmark = bookmark;
     }
    ...
```

You must also implement ListEvent's abstract methods in your event class. Note that these methods support offline mode. Although these methods are briefly described here, supporting offline mode in your Screenlets is addressed in detail in a separate tutorial.

- `getListKey`: returns the ID for the cache. This ID is typically the data each list row displays. For example, the `getListKey` method in `BookmarkEvent` returns the bookmark's URL:

  ```
  @Override
  public String getListKey() {
      return bookmark.getUrl();
  }
  ```

- `getModel`: unwraps the model entity to the cache by returning the model class instance. For example, the `getModel` method in `BookmarkEvent` method returns the bookmark:

  ```
  @Override
  public Bookmark getModel() {
      return bookmark;
  }
  ```

Next, you'll create your Screenlet's listener.

Creating the Listener

Recall that listeners let the app developer respond to events that occur in Screenlets. For example, an app developer using Login Screenlet in an activity must implement `LoginListener` in that activity to respond to login success or failure. When creating a list Screenlet, however, you don't have to create a separate listener. Developers can use your list Screenlet in an activity or fragment by implementing the `BaseListListener` interface parameterized with your model class. For example, to use Bookmark List Screenlet in an activity, an app developer's activity declaration could look like this:

```
public class BookmarkListActivity extends AppCompatActivity
    implements BaseListListener<Bookmark> {...
```

The `BaseListListener` interface defines the following methods that the app developer can implement in their activity or fragment:

- `void onListPageFailed(int startRow, Exception e)`: Responds to the Screenlet's failure to retrieve entities from the server.

- `void onListPageReceived(int startRow, int endRow, List<E> entries, int rowCount)`: Responds to the Screenlet's success in retrieving entities from the server.

- void onListItemSelected(E element, View view): Responds to a user selection in the list.

If these methods meet your list Screenlet's needs, then you can move on to the next section in this tutorial. If you want to let app developers respond to more actions, however, you must create your own listener that extends BaseListListener parameterized with your model class. For example, Bookmark List Screenlet contains such a listener: BookmarkListListener. This listener defines a single method that notifies the app developer when the Interactor is called:

```
public interface BookmarkListListener extends BaseListListener<Bookmark> {
    void interactorCalled();
}
```

Next, you'll create the Interactor class.

Creating the Interactor Class

Recall that as an Interactor's central component, the Interactor class makes the service call to retrieve entities from Liferay DXP, and processes the results of that call. The list Screenlet framework's BaseListInteractor class provides most of the functionality that Interactor classes in list Screenlets require. You must, however, extend BaseListInteractor to make your service calls and handle their results via your model and event classes. Your Interactor class must therefore extend BaseListInteractor, parameterized with BaseListInteractorListener<YourModelClass> and your event class. For example, Bookmark List Screenlet's Interactor class, BookmarkListInteractor, extends BaseListInteractor parameterized with BaseListInteractorListener<Bookmark> and BookmarkEvent:

```
public class BookmarkListInteractor extends
    BaseListInteractor<BaseListInteractorListener<Bookmark>, BookmarkEvent> {...
```

Your Interactor must also override the methods needed to make the server call and process the results:

- getPageRowsRequest: Retrieves the specified page of entities. In the example BookmarkListInteractor, this method first uses the args parameter to retrieve the ID of the folder to retrieve bookmarks from. It then sets the comparator (more on this shortly) if the app developer sets one when inserting the Screenlet XML in a fragment or activity. The getPageRowsRequest method finishes by calling BookmarksEntryService's getEntries method to retrieve a page of bookmarks. Note that the service call, like the service call in the basic Screenlet creation tutorial, uses LiferayServerContext.isLiferay7() to check the portal version to make sure the correct service instance is used. This isn't required if you only plan to use your Screenlet with one portal version. Also note that the groupId variable used to make the service calls isn't set anywhere in getPageRowsRequest or BookmarkListInteractor. Interactors that extend BaseListInteractor, like BookmarkListInteractor, inherit this variable via the Screens framework. You'll set it when you create the Screenlet class. Here's BookmarkListInteractor's complete getPageRowsRequest method:

  ```
  @Override
  protected JSONArray getPageRowsRequest(Query query, Object... args) throws Exception {
      long folderId = (long) args[0];

      if (args[1] ≠ null) {
          query.setComparator((String) args[1]);
      }

      if (LiferayServerContext.isLiferay7()) {
          return new BookmarksEntryService(getSession()).getEntries(groupId, folderId,
              query.getStartRow(), query.getEndRow(), query.getComparatorJSONWrapper());
  ```

```
        } else {
            return new com.liferay.mobile.android.v62.bookmarksentry.BookmarksEntryService(
                getSession()).getEntries(groupId, folderId, query.getStartRow(),
                query.getEndRow(), query.getComparatorJSONWrapper());
        }
    }
```

You might now be asking yourself what a comparator is. A comparator is a class in the Liferay DXP instance that sorts a portlet's entities. For example, the Bookmarks portlet contains several comparators that can sort entities by different criteria. Click here to see these comparators. Although it's not required, you can develop your list Screenlet to use a comparator to sort its entities. Since Bookmark List Screenlet supports comparators, you'll see more of this as you progress through this tutorial.

- `getPageRowCountRequest`: Retrieves the number of entities, to enable pagination. In the example `BookmarkListInteractor`, this method first uses the `args` parameter to get the ID of the folder in which to count bookmarks. It then calls `BookmarksEntryService`'s `getEntriesCount` method to retrieve the number of bookmarks:

```
@Override
protected Integer getPageRowCountRequest(Object... args) throws Exception {
    long folderId = (long) args[0];

    if (LiferayServerContext.isLiferay7()) {
        return new BookmarksEntryService(getSession()).getEntriesCount(groupId, folderId);
    } else {
        return new com.liferay.mobile.android.v62.bookmarksentry.BookmarksEntryService(
            getSession()).getEntriesCount(groupId, folderId);
    }
}
```

- `createEntity`: Returns an instance of your event that contains the server call's results. This method receives the results as `Map<String, Object>`, which it uses to instantiate your model class. It then uses this model instance to create the event object. In the example `BookmarkListInteractor`, this method passes the `Map<String, Object>` to the `Bookmark` constructor. It then uses the resulting `Bookmark` to create and return a `BookmarkEvent`:

```
@Override
protected BookmarkEvent createEntity(Map<String, Object> stringObjectMap) {
    Bookmark bookmark = new Bookmark(stringObjectMap);
    return new BookmarkEvent(bookmark);
}
```

- `getIdFromArgs`: a boilerplate method that returns the value of the first object argument as a string. This serves as a cache key for offline mode:

```
@Override
protected String getIdFromArgs(Object... args) {
    return String.valueOf(args[0]);
}
```

  You must implement this method even if you don't intend to support offline mode in your Screenlet. Having this method in your Interactor class makes it simpler to add offline mode functionality later. Supporting offline mode in your Screenlets is addressed in detail in a separate tutorial.

To see the complete `BookmarkListInteractor` class, click here.
Next, you'll create the Screenlet class.

Creating the Screenlet Class

Recall from the basic Screenlet creation tutorial that the Screenlet class serves as your Screenlet's focal point. It governs the Screenlet's behavior and is the primary component the app developer interacts with. As with non-list Screenlets, you should first define any XML attributes that you want to make available to the app developer. For example, Bookmark List Screenlet defines the following attributes:

- `groupId`: the ID of the site containing the Bookmarks portlet
- `folderId`: the ID of the Bookmarks portlet folder to retrieve bookmarks from
- `comparator`: the name of the comparator to use to sort the bookmarks

The Screenlet defines these attributes in its `res/values/bookmark_attrs.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>
    <declare-styleable name="BookmarkListScreenlet">
        <attr name="groupId"/>
        <attr name="folderId"/>
        <attr format="string" name="comparator"/>
    </declare-styleable>
</resources>
```

Now you're ready to create your Screenlet class. Because the `BaseListScreenlet` class provides the basic functionality for all Screenlet classes in list Screenlets, including methods for pagination and other default behavior, your Screenlet class must extend `BaseListScreenlet` with your model class and Interactor as type arguments.

For example, Bookmark List Screenlet's Screenlet class–`BookmarkListScreenlet`–extends `BaseListScreenlet` parameterized with `Bookmark` and `BookmarkListInteractor`:

```
public class BookmarkListScreenlet
    extends BaseListScreenlet<Bookmark, BookmarkListInteractor> {...
```

You must also create instance variables for the XML attributes that you want to pass to your Interactor. For example, recall that the request methods in `BookmarkListInteractor` receive two `Object` arguments: the folder ID and the comparator. The `BookmarkListScreenlet` class must therefore contain variables for these parameters so it can pass them to the Interactor:

```
private long folderId;
private String comparator;
```

For constructors, leverage the superclass constructors. For example, here are `BookmarkListScreenlet`'s constructors:

```
public BookmarkListScreenlet(Context context) {
    super(context);
}

public BookmarkListScreenlet(Context context, AttributeSet attrs) {
    super(context, attrs);
}

public BookmarkListScreenlet(Context context, AttributeSet attrs, int defStyleAttr) {
    super(context, attrs, defStyleAttr);
}

public BookmarkListScreenlet(Context context, AttributeSet attrs, int defStyleAttr,
    int defStyleRes) {
        super(context, attrs, defStyleAttr, defStyleRes);
}
```

Now you must implement the error method. This is a boilerplate method that uses a listener in the Screenlet framework to propagate any exception, and the user action that produced it, that occurs during the service call. This method does this by checking for a listener and then calling its error method with the Exception and userAction:

```
@Override
public void error(Exception e, String userAction) {
    if (getListener() ≠ null) {
        getListener().error(e, userAction);
    }
}
```

Next, override the createScreenletView method to read the values of the XML attributes you defined earlier and create the Screenlet's View. Recall from the basic Screenlet creation tutorial that this method assigns the attribute values to their corresponding instance variables. For example, the createScreenletView method in BookmarkListScreenlet assigns the folderId and comparator attribute values to variables of the same name. This method also sets the local variable groupId. Recall that the Screens framework propagates this variable to your Interactor. Finish the createScreenletView method by calling the superclass's createScreenletView method. This instantiates the View for you:

```
@Override
protected View createScreenletView(Context context, AttributeSet attributes) {
    TypedArray typedArray = context.getTheme().obtainStyledAttributes(attributes,
        R.styleable.BookmarkListScreenlet, 0, 0);
    groupId = typedArray.getInt(R.styleable.BookmarkListScreenlet_groupId,
        (int) LiferayServerContext.getGroupId());
    folderId = typedArray.getInt(R.styleable.BookmarkListScreenlet_folderId, 0);
    comparator = typedArray.getString(R.styleable.BookmarkListScreenlet_comparator);
    typedArray.recycle();

    return super.createScreenletView(context, attributes);
}
```

Next, override the loadRows method to start your Interactor and thereby retrieve the list rows from the server. This method takes an instance of your Interactor as an argument, which you use to call the Interactor's start method. Note that the Interactor inherits start from BaseListInteractor. You can also use the loadRows method to execute any other code that you want to run when the Interactor starts. For example, the loadRows method in BookmarkListScreenlet first retrieves a listener instance so it can call the listener's interactorCalled method. It then starts the server operation to retrieve the list rows by calling the Interactor's start method with folderId and comparator:

```
@Override
protected void loadRows(BookmarkListInteractor interactor) {

    ((BookmarkListListener) getListener()).interactorCalled();

    interactor.start(folderId, comparator);
}
```

Note that if your Interactor doesn't require arguments, then you can pass the start method 0 or null. Calling start with no arguments, however, causes the server call to fail.

Lastly, override the createInteractor method to instantiate your Interactor. Since that's all this method needs to do, call your Interactor's constructor and return the new instance. For example, BookmarkListScreenlet's createInteractor method returns a new BookmarkListInteractor:

```
@Override
protected BookmarkListInteractor createInteractor(String actionName) {
    return new BookmarkListInteractor();
}
```

You're done! Your Screenlet is a ready-to-use component that you can use in your app. You can even package your Screenlet and contribute it to the Screens project, or distribute it in Maven Central or jCenter.

Using the Screenlet

You can now use your new list Screenlet the same way you use any other Screenlet:

1. Insert the Screenlet's XML in the layout of the activity or fragment you want to use the Screenlet in. For example, here's Bookmark List Screenlet's XML:

   ```
   <com.liferay.mobile.screens.listbookmark.BookmarkListScreenlet
       android:id="@+id/bookmarklist_screenlet"
       android:layout_width="match_parent"
       android:layout_height="match_parent"
       app:comparator="FULLY_QUALIFIED_COMPARATOR_CLASS"
       app:folderId="YOUR_FOLDER_ID"
       app:groupId="YOUR_GROUP_ID"
       app:layoutId="@layout/list_bookmarks"/>
   ```

   Note that to set a comparator, you must use its fully qualified class name. For example, to use the Bookmarks portlet's `EntryURLComparator`, set `app:comparator` in the Screenlet XML as follows:

   ```
   app:comparator="com.liferay.bookmarks.util.comparator.EntryURLComparator"
   ```

2. Implement the Screenlet's listener in the activity or fragment class. If your list Screenlet doesn't have a custom listener, then you can do this by implementing `BaseListListener` parameterized with your model class. For example:

   ```
   public class YourListActivity extends AppCompatActivity
       implements BaseListListener<YourModelClass> {...
   ```

   If you created a custom listener for your list Screenlet, however, then your activity or fragment must implement it instead. For example, recall that the example Bookmark List Screenlet's listener is `BookmarkListListener`. To use this Screenlet, you must therefore implement this listener in the class of the activity or fragment that you want to use the Screenlet in. For example:

   ```
   public class ListBookmarksActivity extends AppCompatActivity
       implements BookmarkListListener {...
   ```

   See the full example of this here in GitHub.

Well done! Now you know how to create list Screenlets.

Using Views in Android Screenlets

Using Screenlets in Android Apps

76.9 Creating Android Views

By creating your own Views, you can customize your mobile app's layout, style, and functionality. You can create them from scratch or use an existing View as a foundation. Views include a View class for implementing Screenlet behavior, a Screenlet class for notifying listeners and invoking Interactors, and an XML file for specifying the UI. The four Liferay Screens View types support different levels of customization and parent View inheritance. Here's what each View type offers:

Themed View: presents the same structure as the current View, but alters the theme colors and tints of the View's resources. All existing Views can be themed with different styles. The View's colors reflect the current value of the Android color palette. If you want to use one View Set with another View Set's colors, you can use those colors in your app's theme (e.g. `colorPrimary_default`, `colorPrimary_material`, `colorPrimary_westeros`).

Child View: presents the same UI components as its parent View, but lets you change their appearance and position.

Extended View: inherits its parent View's functionality and appearance, but lets you add to and modify both.

Full View: provides a complete standalone View for a Screenlet. A full View is ideal for implementing completely different functionality and appearance from a Screenlet's current theme.

This tutorial explains how to create all four types of Views. To understand View concepts and components, you might want to examine the architecture of Liferay Screens for Android. And the tutorial Creating Android Screenlets can help you create or extend any Screenlet classes your View requires. Now get ready to create some great Views!

Determining Your View's Location

First, decide whether you'll reuse your view or if it's just for your current app. If you don't plan to reuse it in another app or don't want to redistribute it, create it in your app project.

If you want to reuse your View in another app, create it in a new Android application module; the tutorial Packaging Android Screenlets explains how. When your View's project is in place, you can start creating it.

First, you'll learn how to create a Themed View.

Themed View

Screens provides several existing View Sets that you can reuse and customize in your app to create a Themed View. If you use or override the Android color palette's values (for example, `primaryColor`, `secondaryColor`, etc...), you'll reuse the View Set's general structure, but be able to use the new colors (also with tinted resources). Note that you must create Themed Views inside your app. This is because Themed Views depend on the app or activity theme.

Each View Set has its own Android theme. These are listed here:

- **Default View Set:** `default_theme`
- **Material View Set:** `material_theme`
- **Westeros View Set:** `westeros_theme`

You can easily style all your Screenlets by setting your app or activity theme to inherit a View Set's Android theme. For example, you can use the following code to reuse the styles (and layouts) from `material_theme` in your own theme:

```
<style name="AppTheme.NoActionBar" parent="material_theme">
    <item name="colorPrimary">#B91D6D</item>
    <item name="colorPrimaryDark">#670E3B</item>
    <item name="colorAccent">#BBBBBB</item>
</style>

<application android:theme="@style/AppTheme.NoActionBar"
    ...
>
```

Note that this code overrides the `AppTheme.NoActionBar` theme's colors with your own color settings for `colorPrimary`, `colorPrimaryDark`, and `colorAccent`. Screenlets will also use these new colors, and tint images and other resources accordingly. Liferay Screens uses the default Android color palette names from the Support Library.

You can also override only the parent View Set's theme colors. This way you can set a default color palette and override only the View Set colors you want. The color names for each View Set are the default Android names, followed by an underscore and the View Set's lowercase name (`_default`, `_material`, and `_westeros`). For example, the following code overrides `colorPrimary`, `colorPrimaryDark`, and `colorAccent` for only the `material_theme`:

```
<resources>
    <color name="colorPrimary_material">#B91D6D</color>
    <color name="colorPrimaryDark_material">#670E3B</color>
    <color name="colorAccent_material">#BBBBBB</color>
</resources>
```

Liferay Screens also lets you use one View Set's layout with a Screenlet, and use another View Set's general style and colors. To do this, pass a `layoutId` attribute to a Screenlet that is already styled with another View Set's theme. The Screenlet uses the layout structure specified in `layoutId`, but inherits the general style and colors from the View Set's theme. For example, this code tells Login Screenlet to use the Default View Set's layout structure, but use the styles and colors defined earlier in `AppTheme.NoActionBar`:

```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:basicAuthMethod="email"
    app:layoutId="@layout/login_default"
    app:credentialsStorage="shared_preferences" />

<application android:theme="@style/AppTheme.NoActionBar"
    ...
>
```

Next, you'll learn how to create a Child View.

Child View

A Child View presents the same behavior and UI components as its parent, but can change the UI components' appearance and position. It can't add or remove any UI components. A Child View specifies visual changes in its own layout XML file; it inherits the parent's View class and Screenlet class. The parent must be a Full View.

The Child View discussed here presents the same UI components as the Login Screenlet's Default View, but uses a more compact layout.

You can follow these steps to create a Child View:

1. Create a new layout XML file named after the View's Screenlet and its intended use case. A good way to start building your UI is to duplicate the parent's layout XML file and use it as a template. However

you start building your UI, name the root element after the parent View's fully-qualified class name and specify the parent's UI components with the same IDs.

In the example here, the Child View's layout file `login_compact.xml` resembles its parent's layout file `login_default.xml`– the layout of the Login Screenlet's Default View. The child View's name *compact* describes its use case: display the Screenlet's components in a more compact layout. The IDs of its `EditText` and `Button` components match those of the parent View. Its root element uses the parent View class's fully-qualified name:

```
<?xml version="1.0" encoding="utf-8"?>
<com.liferay.mobile.screens.viewsets.defaultviews.auth.login.LoginView
    xmlns:android="http://schemas.android.com/apk/res/android"
    style="@style/default_screenlet">

    <EditText
        android:id="@+id/liferay_login"
        style="@style/default_edit_text"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="15dp"
        android:drawableLeft="@drawable/default_mail_icon"
        android:hint="@string/email_address"
        android:inputType="text" />

    <EditText
        android:id="@+id/liferay_password"
        style="@style/default_edit_text"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="15dp"
        android:drawableLeft="@drawable/default_lock_icon"
        android:hint="@string/password"
        android:inputType="textPassword" />

    <Button
        android:id="@+id/liferay_login_button"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        style="@style/default_button"
        android:text="@string/sign_in" />

</com.liferay.mobile.screens.viewsets.defaultviews.auth.login.LoginView>
```

You can browse other layouts for Screens's Default Views on GitHub.

2. Insert your View's Screenlet in any of your activities or fragments, using your new layout's name as the `liferay:layoutId` attribute's value. For example, to use the new `login_compact` layout, insert `LoginScreenlet` in an activity or fragment and set `liferay:layoutId="@layout/login_compact"`.

Another good Child View layout file to examine is `sign_up_material.xml`. It presents the same UI components and functionality as the Sign Up Screenlet's Default View, but using Android's Material design.

Stupendous! Now you know how to create Child Views. Next, you'll learn how to create Extended Views.

Extended View

An Extended View inherits the parent View's behavior and appearance, but lets you change and add to both. You can do so by writing a custom View class and a new layout XML file. An Extended View inherits all of the parent View's other classes, including its Screenlet, listeners, and Interactors. An Extended View's parent must be a Full View.

The example Extended View discussed here presents the same UI components as the Login Screenlet's Default View, but adds functionality: computing password strength. Of course, you're not restricted to password strength computations; you can implement anything you want.

1. Create a new layout XML file named after the View's Screenlet and its intended use case. A good way to start building your UI is to duplicate the parent's layout XML file and use it as a template. The new layout file for the Login Screenlet's Extended View is called `login_password.xml`, because it's based on the Login Screenlet's Default View layout file `login_default.xml` and it adds a password strength computation.

2. Create a new custom View class that extends the parent View class. Name it after the Screenlet and the functionality you'll add or override. The example View class `LoginCheckPasswordView` extends the Default View's `LoginView` class, overriding the `onClick` method to compute password strength:

```
public class LoginCheckPasswordView extends LoginView {

    // parent's constructors go here...

    @Override
    public void onClick(View view) {
        // compute password strength

        if (passwordIsStrong) {
            super.onClick(view);
        }
        else {
            // Present user message
        }
    }

}
```

3. Rename the layout XML file's root element after your custom View's fully-qualified class name. For example, the root element in `login_password.xml` is `com.your.package.LoginCheckPasswordView`:

```
<com.your.package.LoginCheckPasswordView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">
    ...
```

4. Insert your View's Screenlet in any of your activities or fragments, using your new layout's name as the `liferay:layoutId` attribute's value. For example, to use the new `login_password` layout, insert `LoginScreenlet` in an activity or fragment, and set `liferay:layoutId="@layout/login_password"`.

The Bank of Westeros sample app's Westeros View Set has a couple of Extended Views that you can examine. It has an Extended View that adds a new button to show the password in the clear for the Login Screenlet. The View uses custom layout file `login_westeros.xml` and custom View class `LoginView`. The Westeros View Set also contains an Extended View for the User Portrait Screenlet; it changes the border color and width of the user's portrait picture and it uses the custom layout file `userportrait_westeros.xml` and the custom View class `UserPortraitView`.

Awesome! Now you know how to create Extended Views. Next, you can learn how to create a Full View.

Full View

A Full View has a unique Screenlet class, a View class, and layout XML file. It's standalone and doesn't inherit from any View. You should create a Full View if there's no other View that you can extend to meet your needs or if your Screenlet's behavior can only be augmented by customizing its listeners or calling custom Interactors. To create a Full View, you must create its Screenlet class, View class, and layout XML file. The example Full View here for the Login Screenlet presents a single `EditText` component for the user name. For the password, it uses `Secure.ANDROID_ID`. The Screens Test App uses this Full View.

You can follow these steps to create a Full View:

1. Create a new layout XML file and build your UI in it. A good way to start building your UI is to duplicate another View's layout XML file and use it as a template. Name your layout XML file after the View's Screenlet and intended use case. Name its root element after the fully-qualified class name of your custom View (you'll create this next).

   The Test App's Full View layout XML file for the Login Screenlet is called `login_full.xml`. It specifies `EditText` and `Button` elements copied from the LongScreenlet's Default View file `login_default.xml`.

```
<?xml version="1.0" encoding="utf-8"?>
<com.your.package.LoginFullView
        xmlns:android="http://schemas.android.com/apk/res/android"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:orientation="vertical">

<EditText
        android:id="@+id/liferay_login"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginBottom="20dp"
        android:hint="Email Address"
        android:inputType="textEmailAddress"/>

<Button
        android:id="@+id/liferay_login_button"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:text="Sign In"/>

</com.your.package.LoginFullView>
```

2. Create a new custom View class named after the layout's root element. The tutorial on creating Android Screenlets explains how to create a View class. Note that you don't have to extend a View class to implement a View Model interface, but you might want to for convenience. The custom View class `LoginFullView`, for example, implements the `LoginViewModel` interface by extending the Default `LoginView` class. To return the `ANDROID_ID`, the `LoginFullView` custom View class overrides the `getPassword()` method.

3. Create a new Screenlet class that inherits the base Screenlet class. This new class is where you can add custom behavior to the listeners or call custom Interactors. The Screenlet class `LoginFullScreenlet`, for example, extends `LoginScreenlet` and overrides the `onUserAction` method to log Interactor calls.

4. Insert your View's Screenlet in any of your activities or fragments, using your new layout's name as the `liferay:layoutId` attribute's value. For example, to use the new `login_password` layout, insert `LoginScreenlet` in an activity or fragment, and set `liferay:layoutId="@layout/login_password"`.

The Westeros View Set's full view for the Sign Up Screenlet uses a custom Screenlet class to add a new listener. The custom Screenlet class also adds a new user action that calls the base Interactor `SignUpInteractor`.

Sweetness! Now you know how to create a Full View. Next, you'll learn how to package Views for distribution.

Packaging Your Views

If you want to distribute or reuse Views, you should package them in a module that is then added as an app's project dependency. To do this, use the material sub-project as a template for your new `build.gradle` file.

To use a packaged View, you must import its module into your project by specifying its location in your `settings.gradle` file. The Bank of Westeros and test-app projects use custom Views `westeros` and `material`, respectively. These projects exemplify using independent Views in a project.

If you want to redistribute your View and let others use it, you can upload it to jCenter or Maven Central. In the example `build.gradle` file, after entering your bintray api key you can execute `gradlew bintrayupload` to upload your project to jCenter. When finished, anyone can use the View as they would any Android dependency by adding the repository, artifact, group ID, and version to their Gradle file.

Super! Now you know how to create and package Views in Liferay Screens for Android. This gives you extensive control over your app's visual design and behavior and also lets you distribute and reuse your Views.

Creating Android Screenlets

76.10 Packaging Your Android Screenlets

To reuse your Screenlet in another app or distribute it, you can package it in a module (Android library). You can optionally share it with other developers via jCenter or Maven Central. Developers can then use your Screenlet by adding its module as a project dependency in their apps. This tutorial explains how to package and distribute Screenlets by following these steps:

1. Create a new Android module.
2. Configure dependencies between each module.
3. Distribute the module by uploading it to jCenter or Maven Central.

Now get ready to package and distribute Screenlets like a pro!

Create a New Android Module

Android Studio's *Create New Module* wizard can automatically create a module and add it to your `settings.gradle` file. Go to *File → New Module...*, select *Android Library* in the More Modules section, and click *Next*. Then name your module and click *Next*. The wizard's final step lets you add a new activity. Since your module doesn't need one, select *Blank Activity* and click *Finish*. Android Studio creates a new `build.gradle` file with an Android Library configuration and adds the new module to your `settings.gradle` file.

If you prefer to create a new module manually, examine the `build.gradle` file from the Material View set or Westeros app as an example. After creating the module, import it into your project by specifying its location in `settings.gradle`. Here's an example configuration:

```
// Change YOUR_MODULE_NAME and RELATIVE_ROUTE_TO_YOUR_MODULE to match your module

include ':YOUR_MODULE_NAME'
project(':YOUR_MODULE_NAME').projectDir = new File(settingsDir, 'RELATIVE_ROUTE_TO_YOUR_MODULE')
```

Now that you have a module, you're ready to configure its dependencies.

Configure Dependencies Between Each Module

Next, you must configure your app to use the module. To do so, add a project implementation statement to your `build.gradle` file's dependencies:

```
// Change YOUR_MODULE_NAME to match your module's name

dependencies {
    ...
    implementation project (':YOUR_MODULE_NAME')
    ...
}
```

Your module must also specify dependencies for overriding existing Screenlets and creating new ones. This usually requires adding Liferay Screens and the View Sets your Screenlet currently uses to your `build.gradle` file's dependencies. To add Liferay Screens as a dependency, add to your `build.gradle` file's dependencies the following project implementation statement:

```
implementation 'com.liferay.mobile:liferay-screens:+'
```

Awesome! Now you're ready to share your Screenlet with the world!

Upload the Module to jCenter or Maven Central

To make your module available to anyone, you can upload your module to jCenter or Maven Central. Before doing so, you must configure your `build.gradle` file appropriately for those repositories. Use the material or Westeros View Set's `build.gradle` file as an example. After entering your bintray api key, execute `gradlew bintrayupload` to upload your project to jCenter. Developers can then use your Screenlet as any other Android dependency by specifying its repository, artifact, group ID, and version in their Gradle files. Congratulations on publishing your Screenlet!

76.11 Using Liferay Push in Android Apps

Liferay Screens supports push notifications in Android apps. To use them, you must configure some APIs and modify your app to consume and/or produce push notifications. This tutorial shows how to do all these things.

Configuring to Use Liferay Push Notifications

Your first step is to create and configure a Google project to use Google Cloud Messaging (GCM). You also need to configure the Liferay Push app to use the project's GCM API.

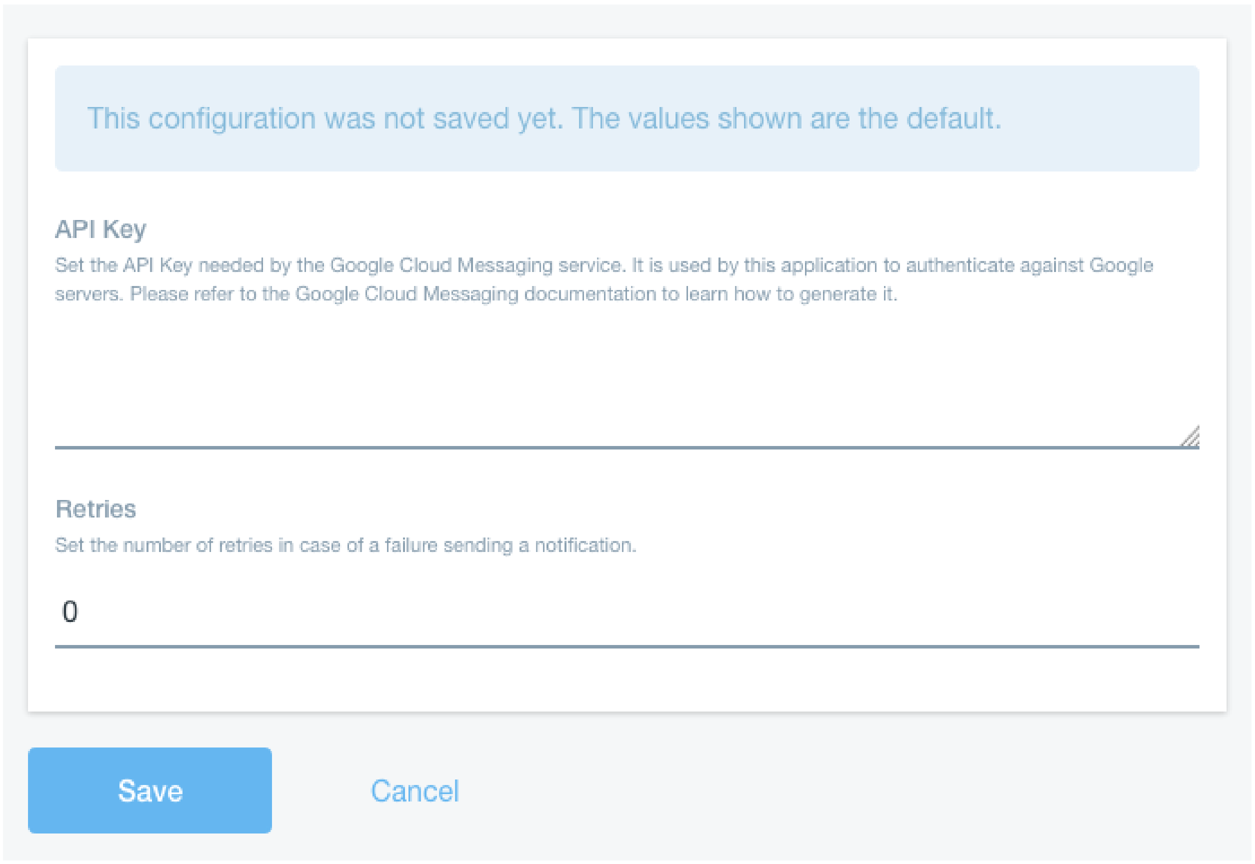
Follow these steps to create and configure a Google project to support cloud messaging:

1. On the Google Cloud Messaging page, create a configuration file by clicking *Get a Configuration File*. On the screen that appears, set your *App name* and *Android package name*, and then click *Continue To Choose and Configure Services*. On the next screen, click *Enable Google Cloud Messaging*.

2. Copy and save the *Server API Key* and *Sender ID* values you're presented with. You'll need to use these values later as the push notifications API keys for Liferay Push.

   `![ You need the Server API Key and Sender ID to enable Liferay Push.](./images/screens-android-push-project-and-server-key.png)`

Now that you've set up your Google project, you can configure the Liferay Push app to use the project's GCM API. Install the Liferay Push app from the Liferay Marketplace. In your Liferay DXP instance's Control Panel, navigate to *Configuration* → *System Settings*, select the *Other* tab, then select *Android Push Notifications Sender*. Set the push notifications *API Key* to the value of the Server API Key you generated in your Google project. You can also set the number of retries in the event that sending a notification fails.



This configuration was not saved yet. The values shown are the default.

API Key

Set the API Key needed by the Google Cloud Messaging service. It is used by this application to authenticate against Google servers. Please refer to the Google Cloud Messaging documentation to learn how to generate it.

Retries

Set the number of retries in case of a failure sending a notification.

0

Figure 76.16: Set the API key and number of retries in your Liferay DXP instance.

Great! Your Liferay DXP instance is now ready to send push notifications to your Android apps!

Receiving and Sending Push Notifications

The Liferay Push Client for Android streamlines registering a device with the portal for receiving and sending push notifications. Although the information below contains the main steps needed to use the client, the readme explains them in detail.

In your Android application's Gradle build file, add a new dependency on the Liferay Push Client for Android:

```
dependencies {

    ...

    implementation 'com.liferay.mobile:liferay-push:1.2.1'
}
```

Make sure your app's `liferay-plugin-package.properties` file specifies the Push Notifications portlet as a required deployment context:

```
required-deployment-contexts=\
    push-notifications-portlet\
    ...
```

Next, you'll learn how to register listeners for push notifications.

Receiving Push Notifications

First, register your device in GCM with the `SENDER_ID` you generated previously:

```
Session session = new SessionImpl(YOUR_SERVER, new BasicAuthentication(YOUR_USER, YOUR_PASSWORD));

Push.with(session).register(this, YOUR_SENDER_ID);
```

If you're using Liferay Screens to maintain a session, you can retrieve it and use it instead of creating a new one:

```
Push.with(SessionContext.createSessionFromCurrentSession()).register(this, YOUR_SENDER_ID);
```

If you use these example lines of code, make sure to replace `YOUR_SERVER`, `YOUR_USER`, `YOUR_PASSWORD`, and `YOUR_SENDER_ID` with your own values.

That's it! You can attach a listener to store the registration ID or to process the notification sent to the activity (using `onPushNotification()`). You can also register a receiver and service to process the notification. You can refer to the Push Notifications project as an example push notifications implementation.

Next, you'll learn how to send push notifications.

Sending Push Notifications

Using the Liferay Push app, sending notifications to your app's users is straightforward. You can specify the user IDs along with the message content:

```
PushNotificationsDeviceLocalServiceUtil.sendPushNotification(userIds, content);
```

This example hook plugin sends a push notification each time a user creates a new DDL record or updates an existing one.

In your app's `portal.properties` file, you can add a listener for a class by creating a *value.object.listener* property, set to a comma separated list of intended listener classes. Here's an example listener setting for `DDLRecord` objects:

```
value.object.listener.com.liferay.portlet.dynamicdatalists.model.DDLRecord=com.liferay.push.hooks.DDLRecordModelListener
```

Great! Now you know how to configure your Android apps to receive push notifications from Liferay DXP.

In this tutorial, you've configured your portal to accommodate push notifications, registered notification listeners, and implemented sending push notifications. Way to go!

Using Screenlets in Android Apps

76.12 Accessing the Liferay Session in Android

A session is a conversation state between the client and server. It typically consists of multiple requests and responses between the two. To facilitate this communication, the session must have the server IP address, and a user's login credentials. Liferay Screens uses a Liferay Session to access and query the JSON web services provided by Liferay Portal. When you log in using a Liferay Session, the portal returns the user's information (name, email, user ID, etc…). Screens stores this information and the active Liferay Session in Screens's `SessionContext` class.

The `SessionContext` class is very powerful and lets you use Screens in many different scenarios. For example, you can use `SessionContext` to request information with the JSON WS API provided by Liferay. You can also use `SessionContext` to create anonymous sessions, or to log in a user without showing a Login Screenlet.

This tutorial explains some common `SessionContext` use cases, and and also describes the class's most important methods.

Creating a Session from an Existing Session

When working with Liferay Screens, you may wish to call the remote JSON web services provided by the Liferay Mobile SDK. Every operation with the Liferay Mobile SDK needs a Liferay Session to provide the server address, user credentials, and any other required parameters. Since the Login Screenlet creates a session when a user successfully logs in, you can retrieve this session with the `SessionContext` method `createSessionFromCurrentSession()`. You can then use that session to make the Mobile SDK service call. The following example shows this for calling the Mobile SDK's `BookmarksEntryService`:

```
Session sessionFromCurrentSession = SessionContext.createSessionFromCurrentSession();
sessionFromCurrentSession.setCallback(callback);

new BookmarksEntryService(sessionFromCurrentSession).methodCall()
```

If you need to check first to see if a user has logged in, you can use `SessionContext.isLoggedIn()`.

Great! Now you know how to retrieve an existing session in your app. But what if you're not using the Login Screenlet? There won't be an existing session to retrieve. No sweat! You can still use `SessionContext` to create one manually. The next section shows you how to do this.

Creating a Session Manually

If you don't use the Login Screenlet, then SessionContext doesn't have a session for you to retrieve. In this case, you must create one manually. You can do this with the SessionContext method createBasicSession. The method takes a username and password as parameters, and creates a session with those credentials. If you also need to access a user's information, you must manually call the User JSON web service, or call SessionContext.setLoggedUser(). The following code creates a session with createBasicSession and then uses setLoggedUser to set the user in SessionContext:

```
LiferayScreensContext.init(this);

Session session = SessionContext.createBasicSession(USERNAME, PASSWORD);
SessionContext.setLoggedUser(USER);
```

Note that you can achieve the same thing by calling the interactor directly:

```
LoginBasicInteractor loginBasicInteractor = new LoginBasicInteractor(0);
loginBasicInteractor.onScreenletAttached(this);
loginBasicInteractor.setLogin(USERNAME);
loginBasicInteractor.setPassword(PASSWORD);
loginBasicInteractor.login();
```

Super! Now you know how to create a session manually. The next section shows you how to implement auto-login, and save or restore a session.

Implementing Auto-login and Saving or Restoring a Session

Although the Login Screenlet is awesome, your users may not want to enter their credentials every time they open your app. It's very common for apps to only require a single login. To implement this in your app, see this video.

In short, you need to pass a storage type to the Login Screenlet, and then use SessionContext.isLoggedIn() to check for a session. If a session doesn't exist, load the stored session from CredentialsStorage with loadStoredCredentials(StorageType storageType). The following code shows a typical implementation of this:

```
LiferayScreensContext.init(this); // If you haven't called a Screenlet yet
SessionContext.loadStoredCredentials(SHARED_PREFERENCES);

if (SessionContext.isLoggedIn()) {
    // logged in
    // consider doing a relogin here (see next section)
} else {
    // send user to login form
}
```

Awesome! Now you know how to implement auto-login in your Liferay Screens apps. For more information on available SessionContext methods, see the Methods section at the end of this tutorial. Next, you'll learn how to implement relogin for cases where a user's credentials change on the server while they're logged in.

Implementing Relogin

A session, whether created via Login Screenlet or auto-login, contains basic user data that verifies the user in the Liferay instance. If that data changes in the server, then your session is outdated, which may cause your app to behave inconsistently. Also, if a user is deleted, deactivated, or otherwise changes their credentials in the server, the auto-login feature won't deny access because it doesn't perform server transactions: it only retrieves an existing session from local storage. This isn't an optimal situation!

For such scenarios, you can use the relogin feature. This feature is implemented in a simple method that determines if the current session is still valid. If the session is still valid, the user's data is updated with the most recent data from the server. If the session isn't valid, the user is logged out and must then log in again to create a new session.

To use this feature, call the `SessionContext` method `relogin`, with an object that implements the `LoginListener` interface as an argument:

```
SessionContext.relogin(listener);
```

This method handles success or failure via the listener's `onLoginSuccess` and `onLoginFailure` methods, respectively. Note that this operation is done asynchronously in a background thread, so the listener is called in that thread. If you also want to perform any UI operations, you must do so in your UI thread. For example:

```
@Override
public void onLoginSuccess(final User user) {
    runOnUiThread(new Runnable() {
        @Override
        public void run() {
            // do any UI operation here
        }
    });
}
```

Great! Now you know how to implement relogin in your app. You've also seen how handy `SessionContext` can be. It can do even more! The next section lists some additional `SessionContext` methods, and some more detail on the ones used in this tutorial.

Methods

Method | Return Type | Explanation | `logout()` | `void` | Clears the stored user attributes and session. | `relogin(LoginListener)` | `void` | Refreshes user data from the server. This recreates the `currentUser` object if successful, or calls `logout()` on failure. When the server data is received, the listener method `onLoginSuccess` is called with received user's attributes. If an error occurs, the listener method `onLoginFailure` is called. | `isLoggedIn()` | `boolean` | Returns `true` if there is a stored Liferay Session in `SessionContext`. | `createBasicSession(String username, String password)` | `Session` | Creates a Liferay Session using the default server and the supplied username and password. | `createSessionFromCurrentSession()` | `Session` | Creates a Liferay Session based on the stored credentials and server. | `getCurrentUser()` | `User` | Returns a `User` object containing the server attributes of the logged-in user. This includes the user's email, user ID, name, and portrait ID. | `storeCredentials(StorageType storageType)` | `void` | Stores the current session in the `StorageType` supplied as a parameter. | `removeStoredCredentials(StorageType storageType)` | `void` | Clears the `StorageType` of any user information and session. | `loadStoredCredentials(StorageType storageType)` | `void` | Loads the session and user information from the `StorageType` parameter, and uses it as the current session and user. |

For more information, see the `SessionContext` source code in GitHub.

Login Screenlet for Android

Using Screenlets in Android Apps

76.13 Adding Custom Interactors to Android Screenlets

Interactors are Screenlet components that implement server communication for a specific use case. For example, the Login Screenlet's interactor calls the Liferay Mobile SDK service that authenticates a user to the portal. Similarly, the interactor for the Add Bookmark Screenlet calls the Liferay Mobile SDK service that adds a bookmark to the Bookmarks portlet.

That's all fine and well, but what if you want to customize a Screenlet's server call? What if you want to use a different back-end with a Screenlet? No problem! You can implement a custom interactor for the Screenlet. You can plug in a different interactor that makes its server call by using custom logic or network code. To do this, you must implement the current interactor's interface and then pass it to the Screenlet you want to override. You should do this inside your app's code, either in an inner class or a separate class.

In this tutorial, you'll see an example interactor that overrides the Login Screenlet to always log in the same user, without a password. You can find the complete code in the test-app on GitHub.. Note that this example implements the custom interactor in an inner class of an activity.

Implementing a Custom Interactor

1. Implement your custom interactor. You must inherit the original interactor's interface, as shown here:

```
private class CustomLoginInteractor extends LoginBasicInteractor {

    public CustomLoginInteractor(int targetScreenletId) {
        super(targetScreenletId);
    }

    @Override
    public void login() throws Exception {
        //custom implementation
    }
}
```

2. Call the interactor's listener. In your custom logic, you must call the interactor's listener. In this example, you must call `onLoginFailure` and `onLoginSuccess`, depending on your custom logic's result:

```
if (SUCCESS) {
    getListener().onLoginSuccess(fakeUser);
}
else {
    getListener().onLoginFailure(new AuthenticationException("bad login"));
}
```

3. Return your interactor in the custom listener. You must use `setCustomInteractorListener` to set a specific listener that expects an Interactor created with `actionName` (a string):

```
_screenlet.setCustomInteractorListener(this);

@Override
public LoginInteractor createInteractor(String actionName) {
    return new CustomLoginInteractor(_loginScreenlet.getScreenletId());
}
```

Great! Now you know how to implement custom interactors for Android Screenlets. The next example builds on this by showing you how to access non-Liferay backends with a custom interactor.

Using Custom Interactors to Access Other Backends

Custom interactors are also capable of communicating with non-Liferay backends. The following example illustrates this by creating a custom interactor for the Add Bookmark Screenlet that can store bookmarks at Delicious. You can find this example's complete code at this gist.

1. Create a new custom interactor. This interactor inherits `BaseRemoteInteractor`, the base class of all interactors, with `AddBookmarkListener` as a type parameter. It also implements the `AddBookmarkInteractor` class. The base code for this new interactor is shown here:

```
public class AddDeliciousInteractorImpl extends BaseRemoteInteractor<AddBookmarkListener>
    implements AddBookmarkInteractor {

    public AddDeliciousInteractorImpl(int targetScreenletId) {
        super(targetScreenletId);
    }

    public void addBookmark(final String url, final String title, long folderId) throws Exception {
        ...
    }
}
```

2. Implement your custom logic. In this example, you must implement the code for accessing Delicious and inserting a new bookmark with the Delicious API. You can use the OkHttp library to pass the API your bookmark's URL and description. The following code shows this:

```
new Thread(new Runnable() {
    @Override
    public void run() {
        try {

            Headers headers = Headers.of("Authorization", "Bearer _OAUTH_TOKEN_");

            OkHttpClient client = new OkHttpClient();

            Request add = new Request.Builder()
                .url("https://api.del.icio.us/api/v1/posts/add?url=" + url + "&description=" + title)
                .headers(headers)
                .build();

            com.squareup.okhttp.Response response = client.newCall(get).execute();

            String text = response.body().string();

            ...

        }
        catch (IOException e) {
            LiferayLogger.e("Error sending", e);
            ...
        }
    }
}).start();
```

3. Notify your app of the results. You should use the `EventBusUtil` class to post an event for this. Use the event to let other classes listen for the event. The following code uses `EventBusUtil.post(text)` to post the event, and the `onEvent` method to notify the listener:

```
EventBusUtil.post(text);

...

public void onEvent(String text) {
    getListener().onAddBookmarkSuccess();
}
```

Note that the code in the gist uses the custom `BookmarkAdded` class to model the operation's results.

4. In the activity or fragment you're using the Screenlet in, implement `CustomInteractorListener`. You must also reference your new custom interactor and connect it to the Screenlet:

```
_screenlet.setCustomInteractorListener(this);

@Override
public Interactor createInteractor(String actionName) {
    return new AddDeliciousInteractorImpl(_screenlet.getScreenletId());
}
```

Awesome! Now you know how to create a custom interactor that can communicate with a non-Liferay backend. This opens up even more possibilities for your apps.

Architecture of Liferay Screens for Android

Creating Android Screenlets

76.14 Rendering Web Content in Your Android App

Liferay DXP represents web content articles as `JournalArticle` entities. Liferay Screens provides several ways to render these entities in your apps.

The simplest way to display a `JournalArticle`'s HTML in your app is to use Web Content Display Screenlet. This Screenlet is very powerful and supports several complex use cases to fit your needs. You can also use Web Content List Screenlet to display lists of web content articles. This tutorial shows you how to use both Screenlets to display web content in your apps.

Retrieving Basic Web Content

Web Content Display Screenlet's simplest use case is to render a `JournalArticle`'s HTML in an Android `WebView`. Simply provide the `JournalArticle`'s `articleId` in the Screenlet XML, and the Screenlet takes care of the rest (including decorating itself with the CSS needed to render it in a small display). The following Screenlet XML shows this:

```
<com.liferay.mobile.screens.webcontent.display.WebContentDisplayScreenlet
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:articleId="YOUR_ARTICLE_ID" />
```

To render the content *exactly* as it appears on your mobile site, however, you must provide the CSS inline or use a template. The HTML returned isn't aware of a Liferay instance's global CSS.

You can also use a listener to modify the HTML, as explained in the Screenlet reference documentation.

In the default security policy, an Android `WebView` doesn't execute a page's JavaScript. You can enable such JavaScript execution by setting the `javascriptEnabled` property via XML:

```
<com.liferay.mobile.screens.webcontent.display.WebContentDisplayScreenlet
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:articleId="YOUR_ARTICLE_ID"
    app:javascriptEnabled="true" />
```

Alternatively, you can set this property in your app's fragment or activity class that contains the Screenlet:

```
...
screenlet.setJavascriptEnabled(true);
...
```

You can also use the `isJavascriptEnabled()` method to check this property's setting.

As you can see, this is all straightforward. What could go wrong? Famous last words. A common mistake is to use the default `groupId` instead of the one for the site that contains your `JournalArticle` entities.

If you need to use a default `groupId` in the rest of your app, but render another site's HTML, you can set the Web Content Display Screenlet's `groupId` with the `app:groupId` attribute. You can alternatively use the `setGroupId` method in the activity or fragment code that uses the Screenlet.

Using Templates

Web Content Display Screenlet can also use templates to render `JournalArticle` entities. For example, your Liferay instance may have a custom template specifically designed to display content on mobile devices.

To use a template, specify its ID in the Screenlet XML's `templateId` property:

```
<com.liferay.mobile.screens.webcontent.display.WebContentDisplayScreenlet
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    app:articleId="YOUR_ARTICLE_ID"
    app:templateId="YOUR_TEMPLATE_ID" />
```

Using Structures

Since mobile devices have limited screen space, you must often display only the most important parts of a web content article. If your web content is structured, you can do this by using Web Content Display Screenlet to display only specific fields from a `JournalArticle`'s structure. The simplest way to do this is to specify the structure's ID and a comma-delimited list of fields in the Screenlet XML's `structureId` and `labelFields` attributes, respectively. The following example illustrates this:

```
<com.liferay.mobile.screens.webcontent.display.WebContentDisplayScreenlet
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    liferay:articleId="YOUR_ARTICLE_ID"
    liferay:labelFields="YOUR_LABELS"
    liferay:layoutId="@layout/webcontentdisplay_structured_default"
    liferay:structureId="YOUR_STRUCTURE_ID" />
```

You can also use your own layout to render the structure fields exactly how you want. To do this, your layout should inherit from `WebContentStructuredDisplayView` and read the information parsed and stored in the `webContent` entity. By displaying two structure fields with such a custom layout, the test app contains a complete example of this:

1. The layout file `webcontentdisplaystructured_example.xml` defines the custom layout:

```
<com.liferay.mobile.screens.testapp.webviewstructured.WebContentDisplayView
    xmlns:android="http://schemas.android.com/apk/res/android"
    android:layout_width="match_parent"
    android:layout_height="match_parent">

    <TextView
        android:id="@+id/web_content_first_field"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:background="@android:color/holo_red_light" />

    <TextView
        android:id="@+id/web_content_second_field"
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:background="@android:color/holo_green_light" />

</com.liferay.mobile.screens.testapp.webviewstructured.WebContentDisplayView>
```

2. The `WebContentDisplayView` class sets the custom layout's functionality:

```
public class WebContentDisplayView extends WebContentStructuredDisplayView {

    ...

    @Override
    public void showFinishOperation(WebContent webContent) {
        super.showFinishOperation(webContent);

        DDMStructure ddmStructure = webContent.getDDMStructure();

        TextView firstField = (TextView) findViewById(R.id.first_field);
        firstField.setText(String.valueOf(ddmStructure.getField(0).getCurrentValue()));

        TextView secondField = (TextView) findViewById(R.id.second_field);
        secondField.setText(String.valueOf(ddmStructure.getField(1).getCurrentValue()));
    }
}
```

3. The Screenlet XML's `layoutId` attribute specifies the custom layout to use:

```
<com.liferay.mobile.screens.webcontent.display.WebContentDisplayScreenlet
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    liferay:articleId="@string/liferay_article_structured_article_id"
    liferay:labelFields="@string/liferay_article_structured_label_fields_first_field"
    liferay:layoutId="@layout/webcontentdisplaystructured_example"
    liferay:offlinePolicy="REMOTE_FIRST"
    liferay:structureId="@string/liferay_article_structured_structure_id" />
```

Great! Now you know how to use structured web content with Web Content Display Screenlet. Next, you'll learn how to display a list of web content articles in your app.

Displaying a List of Web Content Articles

The preceding examples show you how to use Web Content Display Screenlet to display a single web content article's contents in your app. But what if you want to display a list of articles instead? No problem! You can use Web Content List Screenlet for this. Web Content List Screenlet can retrieve the contents of a web content folder and display only the labels you want. The Screenlet is also aware of structured content, so you can render each row with certain structure fields. You can also do this via a custom layout.

To use a web content folder with Web Content List Screenlet, specify the folder's ID in the Screenlet XML's `folderId` attribute. To render a specific structure field for each article in the list, specify that field in the Screenlet XML's `labelFields` attribute. For example:

```
<com.liferay.mobile.screens.webcontent.list.WebContentListScreenlet
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:folderId="YOUR_FOLDER_ID"
    app:labelFields="Text" />
```

You can also see an example of this in the test app's `web_content_display_list.xml` layout file.

Also note that several methods in Screens's `WebContent` class help you render content from different locales. For example, `getLocalized(name)` receives a field's name and returns the value in the mobile device's current locale. Such methods help you render a custom view without worrying about the underlying structure, XML parsing, or HTTP calls.

Displaying a List of Assets

To render a list of different assets in your app, including web content articles, you can use Asset List Screenlet. Asset List Screenlet can display a list of any assets from a Liferay instance. Like Web Content List Screenlet, you can also access a web content article's structure fields, or use a custom layout to render each asset type. For more information, see the reference documentation for Asset List Screenlet.

76.15 Rendering Web Pages in Your Android App

The Rendering Web Content tutorial shows you how to display web content from a Liferay DXP site in your Android app. Displaying content is great, but what if you want to display an entire page? No problem! Web Screenlet lets you display any web page. You can even customize the page by injecting local or remote JavaScript and CSS files. When combined with Liferay DXP's server-side customization features (e.g., Application Display Templates), Web Screenlet gives you almost limitless possibilities for displaying web pages in your Android apps.

In this tutorial, you'll learn how to use Web Screenlet to display web pages in your Android app.

Inserting Web Screenlet in Your App

Inserting Web Screenlet in your app is the same as inserting any Screenlet in your app:

1. Insert the Screenlet's XML in the layout of the activity or fragment you want to use the Screenlet in. Also be sure to set any attributes that you need. For a list of Web Screenlet's available attributes, see the Attributes section of the Web Screenlet reference doc.

   For example, here's Web Screenlet's XML with the Screenlet's `layoutId` and `autoLoad` attributes set to `web_default` and `false`, respectively:

```
<com.liferay.mobile.screens.web.WebScreenlet
    android:id="@+id/web_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:layoutId="@layout/web_default"
    app:autoLoad="false"
    />
```

Note that `web_default` specifies the Screenlet's Default View, which is part of the Default View Set.

2. To use a View that is part of a View Set, like the Default View, the app or activity theme must inherit the theme that sets the View Set's styles. For the Default View Set, this is `default_theme`. For example, to set the app's theme to inherit `default_theme`, open `res/values/styles.xml` and set the base app theme's parent to `default_theme`. In this example, the base app theme is `AppTheme`:

```
<style name="AppTheme" parent="default_theme">
    ...
```

Next, you'll implement Web Screenlet's listener.

Implementing Web Screenlet's Listener

To use any Screenlet in an activity or fragment, you must also implement the Screenlet's listener in that activity or fragment's class. Web Screenlet's listener is `WebListener`. Follow these steps to implement `WebListener`:

1. Change the class declaration to implement `WebListener`, and import `com.liferay.mobile.screens.web.WebListener`:

```
...
import com.liferay.mobile.screens.web.WebListener;
...

public class YourActivity extends AppCompatActivity implements WebListener {...
```

2. Implement `WebListener`'s `onPageLoaded` method. This method is called when the Screenlet loads the page successfully. How you implement it depends on what (if anything) you want to happen upon page load. For example, this `onPageLoaded` implementation displays a toast message indicating success:

```
@Override
public void onPageLoaded(String url) {
    Toast.makeText(this, "Page load successful!", Toast.LENGTH_SHORT).show();
}
```

3. Implement `WebListener`'s `onScriptMessageHandler` method. This method is called when the Screenlet's `WebView` sends a message. The `namespace` argument is the source namespace key, and the `body` argument is the source namespace body. For example, this `onScriptMessageHandler` implementation parses data from the source namespace body if it matches a specific namespace, and then starts a new activity with that data via an intent:

```
@Override
public void onScriptMessageHandler(String namespace, String body) {
    if ("gallery".equals(namespace)) {
        String[] allImgSrc = body.split(",");
        int imgSrcPosition = Integer.parseInt(allImgSrc[allImgSrc.length - 1]);

        Intent intent = new Intent(getApplicationContext(), DetailMediaGalleryActivity.class);
```

```
            intent.putExtra("allImgSrc", allImgSrc);
            intent.putExtra("imgSrcPosition", imgSrcPosition);
            startActivity(intent);
        }
    }
```

4. Implement the `error` method. This method is called when an error occurs in the process. The `e` argument contains the exception, and the `userAction` argument distinguishes the specific action in which the error occurred. In most cases, you'll use these arguments to log or display the error. For example, this `error` implementation displays a toast message with the exception's message:

```
@Override
public void error(Exception e, String userAction) {
    Toast.makeText(this, "Bad things happened: " + e.getMessage(), Toast.LENGTH_LONG).show();
}
```

5. Get a `WebScreenlet` reference and set the activity or fragment class as its listener. To do so, import `com.liferay.mobile.screens.web.WebScreenlet` and add the following code to the end of the `onCreate` method:

```
WebScreenlet screenlet = (WebScreenlet) findViewById(R.id.web_screenlet);
screenlet.setListener(this);
```

   Note that the `findViewById` references the `android:id` value set in the Screenlet's XML.

Next, you'll use the same `WebScreenlet` reference to set the Screenlet's parameters.

Setting Web Screenlet's Parameters

Web Screenlet has `WebScreenletConfiguration` and `WebScreenletConfiguration.Builder` objects that supply the parameters the Screenlet needs to work. These parameters include the URL of the page to load and the location of any JavaScript or CSS files that customize the page. You'll set most of these parameters via `WebScreenletConfiguration.Builder`'s methods.

Note: For a full list of `WebScreenletConfiguration.Builder`'s methods, and a description of each, see the table in the Configuration section of Web Screenlet's reference doc.

To set Web Screenlet's parameters, follow these steps in the method that initializes the activity or fragment containing the Screenlet (e.g., `onCreate` in activities, `onCreateView` in fragments). You can, however, do this in other methods as needed.

1. Use `WebScreenletConfiguration.Builder(<url>)`, where `<url>` is the web page's URL string, to create a `WebScreenletConfiguration.Builder` object. If the page requires Liferay DXP authentication, then the user must be logged in via Login Screenlet or a `SessionContext` method, and you must provide a relative URL to the `WebScreenletConfiguration.Builder` constructor. For example, if such a page's full URL is `http://your.liferay.instance/web/guest/blog`, then the constructor's argument is `/web/guest/blog`. For any other page that doesn't require Liferay DXP authentication, you must supply the full URL to the constructor.

2. Call the `WebScreenletConfiguration.Builder` methods to set the parameters that you need.

```
**Note:** If the URL you supplied to the `WebScreenletConfiguration.Builder`
constructor is to a page that doesn't require Liferay DXP authentication, then
you must call the `WebScreenletConfiguration.Builder` method
`setWebType(WebScreenletConfiguration.WebType.OTHER)`. The default `WebType`
is `LIFERAY_AUTHENTICATED`, which is required to load Liferay DXP pages that
require authentication. If you need to set `LIFERAY_AUTHENTICATED` manually,
call `setWebType(WebScreenletConfiguration.WebType.LIFERAY_AUTHENTICATED)`.
```

3. Call the `WebScreenletConfiguration.Builder` instance's `load()` method, which returns a `WebScreenletConfiguration` object.
4. Use Web Screenlet's `setWebScreenletConfiguration` method to set the `WebScreenletConfiguration` object to the Web Screenlet instance.
5. Call the Web Screenlet instance's `load()` method.

Here's an example snippet of these steps in the `onCreate()` method of an activity in which the Web Screenlet instance is `screenlet`, and the `WebScreenletConfiguration` object is `webScreenletConfiguration`:

```
WebScreenletConfiguration webScreenletConfiguration =
            new WebScreenletConfiguration.Builder("/web/westeros-hybrid/companynews")
                .addRawCss(R.raw.portlet, "portlet.css")
                .addLocalCss("gallery.css")
                .addLocalJs("gallery.js")
                .load();

        screenlet.setWebScreenletConfiguration(webScreenletConfiguration);
        screenlet.load();
```

There are a few things to note about this example:

- The relative URL `/web/westeros-hybrid/companynews` supplied to the `WebScreenletConfiguration.Builder` constructor, and the lack of a `setWebType(WebScreenletConfiguration.WebType.OTHER)` call, indicates that this Web Screenlet instance loads a Liferay DXP page that requires authentication.
- The `addRawCss` method adds the CSS file `portlet.css` from the app's `res/raw` folder. Any files that you add via the methods `addRawCss` or `addRawJs` must be located in `res/raw` (create this folder if it doesn't exist). Also note that you must reference these files with `R.raw.yourfilename`. For instance, the `portlet.css` file in this is example is referenced with `R.raw.portlet`.
- The `addLocalCss` and `addLocalJs` methods add the local files `gallery.css` and `gallery.js`, respectively. Any files that you add via these methods must be in the first level of your app's `assets` folder. This folder must exist at the same level as your app's `res` folder. Create the `assets` folder in that location if it doesn't exist.

Great! Now you know how to use Web Screenlet in your Android apps.

Using Web Screenlet with Cordova in Your Android App

Using Screenlets in Android Apps

Rendering Web Content in Your Android App

76.16 Using Web Screenlet with Cordova in Your Android App

By using Cordova plugins in Web Screenlet, you can extend the functionality of the web page that the Screenlet renders. This lets you tailor that page to your app's needs.

You'll get started by installing and configuring Cordova. There are two ways to do this: automatically, or manually. The automatic method is covered first.

Installing and Configuring Cordova Automatically

Follow these steps to automatically create an empty Android project configured to use Cordova. Note that you must have git, Node.js, and npm installed.

1. Install `screens-cli`:

   ```
   npm install -g screens-cli
   ```

2. Create the file `.plugins.screens` in the folder you want to create your project in. In this file, add all the Cordova plugins you want to use in your app. For example, you can add plugins from Cordova or GitHub:

   ```
   https://github.com/apache/cordova-plugin-wkwebview-engine.git
   cordova-plugin-call-number
   cordova-plugin-camera
   ```

3. In the folder containing your `.plugins.screens` file, run `screens-cli` to create your project:

   ```
   screens-cli android <project-name>
   ```

   This creates your project in the folder `platforms/android/<project-name>`. You can open it with Android Studio.

Installing and Configuring Cordova Manually

To install and configure Cordova manually, follow these steps:

1. Follow the Cordova getting started guide to install Cordova, create a Cordova project, and add the Android platform to your Cordova project.

2. Install any Cordova plugins you want to use in your app. For example, this command adds the Cordova plugin `cordova-plugin-call-number`:

   ```
   cordova plugin add cordova-plugin-call-number
   ```

   You can use `cordova plugin` to view the currently installed plugins.

3. Copy the following files and folders from your Cordova project to your Android project's root folder:

   - `/platforms/android/res/xml/config.xml`
   - `/platforms/android/assets/www`

   You should also review other files like `AndroidManifest.xml`, resource files, and so on. Some plugins add permissions or styles in such files that you may need to copy for those plugins to work correctly in your Android app.

Using Cordova in Web Screenlet

Now that you've installed and configured Cordova in your Android project, you're ready to use it with Web Screenlet. Follow these steps to do so:

1. Insert and configure Web Screenlet in your app.

2. When you set Web Screenlet's parameters via the `WebScreenletConfiguration.Builder` object, you must enable Cordova by calling the `enableCordova` method with a `CordovaLifeCycleObserver` argument. `CordovaLifeCycleObserver` informs Cordova about the activity lifecycle. You can create an instance of this observer by using its no-argument constructor.

   For example, this code creates a `CordovaLifeCycleObserver` object that it then uses with `enableCordova` when setting Web Screenlet's parameters:

   ```
   CordovaLifeCycleObserver observer = new CordovaLifeCycleObserver();

   WebScreenletConfiguration configuration =
           new WebScreenletConfiguration
                   .Builder("/")
                   .addLocalJs("call.js")
                   .enableCordova(observer)
                   .load();

   webScreenlet.setWebScreenletConfiguration(configuration);
   webScreenlet.load();
   ```

3. Override the following `Activity` methods to call their corresponding observer methods:

   ```
   @Override
   protected void onStart() {
       super.onStart();
       observer.onStart();
   }

   @Override
   protected void onStop() {
       super.onStop();

       observer.onStop();
   }

   @Override
   public void onPause() {
       super.onPause();

       observer.onPause();
   }

   @Override
   public void onResume() {
       super.onResume();

       observer.onResume();
   }

   @Override
   public void onDestroy() {
       super.onDestroy();

       observer.onDestroy();
   }
   ```

```
    @Override
    public void onSaveInstanceState(Bundle outState) {
        super.onSaveInstanceState(outState);

        observer.onSaveInstanceState(outState);
    }

    @Override
    protected void onActivityResult(int requestCode, int resultCode, Intent data) {
        super.onActivityResult(requestCode, resultCode, data);

        observer.onActivityResult(requestCode, resultCode, data);
    }

    @Override
    public void onRequestPermissionsResult(int requestCode, @NonNull String[] permissions,
        @NonNull int[] grantResults) {
            super.onRequestPermissionsResult(requestCode, permissions, grantResults);

            observer.onRequestPermissionsResult(requestCode, permissions, grantResults);
    }

    @Override
    public void onConfigurationChanged(Configuration newConfig) {
        super.onConfigurationChanged(newConfig);

        observer.onConfigurationChanged(newConfig);
    }
```

That's it! Note, however, that you may also need to invoke Cordova from a JavaScript file, depending on what you're doing. For example, to use the Cordova plugin `cordova-plugin-call-number` to call a number, you must add a JavaScript file with the following code:

```
function callNumber() {
    //This line triggers the Cordova plugin and makes a call
    window.plugins.CallNumber.callNumber(null, function(){ alert("Calling failed.") }, "900000000", true);
}

setTimeout(callNumber, 3000);
```

If you run the app containing this code and wait three seconds, the plugin activates and calls the number in the JavaScript file.

Great! Now you know how to use Web Screenlet with Cordova.

Web Screenlet for Android

76.17 Adding Offline Mode Support to Your Android Screenlet

Offline mode lets Screenlets function without a network connection. For offline mode to work with your Screenlet, you must manually add support for it. Fortunately, Liferay Screens 2.0 introduced a simpler way of implementing offline mode support in Android Screenlets:

- Update your Screenlet's classes to leverage the offline mode cache
- Create an event class (if your Screenlet doesn't already have one)

Implementing these steps, however, differs somewhat depending on how your Screenlet communicates with the server:

- **A write Screenlet:** writes data to a server. The Add Bookmark Screenlet created in the basic Screenlet creation tutorial is a good example of a simple write Screenlet. It asks the user to enter a URL and a title, which it then sends to the Bookmarks portlet in Liferay DXP to create a bookmark.
- **A read Screenlet:** reads data from a server. The Web Content Display Screenlet included with Liferay Screens is a good example of a read Screenlet. It retrieves web content from Liferay DXP for display in an Android app. Click here to see Web Content Display Screenlet's documentation.

This tutorial shows you how to add offline mode support to both kinds of Screenlets. You'll start with write Screenlets, using Add Bookmark Screenlet as an example. Before getting started, be sure to read the basic Screenlet creation tutorial to familiarize yourself with Add Bookmark Screenlet's code. You'll conclude by learning how offline mode implementation in read Screenlets differs from that of write Screenlets.

Adding Offline Mode Support to Write Screenlets

To add offline mode support to write Screenlets, you'll follow these steps:

1. Create or update the event class.
2. Update the listener interface.
3. Update the Interactor class.
4. Update the Screenlet class.
5. Sync the cache with the server.

Each of the sections that follow detail one of these steps. You'll begin by creating or updating the event class.

Create or Update the Event Class

Recall from the basic Screenlet creation tutorial that an event class is required to handle communication between Screenlet components. Also recall that many Screenlets can use the event class included with Screens, `BasicEvent`, as their event class. For offline mode to work, however, you must create an event class that extends `CacheEvent` (click here to see `CacheEvent`). Your event class has one primary responsibility: store and provide access to the arguments passed to the Interactor. To accomplish this, your event class should do these things:

- Extend `CacheEvent`. For the arguments, define variables and public getter methods.
- Define a no-argument constructor that only calls the corresponding superclass constructor.
- Define a constructor that sets the Interactor's arguments.

In the case of Add Bookmark Screenlet, the arguments are the bookmark's URL, folder ID, and title. For example, here's the full code for this Screenlet's event class, `BookmarkEvent`:

```
public class BookmarkEvent extends CacheEvent {

    private String url;
    private String title;
    private long folderId;

    public BookmarkEvent() {
        super();
    }

    public BookmarkEvent(String url, String title, long folderId) {

        this.url = url;
        this.title = title;
        this.folderId = folderId;
    }

    public String getURL() {
        return url;
    }

    public String getTitle() {
        return title;
    }

    public long getFolderId() {
        return folderId;
    }
}
```

Next, you'll update the listener.

Update the Listener

Recall from the basic Screenlet creation tutorial that the listener interface defines a success method and a failure method. This lets implementing classes respond to the server call's success or failure. Listeners that support offline mode offer the same functionality, although differently. Offline mode listeners must extend `BaseCacheListener`, which defines only this `error` method:

```
void error(Exception e, String userAction);
```

By extending `BaseCacheListener`, your listener no longer needs an explicit failure method because it inherits the `error` method instead. This `error` method also includes an argument for the user action that triggered the exception.

You can therefore update your listener to support offline mode by extending `BaseCacheListener` and deleting the failure method. For example, here's Add Bookmark Screenlet's listener, `AddBookmarkListener`, after being updated to support offline mode:

```
public interface AddBookmarkListener extends BaseCacheListener {

    onAddBookmarkSuccess();
}
```

Note that you must also remove any failure method implementations (such as in an activity or fragment that implements the listener), and replace any failure method calls with `error` method calls. You'll do the latter next when updating the Interactor class.

Update the Interactor Class

Recall from the basic Screenlet creation tutorial that Interactor classes extend `BaseRemoteInteractor` with the listener and event as type arguments. To support offline mode, your Interactor class must instead extend one of the following classes. Which one depends on whether your Interactor writes data to or reads data from a server:

- `BaseCacheWriteInteractor`: writes data to a server. Extend this class if your Screenlet is a write Screenlet. Click here to see this class.

- BaseCacheReadInteractor: reads data from a server. Extend this class if your Screenlet is a read Screenlet. Click here to see this class.

In either case, the type arguments are the same: the listener and the event. Note, however, that the event must extend CacheEvent as described above. For example, since Add Bookmark Screenlet is a write Screenlet, to support offline mode its Interactor class must extend BaseCacheWriteInteractor with AddBookmarkListener and AddBookmarkEvent as type arguments:

```
public class AddBookmarkInteractor extends
    BaseCacheWriteInteractor<AddBookmarkListener, BookmarkEvent> {...
```

You must also make a few changes to the Interactor class's code. The main change is that the execute method now takes the event instead of var args. You can then retrieve the data you need from the event. For example, to support offline mode, the execute method in AddBookmarkInteractor takes BookmarkEvent as an argument. The bookmark's URL, title, and folder ID are then retrieved from the event for use in the getJSONObject method that makes the server call. The execute method finishes by setting the resulting JSONObject to the event, and then returning the event:

```
@Override
public BookmarkEvent execute(BookmarkEvent bookmarkEvent) throws Exception {

    validate(bookmarkEvent.getUrl(), bookmarkEvent.getFolderId());

    JSONObject jsonObject = getJSONObject(bookmarkEvent.getUrl(), bookmarkEvent.getTitle(),
        bookmarkEvent.getFolderId());
    bookmarkEvent.setJSONObject(jsonObject);
    return bookmarkEvent;
}
```

You should also change the onSuccess method to take an instance of your event class instead of BasicEvent. This is the only change you need to make to this method. For example, the onSuccess method in AddBookmarkInteractor supports offline mode by taking a BookmarkEvent instead of a BasicEvent:

```
@Override
public void onSuccess(BookmarkEvent event) {
    getListener().onAddBookmarkSuccess();
}
```

Now make the same change to the onFailure method, but replace the listener's failure method call with a call to the error method inherited from BaseCacheListener (see the listener section above for an explanation of this method). For the error method's arguments, you can retrieve the exception from the event and define a string to use as the user action. For example, to support offline mode the onFailure method in AddBookmarkInteractor takes a BookmarkEvent instead of a BasicEvent. Also, the method's error call defines the "ADD_BOOKMARK" string to indicate that the error occurred while trying to add a bookmark to the server:

```
@Override public void onFailure(BookmarkEvent event) {
    getListener().error(event.getException(), "ADD_BOOKMARK");
}
```

Update the Screenlet Class

Updating the Screenlet class for offline mode is straightforward. In the Screenlet class's `onUserAction` method, you'll change the call to the Interactor's `start` method so that it takes only an event as an argument. Before doing this, however, you should create an event instance and set its cache key. A cache key is a value that identifies an entity in the local cache. This lets you retrieve the entity from the cache for later synchronization with the server.

In Add Bookmark Screenlet, for example, a bookmark's URL makes a good cache key. To support offline mode, the `onUserAction` method in `AddBookmarkScreenlet` creates a new `BookmarkEvent` instance with a bookmark's data and then uses the `setCacheKey` method to set the bookmark's URL as the event's cache key. The Interactor's start method takes this event as its argument:

```
BookmarkEvent event = new BookmarkEvent(url, title, folderId);
event.setCacheKey(url);
interactor.start(event);
```

Note that you don't have to set a cache key to use offline mode. Instead, you can pass the event to the `start` method without calling `setCacheKey`. However, this means that you'll only be able to access the most recent entity in the cache.

That's it! Your write Screenlet now supports offline mode. There's one more detail to keep in mind, however, when using the Screenlet: syncing the cache with the server. You'll learn about this next.

Sync the Cache with the Server

When using a write Screenlet that supports offline mode, new data written to the cache must also be synced with the server. The write Screenlets included with Liferay Screens do this for you. However, you must do this manually when using a custom write Screenlet. You should do this in the activity or fragment that uses the Screenlet–exactly where in this activity or fragment is up to you though.

To sync a write Screenlet's data with the server manually, follow these steps:

1. Retrieve the event that needs to be synced with the server. To do this, you must first get the cache key associated with the event. Then use the key as an argument to the `Cache.getObject` method.
2. Call the Interactor with the event. This syncs the data with the server.

For example, the following code uses the `Cache.findKeys` method to retrieve all `BookmarkEvent` keys in the cache. The loop that follows then retrieves the event that corresponds to each key, and syncs it to the server by calling the Interactor:

```
String[] keys = Cache.findKeys(BookmarkEvent.class, groupId, userId, locale, 0,
    Integer.MAX_VALUE);
for (String key : keys) {

    BookmarkEvent event = Cache.getObject(BookmarkEvent.class, groupId, userId, key);
    new AddBookmarkInteractor().execute(event);
}
```

Note that if you opted not to set a cache key in your Screenlet class, you can pass `null` in place of a key.

Also note that you can use Android's `SharedPreferences` APIs as an alternative way to store and retrieve cache keys. For example, the following code stores cache keys in shared preferences:

```
SharedPreferences sharedPreferences = getSharedPreferences("MY_PREFERENCES", Context.MODE_PRIVATE);
HashSet<String> values = new HashSet<>();
sharedPreferences.edit().putStringSet("keysToSync", values).apply();
```

You can then retrieve the keys as you would retrieve any other key-value set from shared preferences:

```
SharedPreferences sharedPreferences = getSharedPreferences("MY_PREFERENCES", Context.MODE_PRIVATE);
HashSet<String> keysToSync = sharedPreferences.getStringSet("keysToSync", new HashSet<>());
```

Next, you'll learn how to add offline mode support to read Screenlets.

Adding Offline Mode Support to Read Screenlets

Implementing offline mode support in a read Screenlet is almost identical to doing so in a write Screenlet. There are two small differences, though:

1. You can still pass arguments to the Interactor with var args instead of an event.

2. The Interactor class must extend `BaseCacheReadInteractor`, which forces you to implement the `getIdFromArgs` method. This method takes the var args passed to the Interactor so you can return the argument that identifies your entity. Note that because this method requires you to return a `String`, you'll often use `String.valueOf` to return non-string arguments as a string. For example, the `getIdFromArgs` implementation in Comment Display Screenlet's `CommentLoadInteractor` retrieves the comment ID (a `long`) from the first argument and then returns it as a `String`:

```
    @Override
    protected String getIdFromArgs(Object... args) {
        long commentId = (long) args[0];
        return String.valueOf(commentId);
    }
```

That's it! Next, you'll learn about list Screenlets and offline mode support.

Adding Offline Mode Support to List Screenlets

A list Screenlet is a special type of read Screenlet that displays entities in a list. Recall from the list Screenlet creation tutorial that list Screenlets have a model class that encapsulates entities retrieved from the server. To support offline mode, a list Screenlet's event class must extend `ListEvent` with the model class as a type argument. This event class also needs three things:

1. A default constructor
2. A `getListKey` method that returns a unique ID to store the entity with
3. A `getModel` method that returns the model instance

The list Screenlet creation tutorial contains example model and event classes that support offline mode for Bookmark List Screenlet. Click the following links to see the sections in the tutorial that show you how to create these classes:

- Creating the Model Class
- Creating the Event

And that's all! Now you know how to support offline mode in your Screenlets.

76.18 Android Best Practices

When developing Android projects with Liferay Screens, there are a few best practices that you should follow to ensure your code is as clean and bug-free as possible. This tutorial lists these.

Update Your Tools

You should first make sure that you have the latest tools installed. You should use the latest Android API level with the latest version of Android Studio. Although Screens *may* work with Eclipse ADT or manual Gradle builds, Android Studio is the preferred IDE.

See the Breaking Changes Document

When updating an app or Screenlet to a new version of Liferay Screens, make sure to see the Android breaking changes reference article. This article lists changes to Screens that break functionality in prior versions. In most cases, updating your code is relatively straightforward.

Naming Conventions

Using the naming conventions described here leads to consistency and a better understanding of the Screens library. This makes working with your Screenlets much simpler.

Also note that Liferay Screens follows Square's Java conventions for Android, with tabs as separator. The configuration for IDEA, findbugs, PMD, and checkstyle is available in the project's source code.

Screenlet Folder

Your Screenlet folder's name should indicate your Screenlet's functionality. For example, Login Screenlet's folder is named `login`.

If you have multiple Screenlets that operate on the same entity, you can place them inside a folder named for that entity. For example, Asset Display Screenlet and Asset List Screenlet both work with Liferay assets. They're therefore in the Screens library's `asset` folder.

Screenlets

Naming Screenlets properly is very important; they're the main focus of Liferay Screens. You should name your Screenlet with its principal action first, followed by *Screenlet*. Its Screenlet class should also follow this pattern. For example, Login Screenlet's principal action is to log users into a Liferay DXP installation. This Screenlet's Screenlet class is therefore `LoginScreenlet`.

View Models

Name your View models the same way you name Screenlets, but substitute `ViewModel` for `Screenlet`. Also, place your View Models in a `view` folder in your Screenlet's root folder. For example, Login Screenlet's View Model is named `LoginViewModel` and is in the `login/view` folder.

Interactors

Place your Screenlet's Interactors in a folder named `interactor` in your Screenlet's root folder. Name each Interactor first with the object it operates on, followed by its action and the suffix *Interactor*. If you wish, you can also put each Interactor in its own folder named after its action. For example, Rating Screenlet has three Interactors. Each is in its own folder inside the `interactor` folder:

- `delete/RatingDeleteInteractor`: Deletes an asset's ratings
- `load/RatingLoadInteractor`: Loads an asset's ratings
- `update/RatingUpdateInteractor`: Updates an asset's ratings

Views

Place Views in a `view` folder in the Screenlet's root folder. If you're creating a View Set, however, you can place its Views in a separate `viewsets` folder outside your Screenlets' root folders. This is what the Screens Library does for its Material and Westeros View Sets. The `material` and `westeros` folders contain those View Sets, respectively. Also note that in each View, each Screenlet's View class is in its own folder. For example, the View class for Forgot Password Screenlet's Material View is in the folder `viewsets/material/src/main/java/com/liferay/mobile/screens/viewsets/material/auth/forgotpassword`. Note that the `auth` folder in this path is the Screenlet's module. Creating your Screenlets and Views in modules isn't required. Also note that the View's layout file `forgotpassword_material.xml` is in `viewsets/material/src/main/res/layout`.

Name a View's layout XML and View class after your Screenlet, substituting *View* for *Screenlet* where necessary. The layout's filename should also be suffixed with `_yourViewName`. For example, the XIB file and View class for Forgot Password Screenlet's Material View are `forgotpassword_material.xml` and `ForgotPasswordView.java`, respectively.

Avoid Hard Coded Elements

Using constants instead of hard-coded elements is a simple way to avoid bugs. Constants reduce the likelihood that you'll make a typo when referring to common elements. They also gather these elements in a single location. For example, DDL Form Screenlet's Screenlet class defines the following constants for the user action names:

```
public static final String LOAD_FORM_ACTION = "loadForm";
public static final String LOAD_RECORD_ACTION = "loadRecord";
public static final String ADD_RECORD_ACTION = "addRecord";
public static final String UPDATE_RECORD_ACTION = "updateRecord";
public static final String UPLOAD_DOCUMENT_ACTION = "uploadDocument";
```

Avoid State in Interactors

Liferay Screens uses EventBus to ensure that the network or background operation isn't lost when the device changes orientation. For this to work, however, you must ensure that your Interactor's request is stateless.

If an Interactor needs some piece of information, you should pass it to the Interactor via the `start` call and then attach it to the event. You can see an example of this in the sample Add Bookmark Screenlet from the Screenlet creation tutorial. The onUserAction method in the Screenlet class (AddBookmarkScreenlet) passes a Bookmark's URL and title from the View Model to the Interactor via the Interactor's start method:

```
@Override
protected void onUserAction(String userActionName, AddBookmarkInteractor interactor,
    Object... args) {
        AddBookmarkViewModel viewModel = getViewModel();
        String url = viewModel.getURL();
        String title = viewModel.getTitle();

        interactor.start(url, title, folderId);
}
```

The start method calls the Interactor's execute method in a background thread. The execute method in Add Bookmark Screenlet's Interactor (AddBookmarkInteractor) creates a BasicEvent object that contains the start method's arguments:

```
@Override
public BasicEvent execute(Object[] args) throws Exception {
    String url = (String) args[0];
    String title = (String) args[1];
    long folderId = (long) args[2];

    validate(url, folderId);

    JSONObject jsonObject = getJSONObject(url, title, folderId);
    return new BasicEvent(jsonObject);
}
```

Stay in Your Layer

When accessing variables that belong to other Screenlet components, you should avoid those outside your current Screenlet layer. This achieves better decoupling between the layers, which tends to reduce bugs and simplify maintenance. For an explanation of the layers in Liferay Screens, see the architecture tutorial. For example, don't directly access View variables from an Interactor. Instead, pass data from a View Model to the Interactor via the Interactor's start method. The example onUserAction method in the previous section illustrates this.

76.19 Liferay Screens for Android Troubleshooting and FAQs

Even though Liferay developed Screens for Android with great care, you may still run into some common issues. Here are solutions and tips for solving these issues. You'll also find answers to common questions about Screens for Android.

General Troubleshooting

Before delving into specific issues, you should first make sure that you have the latest tools installed and know where to get additional help if you need it. You should use the latest Android API level, with the latest version of Android Studio. Although Screens *can* work with Eclipse ADT or manual Gradle builds, Android Studio is the preferred IDE.

If you're having trouble using Liferay Screens, it may help to investigate the sample apps developed by Liferay. Both serve as good examples of how to use Screenlets and Views:

- Westeros Bank
- Test App

When updating an app or Screenlet to a new version of Liferay Screens, make sure to see the Android breaking changes reference article. This article lists changes to Screens that break functionality in prior versions. In most cases, updating your code is relatively straightforward.

If you get stuck at any point, you can post your question on our forum. We're happy to assist you! If you found a bug or want to suggest an improvement, file a ticket in our Jira. Note that you must log in first to be able to see the project.

Common Issues

This section contains information on common issues that can occur when using Liferay Screens.

1. Could not find `com.liferay.mobile:liferay-screens`

   This error occurs when Gradle isn't able to find Liferay Screens or the repository. First, check that the Screens version number you're trying to use exists in jCenter. You can use this link to see all uploaded versions.

   It's also possible that you're using an old Gradle plugin that doesn't use jCenter as the default repository. Screens uses version 1.2.3 and later. You can add jCenter as a new repository by placing this code in your project's `build.gradle` file:

   ```
   repositories {
       jcenter()
   }
   ```

2. Failed to resolve: `com.android.support:appcompat-v7`

   Liferay Screens uses the appcompat library from Google, as do all new Android projects created with the latest Android Studio. The appcompat library uses a custom repository maintained by Google, so it must be updated manually using the Android SDK Manager.

   In the Android SDK Manager (located at *Tools → Android → SDK Manager* in Android Studio), you must install at least version 14 of the Android Support Repository (in the *Extras* menu), and version 22.1.1 of the Android Support Library.

3. Duplicate files copied in `APK META-INF…`

   This is a common Android error when using libraries. It occurs because Gradle can't merge duplicated files such as license or notice files. To prevent this error, add the following code to your `build.gradle` file:

```
android {
    ...
    packagingOptions {
        exclude 'META-INF/LICENSE'
        exclude 'META-INF/NOTICE'
    }
    ...
}
```

This error may not happen right away, but may only appear later on in the development process. For this reason, it's recommended that you put the above code in your `build.gradle` file after creating your project.

4. Connect failed: ECONNREFUSED (Connection refused), or `org.apache.http.conn.HttpHostConnectException`

   This error occurs when Liferay Screens and the underlying Liferay Mobile SDK can't connect to the Liferay Portal instance. If you get this error, you should first check the IP address of the server to make sure it's available. If you've overridden the default IP address in `server_context.xml`, you should check to make sure that you've set it to the correct IP. Also, if you're using the Genymotion emulator, you must use `192.168.56.1` instead of localhost for your app to communicate with a local Liferay instance.

5. `java.io.IOException`: open failed: EACCES (Permission denied)

   Some Screenlets use temporary files to store information, such as when the User Portrait Screenlet uploads a new portrait, or the DDL Form Screenlet uploads new files to the portal. Your app needs to have the necessary permissions to use a specific Screenlet's functionality. In this case, add the following line to your `AndroidManifest.xml`:

   ```
   <uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>
   ```

   If you're using the device's camera, you also need to add the following permission:

   ```
   <uses-permission android:name="android.permission.CAMERA"/>
   ```

6. No JSON web service action with path …

   This error most commonly occurs if you haven't installed the Liferay Screens Compatibility Plugin. This plugin adds new API calls to Liferay Portal.

FAQs

1. Do I have to use Android Studio?

   No, Liferay Screens also works with Eclipse ADT. You can also compile your project manually with Gradle or another build system. Just make sure you use the compiled aar in your project's `lib` folder.

   We *strongly* recommend, however, that you use Android Studio. Android Studio is the official IDE for developing Android apps, and Eclipse ADT is no longer supported. Using Eclipse ADT or compiling manually may cause unexpected issues that are difficult to overcome.

2. How does Screens handle orientation changes?

   Liferay Screens uses an event bus, the `EventBus` library, to notify activities when the interactor has finished its work.

3. How can I use a Liferay feature not available in Screens?

   There are several ways you can use Liferay features not currently available in Screens. The Liferay Mobile SDK gives you access to all of Liferay's remote APIs. You can also create a custom Screenlet to support any features not included in Screens by default.

4. How do I create a new Screenlet?

   Screenlet creation is explained in detail here.

5. How can I customize a Screenlet?

   You can customize Screenlets by creating new Views. Fortunately, there's a tutorial for this!

6. Does Screens have offline support?

   Yes, since Liferay Screens 1.3!

Chapter 77

iOS Apps with Liferay Screens

Liferay Screens speeds up and simplifies developing native mobile apps that use Liferay. Its power lies in its *Screenlets*. A Screenlet is a visual component that you insert into your native app to leverage Liferay Portal's content and services. On iOS, Screenlets are available to log in to your portal, create accounts, submit forms, display content, and more. You can use any number of Screenlets in your app; they're independent, so you can use them in modular fashion. Screenlets on iOS also deliver UI flexibility with pluggable *Themes* that implement elegant user interfaces. Liferay's reference documentation for iOS Screenlets describes each Screenlet's features and Themes.

You might be thinking, "These Screenlets sound like the greatest thing since taco Tuesdays, but what if they don't fit in with my app's UI? What if they don't behave exactly how I want them to? What if there's no Screenlet for what I want to do?" Fret not! You can customize Screenlets to fit your needs by changing or extending their UI and behavior. You can even write your own Screenlets! What's more, Screens seamlessly integrates with your existing iOS projects.

Screenlets leverage the Liferay Mobile SDK to make server calls. The Mobile SDK is a low-level layer on top of the Liferay JSON API. To write your own Screenlets, you must familiarize yourself with Liferay's remote services. If no existing Screenlet meets your needs, consider customizing an existing Screenlet, creating a Screenlet, or directly using the Mobile SDK. Creating a Screenlet involves writing Mobile SDK calls and constructing the Screenlet; if you don't plan to reuse or distribute the implementation then you may want to forgo writing a Screenlet and, instead, work with the Mobile SDK. A benefit of integrating an existing Screenlet into your app, however, is that the Mobile SDK's details are abstracted from you.

These tutorials show you how to use, customize, create, and distribute Screenlets for iOS. They show you how to create Themes too. There's even a tutorial that explains the nitty-gritty details of the Liferay Screens architecture. No matter how deep you want to go, you'll use Screenlets in no time. Start by preparing your iOS project to use Liferay Screens.

77.1 Preparing iOS Projects for Liferay Screens

To develop iOS apps with Liferay Screens, you must first install and configure Screens in your iOS project. Screens is released as a standard CocoaPods dependency. You must therefore install Screens via CocoaPods. After completing the installation, you must configure your iOS project to communicate with your Liferay DXP instance. This tutorial walks you through these processes. You'll be up and running in no time!

First, you'll review the requirements for Liferay Screens.

Figure 77.1: Here's an app that uses a Liferay Screens Sign Up Screenlet.

Requirements

Liferay Screens for iOS includes the Component Library (the Screenlets) and some sample projects written in Swift. Screens is developed using Swift and development techniques that leverage functional Swift code and the Model View Presenter architecture. You can use Swift or Objective-C with Screens, and you can run Screens apps on iOS 9 and above.

Liferay Screens for iOS requires the following software:

- Xcode 9.3 or newer
- iOS 11 SDK
- CocoaPods 1 or newer
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, or Liferay DXP 7.0
- Liferay Screens Compatibility Plugin (CE or DXP/EE, depending on your portal edition). This app is preinstalled in Liferay CE Portal 7.0/7.1 CE and Liferay DXP 7.0.

Securing JSON Web Services

Each Screenlet in Liferay Screens calls one or more of Liferay DXP's JSON web services, which are enabled by default. The Screenlet reference documentation lists the web services that each Screenlet calls. To use a

Screenlet, its web services must be enabled in the portal. It's possible, however, to disable the web services needed by Screenlets you're not using. For instructions on this, see the tutorial Configuring JSON Web Services. You can also use Service Access Policies for more fine-grained control over accessible services.

Configuring Your Project with CocoaPods

To use CocoaPods to prepare your iOS 9.0 (or above) project for Liferay Screens, follow these steps:

1. In your project's root folder, add the following code to the file named `Podfile`, or create this file if it doesn't exist. Be sure to replace `Your  Target` with your target's name:

   ```
   source 'https://github.com/CocoaPods/Specs.git'

   platform :ios, '9.0'
   use_frameworks!

   target "Your Target" do
       pod 'LiferayScreens'
   end

   # the rest of your podfile
   ```

   Note that Liferay Screens and some of its dependencies aren't compatible with Swift 3.2 or Swift 4.0. If your iOS project is compiled in Swift 3.2 or Swift 4.0, then your `Podfile` must specify Screens and those dependencies for compilation in Swift 4.2. The `post_install` code in the following `Podfile` does this. You must therefore use this `Podfile` if you want to use Screens in a Swift 3.2 or Swift 4.0 app:

   ```
   source 'https://github.com/CocoaPods/Specs.git'

   platform :ios, '9.0'
   use_frameworks!

   target "Your Target" do
       pod 'LiferayScreens'
   end

   post_install do |installer|
     incompatiblePods = [
       'Cosmos',
       'CryptoSwift',
       'KeychainAccess',
       'Liferay-iOS-SDK',
       'Liferay-OAuth',
       'LiferayScreens',
       'Kingfisher'
     ]

     installer.pods_project.targets.each do |target|
       if incompatiblePods.include? target.name
         target.build_configurations.each do |config|
           config.build_settings['SWIFT_VERSION'] = '4.2'
         end
       end
       target.build_configurations.each do |config|
           config.build_settings['CONFIGURATION_BUILD_DIR'] = '$PODS_CONFIGURATION_BUILD_DIR'
       end
     end
   end

   # the rest of your podfile
   ```

2. On the terminal, navigate to your project's root folder and run this command:

   ```
   pod repo update
   ```

   This ensures you have the latest version of the CocoaPods repository on your machine. Note that this command can take a while to run.

3. Still in your project's root folder in the terminal, run this command:

   ```
   pod install
   ```

   Once this completes, quit Xcode and reopen your project by using the `*.xcworkspace` file in your project's root folder. From now on, you must use this file to open your project.

Great! To configure your project's communication with Liferay DXP, you can skip the next section and follow the instructions in the final section.

Configuring Communication with Liferay DXP

Configuring communication between Screenlets and Liferay DXP is easy. Liferay Screens uses a property list (`.plist`) file to access your Liferay DXP instance. It must include the server's URL, the portal's company ID, and the site's group ID. Create a `liferay-server-context.plist` file and specify values required for communicating with your Liferay DXP instance. As an example, refer to `liferay-server-context-sample.plist`.

The values you need to specify in your `liferay-server-context.plist` are:

- `server`: Your Liferay DXP instance's URL.
- `version`: Your Liferay DXP instance's version. Supported values are `71` for Liferay CE Portal 7.1 or Liferay DXP 7.1, `70` for Liferay CE Portal 7.0 or Liferay DXP 7.0, and `62` for Liferay Portal 6.2 CE/EE.
- `companyId`: Your Liferay DXP instance's identifier. You can find this value in the *Instance ID* column of *Control Panel* → *Portal Instances*.
- `groupId`: The ID of the default site you want Screens to communicate with. You can find this value in the Site ID field of the site's *Site Administration* → *Configuration* → *Site Settings* menu.
- `connectorFactoryClassName`: Your Connector's factory class name. This is optional. If you don't include it, the `version` value is used to determine which factory is the most suitable for that version of Liferay DXP.

Great! Your iOS project is ready for Liferay Screens.

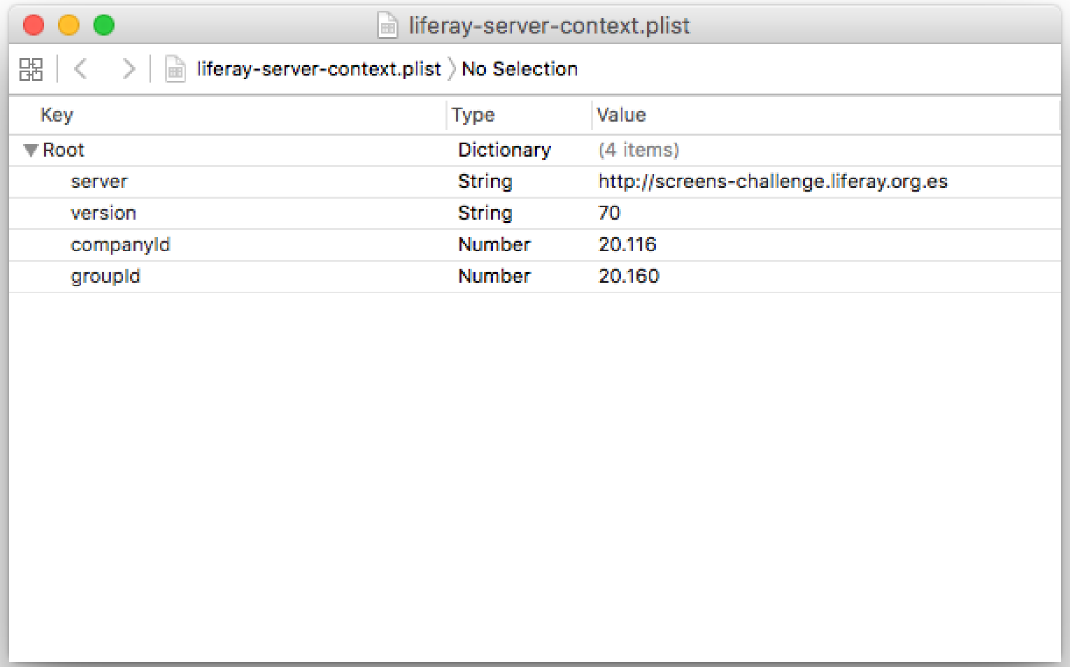
Using Screenlets in iOS Apps

Using Themes in iOS Screenlets

Preparing Android Projects for Liferay Screens

77.2 Using Screenlets in iOS Apps

Once you've prepared your iOS project to use Liferay Screens, you can use Screenlets in your app. There are plenty of Liferay Screenlets available, and they're described in the Screenlet reference documentation. This tutorial shows you how to insert and configure Screenlets in iOS apps written in Swift and Objective-C. It also explains how to localize them. You'll be a Screenlet master in no time!



liferay-server-context.plist
liferay-server-context.plist 〉 No Selection

Key	Type	Value
▼ Root	Dictionary	(4 items)
server	String	http://screens-challenge.liferay.org.es
version	String	70
companyId	Number	20.116
groupId	Number	20.160

Figure 77.2: Here's a property list file, called `liferay-context.plist`.

Inserting and Configuring Screenlets in iOS Apps

The first step to using Screenlets in your iOS project is to add a new UIView to your project. In Interface Builder, insert a new UIView into your Storyboard or XIB file. Figure 1 shows this.

Next, enter the Screenlet's name as the Custom Class. For example, if you're using the Login Screenlet, then enter Login Screenlet as the class.

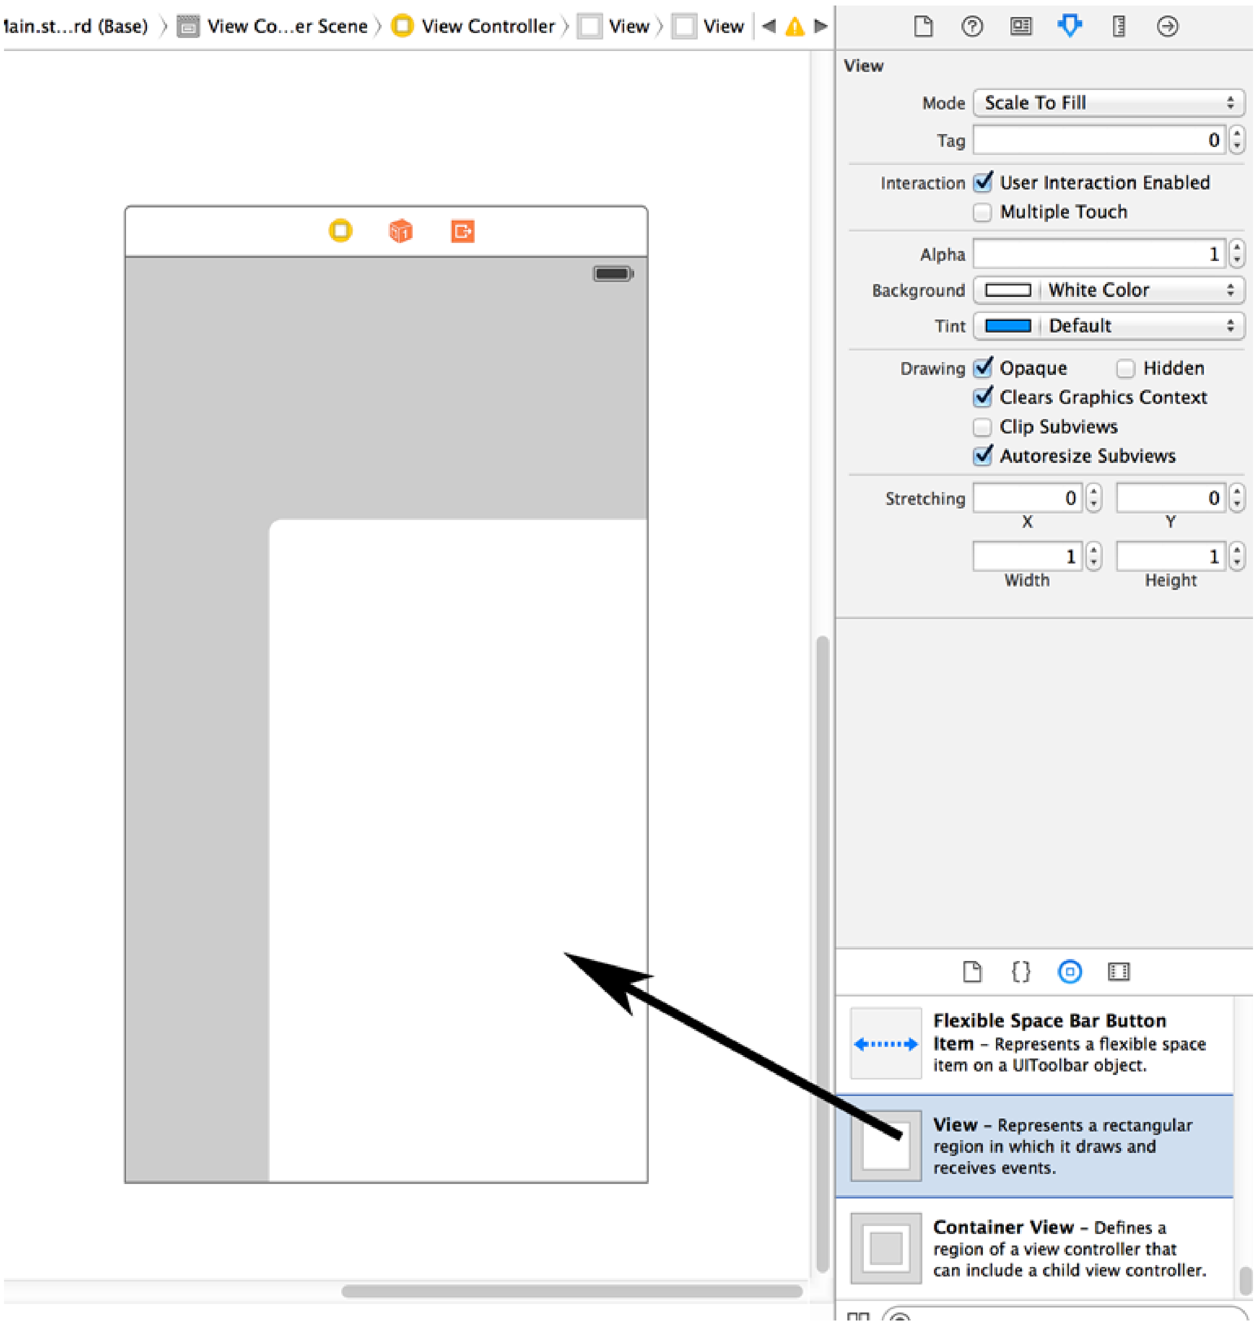
Now you need to conform the Screenlet's delegate protocol in your `ViewController` class. For example, the Login Screenlet's delegate class is `LoginScreenletDelegate`. This is shown in the code that follows. Note that you need to implement the functionality of `onLoginResponse` and `onLoginError`. This is indicated by the comments in the code here:

```
class ViewController: UIViewController, LoginScreenletDelegate {

    ...

   func screenlet(screenlet: BaseScreenlet,
           onLoginResponseUserAttributes attributes: [String:AnyObject]) {
       // handle succeeded login using passed user attributes
    }

    func screenlet(screenlet: BaseScreenlet,
            onLoginError error: NSError) {
        // handle failed login using passed error
    }
```



View

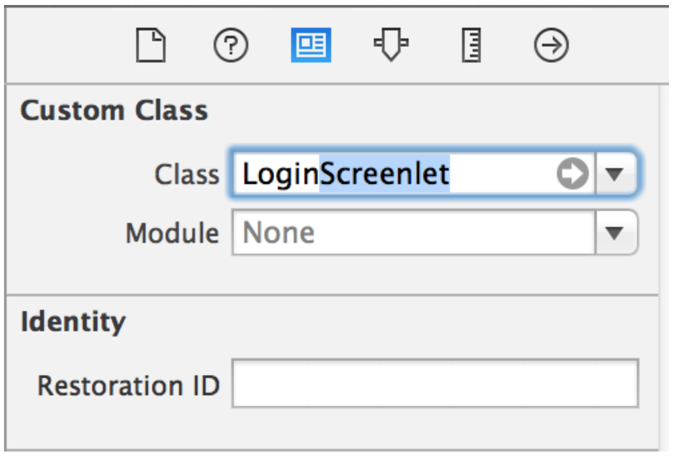
Mode: Scale To Fill
Tag: 0
Interaction: ✓ User Interaction Enabled
☐ Multiple Touch
Alpha: 1
Background: White Color
Tint: Default
Drawing: ✓ Opaque ☐ Hidden
✓ Clears Graphics Context
☐ Clip Subviews
✓ Autoresize Subviews
Stretching: X 0, Y 0, Width 1, Height 1

Flexible Space Bar Button Item – Represents a flexible space item on a UIToolbar object.

View – Represents a rectangular region in which it draws and receives events.

Container View – Defines a region of a view controller that can include a child view controller.

Figure 77.3: Add a new UIView to your project.



Custom Class

Class LoginScreenlet

Module None

Identity

Restoration ID

Figure 77.4: Change the Custom Class to match the Screenlet.

```
    ...
```

If you're using CocoaPods, you need to import Liferay Screens in your View Controller:

```
import LiferayScreens
```

Now that the Screenlet's delegate protocol conforms in your `ViewController` class, go back to Interface Builder and connect the Screenlet's delegate to your View Controller. If the Screenlet you're using has more outlets, you can assign them as well.

Note that currently Xcode has some issues connecting outlets to Swift source code. To get around this, you can change the delegate data type or assign the outlets in your code. In your View Controller, follow these steps:

1. Declare an outlet to hold a reference to the Screenlet. You can connect it in Interface Builder without any issues.

2. Assign the Screenlet's delegate the `viewDidLoad` method. This is the connection typically done in Interface Builder.

These steps are shown in the following code for Login Screenlet's View Controller.

```
class ViewController: UIViewController, LoginScreenletDelegate {

    @IBOutlet var screenlet: LoginScreenlet?

    override func viewDidLoad() {
        super.viewDidLoad()
        self.screenlet?.delegate = self
    }

    ...
```

Awesome! Now you know how to use Screenlets in your apps. If you need to use Screenlets from Objective-C code, follow the instructions in the next section.

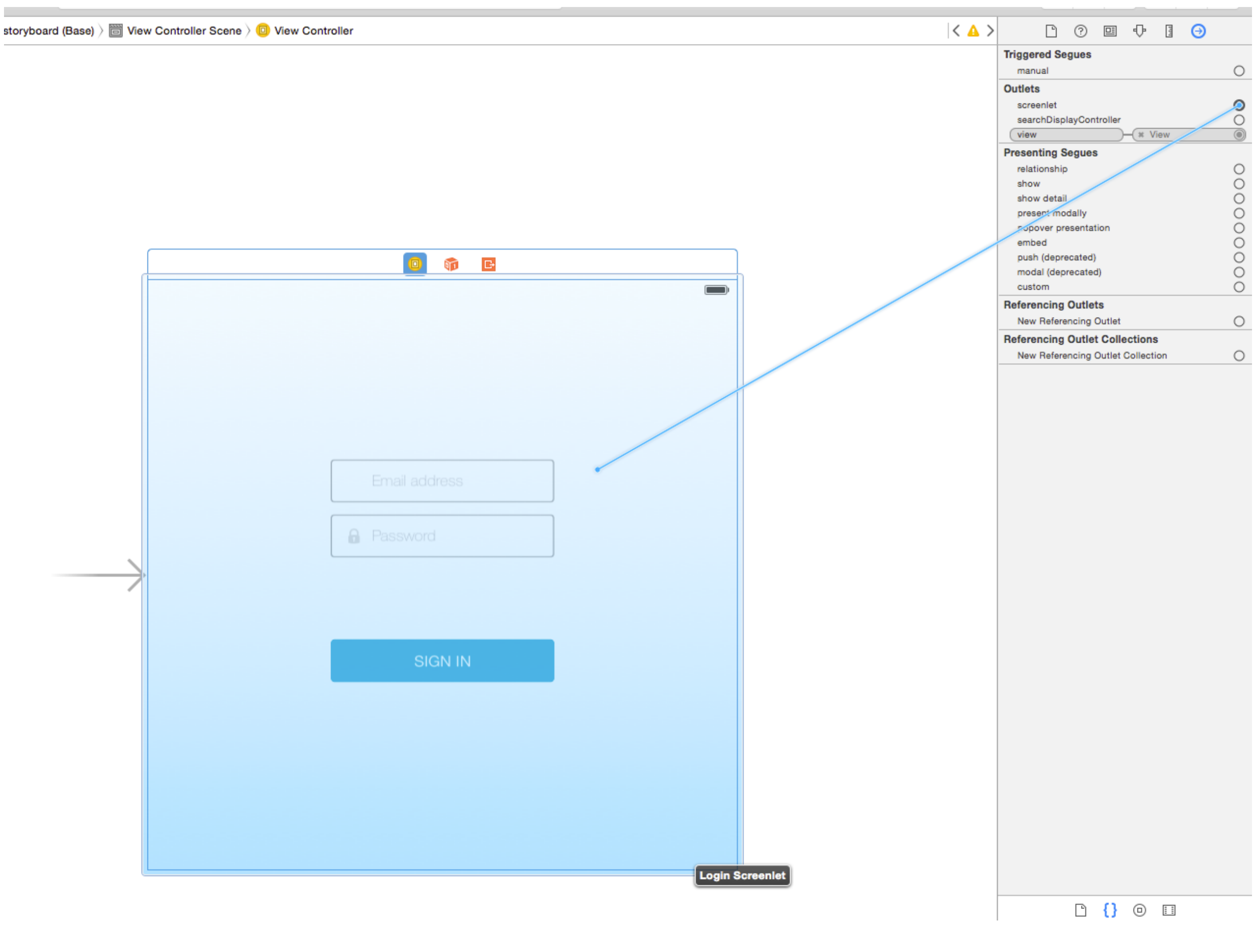


Figure 77.5: Connect the outlet with the Screenlet reference.

Using Screenlets from Objective-C

If you want to invoke Screenlet classes from Objective-C code, there is an additional header file that you must import. You can import the header file `LiferayScreens-Swift.h` in all your Objective-C files or configure a precompiler header file.

The first option involves adding the following import line all of your Objective-C files:

```
#import "LiferayScreens-Swift.h"
```

Alternatively, you can configure a precompiler header file by following these steps:

1. Create a precompiler header file (e.g., `PrefixHeader.pch`) and add it to your project.

2. Import `LiferayScreens-Swift.h` in the precompiler header file you just created.

3. Edit the following build settings of your target. Remember to replace `path/to/your/file/` with the path to your `PrefixHeader.pch` file:

    - Precompile Prefix Header: `Yes`
    - Prefix Header: `path/to/your/file/PrefixHeader.pch`

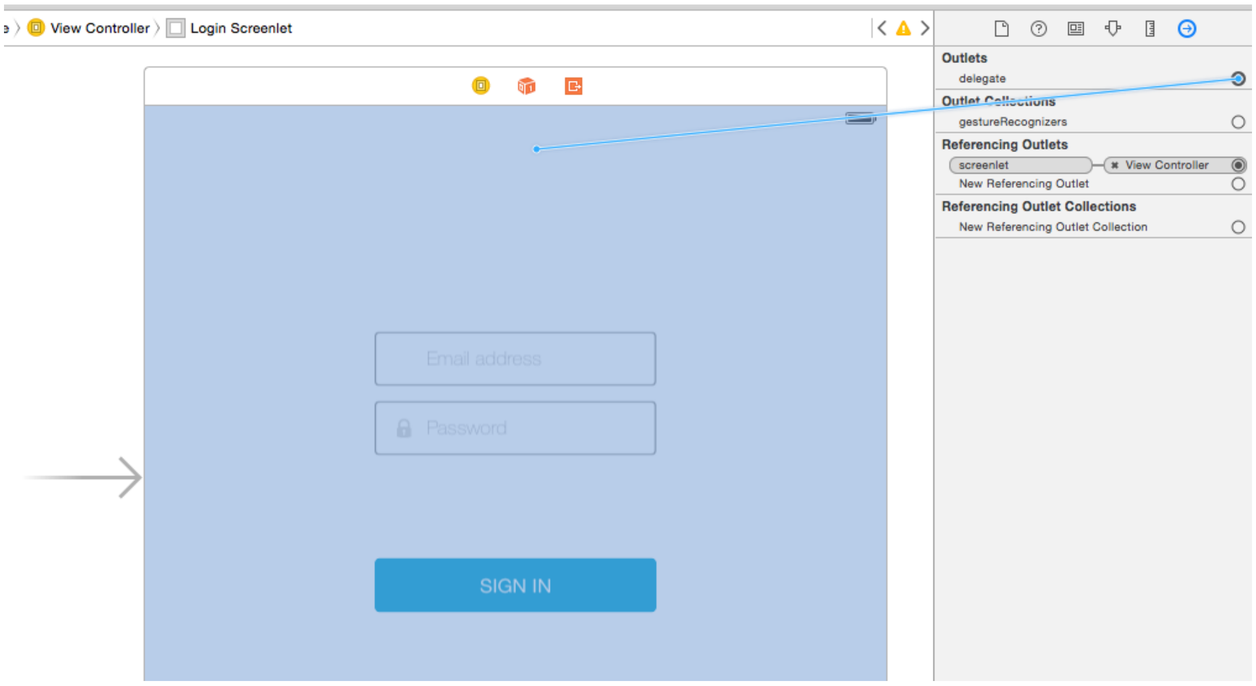

Figure 77.6: Connect the Screenlet's delegate in Interface Builder.

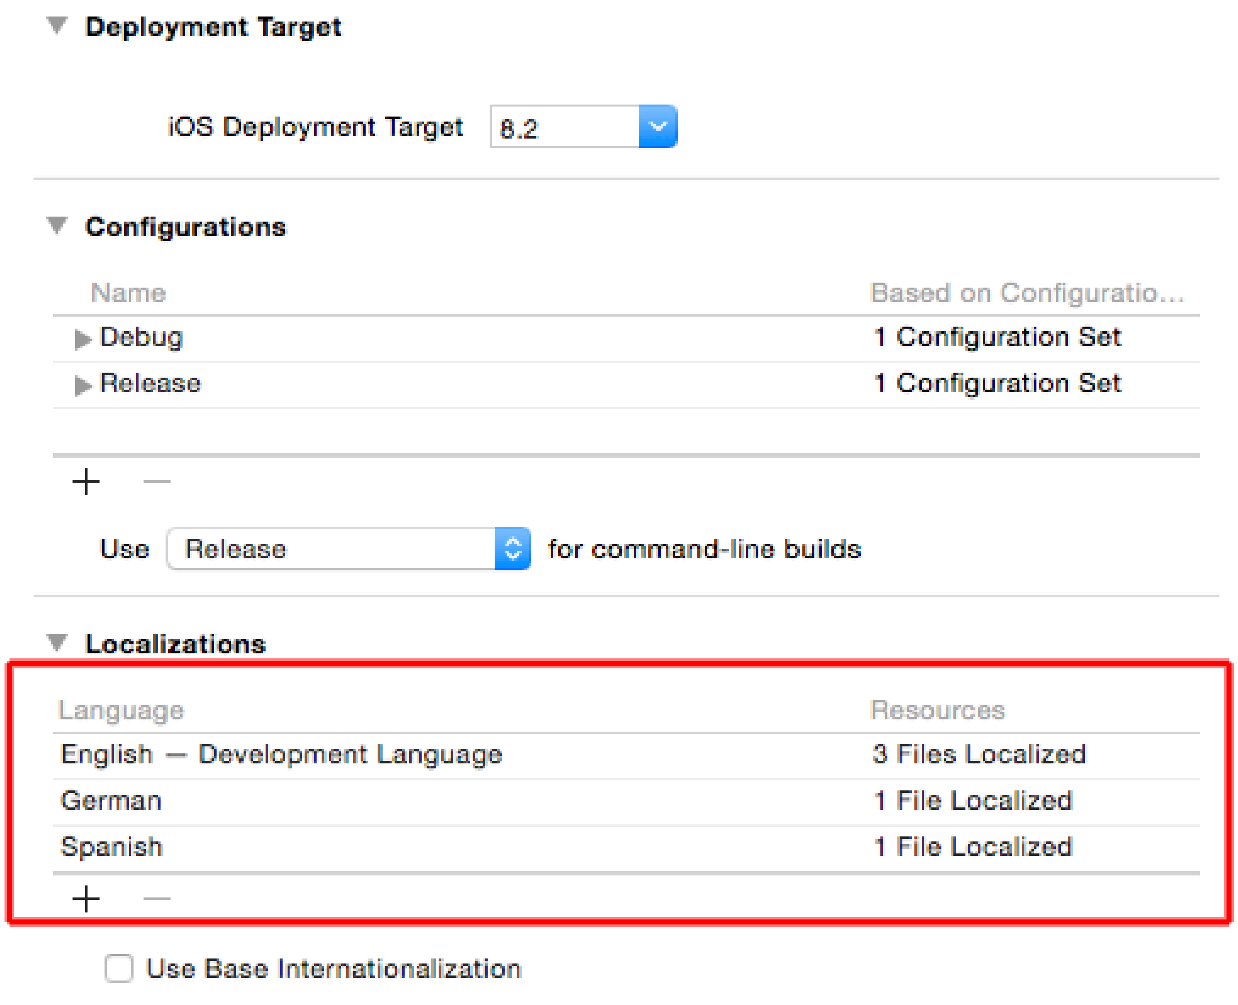
Figure 77.7: The `PrefixHeader.pch` configuration in Xcode settings.

You can use the precompiler header file `PrefixHeader.pch` as a template.
Super! Now you know how to use Screenlets from Objective-C code in your apps.

Localizing Screenlets

Follow Apple's standard mechanism to implement localization in your Screenlet. Note: even though a Screenlet may support several languages, you must also support those languages in your app. In other words, a Screenlet's support for a language is only valid if your app supports that language. To support a language, make sure to add it as a localization in your project's settings.



Deployment Target

iOS Deployment Target: 8.2

Configurations

Name	Based on Configuratio...

Preparing iOS Projects for Liferay Screens
Using Themes in iOS Screenlets
Creating iOS Screenlets

Using Screenlets in Android apps

77.3 Using Themes in iOS Screenlets

Using a Liferay Screens *Theme*, you can set your Screenlet's UI components, style, and behavior. They let you focus on a Screenlet's UI and UX, without having to worry about its core functionality. Liferay's Screenlets come with several Themes, and more are being developed by Liferay and the community. A Liferay Screenlet's Themes are specified in its reference documentation. This tutorial shows you how to use Themes in your iOS Screenlets.

To install a Theme in your iOS app's Screenlet, you have two options, depending on how the Theme has been published:

1. If the Theme has been packaged as a CocoaPods pod dependency, you can install it by adding a line to your Podfile:

   ```
   pod 'LiferayScreensThemeName'
   ```

   Make sure to replace `LiferayScreensThemeName` with the Theme's CocoaPods project name.

2. If the Theme isn't available through CocoaPods, you can drag and drop the Theme's folder into your project. Liferay Screens detects the new classes and then applies the new design in the runtime and in Interface Builder.

To use the installed Theme, specify its name in the *Theme Name* property field of the *Base Screenlet* in Interface Builder. The names of each Screenlet's Themes are listed in the *Themes* section of the Screenlet's reference documentation. If you leave the Theme name property blank or enter a name for a Theme that can't be found, the Screenlet's Default Theme is used.

The initial release of Liferay Screens for iOS includes the following Themes for its Screenlets:

- *Default*: Comes standard with a Screenlet. It's used by a Screenlet if no Theme name is specified or the named Theme can't be found. The Default Theme can be used as the parent Theme for your custom Themes. Refer to the architecture tutorial for more details.
- *Flat7*: Demonstrates a Theme made from scratch. Refer to the Theme creation tutorial for instructions on creating your own Theme.
- *Westeros*: Customizes the behavior and appearance of the Westeros Bank demo app.

That's all there is to it! Great! Now you know how to use Themes to dress up Screenlets in your iOS app. This opens up a world of possibilities–like writing your own Themes.

77.4 Using Offline Mode in iOS

Offline mode in Liferay Screens lets your apps function when connectivity is unavailable or intermittent. Even though the steady march of technology makes connections more stable and prevalent, there are still plenty of places the Internet has trouble reaching. Areas with complex terrain, including cities with large buildings, often lack stable connections. Remote areas typically don't have connections at all. Using Screens's offline mode in your apps gives your users flexibility in these situations.

This tutorial shows you how to use offline mode in Screenlets. For an explanation of how offline mode works, see the tutorial Architecture of Offline Mode in Liferay Screens. Offline mode's architecture is the same on iOS and Android, although its use on these platforms differs.

Configuring Screenlets for Offline Mode

If you want to enable the offline mode in any of your screenlets, you must configure the attribute `offlinePolicy`. This attribute can take four possible values. For a description of these values, see the section Using Policies with Offline Mode in the offline mode architecture tutorial. Note that each Screenlet behaves a bit differently with offline mode. For specific details, see the Screenlet reference documentation.

Handling Synchronization

Under some scenarios, values stored in the local cache need to be synchronized with the portal. For that purpose you must use the `SyncManager` class. This class is responsible for sending the information stored in the local cache that hasn't been sent to the portal yet.

Use the following steps to start a synchronization process:

1. Create an instance of the `SyncManager` class. You must pass a `CacheManager` object in the constructor. You can get the current cache manager using `SessionContext.currentCacheManager`.

2. Set the delegate property. This delegate object receives the events produced in the synchronization process. For more details on the delegate's methods, see the API reference documentation for the `SyncManagerDelegate` class.

3. Make sure you keep a strong reference to the `SyncManager` object while the process is running.

77.5 Architecture of Liferay Screens for iOS

Liferay Screens separates its presentation and business-logic code using ideas from Model View Presenter, Model View ViewModel, and VIPER. However, Screens isn't a canonical implementation of these architectures because they're designed for apps. Screens isn't an app; it's a suite of visual components intended for use *in* apps.

This tutorial explains the architecture of Liferay Screens for iOS. It begins with an overview of the high level components that make up the system. This includes the Core, Screenlets, and Themes. These components are then described in detail in the sections that follow. After you get done examining Screens's building blocks, you'll be ready to create some amazing Screenlets and Themes!

High Level Architecture of Liferay Screens for iOS

Liferay Screens for iOS is composed of a Core, a Screenlet layer, a View layer, and Server Connectors. Server Connectors are technically part of the Core, but are worth describing separately. They facilitate interaction with local and remote data sources and communication between the Screenlet layer and the Liferay Mobile SDK.

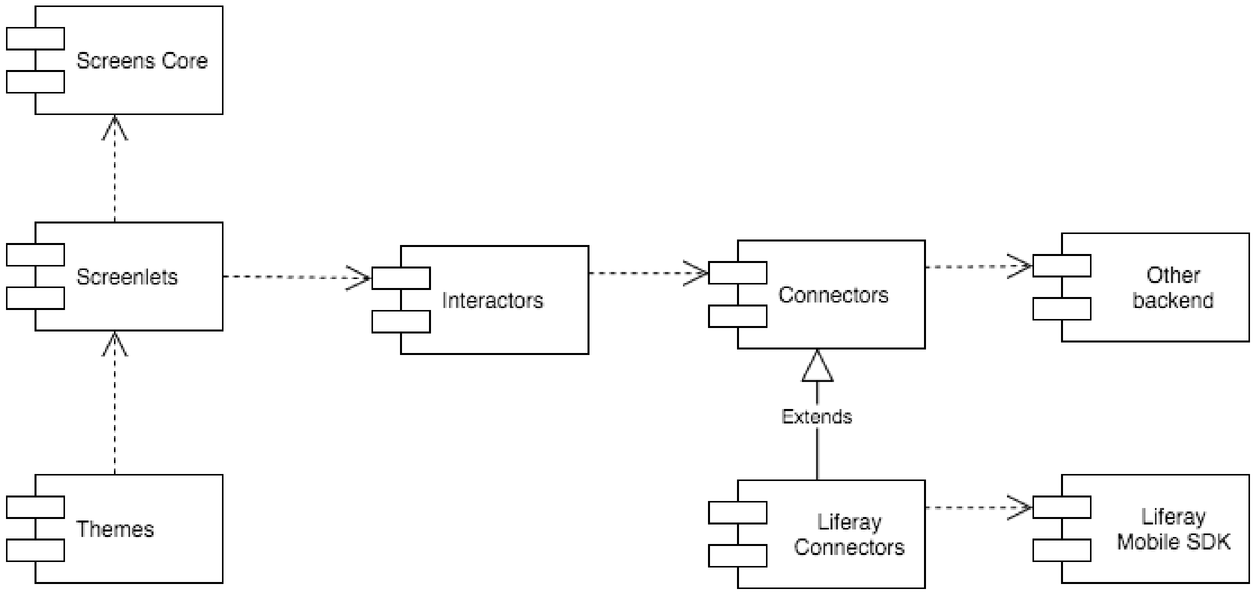

Figure 77.11: The high level components of Liferay Screens for iOS.

Each component is described below.

Core: includes all the base classes for developing other Screens components. It's a micro-framework that lets developers write their own Screenlets, views, and Server Connector classes.

Screenlets: Swift classes for inserting into any `UIView`. They render a selected Theme in the runtime and in Interface Builder. They also react to UI events to start server requests (via Server Connectors), and define a set of `@IBInspectable` properties that can be configured from Interface Builder. The Screenlets bundled with Liferay Screens are known as the Screenlet library.

Interactors: implement specific use cases for communicating with servers or any other data store. Interactors can use local and remote data sources by using *Server Connectors* or custom classes. If a user action or use case needs to execute more than one query on a local or remote store, the sequence is done in the corresponding Interactor. If a Screenlet supports more than one user action or use case, an Interactor must be created for each.

Connectors (or Server Connectors): a collection of classes that can interact with local and remote data sources and Liferay instances. Liferay's own set of Connectors, Liferay Connector, use the Liferay Mobile SDK. All Server Connectors can be run concurrently since they use the `NSOperation` framework. It's very easy to define priorities and dependencies between Connectors, so you can build your own graph of Connectors (aka operations) that can be resolved by the framework. Connectors are always created using a factory class so they can be injected by the app developer.

Themes: a set of XIB files and accompanying `UIView` classes that present Screenlets to the user.

The next section describes the Core in detail.

Core

The Core is the micro-framework that lets developers write Screenlets in a structured and isolated way. All Screenlets share a common structure based on the Core classes, but each Screenlet can have a unique purpose and communication API.

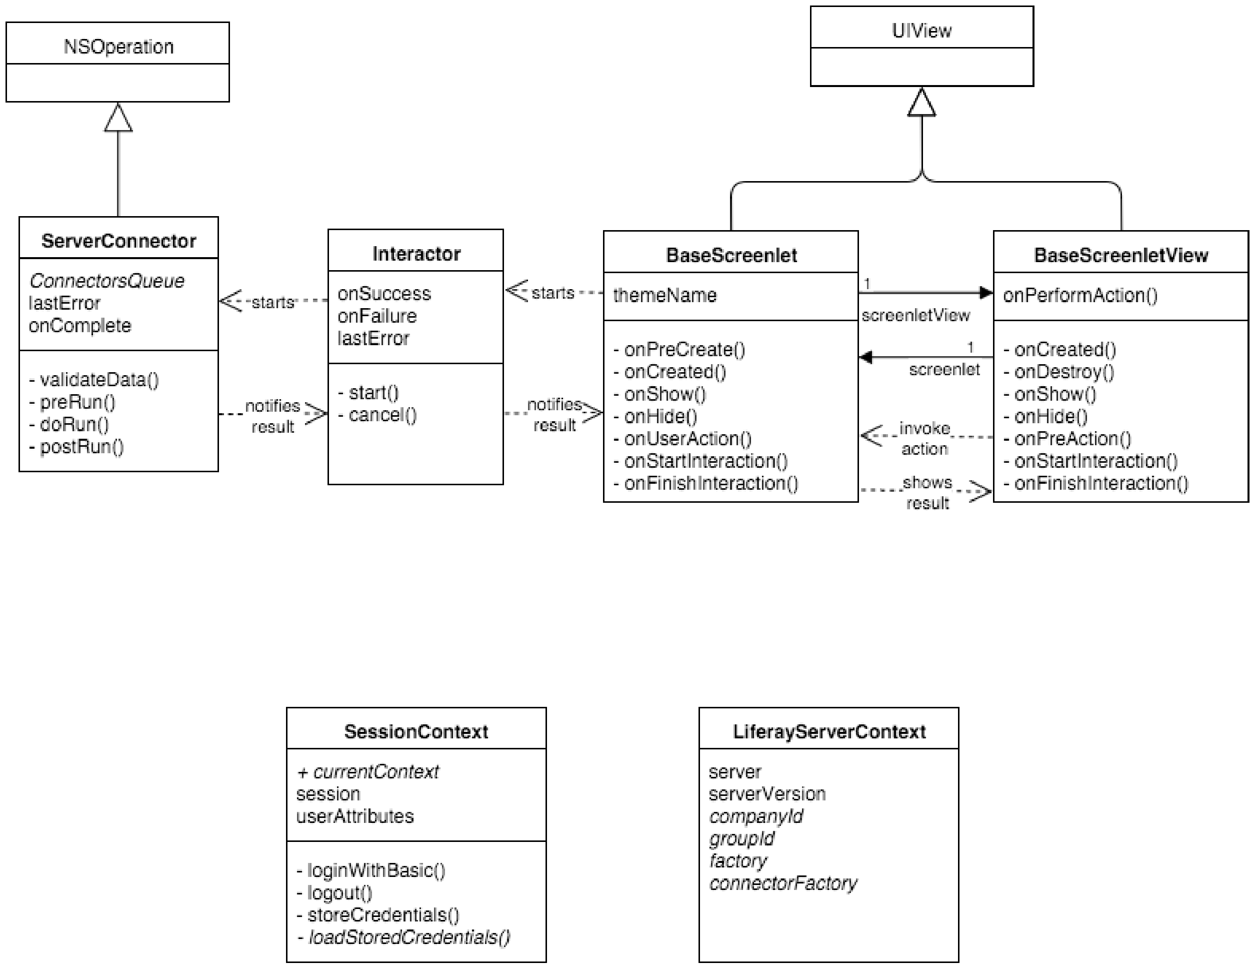

Figure 77.12: Here's the core layer of Liferay Screens for iOS.

From right to left, these are the main components:

BaseScreenletView: the base class for all Screenlet View classes. Its child classes belong to the Theme layer. View classes use standard XIB files to render a UI and then update it when the data changes. The `BaseScreenletView` class contains template methods that child classes may overwrite. When developing your own Theme from a parent Theme, you can read the Screenlet's properties or call its methods from this class. Any user action in the UI is received in this class, and then redirected to the Screenlet class.

BaseScreenlet: the base class for all Screenlet classes. Screenlet classes receive UI events through the `ScreenletView` class, then instantiate Interactors to process and respond to that UI event. When the

Interactor's result is received, the `ScreenletView` (the UI) is updated accordingly. The `BaseScreenlet` class contains a set of template methods that child classes may overwrite.

Interactor: the base class for all Interactors that a Screenlet supports. The Interactor class implements a specific use case supported by the Screenlet. If the Screenlet supports several use cases, it needs different Interactors. If the Interactor needs to retrieve remote data, it uses a Server Connector to do so. When the Server Connector returns the operation's result, the Interactor returns that result to the Screenlet. The Screenlet then changes the `ScreenletView` (the UI) status.

ServerConnector: the base class for all Liferay Connectors that a Screenlet supports. Connectors retrieve data asynchronously from local or remote data sources. The Interactor classes instantiate and start these Connector classes.

SessionContext: an object (typically a singleton) that holds the logged in user's session. Apps can use an implicit login, invisible to the user, or a login that relies on explicit user input to create the session. User logins can be implemented with Login Screenlet. This is explained in detail here.

LiferayServerContext: a singleton object that holds server configuration parameters. It's loaded from the `liferay-server-context.plist` file. Most Screenlets use these parameters as default values.

Now that you know what the Core contains, you're ready to learn the Screenlet layer's details.

Screenlet Layer

The Screenlet layer contains the available Screenlets in Liferay Screens for iOS. The following diagram shows the Screenlet layer in relation to the Core, Interactor, Theme, and Connector layers. The Screenlet classes in the diagram are explained in this section.

Screenlets are comprised of several Swift classes and an XIB file:

MyScreenletViewModel: a protocol that defines the attributes shown in the UI. It typically accounts for all the input and output values presented to the user. For example, `LoginViewModel` includes attributes like the user name and password. A Connector can be configured by reading and validating these values. Also, the Screenlet can change these values based on any default values and operation results.

MyScreenlet: a class that represents the Screenlet component the app developer interacts with. It includes the following things:

- Inspectable parameters for configuring the Screenlet's behavior. The initial state can be set in the Screenlet's data.
- A reference to the Screenlet's View, based on the selected Theme. To meet the Screenlet's requirements, all Themes must implement the `ViewModel` protocol.
- Any number of methods for invoking Connectors. You can optionally make them public for app developers to call.

- An optional (but recommended) delegate object the Screenlet can call on for particular events.

MyUserCaseInteractor: Each Interactor runs the operations that implement the use case. These can be local operations, remote operations, or a combination thereof. Operations can be executed sequentially or in parallel. The final results are stored in a `result` object that can be read by the Screenlet when notified. The number of Interactor classes a Screenlet requires depends on the number of use cases it supports.

MyOperationConnector: This is related to the Interactor, but has one or more Connectors. If the Server Connector is a back-end call, then there's typically only a single request. Each Server Connector is responsible for retrieving a set of related values. The results are stored in a `result` object that can be read by the Interactor when notified. The number of Server Connector classes an Interactor requires depends on the number of endpoints you need to query, or even the number of different servers you need to support. Connectors are

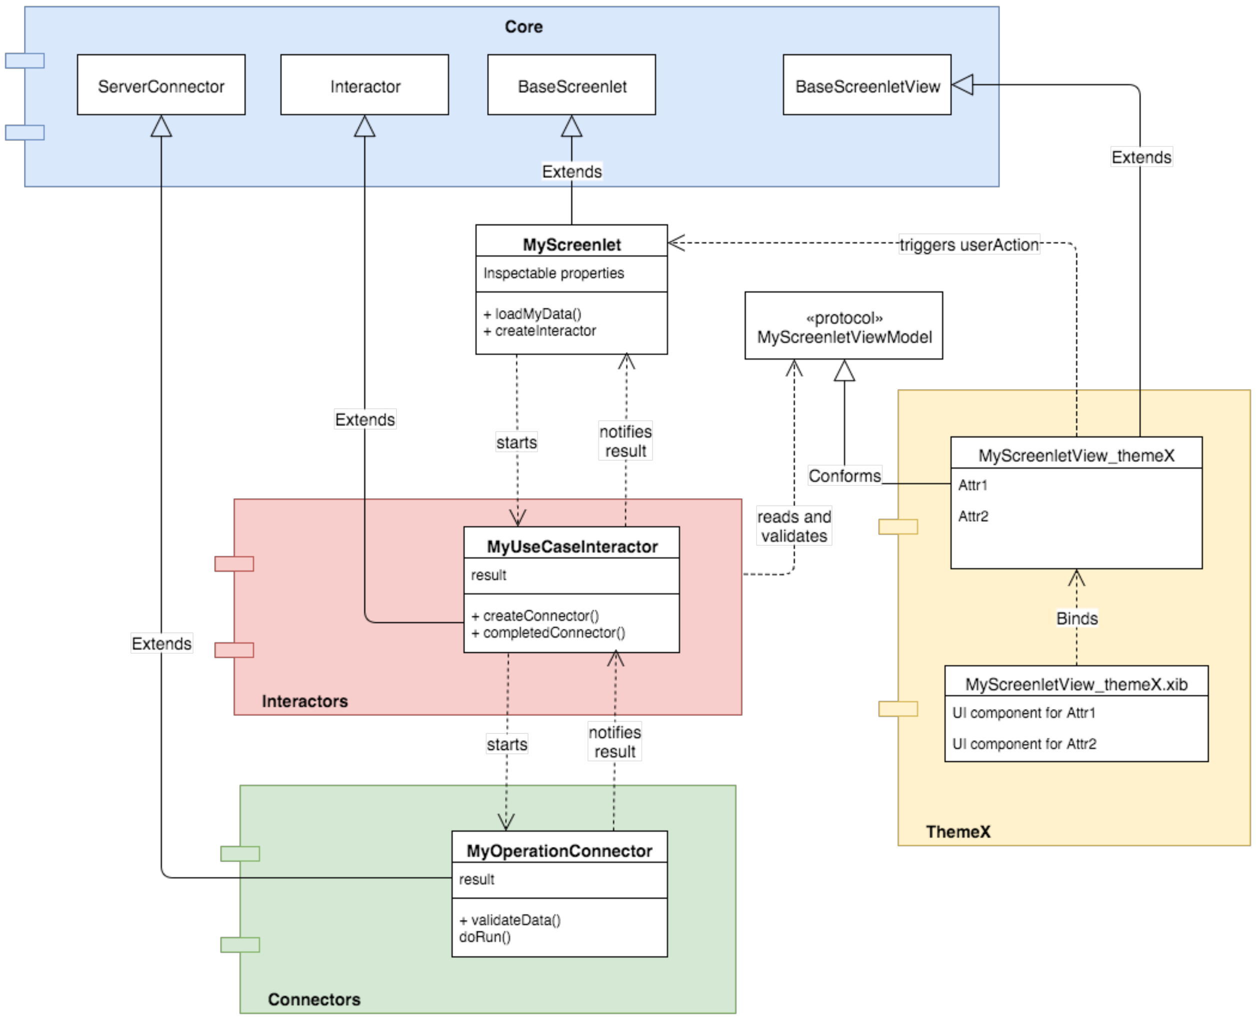

Figure 77.13: This diagram illustrates the iOS Screenlet Layer's relationship to other Screens components.

always created using a factory class. You can therefore take advantage of Inversion of Control. This way, you can implement your own factory class to use to create your own Connector objects. To tell Screens to use your factory class, specify it in the `liferay-server-context.plist` file as described in the tutorial on preparing your iOS project for Screens.

MyScreenletView_themeX: A class that belongs to one specific Theme. In the diagram, this Theme is *ThemeX*. The class renders the Screenlet's UI by using its related XIB file. The View object and XIB file communicate using standard mechanisms like `@IBOutlet` and `@IBAction`. When a user action occurs in the XIB file, it's received by `BaseScreenletView` and then passed to the Screenlet class via the `performAction` method. To identify different events, the component's `restorationIdentifier` property is passed to the `performAction` method.

MyScreenletView_themeX.xib: an XIB file that specifies how to render the Screenlet's View. Its name is very important. By convention, a Screenlet with a view class named *FooScreenletView* and a Theme named *BarTheme* must have an XIB file named `FooScreenletView_barTheme.xib`.

For more details, refer to the tutorial Creating iOS Screenlets. Next, the Theme Layer of Screens for iOS is described.

Theme Layer

The Theme Layer lets developers set a Screenlet's look and feel. The Screenlet property `themeName` determines the Theme to load. This can be set by the Screenlet's *Theme Name* field in Interface Builder. A Theme consists of a view class for Screenlet behavior and an XIB file for the UI. By inheriting one or more of these components from another Theme, the different Theme *types* allow varying levels of control over a Screenlet's UI design and behavior.

There are several different Theme types:

Default Theme: The standard Theme provided by Liferay. It can be used as a template to create other Themes, or as the parent Theme of other Themes. Each Theme for each Screenlet requires a View class. A Default Theme's View class is named `MyScreenletView_default`, where `MyScreenlet` is the Screenlet's name. This class is similar to the standard `ViewController` in iOS; it receives and handles UI events by using the standard `@IBAction` and `@IBOutlet`. The View class usually uses an XIB file to build the UI components. This XIB file is bound to the class.

Child Theme: Presents the same UI components as the parent Theme, but can change the UI components' appearance and position. A Child Theme specifies visual changes in its own XIB file; it can't add or remove any UI components. In the diagram, the Child Theme inherits from the Default Theme. Creating a Child Theme is ideal when you only need to make visual changes to an existing Theme. For example, you can create a Child Theme that sets new positions and sizes for the standard text boxes in Login Screenlet's Default Theme, but without adding or overwriting existing code.

Full: Provides a complete standalone theme. It has no parent Theme and implements unique behavior and appearance for a Screenlet. Its View class must extend Screens's `BaseScreenletView` class and conform to the Screenlet's view model protocol. It must also specify a new UI in an XIB file. Refer to the Default Theme for an example of a Full Theme.

Extended: Inherits the parent Theme's behavior and appearance, but lets you change and add code to both. You can do so by creating a new XIB file and a custom View class that extends the parent Theme's View class. In the diagram, the Extended Theme inherits the Full Theme and extends its Screenlet's View class. Refer to the Flat7 Theme for an example of an Extended Theme.

Themes in Liferay Screens are organized into sets that contain Themes for several Screenlets. Liferay's available Theme sets are listed here:

- *Default:* A mandatory Theme set supplied by Liferay. It's used if the Screenlet's `themeName` isn't specified or is invalid. The Default Theme uses a neutral, flat white and blue design with standard UI components. For example, the Login Screenlet uses standard text boxes for the user name and password fields, but uses the Default Theme's flat white and blue design.

- *Flat7:* A collection of Themes that use a flat black and green design, and UI components with rounded edges. They're Extended Themes.

- *Westeros:* The Theme for the Bank of Westeros sample app.

For more details on Theme creation, see the tutorial Creating iOS Themes.

Awesome! Now you know the nitty gritty details of Liferay Screens for iOS. This information is invaluable when using Screens to develop your apps.

Creating iOS Screenlets

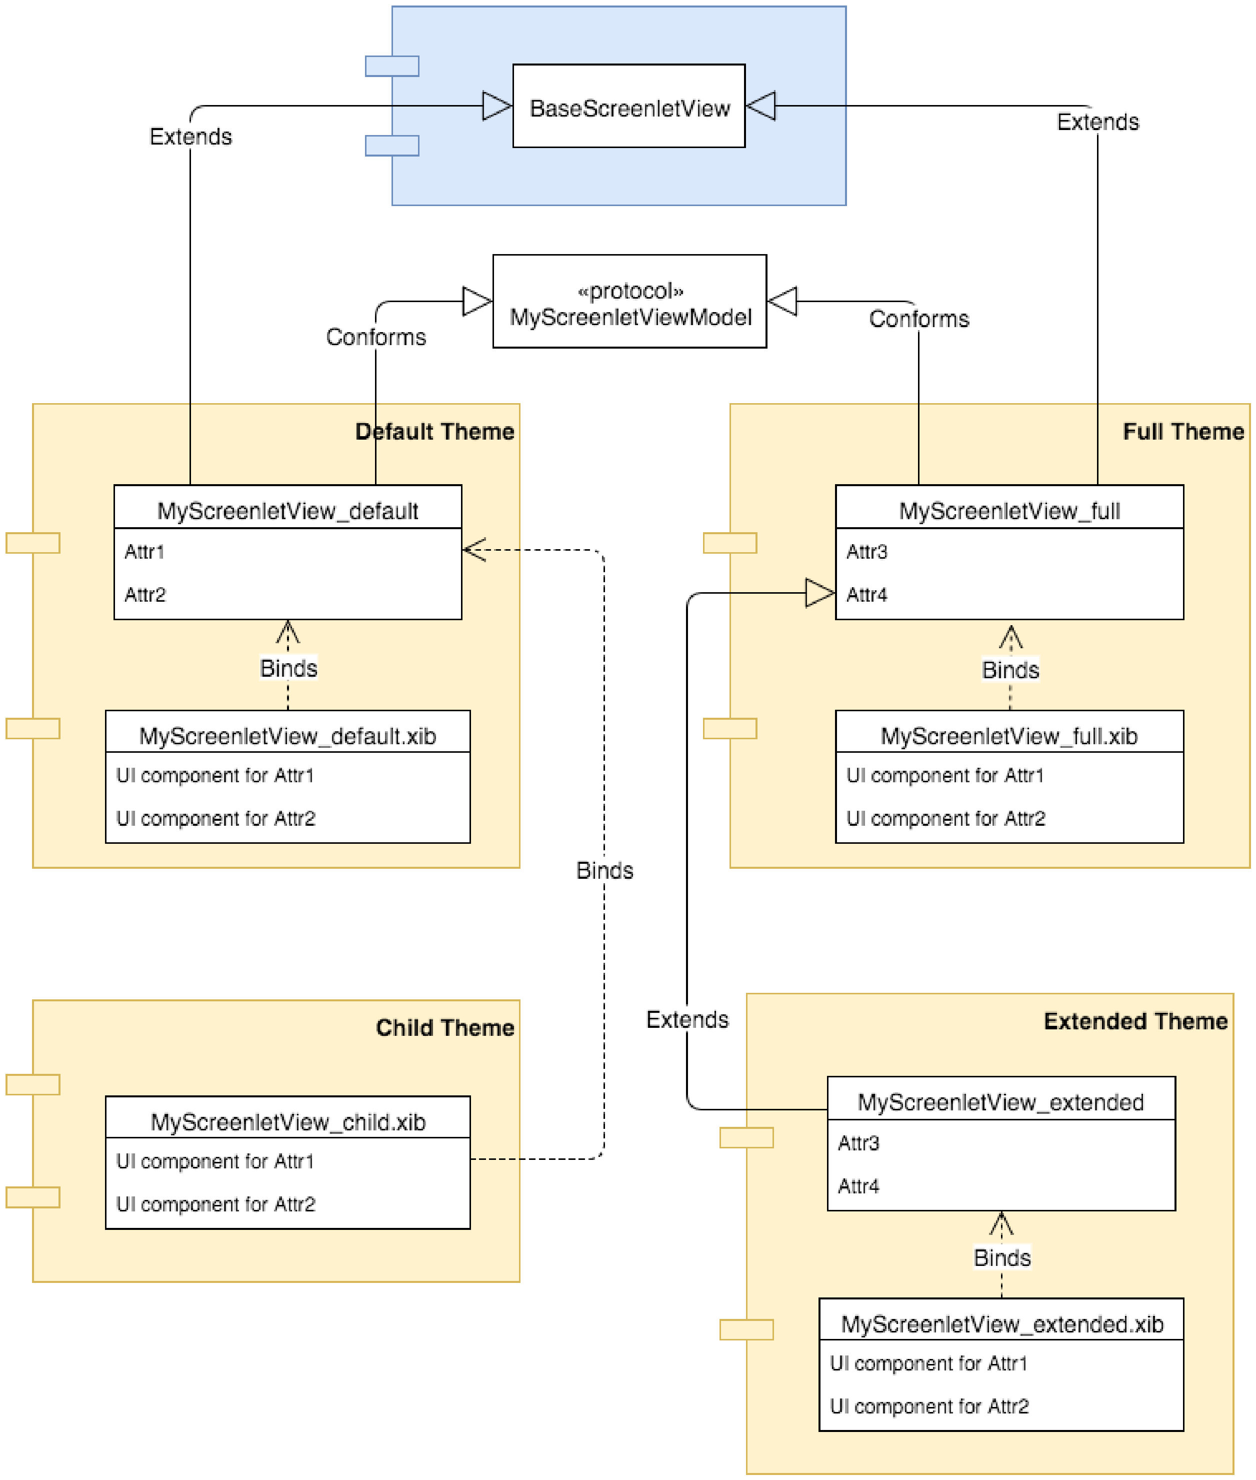

Figure 77.14: The Theme Layer of Liferay Screens for iOS.

77.6 Creating iOS Screenlets

The built-in Screenlets cover common use cases for mobile apps that use Liferay. They authenticate users, interact with Dynamic Data Lists, display assets, and more. What if, however, there's no Screenlet for *your* use case? No problem! You can create your own. Extensibility is a key strength of Liferay Screens.

This tutorial explains how to create your own Screenlets. As an example, it references code from the sample Add Bookmark Screenlet, that saves bookmarks to Liferay's Bookmarks portlet.

In general, you use the following steps to create Screenlets:

1. Plan Your Screenlet: Your Screenlet's features and use cases determine where you'll create it and the Liferay remote services you'll call.

2. Create Your Screenlet's UI (its Theme): Although this tutorial presents all the information you need to create a Theme for your Screenlet, you may first want to learn the steps for creating a Theme. For more information on Themes in general, see the tutorial on using Themes with Screenlets.

3. Create the Screenlet's Interactor. Interactors are Screenlet components that make server calls.

4. Create the Screenlet class. The Screenlet class is the Screenlet's central component. It controls the Screenlet's behavior and is the component the app developer interacts with when inserting a Screenlet.

Before getting started, make sure that you're familiar with the architecture of Liferay Screens. Click here to read the Screens architecture tutorial.

Without further ado, let the Screenlet creation begin!

Planning Your Screenlet

Before creating your Screenlet, you must determine what it needs to do and how you want developers to use it. This determines where you'll create your Screenlet and its functionality.

Where you should create your Screenlet depends on how you plan to use it. If you want to reuse or redistribute it, you should create it in an empty Cocoa Touch Framework project in Xcode. You can then use CocoaPods to publish it. The tutorial Packaging iOS Themes explains how to publish an iOS Screenlet. Even though that tutorial refers to Themes, the steps for preparing Screenlets for publication are the same. If you don't plan to reuse or redistribute your Screenlet, create it in your app's Xcode project.

You must also determine your Screenlet's functionality and what data your Screenlet requires. This determines the actions your Screenlet must support and the Liferay remote services it must call. For example, Add Bookmark Screenlet only needs to respond to one action: adding a bookmark to Liferay's Bookmarks portlet. To add a bookmark, this Screenlet must call the Liferay instance's `add-entry` service for `BookmarksEntry`. If you're running a Liferay instance locally on port 8080, click here to see this service. To add a bookmark, this service requires the following parameters:

- `groupId`: The site ID in the Liferay instance that contains the Bookmarks portlet.

- `folderId`: The folder ID in the Bookmarks portlet that receives the new bookmark.

- `name`: The new bookmark's title.

- `url`: The new bookmark's URL.

- `description`: The new bookmark's description.
- `serviceContext`: A Liferay `ServiceContext` object.

Add Bookmark Screenlet must therefore account for each of these parameters. When saving a bookmark, the Screenlet asks the user to enter the bookmark's URL and name. The user isn't required, however, to enter any other parameters. This is because the app developer sets the `groupId` and `folderId` via the app's code. Also, the Screenlet's code automatically populates the `description` and `serviceContext`.

Great! Now you're ready to create your Screenlet's Theme!

Creating the Screenlet's UI

In Liferay Screens for iOS, a Screenlet's UI is called a Theme. Every Screenlet must have at least one Theme. A Theme has the following components:

1. An XIB file: defines the UI components that the Theme presents to the end user.
2. A View class: renders the UI, handles user interactions, and communicates with the Screenlet class.

First, create a new XIB file and use Interface Builder to construct your Screenlet's UI. In many cases, the Screenlet's actions must be triggered from the Theme. To achieve this, make sure to use a `restorationIdentifier` property to assign a unique ID to each UI component that triggers an action. The user triggers the action by interacting with the UI component. If the action only changes the UI's state (that is, changes the UI component's properties), then you can associate that component's event to an `IBAction` method as usual. Actions using `restorationIdentifier` are intended for use by actions that need an Interactor, such as actions that make server requests or retrieve data from a database.

For example, Add Bookmark Screenlet's UI needs text boxes for entering a bookmark's URL and title. This UI also needs a button to support the Screenlet's action: sending the bookmark to a Liferay instance. The XIB file `AddBookmarkView_default.xib` defines this UI. Because the button triggers the Screenlet's action, it contains `restorationIdentifier="add-bookmark"`.

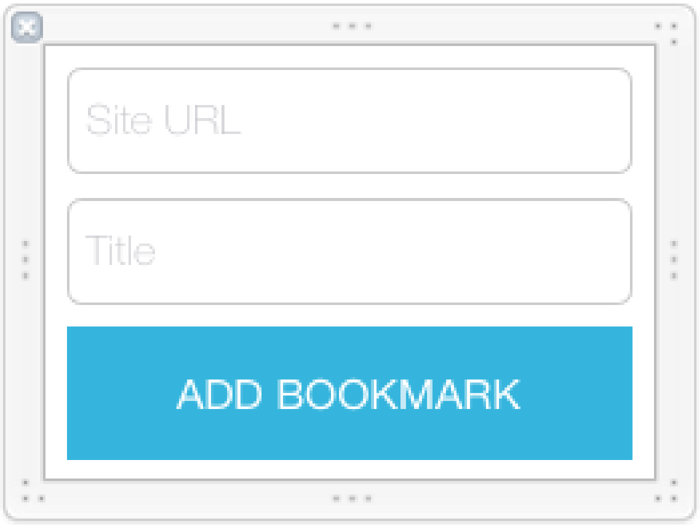

Figure 77.15: Here's the sample Add Bookmark Screenlet's XIB file rendered in Interface Builder.

Note: The Screenlet in this tutorial doesn't support multiple Themes. If you want your Screenlet to support multiple Themes, your View class must also conform a *View Model* protocol that you create. For instructions on this, see the tutorial Supporting Multiple Themes in Your Screenlet.

Now you must create your Screenlet's View class. This class controls the UI you just defined. In the `BaseScreenletView` class, Screens provides the default functionality required by all View classes. Your View class must therefore extend `BaseScreenletView` to provide the functionality unique to your Screenlet. To support your UI, use standard `@IBOutlets` and `@IBActions` to connect all your XIB's UI components and events to your View class. You should also implement getters and setters to get values from and set values to the UI components. Your View class should also implement any required animations or front-end logic.

For example, `AddBookmarkView_default` is Add Bookmark Screenlet's View class. This class extends `BaseScreenletView` and contains `@IBOutlet` references to the XIB's text fields. The getters for these references let the Theme retrieve the data the user enters into the corresponding text field:

```
import UIKit
import LiferayScreens

class AddBookmarkView_default: BaseScreenletView {

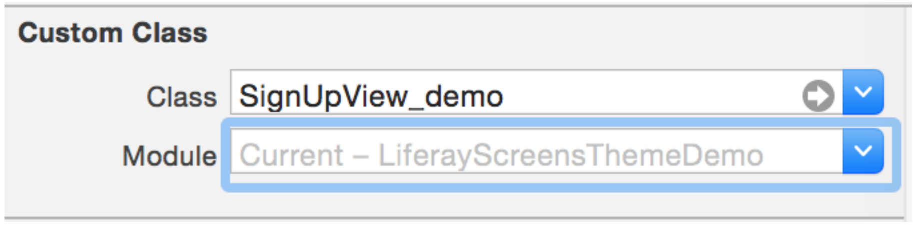
   @IBOutlet weak var URLTextField: UITextField?
   @IBOutlet weak var titleTextField: UITextField?

   var URL: String? {
       return URLTextField?.text
   }

   var title: String? {
       return titleTextField?.text
   }
}
```

In Interface Builder, you must now specify your View class as your XIB file's custom class. In Add Bookmark Screenlet, for example, `AddBookmarkView_default` is set as the `AddBookmarkView_default.xib` file's custom class in Interface Builder.

If you're using CocoaPods, make sure to explicitly set a valid module for the custom class–the grayed-out *Current* default value only suggests a module.



Custom Class

Class: SignUpView_demo

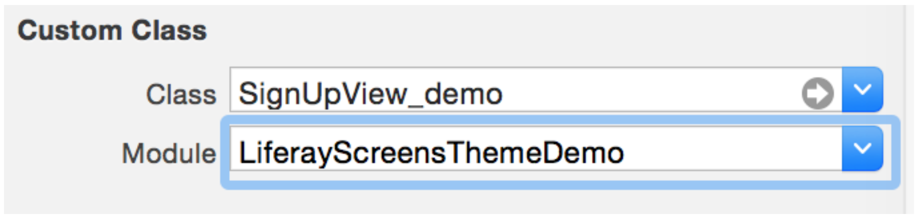
Module: Current – LiferayScreensThemeDemo

Figure 77.16: In this XIB file, the custom class's module is NOT specified.

Next, you'll create your Screenlet's Interactor.

Creating the Interactor

Create an Interactor class for each of your Screenlet's actions. In the Interactor class, Screens provides the default functionality required by all Interactor classes. Your Interactor class must therefore extend Interactor to provide the functionality unique to your Screenlet.



Custom Class

Class SignUpView_demo

Module LiferayScreensThemeDemo

Figure 77.17: The XIB file is bound to the custom class name, with the specified module.

Note: You may wish to make your server call in a Connector instead of an Interactor. Doing so provides an additional abstraction layer for your server call, leaving your Interactor to instantiate your Connector and receive its results. For instructions on this, see the tutorial Create and Use a Connector with Your Screenlet.

Interactors work synchronously, but you can use callbacks (delegates) or Connectors to run their operations in the background. For example, the Liferay Mobile SDK provides the `LRCallback` protocol for this purpose. This is described in the Mobile SDK tutorial on invoking Liferay services asynchronously. Screens bridges this protocol to make it available in Swift. Your Interactor class can conform this protocol to make its server calls asynchronously. To implement an Interactor class:

- Your initializer must receive all required properties and a reference to the Screenlet.
- Override Interactor's `start` method to perform the server operations your Screenlet requires (e.g., invoke a Liferay operation via a Liferay Mobile SDK service).
- Save the server response to an accessible property, if necessary. For example, if the server call returns objects from a Liferay instance, you should store these objects in an accessible property. This way your Screenlet can display those results to the user.
- You must invoke the methods `callOnSuccess` and `callOnFailure` to execute the closures `onSuccess` and `onFailure`, respectively.

For example, the sample Add Bookmark Screenlet's Interactor class `AddBookmarkInteractor` makes the server call that adds a bookmark to a Liferay instance. This class extends the `Interactor` class and conforms the `LRCallback` protocol. The latter ensures that the Interactor's server call runs asynchronously:

```
public class AddBookmarkInteractor: Interactor, LRCallback {...
```

To save the server call's results, `AddBookmarkInteractor` defines the public variable `resultBookmarkInfo`. This class also defines public constants for the bookmark's folder ID, title, and URL. The initializer sets these variables and calls Interactor's constructor with a reference to the base Screenlet class (`BaseScreenlet`):

```
public var resultBookmarkInfo: [String:AnyObject]?
public let folderId: Int64
public let title: String
public let url: String

public init(screenlet: BaseScreenlet, folderId: Int64, title: String, url: String) {
    self.folderId = folderId
    self.title = title
    self.url = url
    super.init(screenlet: screenlet)
}
```

The `AddBookmarkInteractor` class's `start` method makes the server call. To do so, it must first get a `Session`. Since Login Screenlet creates a session automatically upon successful login, the `start` method retrieves this session with SessionContext.createSessionFromCurrentSession(). To make the server call asynchronously, the start method must set a callback to this session. Because AddBookmarkInteractor conforms the LRCallback protocol, setting self as the session's callback accomplishes this. The start method must then create a LRBookmarksEntryService_v7 instance and call this instance's addEntryWithGroupId method. The latter method calls a Liferay instance's add-entry service for BookmarksEntry. The start method therefore provides the groupId, folderId, name, url, description, and serviceContext arguments to addEntryWithGroupId. Note that this example provides a hard-coded string for the description. Also, the serviceContext is nil because the Mobile SDK handles the ServiceContext object for you:

```
override public func start() -> Bool {
    let session = SessionContext.createSessionFromCurrentSession()
    session?.callback = self

    let service = LRBookmarksEntryService_v7(session: session)

    do {
        try service.addEntryWithGroupId(LiferayServerContext.groupId,
                        folderId: folderId,
                        name: title,
                        url: url,
                        description: "Added from Liferay Screens",
                        serviceContext: nil)

        return true
    }
    catch {
        return false
    }
}
```

Finally, the AddBookmarkInteractor class must conform the LRCallback protocol by implementing the onFailure and onSuccess methods. The onFailure method communicates the NSError object that results from a failed server call. It does this by calling the base Interactor class's callOnFailure method with the error. When the server call succeeds, the onSuccess method sets the server call's results (the result argument) to the resultBookmarkInfo variable. The onSuccess method finishes by calling the base Interactor class's callOnSuccess method to communicate the success status throughout the Screenlet:

```
public func onFailure(error: NSError!) {
    self.callOnFailure(error)
}

public func onSuccess(result: AnyObject!) {
    //Save result bookmark info
    resultBookmarkInfo = (result as! [String:AnyObject])

    self.callOnSuccess()
}
```

Next, you'll create the Screenlet class.

Creating the Screenlet Class

The Screenlet class is the central hub of a Screenlet. It contains the Screenlet's properties, a reference to the Screenlet's View class, methods for invoking Interactor operations, and more. When using a Screenlet, app developers primarily interact with its Screenlet class. In other words, if a Screenlet were to become self-aware, it would happen in its Screenlet class (though we're reasonably confident this won't happen).

Screens's BaseScreenlet class is a base Screenlet class implementation. Since BaseScreenlet provides most of a Screenlet class's required functionality, your Screenlet class should extend BaseScreenlet. This lets you focus on your Screenlet's unique functionality. Your Screenlet class must also include any @IBInspectable properties your Screenlet requires and a reference to your Screenlet's View class. To perform your Screenlet's action, your Screenlet class must override BaseScreenlet's createInteractor method. This method should create an instance of your Interactor and then set the Interactor's onSuccess and onFailure closures to define what happens when the server call succeeds or fails, respectively.

For example, the AddBookmarkScreenlet class is the Screenlet class in Add Bookmark Screenlet. This class extends BaseScreenlet and contains an @IBInspectable variable for the bookmark folder's ID (folderId). The AddBookmarkScreenlet class's createInteractor method first gets a reference to the View class (AddBookmarkView_default). It then creates an AddBookmarkInteractor instance with this Screenlet class (self), the folderId, the bookmark's title, and the bookmark's URL. Note that the View class reference contains the bookmark title and URL that the user entered into the UI. The createInteractor method then sets the Interactor's onSuccess closure to print a success message when the server call succeeds. Likewise, the Interactor's onFailure closure is set to print an error message when the server call fails. Note that you're not restricted to only printing messages here: you should set these closures to do whatever is best for your Screenlet. The createInteractor method finishes by returning the Interactor instance. Here's the complete AddBookmarkScreenlet class:

```
import UIKit
import LiferayScreens

public class AddBookmarkScreenlet: BaseScreenlet {

    //MARK: Inspectables

    @IBInspectable var folderId: Int64 = 0

    //MARK: BaseScreenlet

    override public func createInteractor(name name: String?, sender: AnyObject?) -> Interactor? {

        let view = self.screenletView as! AddBookmarkView_default

        let interactor = AddBookmarkInteractor(screenlet: self,
                                         folderId: folderId,
                                         title: view.title!,
                                         url: view.URL!)

        //Called when the Interactor's server call finishes succesfully
        interactor.onSuccess = {
            let bookmarkName = interactor.resultBookmarkInfo!["name"] as! String
            print("Bookmark \"\(bookmarkName)\" saved!")
        }

        //Called when the Interactor's server call fails
        interactor.onFailure = { _ in
            print("An error occurred saving the bookmark")
        }

        return interactor
    }

}
```

For reference, the sample Add Bookmark Screenlet's final code is here on GitHub.

You're done! Your Screenlet is a ready-to-use component that you can add to your storyboard. You can even package it to contribute to the Screens project or distribute it with CocoaPods. Now you know how to create iOS Screenlets!

77.7 Supporting Multiple Themes in Your Screenlet

Themes let you present the same Screenlet with a different look and feel. For example, if you have multiple apps that use the same Screenlet, you can use different Themes to match the Screenlet's appearance to each app's style. Each Screenlet that comes with Liferay Screens supports the use of multiple Themes. For your custom Screenlet to support different Themes, however, it must contain a *View Model* protocol. A View Model abstracts the Theme used to display the Screenlet, thus letting developers use other Themes. For example, note that the Screenlet class's `createInteractor` method in the Screenlet creation tutorial accesses the View class (`AddBookmarkView_default`) directly when getting a reference to the View class:

```
let view = self.screenletView as! AddBookmarkView_default
```

This is all fine and well, except it hard codes the Theme defined by `AddBookmarkView_default`! To use a different Theme, you'd have to rewrite this line of code to use that Theme's View class. This isn't very flexible! Instead of making your Screenlet take expensive yoga classes, you can abstract the Theme's View class via a View Model protocol.

This tutorial shows you how to add a View Model to your Screenlet. The Add Bookmark Screenlet created in the Screenlet creation tutorial is used as an example. Note that you can also follow these steps to add a View Model while creating your Screenlet.

Creating and Using a View Model

Follow these steps to add and use a View Model in your Screenlet:

1. Create a View Model protocol that defines your Screenlet's attributes. These attributes are the View class properties your Screenlet class uses. For example, the Screenlet class in Add Bookmark Screenlet uses the View class properties `title` and `URL`. Add Bookmark Screenlet's View Model protocol (`AddBookmarkViewModel`) must therefore define variables for these properties:

```
import UIKit

@objc protocol AddBookmarkViewModel {

    var URL: String? {get}

    var title: String? {get}

}
```

2. Conform your View class to your Screenlet's View Model protocol. Make sure to get/set all the protocol's properties. For example, here's Add Bookmark Screenlet's View Class (`AddBookmarkView_default`) conformed to `AddBookmarkViewModel`:

```
import UIKit
import LiferayScreens

class AddBookmarkView_default: BaseScreenletView, AddBookmarkViewModel {

    @IBOutlet weak var URLTextField: UITextField?
    @IBOutlet weak var titleTextField: UITextField?

    var URL: String? {
        return URLTextField?.text
    }

    var title: String? {
        return titleTextField?.text
    }

}
```

3. Create and use a View Model reference in your Screenlet class. By retrieving data from this reference instead of a direct View class reference, you can use your Screenlet with other Themes. For example, here's the `AddBookmarkScreenlet` class with a `viewModel` property instead of a direct reference to `AddBookmarkView_default`. This class's `createInteractor` method then uses this property to get the `title` and `URL` properties in the `AddBookmarkInteractor` constructor:

```
...
//View Model reference
var viewModel: AddBookmarkViewModel {
    return self.screenletView as! AddBookmarkViewModel
}

override public func createInteractor(name name: String?, sender: AnyObject?) -> Interactor? {

    let interactor = AddBookmarkInteractor(screenlet: self,
                                           folderId: folderId,
                                           title: viewModel.title!,
                                           url: viewModel.URL!)

    // Called when the Interactor finishes succesfully
    interactor.onSuccess = {
        let bookmarkName = interactor.resultBookmarkInfo!["name"] as! String
        print("Bookmark \"\(bookmarkName)\" saved!")
    }

    // Called when the Interactor finishes with an error
    interactor.onFailure = { _ in
        print("An error occurred saving the bookmark")
    }

    return interactor
}
...
```

That's it! Now your Screenlet is ready to use other Themes that you create for it. See the tutorial Creating iOS Themes for instructions on creating a Theme.

77.8 Adding Screenlet Actions

With multiple Interactors, it's possible for a Screenlet to have multiple actions. You must create an Interactor class for each action. For example, if your Screenlet needs to make two server calls, then you need two Interactors: one for each call. Your Screenlet class's `createInteractor` method must return an instance of each Interactor. Also, recall that each action name is given by the `restorationIdentifier` of the UI components that trigger them. You should set this `restorationIdentifier` to a constant in your Screenlet.

This tutorial walks you through the steps necessary to add an action to your Screenlet, and trigger an action programmatically. As an example, this tutorial uses the advanced version of the sample Add Bookmark Screenlet. This Screenlet is similar to the sample Add Bookmark Screenlet created in the Screenlet creation tutorial. The advanced Add Bookmark Screenlet, however, contains two actions:

1. Add Bookmark: Adds a bookmark to the Bookmarks portlet in a Liferay DXP installation. This is the Screenlet's main action, created in the Screenlet creation tutorial.

2. Get Title: Retrieves the title from a bookmark URL entered by the user. This tutorial shows you how to implement this action.

Note that this tutorial doesn't explain Screenlet creation in general. Before proceeding, make sure you've read the Screenlet creation tutorial. And without any further ado, it's time to implement your Screenlet's action!

Implementing Your Action

Use the following steps to add an action to your your Screenlet:

1. Create a constant in your Screenlet class for each of your Screenlet's actions. For example, here are the constants in Add Bookmark Screenlet's Screenlet class (`AddBookmarkScreenlet`):

   ```
   static let AddBookmarkAction = "add-bookmark"
   static let GetTitleAction = "get-title"
   ```

2. In your Theme's XIB file, add any new UI components that you need to perform the action. For example, Add Boookmark Screenlet's XIB file needs a new button for getting the URL's title:

3. Wire the UI components in your XIB file to your View class. In your View class, you must also register the events you want to react to (e.g., button clicks). The `BaseScreenletView` class contains a set of `userAction` methods that you can call in your View class to perform actions programmatically. For example, it's possible to trigger Add Bookmark Screenlet's `GetTitleAction` automatically whenever the user leaves the `URLTextField`. Since `BaseScreenletView` is the delegate for all `UITextField` objects by default, this is done in the View class (`AddBookmarkView_default`) by implementing the `textFieldDidEndEditing` method to call the `userAction` method with the action name:

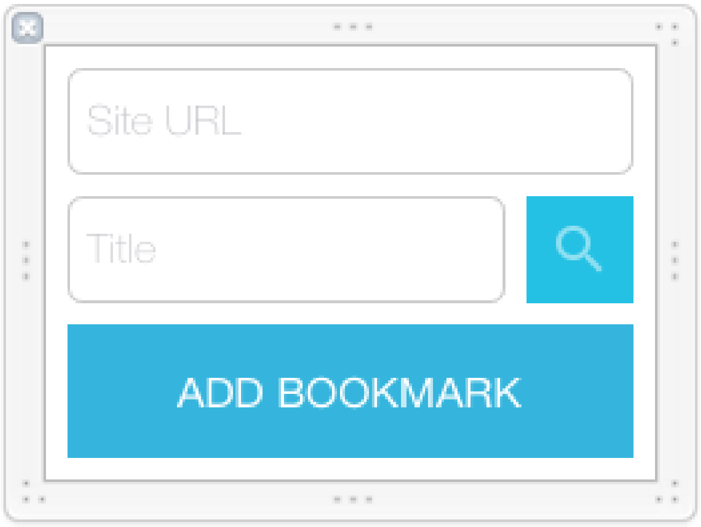

Figure 77.18: The sample Add Bookmark Screenlet's XIB file contains a new button next to the *Title* field for retrieving the URL's title.

```
func textFieldDidEndEditing(textField: UITextField) {
    if textField == URLTextField {
        userAction(name: AddBookmarkScreenlet.GetTitleAction)
    }
}
```

4. Update your View class or View Model protocol to account for the new action. For example, Add Bookmark Screenlet contains a View Model (`AddBookmarkViewModel`) so it can support multiple Themes. This View Model must allow the new action to set its `title` variable:

```
import UIKit

@objc protocol AddBookmarkViewModel {
    var URL: String? {get}
    var title: String? {set get}
}
```

5. If your Screenlet uses a View Model, conform your View class to the updated View Model. For example, the `title` variable in Add Bookmark Screenlet's View class (`AddBookmarkView_default`) must implement the setter from the previous step:

```
var title: String? {
    get {
        return titleTextField?.text
    }
    set {
        self.titleTextField?.text = newValue
    }
}
```

6. Create a new Interactor class for the new action. To do this, use the same steps detailed in the Screenlet creation tutorial. For example, here's the Interactor class for Add Bookmark Screenlet's Get Title action:

```
import UIKit
import LiferayScreens
```

```
public class GetWebTitleInteractor: Interactor {

    public var resultTitle: String?

    var url: String

    //MARK: Initializer

    public init(screenlet: BaseScreenlet, url: String) {
        self.url = url
        super.init(screenlet: screenlet)
    }

    override public func start() -> Bool {
        if let URL = NSURL(string: url) {

            // Use the NSURLSession class to retrieve the HTML
            NSURLSession.sharedSession().dataTaskWithURL(URL) {
                    (data, response, error) in

                if let errorValue = error {
                    self.callOnFailure(errorValue)
                }
                else {
                    if let data = data, html = NSString(data: data, encoding: NSUTF8StringEncoding) {
                        self.resultTitle = self.parseTitle(html)
                    }

                    self.callOnSuccess()
                }
            }.resume()

            return true
        }

        return false
    }

    // Parse the title from a webpage HTML
    private func parseTitle(html: NSString) -> String {
        let range1 = html.rangeOfString("<title>")
        let range2 = html.rangeOfString("</title>")

        let start = range1.location + range1.length

        return html.substringWithRange(NSMakeRange(start, range2.location - start))
    }

}
```

7. Update your Screenlet class's `createInteractor` method so it returns the correct Interactor for each action. For example, the `createInteractor` method in Add Bookmark Screenlet's Screenlet class (`AddBookmarkScreenlet`) contains a `switch` statement that returns an `AddBookmarkInteractor` or `GetWebTitleInteractor` instance when the Add Bookmark or Get Title action is called, respectively. Note that the `createAddBookmarkInteractor()` and `createGetTitleInteractor()` methods create these instances. Although you don't have to create your Interactor instances in separate methods, doing so leads to cleaner code:

```
...
override public func createInteractor(name name: String, sender: AnyObject?)
    -> Interactor? {
        switch name {
        case AddBookmarkScreenlet.AddBookmarkAction:
            return createAddBookmarkInteractor()
        case AddBookmarkScreenlet.GetTitleAction:
            return createGetTitleInteractor()
        default:
            return nil
        }
    }

private func createAddBookmarkInteractor() -> Interactor {
    let interactor = AddBookmarkInteractor(screenlet: self,
                                           folderId: folderId,
                                           title: viewModel.title!,
                                           url: viewModel.URL!)

    // Called when the Interactor finishes succesfully
    interactor.onSuccess = {
        let bookmarkName = interactor.resultBookmarkInfo!["name"] as! String
        print("Bookmark \"\(bookmarkName)\" saved!")
    }

    // Called when the Interactor finishes with an error
    interactor.onFailure = { _ in
        print("An error occurred saving the bookmark")
    }

    return interactor
}

private func createGetTitleInteractor() -> Interactor {
    let interactor = GetWebTitleInteractor(screenlet: self, url: viewModel.URL!)

    // Called when the Interactor finishes succesfully
    interactor.onSuccess = {
        let title = interactor.resultTitle
        self.viewModel.title = title
    }

    // Called when the Interactor finishes with an error
    interactor.onFailure = { _ in
        print("An error occurred retrieving the title")
    }

    return interactor
}
...
```

Great! Now you know how to support multiple actions in your Screenlets.

77.9 Create and Use a Connector with Your Screenlet

In Liferay Screens, a Connector is a class that interacts asynchronously with local and remote data sources and Liferay instances. Recall that callbacks also make asynchronous service calls. So why bother with a Connector? Connectors provide a layer of abstraction by making your service call outside your Interactor.

For example, the Interactor in the Screenlet creation tutorial makes the server call and and processes its results via `LRCallback`. This Screenlet could instead make its server call in a separate Connector class, leaving the Interactor to instantiate the Connector and receive its results. Connectors also let you validate your Screenlet's data. For more information on Connectors, see the tutorial on the architecture of Liferay Screens for iOS.

This tutorial walks you through the steps required to create and use a Connector with your Screenlets, using the advanced version of the sample Add Bookmark Screenlet as an example. This Screenlet contains two actions:

1. Add Bookmark: Adds a bookmark to the Bookmarks portlet in a Liferay DXP installation. This tutorial shows you how to create and use a Connector for this action.

2. Get Title: Retrieves the title from a bookmark URL entered by the user. This tutorial shows you how to use a pre-existing Connector with this action.

Before proceeding, make sure you've read the Screenlet creation tutorial. First, you'll learn how to create your Connector.

Creating Connectors

When you create your Connector class, be sure to follow the naming convention specified in the best practices tutorial.

Use the following steps to implement your Connector class:

1. Create your Connector class by extending the `ServerConnector` class. For example, here's the class declaration for Add Bookmark Screenlet's Connector class, `AddBookmarkLiferayConnector`:

   ```
   public class AddBookmarkLiferayConnector: ServerConnector {
       ...
   }
   ```

2. Add the properties needed to call the Mobile SDK service, then create an initializer that sets those properties. For example, `AddBookmarkLiferayConnector` needs properties for the bookmark's folder ID, title, and URL. It also needs an initializer to set those properties:

   ```
   public let folderId: Int64
   public let title: String
   public let url: String

   public init(folderId: Int64, title: String, url: String) {
       self.folderId = folderId
       self.title = title
       self.url = url
       super.init()
   }
   ```

3. If you want to validate any of your Screenlet's properties, override the `validateData` method to implement validation for those properties. You can use the `ValidationError` class to encapsulate the errors. For example, the following `validateData` implementation in `AddBookmarkLiferayConnector` ensures that `folderId` is greater than `0`, and `title` and `url` contain values. This method also uses `ValidationError` to represent the error:

```
override public func validateData() -> ValidationError? {
    let error = super.validateData()

    if error == nil {

        if folderId <= 0 {
            return ValidationError("Undefined folderId")
        }

        if title.isEmpty {
            return ValidationError("Title cannot be empty")
        }

        if url.isEmpty {
            return ValidationError("URL cannot be empty")
        }
    }

    return error
}
```

4. Override the doRun method to call the Mobile SDK service you need to call. This method should retrieve the result from the service and store it in a public property. Also be sure to handle errors and empty results. For example, the following code defines the resultBookmarkInfo property for storing the service's results retrieved in the doRun method. Note that this method's service call is identical to the one in the AddBookmarkInteractor class's start method in the Screenlet creation tutorial. The doRun method, however, takes the additional step of saving the result to the resultBookmarkInfo property. Also note that this doRun method handles errors as NSError objects:

```
public var resultBookmarkInfo: [String:AnyObject]?

override public func doRun(session session: LRSession) {

    let service = LRBookmarksEntryService_v7(session: session)

    do {
        let result = try service.addEntryWithGroupId(LiferayServerContext.groupId,
                                                     folderId: folderId,
                                                     name: title,
                                                     url: url,
                                                     description: "Added from Liferay Screens",
                                                     serviceContext: nil)

        if let result = result as? [String: AnyObject] {
            resultBookmarkInfo = result
            lastError = nil
        }
        else {
            lastError = NSError.errorWithCause(.InvalidServerResponse)
            resultBookmarkInfo = nil
        }
    }
    catch let error as NSError {
        lastError = error
        resultBookmarkInfo = nil
    }

}
```

Well done! Now you know how to create a Connector class. To see the finished example AddBookmarkLiferayConnector class, click here.

Using Connectors

To use a Connector, your Interactor class must extend the ServerConnectorInteractor class or one of its following subclasses:

- ServerReadConnectorInteractor: Your Interactor class should extend this class when implementing an action that retrieves information from a server or data source.

- ServerWriteConnectorInteractor: Your Interactor class should extend this class when implementing an action that writes information to a server or data source.

When extending ServerConnectorInteractor or one of its subclasses, your Interactor class only needs to override the createConnector and completedConnector methods. These methods create a Connector instance and recover the Connector's result, respectively.

Follow these steps to use a Connector in your Interactor:

1. Set your Interactor class's superclass to ServerConnectorInteractor or one of its subclasses. You should also remove any code that conforms a callback protocol, if it exists. For example, Add Bookmark Screenlet's Interactor class (AddBookmarkInteractor) extends ServerWriteConnectorInteractor because it writes data to a Liferay DXP installation. At this point, your Interactor should contain only the properties and initializer that it requires:

```
public class AddBookmarkInteractor: ServerWriteConnectorInteractor {

    public let folderId: Int64
    public let title: String
    public let url: String

    public var resultBookmark: Bookmark?

    //MARK: Initializer

    public init(screenlet: BaseScreenlet, folderId: Int64, title: String, url: String) {
        self.folderId = folderId
        self.title = title
        self.url = url
        super.init(screenlet: screenlet)
    }
}
```

2. Override the createConnector method to return an instance of your Connector. For example, the createConnector method in AddBookmarkInteractor returns an AddBookmarkLiferayConnector instance created with the folderId, title, and url properties:

```
public override func createConnector() -> ServerConnector? {
    return AddBookmarkLiferayConnector(folderId: folderId, title: title, url: url)
}
```

3. Override the completedConnector method to get the result from the Connector and store it in the appropriate property. For example, the completedConnector method in AddBookmarkInteractor first casts its ServerConnector argument to AddBookmarkLiferayConnector. It then gets the Connector's resultBookmarkInfo property and sets it to the Interactor's resultBookmark property:

```
    override public func completedConnector(c: ServerConnector) {
        if let addCon = (c as? AddBookmarkLiferayConnector),
            bookmarkInfo = addCon.resultBookmarkInfo {
            self.resultBookmark = bookmarkInfo
        }
    }
```

That's it! To see the complete example `AddBookmarkInteractor`, click here.

If your Screenlet uses multiple Interactors, follow the same steps to use Connectors. Also, Screens provides the ready-to-use `HttpConnector` for interacting with non-Liferay URL's. To use this Connector, set your Interactor to use `HttpConnector`. For example, the Add Bookmark Screenlet action that retrieves a URL's title doesn't interact with a Liferay DXP installation; it retrieves the title directly from the URL. Because this action's Interactor class (`GetWebTitleInteractor`) retrieves data, it extends `ServerReadConnectorInteractor`. It also overrides the `createConnector` and `completedConnector` methods to use `HttpConnector`. Here's the complete `GetWebTitleInteractor`:

```
import UIKit
import LiferayScreens

public class GetWebTitleInteractor: ServerReadConnectorInteractor {

    public let url: String?

    // title from the webpage
    public var resultTitle: String?

    //MARK: Initializer

    public init(screenlet: BaseScreenlet, url: String) {
        self.url = url
        super.init(screenlet: screenlet)
    }

    //MARK: ServerConnectorInteractor

    public override func createConnector() -> ServerConnector? {
        if let url = url, URL = NSURL(string: url) {
            return HttpConnector(url: URL)
        }

        return nil
    }

    override public func completedConnector(c: ServerConnector) {
        if let httpCon = (c as? HttpConnector), data = httpCon.resultData,
            html = NSString(data: data, encoding: NSUTF8StringEncoding) {
            self.resultTitle = parseTitle(html)
        }
    }

    //MARK: Private methods

    // Parse the title from the webpage's HTML
    private func parseTitle(html: NSString) -> String {
        let range1 = html.rangeOfString("<title>")
        let range2 = html.rangeOfString("</title>")

        let start = range1.location + range1.length

        return html.substringWithRange(NSMakeRange(start, range2.location - start))
    }

}
```

Awesome! Now you know how to create and use Connectors in your Screenlets.

Creating iOS List Screenlets

77.10 Add a Screenlet Delegate

Screenlet delegates let other classes respond to your Screenlet's actions. For example, Login Screenlet's delegate lets the app developer implement methods that respond to login success or failure. Note that the reference documentation for each Screenlet that comes with Liferay Screens lists the Screenlet's delegate methods.

You can also create a delegate for your own Screenlet. This tutorial walks you through the steps required to do this, using code from the advanced version of the sample Add Bookmark Screenlet as an example. All the example code in this tutorial resides in this Screenlet's Screenlet class. Also note that this sample Screenlet has two actions: adding a bookmark to a Liferay instance's Bookmarks portlet, and retrieving a bookmark's title from its URL. This tutorial only details creating a delegate for adding a bookmark.

Follow these steps to add a delegate to your Screenlet:

1. Define a delegate protocol that extends the `BaseScreenletDelegate` class. In this protocol, define success and failure methods so the conforming class can respond to the server call's success and failure, respectively. As parameters, these methods should take a Screenlet instance and the success or failure object. For example, Add Bookmark Screenlet's delegate protocol (`AddBookmarkScreenletDelegate`) defines the following success and failure methods:

```
@objc public protocol AddBookmarkScreenletDelegate: BaseScreenletDelegate {

    optional func screenlet(screenlet: AddBookmarkScreenlet,
                    onBookmarkAdded bookmark: [String: AnyObject])

    optional func screenlet(screenlet: AddBookmarkScreenlet,
                    onAddBookmarkError error: NSError)

}
```

   Both take an `AddBookmarkScreenlet` instance as their first argument. For their second argument, the success method contains the bookmark added to the server, and the failure method contains the `NSError` object. Note that in this example, the methods are optional. This means that the delegate class doesn't have to implement them.

2. In your Screenlet class, add a property for your delegate. This property should return `BaseScreenlet`'s `delegate` property as an instance of your delegate. For example, the `addBookmarkDelegate` property in `AddBookmarkScreenlet` returns the `self.delegate` property as `AddBookmarkScreenletDelegate`:

```
var addBookmarkDelegate: AddBookmarkScreenletDelegate? {
    return self.delegate as? AddBookmarkScreenletDelegate
}
```

3. Also in your Screenlet class, invoke the appropriate delegate methods in your Interactor's closures. For example, the `interactor.onSuccess` closure in `AddBookmarkScreenlet` calls the delegate method that responds when the Screenlet successfully adds a bookmark. The `interactor.onFailure` closure calls the delegate method that responds when the Screenlet fails to add a bookmark. Note that in this example, these closures are in the Screenlet class's Interactor method that adds a bookmark (`createAddBookmarkInteractor`). Be sure to call your delegate methods wherever the appropriate Interactor's closures are in your Screenlet class:

```
 private func createAddBookmarkInteractor() -> Interactor {
     let interactor = AddBookmarkInteractor(screenlet: self,
                                            folderId: folderId,
                                            title: viewModel.title!,
                                            url: viewModel.URL!)

     // Called when the Interactor finishes successfully
     interactor.onSuccess = {
         if let bookmark = interactor.resultBookmark {
             self.addBookmarkDelegate?.screenlet?(self, onBookmarkAdded: bookmark)
         }
     }

     // Called when the Interactor finishes with an error
     interactor.onFailure = { error in
         self.addBookmarkDelegate?.screenlet?(self, onAddBookmarkError: error)
     }

     return interactor
 }
```

Great! Now you know how to add a delegate to your Screenlets.

Architecture of Liferay Screens for iOS

77.11 Using and Creating Progress Presenters

Many apps display a progress indicator while performing an operation. For example, you've likely seen the spinners in iOS apps that let you know the app is performing some kind of work. For more information, see the iOS Human Interface Guidelines article on Progress Indicators.

You can display these in Screenlets by using classes that conform the `ProgressPresenter` protocol. Liferay Screens includes two such classes:

- `MBProgressHUDPresenter`: Shows a message with a spinner in the middle of the screen. Liferay Screens shows this presenter by default.

- `NetworkActivityIndicatorPresenter`: Shows the progress using the iOS network activity indicator. This presenter doesn't support messages.

This tutorial shows you how to use and create progress presenters, using code from the advanced version of the sample Add Bookmark Screenlet as an example. First, you'll learn how to use progress presenters.

Using Progress Presenters

The BaseScreenletView class contains the default progress presenter functionality. To show a presenter other than the default MBProgressHUDPresenter, your View class must therefore override certain BaseScreenletView functionality. Follow these steps to do this:

1. In your View class, override the BaseScreenletView method createProgressPresenter to return an instance of the desired presenter. For example, to use NetworkActivityIndicatorPresenter in the sample Add Bookmark Screenlet, you must override the createProgressPresenter method in AddBookmarkView_default to return a NetworkActivityIndicatorPresenter instance:

```
override func createProgressPresenter() -> ProgressPresenter {
    return NetworkActivityIndicatorPresenter()
}
```

2. In your View class, override the BaseScreenletView property progressMessages to return the messages you want to use in the presenter. If the presenter doesn't display messages, then return an empty string. The progressMessages property should return the messages as [String : ProgressMessages], where String is the Screenlet's action name. ProgressMessages is a type alias representing a dictionary where the progress type is the key, and the actual message is the value. The three possible progress types correspond to the Screenlet action's status: Working, Failure, or Success. The progressMessages property therefore lets the presenter display the appropriate message for the Screenlet action's current status.

   For example, the following code overrides the progressMessages property in Add Bookmark Screenlet's View class (AddBookmarkView_default). For each Screenlet action (AddBookmarkAction and GetTitleAction), a message (NoProgressMessage) is assigned to the Screenlet operation's Working status. Since NoProgressMessage is an alias for an empty string, this tells the presenter to display no message when the Screenlet attempts to add a bookmark or get a title. Note, however, that the presenter still displays its progress indicator:

```
override var progressMessages: [String : ProgressMessages] {
    return [
        AddBookmarkScreenlet.AddBookmarkAction : [.Working: NoProgressMessage],
        AddBookmarkScreenlet.GetTitleAction : [.Working: NoProgressMessage],
    ]
}
```

   To display a message, replace NoProgressMessage with your message. For example, the following code defines separate messages for Working, Success, and Failure:

```
override var progressMessages: [String : ProgressMessages] {
    return [
        AddBookmarkScreenlet.AddBookmarkAction : [
            .Working: "Saving bookmark...",
            .Success: "Bookmark saved!",
            .Failure: "An error occurred saving the bookmark"
        ],
        AddBookmarkScreenlet.GetTitleAction : [
            .Working: "Getting site title...",
            .Failure: "An error occurred retrieving the title"
        ],
    ]
}
```

Great! Now you know how to use progress presenters. Next, you'll learn how to create your own.

Creating Progress Presenters

Creating your own progress presenter isn't as complicated as you might think. Recall that a presenter in Liferay Screens is a class that conforms the ProgressPresenter protocol. You can create your presenter by conforming this protocol from scratch, or by extending one of Screens's existing presenters that already conform this protocol (MBProgressHUDPresenter or NetworkActivityIndicatorPresenter). In most cases, extending MBProgressHUDPresenter is sufficient.

For example, Add Bookmark Screenlet's AddBookmarkProgressPresenter extends MBProgressHUDPresenter to display a different progress indicator for the Screenlet's get title action. Use the following steps to create a progress presenter that extends from an existing presenter. As an example, these steps extend MBProgressHUDPresenter to add a progress indicator for the get title button:

1. In your View's XIB file, add the activity indicator you want to use. For example, the XIB file in Add Bookmark Screenlet contains an iOS UIActivityIndicatorView over the get title button:

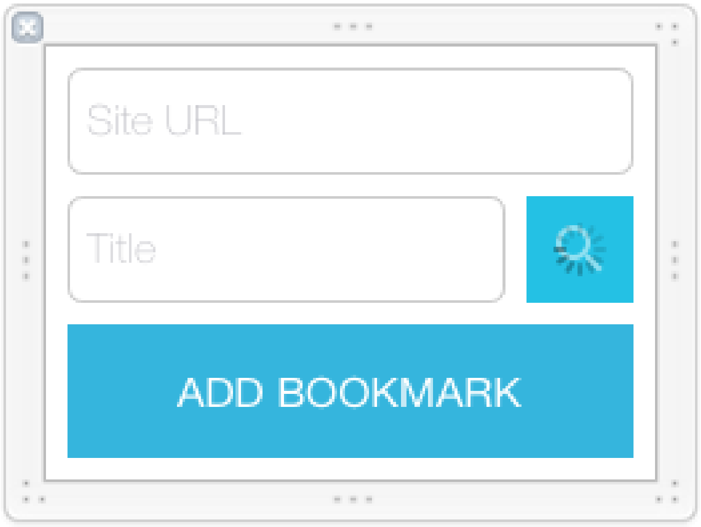

Figure 77.19: The updated Add Bookmark Screenlet's XIB file contains a new activity indicator over the get title button.

2. In your View class, create an outlet for the XIB's new activity indicator. For example, Add Bookmark Screenlet's View class (AddBookmarkView_default) contains an @IBOutlet for the UIActivityIndicatorView from the XIB:

```
@IBOutlet weak var activityIndicatorView: UIActivityIndicatorView?
```

Now you must create your presenter class. You'll do this here by extending an existing presenter class. Use the following steps to do this:

1. Extend the existing presenter class you want to base your presenter on. Your presenter class must contain properties for your presenter's activity indicator and any other UI components. It must also contain an initializer that sets these properties. For example, AddBookmarkProgressPresenter extends MBProgressHUDPresenter and contains properties for the get title button and UIActivityIndicatorView. Its initializer sets these properties:

```
public class AddBookmarkProgressPresenter: MBProgressHUDPresenter {

    let button: UIButton?

    let activityIndicator: UIActivityIndicatorView?

    public init(button: UIButton?, activityIndicator: UIActivityIndicatorView?) {
        self.button = button
        self.activityIndicator = activityIndicator
        super.init()
    }
    ...
```

2. Implement your presenter's behavior by overriding the appropriate methods from the presenter class that you're extending. For example, `AddBookmarkProgressPresenter` overrides `MBProgressHUDPresenter`'s `showHUDInView` and `hideHUDFromView` methods. The overridden `showHUDInView` method hides the button and starts animating the activity indicator. The overridden `hideHUDFromView` method stops this animation and restores the button:

```
public override func showHUDInView(view: UIView, message: String?,
    forInteractor interactor: Interactor) {
        guard interactor is GetWebTitleInteractor else {
            return super.showHUDInView(view, message: message,
                forInteractor: interactor)
        }

        button?.hidden = true
        activityIndicator?.startAnimating()
}

public override func hideHUDFromView(view: UIView?, message: String?,
    forInteractor interactor: Interactor, withError error: NSError?) {
        guard interactor is GetWebTitleInteractor else {
            return super.hideHUDFromView(view, message: message,
                forInteractor: interactor, withError: error)
        }

        activityIndicator?.stopAnimating()
        button?.hidden = false
    }

}
```

Great, that's it! Now you can use your presenter the same way you would any other.

    Creating iOS List Screenlets
    Architecture of Liferay Screens for iOS

77.12 Creating and Using Your Screenlet's Model Class

Liferay Screens typically receives entities from a Liferay instance as `[String:AnyObject]`, where `String` is the entity's attribute and `AnyObject` is the attribute's value. Although you can use these dictionary objects throughout your Screenlet, it's often easier to create a *model class* that converts each into an object that represents the corresponding Liferay entity. This is especially convenient for complex entities composed of many attribute-value pairs. Note that Liferay Screens already provides several model classes for you. Click here to see them.

At this point, you might be saying, "Ugh! I have complex entities and Screens doesn't provide a model class for them! I'm just going to give up and watch football." Fret not! Although we'd never come between you and football, creating and using your own model class is straightforward.

Using the advanced version of the sample Add Bookmark Screenlet as an example, this tutorial shows you how to create and use a model class in your Screenlet. First, you'll create your model class.

Creating Your Model Class

Your model class must contain all the code necessary to transform each `[String:AnyObject]` that comes back from the server into a model object that represents the corresponding Liferay entity. This includes a constant for holding each `[String:AnyObject]`, and initializer that sets this constant, and a public property for each attribute value.

For example, the sample Add Bookmark Screenlet adds a bookmark to a Liferay instance's Bookmarks portlet. Since the Mobile SDK service method that adds the bookmark also returns it as `[String:AnyObject]`, the Screenlet can convert it into an object that represents bookmarks. It does so with its `Bookmark` model class. This class extends `NSObject` and sets the `[String:AnyObject]` to the `attributes` constant via the initializer. This class also defines computed properties that return the attribute values for each bookmark's name and URL:

```
@objc public class Bookmark : NSObject {

    public let attributes: [String:AnyObject]

    public var name: String {
        return attributes["name"] as! String
    }

    override public var description: String {
        return attributes["description"] as! String
    }

    public var url: String {
        return attributes["url"] as! String
    }

    public init(attributes: [String:AnyObject]) {
        self.attributes = attributes
    }

}
```

Next, you'll put your model class to work.

Using Your Model Class

Now that your model class exists, you can use model objects anywhere your Screenlet handles results. Exactly where depends on what Screenlet components your Screenlet uses. For example, Add Bookmark Screenlet's Connector, Interactor, delegate, and Screenlet class all handle the Screenlet's results. The steps here therefore show you how to use model objects in each of these components. Note, however, that your Screenlet may lack a Connector or delegate: these components are optional. Variations on these steps are therefore noted where applicable.

1. Create model objects where the `[String: AnyObject]` results originate. For example, the `[String: AnyObject]` results in Add Bookmark Screenlet originate in the Connector. Therefore, this is

where the Screenlet creates Bookmark objects. The following code in the Screenlet's Connector (AddBookmarkLiferayConnector) does this. The if statement following the service call casts the results to [String: AnyObject], calls the Bookmark initializer with those results, and stores the resulting Bookmark object to the public resultBookmarkInfo variable. Note that this is only the code that makes the service call and creates the Bookmark object. Click here to see the complete AddBookmarkLiferayConnector class:

```
...
// Public property for the results
public var resultBookmarkInfo: Bookmark?

...

override public func doRun(session session: LRSession) {
    let service = LRBookmarksEntryService_v7(session: session)

    do {
        let result = try service.addEntryWithGroupId(LiferayServerContext.groupId,
                                                     folderId: folderId,
                                                     name: title,
                                                     url: url,
                                                     description: "Added from Liferay Screens",
                                                     serviceContext: nil)

        // Creates Bookmark objects from the service call's results
        if let result = result as? [String: AnyObject] {
            resultBookmarkInfo = Bookmark(attributes: result)
            lastError = nil
        }
        ...
    }
    ...
}
```

If your Screenlet doesn't have Connector, then your Interactor's start method makes your server call and handles its results. Otherwise, the process for creating a Bookmark object from [String: AnyObject] is the same.

2. Handle your model objects in your Screenlet's Interactor. The Interactor processes your Screenlet's results, so it must also handle your model objects. If your Screenlet doesn't use a Connector, then you already did this in your Interactor's start method as mentioned at the end of the previous step. If your Screenlet uses a Connector, however, then this happens in your Interactor's completedConnector method. For example, the completedConnector method in Add Bookmark Screenlet's Interactor (AddBookmarkInteractor) retrieves the Bookmark via the Connector's resultBookmarkInfo variable. This method then assigns the Bookmark to the Interactor's public resultBookmark variable. Note that this is only the code that handles Bookmark objects. Click here to see the complete AddBookmarkInteractor class:

```
...
// Public property for the results
public var resultBookmark: Bookmark?

...

// The completedConnector method gets the results from the Connector
override public func completedConnector(c: ServerConnector) {
    if let addCon = (c as? AddBookmarkLiferayConnector),
        bookmark = addCon.resultBookmarkInfo {
            self.resultBookmark = bookmark
        }
}
```

3. If your Screenlet uses a delegate, your delegate protocol must account for your model objects. Skip this step if you don't have a delegate. For example, Add Bookmark Screenlet's delegate (`AddBookmarkScreenletDelegate`) must communicate `Bookmark` objects. The delegate's first method does this via its second argument:

```
@objc public protocol AddBookmarkScreenletDelegate: BaseScreenletDelegate {

    optional func screenlet(screenlet: AddBookmarkScreenlet,
                    onBookmarkAdded bookmark: Bookmark)

    optional func screenlet(screenlet: AddBookmarkScreenlet,
                    onAddBookmarkError error: NSError)

}
```

4. Get the model object from the Interactor in your Screenlet class's `interactor.onSuccess` closure. You can then use the model object however you wish. For example, the `interactor.onSuccess` closure in Add Bookmark Screenlet's Screenlet class (`AddBookmarkScreenlet`) retrieves the `Bookmark` from the Interactor's `resultBookmark` property. It then handles the `Bookmark` via the delegate. Note that in this example, the closure is in the Screenlet class's Interactor method that adds a bookmark (`createAddBookmarkInteractor`). Be sure to get your model object wherever the `interactor.onSuccess` closure is in your Screenlet class. Click here to see the complete `AddBookmarkScreenlet`:

```
...
private func createAddBookmarkInteractor() -> Interactor {
    let interactor = AddBookmarkInteractor(screenlet: self,
                                       folderId: folderId,
                                       title: viewModel.title!,
                                       url: viewModel.URL!)

    // Called when the Interactor finishes successfully
    interactor.onSuccess = {
        if let bookmark = interactor.resultBookmark {
            self.addBookmarkDelegate?.screenlet?(self, onBookmarkAdded: bookmark)
        }
    }

    // Called when the Interactor finishes with an error
    interactor.onFailure = { error in
        self.addBookmarkDelegate?.screenlet?(self, onAddBookmarkError: error)
    }

    return interactor
}
...
```

Awesome! Now you know how to create and use a model class in your Screenlet.

Creating iOS List Screenlets

Architecture of Liferay Screens for iOS

77.13 Creating iOS List Screenlets

It's very common for mobile apps to display lists. Liferay Screens lets you display asset lists and DDL lists in your iOS app by using Asset List Screenlet and DDL List Screenlet, respectively. Screens also includes list Screenlets for displaying lists of other Liferay entities like web content articles, images, and more. The Screenlet reference documentation lists all the Screenlets included with Liferay Screens. If there's not a list Screenlet for the entity you want to display in a list, you must create your own list Screenlet. A list Screenlet can display any entity from a Liferay instance. For example, you can create a list Screenlet that displays standard Liferay entities like `User`, or custom entities from custom Liferay apps.

This tutorial uses code from the sample Bookmark List Screenlet to show you how to create your own list Screenlet. This Screenlet displays a list of bookmarks from Liferay's Bookmarks portlet. You can find this Screenlet's complete code here in GitHub.

Note that because this tutorial focuses on creating a list Screenlet, it doesn't explain general Screenlet concepts and components. Before beginning, you should therefore read the following tutorials:

- Creating iOS Screenlets
- Supporting Multiple Themes in Your Screenlet
- Create and Use a Connector with Your Screenlet
- Add a Screenlet Delegate
- Creating and Using Your Screenlet's Model Class

This tutorial uses the following steps to show you how to create a list Screenlet:

1. Creating the Model class
2. Creating the Theme
3. Creating the Connector
4. Creating the Interactor
5. Creating the Delegate
6. Creating the Screenlet class

First though, you should understand how pagination works with list Screenlets.

Pagination

To ensure that users can scroll smoothly through large lists of items, list Screenlets support fluent pagination. Support for this is built into the list Screenlet framework. You'll see this as you construct your list Screenlet.

Now you're ready to begin!

Creating the Model Class

Recall that a model class transforms each `[String:AnyObject]` entity Screens receives into a model object that represents the corresponding Liferay entity. For instructions on creating your model class, see the tutorial Creating and Using Your Screenlet's Model Class. The example model class in that tutorial is identical to Bookmark List Screenlet's.

Next, you'll create your Screenlet's Theme.

Creating the Theme

Recall that each Screenlet needs a Theme to serve as its UI. A Theme needs an XIB file to define the UI's components and layout. Since a list Screenlet displays a list of entities, its XIB file must contain a Table View. Use these steps to create your Theme's XIB file:

1. In Xcode, create a new XIB file and name it according to these naming conventions. For example, the XIB for Bookmark List Screenlet's Default Theme is `BookmarkListView_default.xib`.

2. In Interface Builder, drag and drop a View from the Object Library to the canvas. Then add a Table View to the View.

3. Resize the Table View to take up the entire View, and set the constraints the Table View needs to maintain this size dynamically. This ensures that the list fills the Screenlet's UI regardless of the iOS device's size or orientation.

For example, Bookmark List Screenlet's XIB file uses a `UITableView` inside a parent View to show the list of bookmarks.

Now you'll create your Theme's View class. Every Theme needs a View class that controls its behavior. Since the XIB file uses a `UITableView` to show a list of guestbooks, your View class must extend the `BaseListTableView` class. Liferay Screens provides this class to serve as the base class for list Screenlets' View classes. Since `BaseListTableView` provides most of the required functionality, extending it lets you focus on the parts of your View class that are unique to your Screenlet. You must also configure the XIB file to use your View class.

Follow these steps to create your Screenlet's View class and configure the XIB file to use it:

1. Create your Theme's View class, and name it according to these naming conventions. Since the XIB uses `UITableView`, your View class must extend `BaseListTableView`. For example, this is Bookmark List Screenlet's View class declaration:

   ```
   public class BookmarkListView_default: BaseListTableView {...
   ```

2. Now you must override the View class methods that fill the table cells' contents. There are two methods for this, depending on the cell type:

   - **Normal cells:** the cells that show the entities. These cells typically use `UILabel`, `UIImage`, or another UI component to show the entity. Override the `doFillLoadedCell` method to fill these cells. For example, Bookmark List Screenlet's View class overrides `doFillLoadedCell` to set each cell's `textLabel` to a bookmark's name:

     ```
     override public func doFillLoadedCell(row row: Int, cell: UITableViewCell,
         object: AnyObject) {

             let bookmark = object as! Bookmark

             cell.textLabel?.text = bookmark.name
     }
     ```

   - **Progress cell:** the cell at the bottom of the list that indicates the list is loading the next page of items. Override the `doFillInProgressCell` method to fill this cell. For example, Bookmark List Screenlet's View class overrides this method to set the cell's `textLabel` to the string `"Loading..."`:

```
    override public func doFillInProgressCell(row row: Int, cell: UITableViewCell) {
        cell.textLabel?.text = "Loading..."
    }
```

3. Return to the Theme's XIB in Interface Builder, and set the View class as the the parent View's custom class. For example, if you were doing this for Bookmark List Screenlet you'd select the Table View's parent View, click the Identity inspector, and enter `BookmarkListView_default` as the custom class.

4. With the Theme's XIB still open in Interface Builder, set the parent View's `tableView` outlet to the Table View. To do this, select the parent View and click the Connections inspector. In the Outlets section, drag and drop from the `tableView`'s circle icon (it turns into a plus icon on mouseover) to the Table View in the XIB. The new outlet then appears in the Connections inspector.

That's it! Now that your Theme is finished, you can create the Connector.

Creating the Connector

Recall that Connectors make a server call. To support pagination, a List Screenlet's Connector class must extend the `PaginationLiferayConnector` class. The Connector class must also contain any properties it needs to make the server call, and an initializer that sets them. To support pagination, the initializer must also contain the following arguments, which you'll pass to the superclass initializer:

- `startRow`: The number representing the page's first row.
- `endRow`: The number representing the page's last row.
- `computeRowCount`: Whether to call the Connector's `doAddRowCountServiceCall` method (you'll learn about this method shortly).

For example, Bookmark List Screenlet must retrieve bookmarks from a Bookmarks portlet folder in a specific site. The Screenlet's Connector class must therefore have properties for the `groupId` (site ID) and `folderId` (Bookmarks folder ID), and an initializer that sets them. The initializer also calls the superclass initializer with the `startRow`, `endRow`, and `computeRowCount` arguments:

```
import UIKit
import LiferayScreens

public class BookmarkListPageLiferayConnector: PaginationLiferayConnector {

    public let groupId: Int64
    public let folderId: Int64

    //MARK: Initializer

    public init(startRow: Int, endRow: Int, computeRowCount: Bool, groupId: Int64,
        folderId: Int64) {

            self.groupId = groupId
            self.folderId = folderId

            super.init(startRow: startRow, endRow: endRow, computeRowCount: computeRowCount)
    }
    ...
```

Next, if you want to validate any of your Screenlet's properties, override the `validateData` method as described in the tutorial on creating Connectors. Note that Bookmark List Screenlet only needs to validate the `folderId`:

```
override public func validateData() -> ValidationError? {
    let error = super.validateData()

    if error == nil {
        if folderId <= 0 {
            return ValidationError("Undefined folderId")
        }
    }

    return error
}
```

Lastly, you must override the following two methods in the Connector class:

- `doAddPageRowsServiceCall`: calls the Liferay Mobile SDK service method that retrieves a page of entities. The `doAddPageRowsServiceCall` method's `startRow` and `endRow` arguments specify the page's first and last entities, respectively. Make the service call as you would in any Screenlet. For example, the `doAddPageRowsServiceCall` method in `BookmarkListPageLiferayConnector` calls the service's `getEntriesWithGroupId` method to retrieve a page of bookmarks from the folder specified by `folderId`:

  ```
  public override func doAddPageRowsServiceCall(session session: LRBatchSession,
      startRow: Int, endRow: Int, obc: LRJSONObjectWrapper?) {
          let service = LRBookmarksEntryService_v7(session: session)

      do {
          try service.getEntriesWithGroupId(groupId,
                                            folderId: folderId,
                                            start: Int32(startRow),
                                            end: Int32(endRow))
      }
      catch  {
          // ignore error: the service method returns nil because
          // the request is sent later, in batch
      }
  }
  ```

  Note that you don't need to do anything in the catch statement because the request is sent later, in batch. The session type `LRBatchSession` handles this for you. You'll receive the request's results elsewhere, once the request completes.

- `doAddRowCountServiceCall`: calls the Liferay Mobile SDK service method that retrieves the total number of entities. This supports pagination. Make the service call as you would in any Screenlet. For example, the `doAddRowCountServiceCall` in `BookmarkListPageLiferayConnector` calls the service's `getEntriesCountWithGroupId` method to retrieve the total number of bookmarks in the folder specified by `folderId`:

  ```
  override public func doAddRowCountServiceCall(session session: LRBatchSession) {
      let service = LRBookmarksEntryService_v7(session: session)

      do {
          try service.getEntriesCountWithGroupId(groupId, folderId: folderId)
      }
      catch  {
          // ignore error: the service method returns nil because
          // the request is sent later, in batch
      }
  }
  ```

Now that you have your Connector class, you're ready to create the Interactor.

Creating the Interactor

Recall that Interactors implement your Screenlet's actions. In list Screenlets, loading entities is usually the only action a user can take. The Interactor class of a list Screenlet that implements fluent pagination must extend the BaseListPageLoadInteractor class. Your Interactor class must also contain any properties the Screenlet needs, and an initializer that sets them. This initializer also needs arguments for the following properties, which it passes to the superclass initializer:

- screenlet: A BaseListScreenlet reference. This ensures the Interactor always has a Screenlet reference.
- page: The page number to retrieve.
- computeRowCount: Whether to call the Connector's doAddRowCountServiceCall method.

For example, Bookmark List Screenlet's Interactor class contains the same groupId and folderId properties as the Connector, and an initializer that sets them. This initializer also passes the screenlet, page, and computeRowCount arguments to the superclass initializer:

```
public class BookmarkListPageLoadInteractor : BaseListPageLoadInteractor {

    private let groupId: Int64
    private let folderId: Int64

    init(screenlet: BaseListScreenlet,
        page: Int,
        computeRowCount: Bool,
        groupId: Int64,
        folderId: Int64) {

            self.groupId = (groupId ≠ 0) ? groupId : LiferayServerContext.groupId
            self.folderId = folderId

            super.init(screenlet: screenlet, page: page, computeRowCount: computeRowCount)
    }
    ...
```

The Interactor class must also initiate the server request by instantiating the Connector, and convert the results into model objects. Override the createListPageConnector method to create and return an instance of your Connector. This method must first get a reference to the Screenlet via the screenlet property. When calling the Connector's initializer, use screenlet.firstRowForPage to convert the page number (page) to the page's start and end indices. You must also pass the initializer any other properties it needs, like groupId. For example, BookmarkListPageLoadInteractor's createListPageConnector method does this to create a BookmarkListPageLiferayConnector instance:

```
public override func createListPageConnector() -> PaginationLiferayConnector {
    let screenlet = self.screenlet as! BaseListScreenlet

    return BookmarkListPageLiferayConnector(
        startRow: screenlet.firstRowForPage(self.page),
        endRow: screenlet.firstRowForPage(self.page + 1),
        computeRowCount: self.computeRowCount,
        groupId: groupId,
        folderId: folderId)
}
```

Next, override the convertResult method to convert each [String:AnyObject] result into a model object. The Screenlet calls this method once for each entity retrieved from the server. For example, BookmarkListPageLoadInteractor's convertResult method converts the [String:AnyObject] result into a Bookmark object:

```
override public func convertResult(_ serverResult: [String:AnyObject]) -> AnyObject {
    return Bookmark(attributes: serverResult)
}
```

You may also want to support offline mode in your Interactor. To do so, the Interactor must override the cacheKey method to return a cache key unique to your Screenlet. For example, BookmarkListPageLoadInteractor's cacheKey method returns a cache key that includes the Screenlet's groupId and folderId settings:

```
override public func cacheKey(_ op: PaginationLiferayConnector) -> String {
    return "\(groupId)-\(folderId)"
}
```

Great! Next, you'll create your Screenlet's delegate.

Creating the Delegate

Recall that a delegate is required if you want other classes to respond to your Screenlet's actions. Create your delegate by following the first step in the tutorial on adding a Screenlet delegate. A list Screenlet's delegate must also define a method for responding to a list item selection. For example, Bookmark List Screenlet's delegate needs the following methods:

- screenlet(_:onBookmarkListResponse:): Returns the Bookmark results when the server call succeeds.
- screenlet(_:onBookmarkListError:): Returns the NSError object when the server call fails.
- screenlet(_:onBookmarkSelected:): Returns the Bookmark when a user selects it in the list.

The BookmarkListScreenletDelegate protocol defines these methods:

```
@objc public protocol BookmarkListScreenletDelegate : BaseScreenletDelegate {

    optional func screenlet(screenlet: BookmarkListScreenlet,
                            onBookmarkListResponse bookmarks: [Bookmark])

    optional func screenlet(screenlet: BookmarkListScreenlet,
                            onBookmarkListError error: NSError)

    optional func screenlet(screenlet: BookmarkListScreenlet,
                            onBookmarkSelected bookmark: Bookmark)

}
```

Nice work! Next, you'll create the Screenlet class.

Creating the Screenlet Class

Now that your list Screenlet's other components exist, you can create the Screenlet class. A list Screenlet's Screenlet class must extend the BaseListScreenlet class and define the configurable properties the Screenlet needs. You should define these as IBInspectable properties. If you want to support offline mode, you should also add an offlinePolicy property.

For example, Bookmark List Screenlet's Screenlet class contains the IBInspectable properties groupId, folderId, and offlinePolicy:

```
public class BookmarkListScreenlet: BaseListScreenlet {

    @IBInspectable public var groupId: Int64 = 0
    @IBInspectable public var folderId: Int64 = 0
    @IBInspectable public var offlinePolicy: String? = CacheStrategyType.RemoteFirst.rawValue

    ...
```

Next, override the createPageLoadInteractor method to create and return the Interactor. If your Screenlet supports offline mode, you should also use offlinePolicy to pass a CacheStrategyType object to the Interactor. For example, the createPageLoadInteractor method in BookmarkListScreenlet creates and returns a BookmarkListPageLoadInteractor instance. This method also sets the Interactor's cacheStrategy property to a CacheStrategyType object created with offlinePolicy:

```
override public func createPageLoadInteractor(
    page page: Int,
    computeRowCount: Bool) -> BaseListPageLoadInteractor {

    let interactor = BookmarkListPageLoadInteractor(screenlet: self,
                                                     page: page,
                                                     computeRowCount: computeRowCount,
                                                     groupId: self.groupId,
                                                     folderId: self.folderId)

    interactor.cacheStrategy = CacheStrategyType(rawValue: self.offlinePolicy ?? "") ?? .RemoteFirst

    return interactor
}
```

Now get a reference to your delegate. The BaseScreenlet class, which BaseListScreenlet extends, already defines the delegate property for the delegate object. Every list Screenlet therefore has this property, and any app developer using the Screenlet can access it. To avoid casting this property to your delegate every time you use it, add a computed property to your Screenlet class that does so. For example, the following bookmarkListDelegate property in BookmarkListScreenlet casts the delegate property to BookmarkListScreenletDelegate:

```
public var bookmarkListDelegate: BookmarkListScreenletDelegate? {
    return delegate as? BookmarkListScreenletDelegate
}
```

Next, override the BaseListScreenlet methods that handle the Screenlet's events. Because these events correspond to the events your delegate methods handle, you'll call your delegate methods in these BaseListScreenlet methods:

- onLoadPageResult: Called when the Screenlet loads a page successfully. Override this method to call your delegate's screenlet(_:onBookmarkListResponse:) method. For example, here's BookmarkListScreenlet's onLoadPageResult method:

  ```
  override public func onLoadPageResult(page page: Int, rows: [AnyObject], rowCount: Int) {
      super.onLoadPageResult(page: page, rows: rows, rowCount: rowCount)

      bookmarkListDelegate?.screenlet?(screenlet: self, onBookmarkListResponse: rows as! [Bookmark])
  }
  ```

- onLoadPageError: Called when the Screenlet fails to load a page. Override this method to call your delegate's screenlet(_:onBookmarkListError:) method. For example, here's BookmarkListScreenlet's onLoadPageError method:

  ```
  override public func onLoadPageError(page page: Int, error: NSError) {
      super.onLoadPageError(page: page, error: error)

      bookmarkListDelegate?.screenlet?(screenlet: self, onBookmarkListError: error)
  }
  ```

- `onSelectedRow`: Called when an item is selected in the list. Override this method to call your delegate's `screenlet(_:onBookmarkSelected:)` method. For example, here's `BookmarkListScreenlet`'s `onSelectedRow` method:

```
override public func onSelectedRow(_ row: AnyObject) {
    bookmarkListDelegate?.screenlet?(screenlet: self, onBookmarkSelected: row as! Bookmark)
}
```

Awesome! You're done! Your list Screenlet, like any other Screenlet, is a ready-to-use component that you can add to your storyboard. You can even package it using the same steps you use to package a Theme, and then contribute it to the Liferay Screens project or distribute it with CocoaPods.

77.14 Using Custom Cells with List Screenlets

In most list Screenlets, including those that come with Liferay Screens, the Default Theme uses the default cells in iOS's `UITableView` to show the list. The Theme creation steps in the list Screenlet creation tutorial also instruct you to use these cells. You can, however, use custom cells to tailor the list to your needs. To do this, you must create an extended Theme from a Theme that uses `UITableView`'s default cells. This usually means extending a list Screenlet's Default theme. This tutorial shows you how to create such an extended Theme that contains a custom cell for your list Screenlet. As an example, this tutorial uses code from the sample Bookmark List Screenlet's Custom Theme. You can refer to this Theme's finished code here in GitHub at any time.

Note that besides creating your custom cell, this tutorial follows the same basic steps as the Theme creation tutorial for creating an extended Theme. For example, you must still determine where to create your Theme, and create your Theme's XIB and View class.

First, you'll create your Theme's custom cell.

Creating Your Custom Cell

Once you decide where to create your Theme, you can get started. First, create your custom cell's XIB file and its companion class. Name them according to the naming conventions in the best practices tutorial. After defining your cell's UI in the XIB, create as many outlets and actions as you need in its companion class. Also be sure to assign this class as the XIB's custom class in Interface Builder. Note that if you want to use different layouts for different rows, you must create an XIB file and companion class for each.

For example, the following screenshot shows the XIB file `BookmarkCell_default-custom.xib` for Bookmark List Screenlet's custom cell. This cell must show a bookmark's name and URL, so it contains two labels.

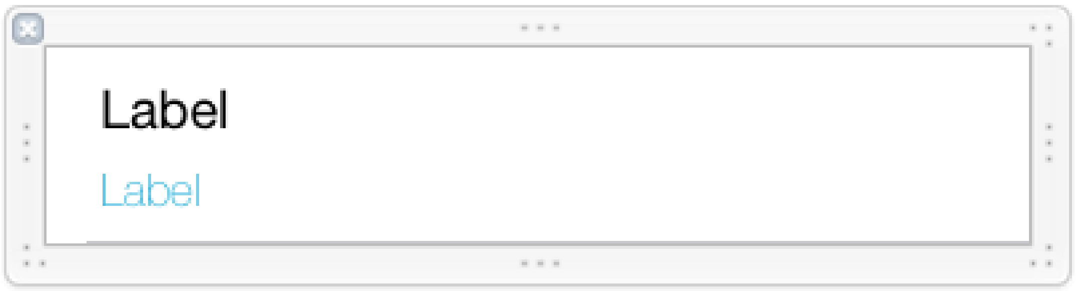

Figure 77.20: The XIB file for Bookmark List Screenlet's custom cell.

This XIB's custom class, `BookmarkCell_default_custom`, contains an outlet for each label. The `bookmark` variable also contains a `didSet` observer that sets the bookmark's name and URL to the respective label:

```
import UIKit

class BookmarkCell_default_custom: UITableViewCell {

    @IBOutlet weak var nameLabel: UILabel?
    @IBOutlet weak var urlLabel: UILabel?

    var bookmark: Bookmark? {
        didSet {
            nameLabel?.text = bookmark?.name
            urlLabel?.text = bookmark?.url
        }
    }

}
```

Great! Now you have your custom cell. Next, you'll create the rest of your Theme.

Creating Your Theme's XIB and View Class

Now you're ready to create your Theme's XIB file and View class. Create your XIB by copying the parent Theme's XIB and making any changes you need. You may not need to make any changes besides the file name and custom class name. For example, the custom cell is the only difference between Bookmark List Screenlet's Custom and Default Themes. These Themes' XIB files (`BookmarkListView_default-custom.xib` and `BookmarkListView_default.xib`) are therefore identical besides their name and custom class; the size and position of their UI components are the same.

Now create your View class by extending the parent Theme's View class. You should also add a string constant to serve as the cell ID. In a moment, you'll use this constant to register your custom cell. For example, the View class in Bookmark List Screenlet's Custom Theme (`BookmarkListView_default_custom`) extends the Default Theme's View class (`BookmarkListView_default`) and defines the string constant `BookmarkCellId`:

```
public class BookmarkListView_default_custom: BookmarkListView_default {

    let BookmarkCellId = "bookmarkCell"
    …
```

Next, override the `doRegisterCellNibs` method to register your custom cell. In this method, create a `UINib` instance for your cell and then register it with the `UITableView` instance (`tableView`) inherited from the `BaseListTableView` class. When registering the nib file, you must use the string constant you created earlier as the `forCellReuseIdentifier`. For example, here's the `doRegisterCellNibs` method in `BookmarkListView_default-custom`:

```
  public override func doRegisterCellNibs() {
      let nib = UINib(nibName: "BookmarkCell_default-custom", bundle: NSBundle.mainBundle())

      tableView?.registerNib(nib, forCellReuseIdentifier: BookmarkCellId)
}
```

Also in your View class, override the `doGetCellId` method to return the cell ID for each row. All you need to do in this method is return the string constant you created earlier. For example, the `doGetCellId` method in `BookmarkListView_default-custom` returns the `BookmarkCellId` constant:

```
override public func doGetCellId(row row: Int, object: AnyObject?) -> String {
    return BookmarkCellId
}
```

Now override the `doFillLoadedCell` method to fill the cell with data. Note that this method isn't called for in-progress cells; it's only called for cells that display data. Also note that this method's `object` argument contains the data as `AnyObject`. You must cast this to your desired type and then set it to the appropriate cell variable. For example, the `doFillLoadedCell` method in `BookmarkListView_default-custom` casts the `object` argument to `Bookmark` and then sets it to the cell's `bookmark` variable:

```
override public func doFillLoadedCell(row row: Int, cell: UITableViewCell, object:AnyObject) {
    if let bookmarkCell = cell as? BookmarkCell_default_custom, bookmark = object as? Bookmark {
        bookmarkCell.bookmark = bookmark
    }
}
```

The typical iOS `UITableViewDelegate` protocol and `UITableViewDataSource` protocol methods are also available in your View class. You can override any of them if you need to (check first to make sure they're not already overridden). For example, `BookmarkListView_default-custom` implements the following method to use a different cell height for each row:

```
public func tableView(tableView: UITableView, heightForRowAtIndexPath indexPath: NSIndexPath) -> CGFloat {
    return 80
}
```

When you finish, set your View class as your XIB file's custom class.

Awesome! You're done! Now you know how to implement your own custom cells for use in list Screenlets.

Sorting Your List Screenlet

Creating Complex Lists in Your List Screenlet

iOS Best Practices

77.15 Sorting Your List Screenlet

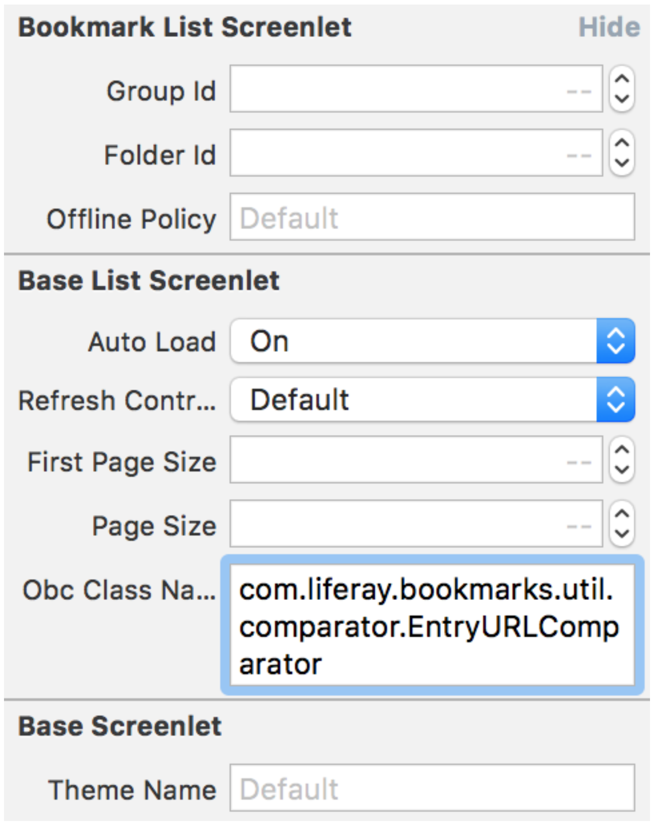
To sort your list Screenlet, you must point it to a *comparator class* in your portal. A comparator class implements the logic that sorts your entities. You can create your own comparator class or use those that already exist in your portal. Once your list is sorted, you can split it into sections. This tutorial shows you how to sort your list Screenlet with a comparator and create sections for your sorted list.

Note: To create a new comparator, you must create a class that extends the portal's `OrderByComparator` class with your entity as a type argument. Then you must override the methods that implement the sort. For example, the portal's `EntryURLComparator` class sorts bookmarks in Liferay's Bookmarks portlet by URL.

First, you'll learn how to use a comparator to sort your list Screenlet.

Using a Comparator

To use a comparator, you must set the list Screenlet's `obcClassName` property to the comparator's fully qualified class name. Do this in Interface Builder when inserting the Screenlet in an app, just as you would set any other Screenlet property. For example, to set the sample Bookmark List Screenlet to sort its list of bookmarks by URL, you must set *Obc Class Name* to *com.liferay.bookmarks.util.comparator.EntryURLComparator* in Interface Builder:



Bookmark List Screenlet	Hide
Group Id	--
Folder Id	--
Offline Policy	Default
Base List Screenlet	
Auto Load	On
Refresh Contr...	Default
First Page Size	--
Page Size	--
Obc Class Na...	com.liferay.bookmarks.util.comparator.EntryURLComparator
Base Screenlet	
Theme Name	Default

Figure 77.21: To use a comparator, set the *Obc Class Name* property in Interface Builder to the comparator's fully qualified class name.

That's it! Note that although all list Screenlets inherit the `obcClassName` property from the `BaseListScreenlet` class, the list Screenlet must also make its service call with this property. See the Screenlet reference documentation to see which list Screenlets included with Liferay Screens support the `obcClassName` property. Also, Liferay DXP's comparator classes can change between versions. If you're using one of these comparators, make sure you specify the one that matches your Liferay DXP version.

Create Sections for Your List

Dividing lists into sections that contain like elements is common in iOS apps. To do this in list Screenlets, first use a comparator to sort the list by the criteria you'll use to create the sections. Then override the

BookmarkListPageLoadInteractor class's sectionForRowObject method in your list Screenlet's Interactor. This method is called for each item in the list and should return the information necessary to place the item in a section. For example, the sample Bookmark List Screenlet's Interactor overrides the sectionForRowObject method to group results by hostname:

```
public override func sectionForRowObject(object: AnyObject) -> String? {
    guard let bookmark = object as? Bookmark else {
        return nil
    }

    let host = NSURL(string: bookmark.url)?.host?.lowercaseString

    return host?.stringByReplacingOccurrencesOfString("www.", withString: "")
}
```

Note that this only produces predictable results when Bookmark List Screenlet is sorted by EntryURLComparator as detailed in the preceding section.

And that's all there is to it! Now you know how to sort and section your list Screenlet's list.

77.16 Creating Complex Lists in Your List Screenlet

Most list Screenlets' Themes use iOS's UITableView to display simple lists. Although UITableView is great for this, it's not so great for complex lists like grids or stacks. To create complex lists, you should use iOS's UICollectionView in your list Screenlet's Theme.

This tutorial shows you how to create such a Theme, using the sample Bookmark List Screenlet's Collection Theme as an example. First, you'll create the list's cell.

Creating the Cell

You'll create your list's cell with the same sequence of steps used to create any list Screenlet's cell. Note, however, that how you perform these steps is a bit different:

1. Define your cell's UI in a new XIB file. Because this cell is part of a Theme that uses UICollectionView, you can shape it however you want. For example, here's the BookmarkCell_default-collection.xib file for the cell in Bookmark List Screenlet's Collection Theme. It's a simple square that displays the bookmark's URL and the URL's first letter.

2. Create your XIB file's class by extending UICollectionViewCell. Create as many outlets and actions as you need for your UI components and write the logic required for your cell's UI to function. For example, BookmarkCell_default_collection is the XIB file's class in Bookmark List Screenlet's Custom Theme. This class extends UICollectionViewCell and contains outlets for the URL (urlLabel) and the URL's first letter (centerLabel). The bookmark variable's didSet observer sets the bookmark's name and URL to the respective label. Also note that the overridden prepareForReuse method resets the labels for reuse:

Figure 77.22: The XIB file for the cell in Bookmark List Screenlet's custom View.

```
import UIKit
import LiferayScreens

public class BookmarkCell_default_collection: UICollectionViewCell {

    //MARK: Outlets

    @IBOutlet weak var centerLabel: UILabel?
    @IBOutlet weak var urlLabel: UILabel?

    //MARK: Public properties

    public var bookmark: Bookmark? {
        didSet {
            if let bookmark = bookmark, url = NSURL(string: bookmark.url),
                firstLetter = url.host?.remove("www.").characters.first {

                    self.centerLabel?.text = String(firstLetter).uppercaseString
                    self.urlLabel?.text = bookmark.url.remove("http://").remove("https://").remove("www.")
            }
        }
    }

    //MARK: UICollectionViewCell

    override public func prepareForReuse() {
        super.prepareForReuse()

        centerLabel?.text = "..."
        urlLabel?.text = "..."
    }
}
```

Now that your cell exists, you can create the rest of your Theme.

Creating the Theme's XIB and View Class

You'll create the rest of your Theme with the same sequence of steps used to create any list Screenlet's Theme. Like creating the cell, how you perform these steps is a bit different because your Theme uses `UICollectionView` instead of `UITableView`.

First, define your Theme's UI in a new XIB file. Add a `UICollectionView` instead of a `UITableView` to this file. For example, the `BookmarkListView_default-collection.xib` file for Bookmark List Screenlet's Custom Theme contains a collection view.

Next, create the View class. Instead of extending `BaseListTableView`, this class must extend Screens's `BaseListCollectionView` class. The `BaseListCollectionView` class implements most of the code necessary to use `UICollectionView` in your Screenlet. By extending it, you can focus on the code unique to your

Screenlet. Your View class should also contain a string constant to serve as the cell ID. You'll use this constant when you register your cell. For example, the View class in Bookmark List Screenlet's Collection Theme (`BookmarkListView_default_collection`) extends `BaseListCollectionView` and defines the string constant `BookmarkCellId`:

```
public class BookmarkListView_default_collection : BaseListCollectionView {

    let BookmarkCellId = "bookmarkCell"
    ...
```

In Interface Builder, set this new class as the XIB's Custom Class.

Next, override the `doRegisterCellNibs` method to register the cell you created in the previous section. In this method, create a `UINib` instance for your cell and then register it with the `UICollectionView` instance (`collectionView`) inherited from `BaseListCollectionView`. When registering the nib file, you must use the string constant you created earlier as the `forCellReuseIdentifier`. For example, here's the `doRegisterCellNibs` method in `BookmarkListView_default_collection`:

```
public override func doRegisterCellNibs() {
    let cellNib = UINib(nibName: "BookmarkCell_default-collection", bundle: nil)
    collectionView?.registerNib(cellNib, forCellWithReuseIdentifier: BookmarkCellId)
}
```

Also in your View class, override the `doGetCellId` method to return the ID you registered the cell with. For example, the `doGetCellId` method in `BookmarkListView_default_collection` returns the string constant `BookmarkCellId`:

```
public override func doGetCellId(indexPath indexPath: NSIndexPath, object: AnyObject?) -> String {
    return BookmarkCellId
}
```

Next, override the `doFillLoadedCell` method to fill the cell with data. This method's `object` argument contains the data as `AnyObject`. You must cast this to your desired type and then set it to the appropriate cell variable. For example, the `doFillLoadedCell` method in `BookmarkListView_default_collection` casts the `object` argument to `Bookmark` and then sets it to the cell's `bookmark` variable:

```
public override func doFillLoadedCell(
        indexPath indexPath: NSIndexPath,
        cell: UICollectionViewCell,
        object: AnyObject) {

    if let cell = cell as? BookmarkCell_default_collection, bookmark = object as? Bookmark {
        cell.bookmark = bookmark
    }
}
```

Next, you'll create the layout.

Creating the Layout

The layout object is a key part of `UICollectionView`. This object controls the position of the UI elements, their size, and more. To customize the layout object, override the `doCreateLayout` method in your View class. For example, the `doCreateLayout` method in Bookmark List Screenlet's View class (`BookmarkListView_default_collection`) returns a `UICollectionViewFlowLayout` for the layout object. This is a basic layout that gives you a simple way to customize things like item size, spacing between items, scroll direction, and more:

```
public override func doCreateLayout() -> UICollectionViewLayout {
    let layout = UICollectionViewFlowLayout()
    layout.itemSize = CGSize(width: 110, height: 110)
    layout.minimumLineSpacing = 10
    layout.minimumInteritemSpacing = 10

    return layout
}
```

Great! You're done! You can now use your new Theme the same way you would any other.

If you want to package your Theme to contribute it to the Liferay Screens project or distribute it with CocoaPods, see the tutorial on packaging Themes.

Creating iOS List Screenlets

Creating iOS Themes

Sorting Your List Screenlet

Using Custom Cells with List Screenlets

iOS Best Practices

77.17 Creating iOS Themes

By creating your own Themes, you can customize your mobile app's design and functionality. You can create them from scratch or use an existing Theme as a foundation. Themes include a View class for implementing Screenlet behavior and an XIB file for specifying the UI. The three Liferay Screens Theme types support different levels of customization and parent Theme inheritance. Here's what each Theme type offers:

Child Theme: presents the same UI components as its parent Theme, but lets you change their appearance and position.

Extended Theme: inherits its parent Theme's functionality and appearance, but lets you add to and modify both.

Full Theme: provides a complete standalone View for a Screenlet. A full Theme is ideal for implementing functionality and appearance completely different from a Screenlet's current Theme.

This tutorial explains how to create all three types. To understand Theme concepts and components, you might want to examine the architecture of Liferay Screens for iOS. The tutorial Creating iOS Screenlets can help you create any Screenlet classes your Theme requires. Now get ready to create some Themes!

Determining Your Theme's Location

After determining the type of Theme to create, you need to decide where to create it. If you want to reuse or redistribute it, you should create it in an empty Cocoa Touch Framework project in Xcode. The packaging tutorial explains how to package and publish with CocoaPods. If you're not planning to reuse or redistribute your Theme, you can create it directly inside your app project.

The rest of this tutorial explains how to create each type of Theme. First, you'll learn how to create a Child Theme.

Creating a Child Theme

In a Child Theme, you leverage a parent Theme's behavior and UI components, but you can modify the appearance and position of the UI components. Note that you can't add or remove any components and the parent Theme must be a Full Theme. The Child Theme presents visual changes with its own XIB file and inherits the parent's View class.

For example, the Child Theme in Figure 1 presents the same UI components as the Login Screenlet's Default Theme, but enlarges them for viewing on devices with larger screens.

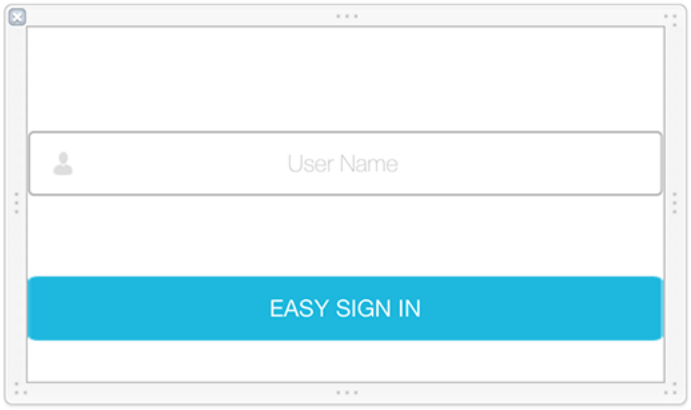

Figure 77.23: The UI components are enlarged in the example Child Theme's XIB file.

You can follow these steps to create a Child Theme:

1. In Xcode, create a new XIB file that's named after the Screenlet's View class and your Theme. By convention, an XIB file for a Screenlet with a View class named *FooScreenletView* and a Theme named *BarTheme* must be named `FooScreenletView_barTheme.xib`. You can use content from the parent Theme's XIB file as a foundation for your new XIB file. In your new XIB, you can change the UI components' visual properties (e.g., their position and size). You mustn't change, however, the XIB file's custom class, outlet connection, or `restorationIdentifier`–these must match those of the parent's XIB file.

```
The XIB file name serves as the Theme's Xcode name. For example, the Theme
in Figure 1 inherits from the Login Screenlet's Default Theme, which uses
the View class `LoginView_default`. The new child Theme is named *Large*
because it's purpose is to enlarge the Screenlet's UI components. In Xcode,
it's assigned the Theme Name *large*. The XIB file is named
`LoginView_large.xib`, after the Login Screenlet's View class and the
Theme's Xcode name.
```

You can optionally package your Theme and/or start using it. Fantastic! Next, you'll learn how to create an Extended Theme.

Extended Theme

An Extended Theme inherits another Theme's UI components and behavior, but lets you add to or alter it by extending the parent Theme's View class and creating a new XIB file. An Extended Theme's parent must be a Full Theme. The Flat7 Theme is an Extended Theme.

These steps explain how to create an Extended Theme:

1. In Xcode, create a new XIB file named after the Screenlet's View class and your Theme. By convention, an XIB file for a Screenlet with a View class named *FooScreenletView* and a Theme named *BarTheme* must be named `FooScreenletView_barTheme.xib`. You can use the XIB file of your parent Theme as a template. Build your UI changes in your new XIB file with Interface Builder.

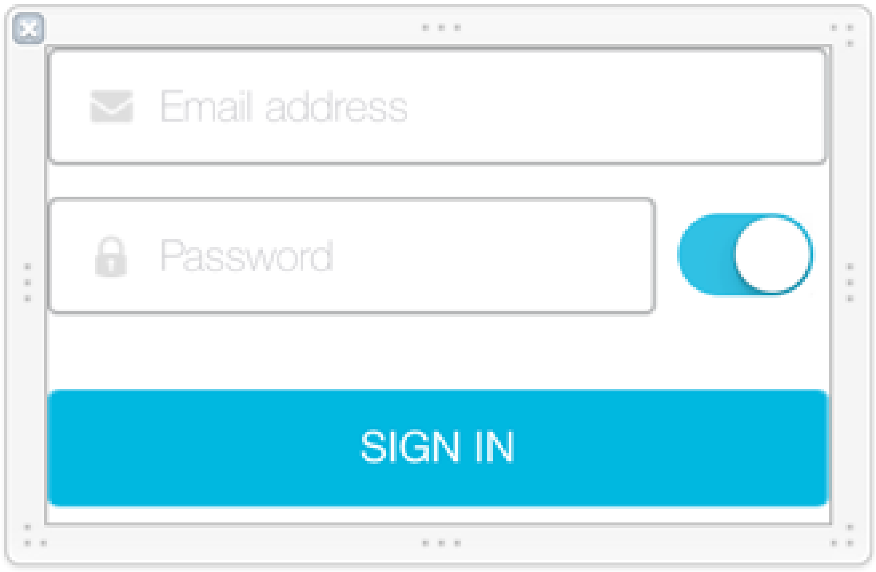

Figure 77.24: This example Extended Theme's XIB file extends the Login Portlet's UI and behavior with a switch that lets the user show or hide the password field value.

2. Create a new View class that extends the parent Theme's View class. You should name this class after the XIB file you just created. You can add or override functionality of the parent Theme's View class.

3. Set your new View class as the custom class for your Theme's XIB file. If you added `@IBOutlet` or `@IBAction` actions, bind them to your class.

Well done! You can optionally package your Theme and/or start using it. Now you know how to create and use an Extended Theme. Next, you'll learn how to create a Full Theme.

Full Theme

A Full Theme implements unique behavior and appearance for a Screenlet, without using a parent Theme. Its View class must inherit Screens's `BaseScreenletView` and conform to the Screenlet's View Model protocol. It must also specify a new UI in an XIB file. As you create a Full Theme, you can refer to the tutorial Creating iOS Screenlets to learn how to create these classes.

Follow these steps to create a Full Theme:

1. Create a new XIB file and use Interface Builder to build your UI. By convention, an XIB file for a Screenlet with a View class named *FooScreenletView* and a Theme named *BarTheme* must be named `FooScreenletView_barTheme.xib`. You can use the XIB file from the Screenlet's default Theme as a template.

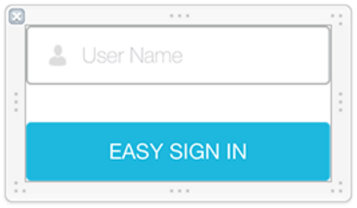

Figure 77.25: This Full Theme for the Login Screenlet, includes a text field for entering the user name, uses the UDID for the password, and adds a *Sign In* button with the same `restorationIdentifier` as the Default Theme.

2. Create a new View class for your Theme named after the XIB file you just created. As a template, you can use the View class of your Screenlet's Default Theme. Your new View class must inherit `BaseScreenletView` and conform to the Screenlet's `*ScreenletViewModel` protocol, implementing the corresponding getters and setters. It should also add all the `@IBOutlet` properties or `@IBAction` methods you need to bind your UI components.

3. Set your Theme's new View class as your XIB file's custom class and bind any `@IBOutlet` and `@IBAction` actions to your class.

Super! You can optionally package your Theme and/or start using it. Now you know how to create a Full Theme. Note that a Full Theme can serve as a parent to a Child and Extended Theme.

You've mastered Themes!

Creating iOS Screenlets

77.18 Packaging iOS Themes

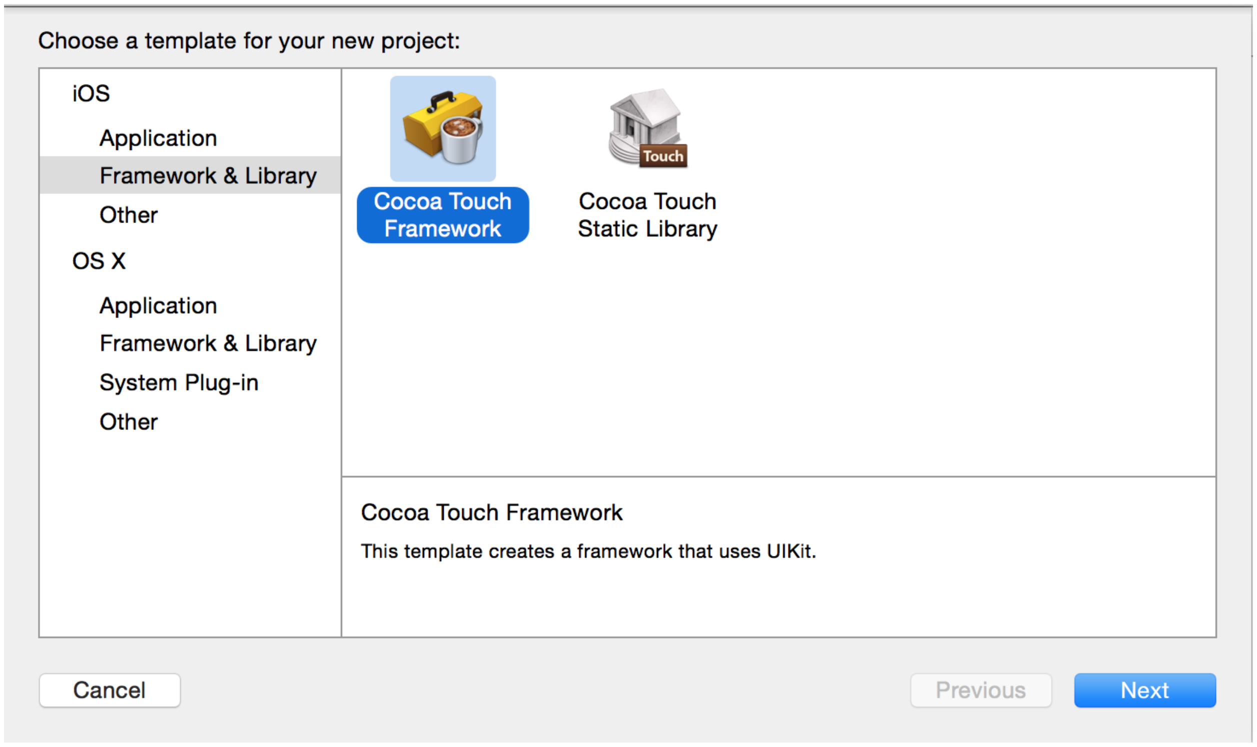
Once you've created a Theme, you can package it up to install and use with its Screenlet. Your Theme is a code library that you can package using CocoaPods.

Follow the steps below to package your Theme for use with CocoaPods. (Note that it's important that you use the same names and identifiers described in these steps):

1. Create an empty *Cocoa Touch Framework* Xcode project.

2. Name your project `LiferayScreensThemeName`, replacing `Name` with your Theme's name. You can specify any name, but it's a best practice to use your Theme's Xcode name, capitalizing its first letter. The entire name becomes the Theme's CocoaPods name.

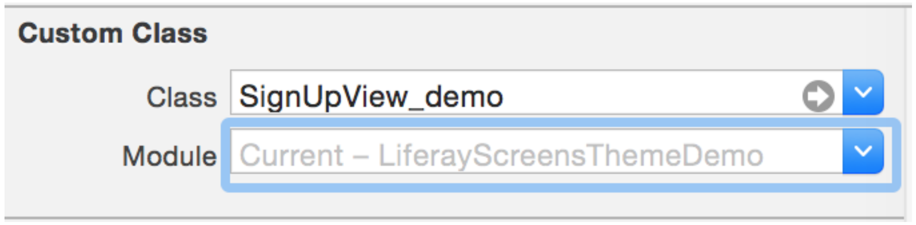
3. Configure Liferay Screens for CocoaPods, using the steps described in Preparing iOS Projects for Liferay Screens.



Cocoa Touch Framework

This template creates a framework that uses UIKit.

Figure 77.26: Choose *Cocoa Touch Framework* when creating a project for your Theme.



Custom Class

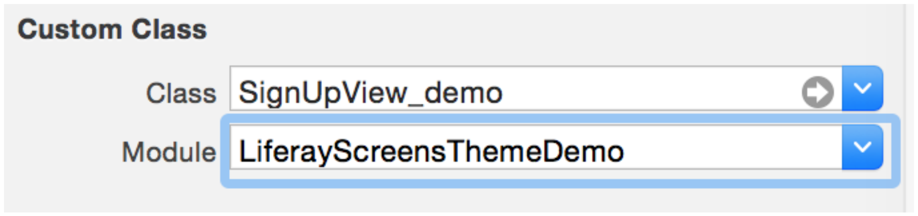
Class: SignUpView_demo

Module: Current – LiferayScreensThemeDemo

Figure 77.27: This XIB file's custom class's module is NOT specified.

4. Prepare your Theme's classes and resources by making sure your classes compile successfully in Xcode and by explicitly specifying a valid module for the custom class–the grayed-out *Current* default value only suggests a module.

   In the following screenshot, the setting for the custom class is correct:



Custom Class

Class: SignUpView_demo

Module: LiferayScreensThemeDemo

Figure 77.28: The XIB file is bound to the custom class name, with the specified module.

5. In your project's root folder, add a file named `LiferayScreensTheme-Name.podspec` (change `Name` to your

Theme's CocoaPods name–the value you used to replace `Name` in step 2). Note: you must start your the `.podspec` file's name and the project's name with `LiferayScreens`.

Add the following content to the file:

```
Pod::Spec.new do |s|
    s.name = 'LiferayScreensThemeName'
    s.version = '1.0'
    s.summary = 'Your theme description'
    s.source = {
        :git => 'https://your_repository_url.git',
        :tag => 'v1.0'
    }

    s.platform = :ios, '8.0'
    s.requires_arc = true

    s.source_files = 'Your/Relative/Folder/**/*.{h,m,swift}'
    s.resources = 'Your/Relative/Folder/**/*.{xib,png,plist,lproj}'

    s.dependency 'LiferayScreens'
end
```

Make the following substitutions in the `.podspec` file:

- Replace `Name` in `LiferayScreensThemeName`, with your Theme's CocoaPods name–the value you used to replace `Name` in step 2.
- Replace `your_repository_url` with your repository's URL.
- Replace `Your/Relative/Folder/` with the path to your source and resource files.

6. Commit your changes and push your project's branch to your Git repository.

Your Theme is now available for other developers to pull from your Git repository. You can, alternatively, publish your Theme as a public Pod. For instructions, see the chapter *Deploying a library* in the official CocoaPods guide.

Developers can now use your Theme by adding the following line to their app's `Podfile`; they must, of course, change `Name` to the Theme's CocoaPods name and `your_repository_url` to your repository's URL:

```
pod 'LiferayScreensThemeName', :git => 'https://your_repository_url.git'
```

Nice work! Now you know how to package and distribute Screenlet Themes with CocoaPods.

Preparing Android Projects for Liferay Screens

77.19 Accessing the Liferay Session in iOS

A session is a conversation state between the client and server. It typically consists of multiple requests and responses between the two. To facilitate this communication, the session must have the server IP address, and a user's login credentials. Liferay Screens uses a Liferay Session to access and query the JSON web services provided by Liferay Portal. When you log in using a Liferay Session, the portal returns the user's information (name, email, user ID, etc...). Screens stores this information and the active Liferay Session in Screens's `SessionContext` class.

The `SessionContext` class is very powerful and lets you use Screens in many different scenarios. For example, you can use `SessionContext` to request information with the JSON WS API provided by Liferay, or with the Liferay Mobile SDK. You can also use `SessionContext` to create anonymous sessions, or log in a user without showing Login Screenlet.

This tutorial explains some common `SessionContext` use cases, and also describes the class's most important methods.

Getting the current session

The current session is established after the user successfully logs in with Login Screenlet. Use `SessionContext.currentContext` to retrieve the session. Note this will return `nil` if the user didn't sign in with Login Screenlet. You can also use the `SessionContext` property `isLoggedIn` to determine if a session exists. This returns `false` if there's no current session.

Creating a Liferay Session

When working with Liferay Screens, you may wish to call the remote JSON web services provided by the Liferay Mobile SDK. Every operation with the Liferay Mobile SDK needs a Liferay Session to provide the server address, user credentials, and any other required parameters. Login Screenlet creates a session when a user successfully logs in. You can retrieve this session with the `SessionContext` method `createRequestSession()`. Typically, you call this method through the `currentContext` object. For example:

```
SessionContext.currentContext?.createRequestSession()
```

You can then use the session to make the Mobile SDK service call. If you need to check first to see if a user has logged in, you can use the `SessionContext` property `isLoggedIn`.

Great! Now you know how to retrieve an existing session in your app. But what if you're not using Login Screenlet? There won't be an existing session to retrieve. No sweat! You can still use `SessionContext` to create one manually. The next section shows you how to do this.

Creating a Session Manually

If you don't use Login Screenlet, then `SessionContext` doesn't have a session for you to retrieve. In this case, you must create one manually. You can do this with the `SessionContext` method `loginWithBasic`. The method takes a username, password, and user attributes as parameters, and creates a session with those credentials. The following code uses `loginWithBasic` to create a session:

```
Session session = SessionContext.loginWithBasic(username: USERNAME, password: PASSWORD, userAttributes: [:]);
```

For the `userAttributes` parameter, you must provide some attributes associated with the logged in user, such as their `userId`. For a complete list of attributes, see the user model interface.

Super! Now you know how to create a session manually. The next section shows you how to implement auto-login, and save or restore a session.

Implementing Auto-login and Saving or Restoring a Session

Although Login Screenlet is awesome, your users may not want to enter their credentials every time they open your app. It's very common for apps to only require a single login. To implement this in your app, see this video.

In short, you need to set `saveCredentials` to `true` in Login Screenlet. The next login then uses the saved credentials. To make sure this also works when the app restarts, you must retrieve the stored credentials by using the `SessionContext` method `loadStoredCredentials`. The following Swift code shows a typical implementation of this:

```
if SessionContext.loadStoredCredentials() {
    // user auto-logged in
    // consider doing a relogin here (see next section)
}
else {
    // send user to login screen with the login screenlet
}
```

Awesome! Now you know how to implement auto-login in your Liferay Screens apps. For more information on available `SessionContext` methods, see the Methods section at the end of this tutorial. Next, you'll learn how to implement relogin for cases where a user's credentials change on the server while they're logged in.

Implementing Relogin

A session, whether created via Login Screenlet or auto-login, contains basic user data that verifies the user in the Liferay instance. If that data changes in the server, then your session is outdated, which may cause your app to behave inconsistently. Also, if a user is deleted, deactivated, or otherwise changes their credentials in the server, the auto-login feature won't deny access because it doesn't perform server transactions: it only retrieves an existing session from local storage. This isn't an optimal situation!

For such scenarios, you can use the relogin feature. This feature is implemented in a method that determines if the current session is still valid. If the session is still valid, the user's data is updated with the most recent data from the server. If the session isn't valid, the user is logged out and must then log in again to create a new session.

To this feature, call the `SessionContext.currentContext` method `relogin`:

```
SessionContext.currentContext?.relogin(closure)
```

Note that this operation is done asynchronously in a background thread. The `closure` argument is a function that eventually receives the new user attributes. In case of error, the closure is called with `nil` attributes and the user is logged out of the session. The typical Swift code for a full relogin is as follows. Note a trailing closure is used:

```
SessionContext.currentContext?.relogin { userAttributes in
    if userAttributes == nil {
        // couldn't retrieve the user attributes: user invalidated or password changed?
    }
    else {
        // full re-login made. Everything is updated
    }
}
```

Great! Now you know how to implement relogin in your app. You've also seen how handy `SessionContext` can be. It can do even more! The next section lists some additional `SessionContext` methods, and some more detail on the ones used in this tutorial.

Methods

Method	Return Type	Explanation
`logout()`	`void`	Clears the stored user attributes and session.
`relogin(closure)`	`void`	Refreshes user data from the server. This recreates `currentContext` if successful, or calls `logout()` on failure. When the server data is received, the closure is called with received user's attributes. If an error occurs, the closure is called with `nil`.
`loginWithBasic(username, password, userAttributes)`	`LRSession`	Creates a Liferay Session using the default server, and the supplied username, password, and user information.
`loginWithOAuth(authentication, userAttributes)`	`LRSession`	Creates a Liferay Session using the default server and the supplied OAuth tokens. This is intended to be used together with the Liferay iOS OAuth library.
`createRequestSession()`	`LRSession`	Creates a Liferay Session based on the current session's server and user credentials. This Liferay Session is intended to be used for only a single request (don't reuse it).
`createEphemeralBasicSession(username, password)`	`LRSession`	Creates a Liferay Session based on the provided username and password. Note that this session isn't stored anywhere. This is the method used to create a session for anonymous access. Anonymous access is used by the Sign Up and Forgot Password Screenlets.
`userAttribute(key: String)`	`AnyObject`	Returns a `User` object with the server attributes of the logged-in user. This includes the user's email, user ID, name, and portrait ID.
`storeCredentials()`	`Bool`	Stores the current session.
`removeStoredCredentials()`	`Bool`	Clears the session and user information from storage.
`loadStoredCredentials()`	`Bool`	Loads the session and user information from storage. They're then used, respectively, as the current session and user.

Properties

Property	Type	Explanation
`currentContext`	`SessionContext`	The current session established through Login Screenlet, or the `loginWithBasic` or `loginWithOAuth` methods.
`isLoggedIn`	`Bool`	Returns `true` if `SessionContext` contains a Liferay Session.
`basicAuthUsername`	`String`	The username used to establish the current session (if any).
`basicAuthPassword`	`String`	The password used to establish the current session (if any).
`userId`	`Number`	The user identifier used to establish the current session (if any).

For more information, see the `SessionContext` source code in GitHub.

Using Screenlets in iOS Apps

77.20 Adding Custom Interactors to iOS Screenlets

Interactors are Screenlet components that implement server communication for a specific use case. For example, the Login Screenlet's interactor calls the Liferay Mobile SDK service that authenticates a user to the portal. Similarly, the interactor for the Add Bookmark Screenlet calls the Liferay Mobile SDK service that adds a bookmark to the Bookmarks portlet.

That's all fine and well, but what if you want to customize a Screenlet's server call? What if you want to use a different back-end with a Screenlet? No problem! You can implement a custom interactor for the Screenlet. You can plug in a different interactor that makes its server call by using custom logic or network code. To do this, you must implement the current interactor's interface and then pass it to the Screenlet you want to override. You should do this inside your app's code.

In this tutorial, you'll see an example interactor that overrides the Login Screenlet to always log in the same user, without a password.

Implementing a Custom Interactor

1. Implement your custom interactor. You must inherit `ServerConnectorInteractor`, as shown here:

```
class LoginCustomInteractor: ServerConnectorInteractor {

    override func createConnector() -> ServerConnector? {

        ...

        return connector
    }

}
```

2. Implement the optional protocol that receives a `customInteractorForAction`, and return your own interactor:

```
func screenlet(screenlet: BaseScreenlet,
        customInteractorForAction: String,
        withSender: AnyObject?) -> Interactor? {

    return LoginCustomInteractor()
}
```

Great! Now you know how to implement custom interactors for iOS Screenlets.

Creating iOS Screenlets

77.21 Rendering Web Content in Your iOS App

Liferay Screens provides several ways to render web content in your app. For historical reasons, web content articles are `JournalArticle` entities in Liferay. Using Web Content Display Screenlet is a simple and powerful way to display HTML from a `JournalArticle` in your app. To fit your needs, this Screenlet supports several use cases. This tutorial describes them.

Retrieving Basic Web Content

The simplest use case for Web Content Display Screenlet is to retrieve a web content article's HTML and render it in a `UIWebView`. To do this, provide the web content article's ID via the *Article Id* attribute in Interface Builder. The Screenlet takes care of the rest. This includes rendering the content to fit mobile devices, performing any required caching, and more.

To render the content *exactly* as it appears on your mobile site, however, you must provide the CSS inline or use a template. The HTML returned isn't aware of a Liferay instance's global CSS.

You can also modify the rendered HTML with a delegate, as explained in the Web Content Display Screenlet reference documentation.

As you can see, this is all fairly straightforward. What could go wrong? Famous last words. A common mistake is to use the default site ID (groupId) instead of the one for the site that contains your web content articles. To continue using a default groupId in your app, but use a different one for Web Content Display Screenlet, assign the Screenlet's *Group Id* property in Interface Builder.

Using Templates

Web Content Display Screenlet can also use templates to render web content articles. For example, your Liferay instance may have a custom template specifically designed to display content on mobile devices. To use a template, set the template's ID as the Screenlet's templateId property (*Template Id* in Interface Builder).

Recall that structured web content in Liferay can have many templates. You can create your own template if there's not one suitable for displaying web content in your app.

Rendering Structured Web Content

To render structured web content in Web Content Display Screenlet, you must create a custom theme capable of doing so. Also, you must create a custom theme for each structure you want to display in your app. In this case, you may find it convenient to create each theme inside a single parent theme and use compound naming to indicate this relationship. For example, if you have structures in your Liferay instance called *book*, *employee*, and *meeting*, you must create a custom theme for each. If you create these themes as children of another custom theme called *mytheme*, you could name them *mytheme.book*, *mytheme.employee*, and *mytheme.meeting*.

Regardless of where you create your themes or what you name them, use the following steps to create them:

1. Create a theme to render your web content. If you've already created your own theme, you can skip this step.

2. In your theme, create a new class called WebContentDisplayView_themeName, extending from BaseScreenletView. This class will hold the outlets and actions associated with the web content's UI.

3. Create the UI in the WebContentDisplayView_themeName.xib file. This file should have a UIView that contains the components you need to render the web content's structure fields. For example, if your structured web content contains latitude and longitude fields, you can use a MKMapView component to render the map point.

4. Once your components are ready, change the root view's class to WebContentDisplayView_themeName (the class you created in the first step), and create the outlets and actions you need to manage your UI components.

5. Conform the WebContentDisplayViewModel protocol in the WebContentDisplayView_themeName class. This protocol requires you to add the htmlContent and recordContent properties. The htmlContent property is intended for HTML web content; this isn't your theme's use case. Your theme must display structured web content; use the recordContent property for this content. In this property, set the structure field's value as the corresponding outlet's value. For example:

```
public var htmlContent: String? {
    get {
        return nil
    }
    set {
        // not used for structured Web Contents
    }
}

public var recordContent: DDLRecord? {
    didSet {
        // set the outlets with record's values
        set.myOutlet.myProperty = recordContent?["my_field_name"]?.currentValueAsLabel
    }
}
```

Next, you'll learn how to display a list of web content articles in your app.

Displaying a List of Web Content Articles

The preceding examples show you how to use Web Content Display Screenlet to display a single web content article's contents in your app. But what if you want to display a list of articles instead? No problem! You can do this by using Web Content List Screenlet, or Asset List Screenlet.

First, you'll learn how to use Web Content List Screenlet.

Using Web Content List Screenlet

Web Content List Screenlet lets you retrieve and display a list of web content articles from a web content folder. Follow these steps to use the Screenlet:

- Insert Web Content List Screenlet in your View Controller.
- Configure the *Group Id* and *Folder Id* properties in Interface Builder. The folder ID is the ID of the web content folder you want to display articles from. To use the root folder, use `0` for the Folder Id.
- To receive events related to the list, conform `WebContentListScreenletDelegate`. The events contain the `WebContent` objects.

For more information on the Screenlet and its supported functionality, see the Web Content List Screenlet reference documentation.

Using Asset List Screenlet

Asset List Screenlet is similar to Web Content Display Screenlet in that it can display a list of items from a Liferay instance. Asset List Screenlet, however, displays a list of assets. Since web content is an asset, you can use Asset List Screenlet to show a list of web content articles. Consider the following when doing this:

- In the delegate, `screenlet:onAssetListResponse` gets an array of `Asset` objects that represent `WebContent` objects. Since `WebContent` is a child of `Asset`, you can cast the `Asset` objects to `WebContent`. Each `WebContent` object has the `html`, `structure`, or `structuredRecord` properties.
- To render Asset List Screenlet with `WebContent` objects, you must create your own theme. Create a class in your theme that extends `AssetListView_default`, and override the `doFillLoadedCell` method. In this method, cast the `object` parameter as `WebContent` and then retrieve field values from the web content's `structuredRecord` property. If you want custom cells, you can also override the `doRegisterCellNibs` and `doCreateCell` methods. See the Asset List Screenlet reference documentation for more details on customizing your asset list.

77.22 Rendering Web Pages in Your iOS App

The Rendering Web Content tutorial shows you how to display web content from a Liferay DXP site in your iOS app. Displaying content is great, but what if you want to display an entire page? No problem! Web Screenlet lets you display any web page. You can even customize the page by injecting local or remote JavaScript and CSS files. When combined with Liferay DXP's server-side customization features (e.g., Application Display Templates), Web Screenlet gives you almost limitless possibilities for displaying web pages in your iOS apps.

In this tutorial, you'll learn how to use Web Screenlet to display web pages in your iOS app.

Inserting Web Screenlet in Your App

Inserting Web Screenlet in your app is the same as inserting any Screenlet in your app:

1. In Interface Builder, insert a new view (`UIView`) in a new view controller. This new view should be nested under the view controller's existing view.

2. With the new view selected, open the Identity inspector and set the view's Custom Class to `WebScreenlet`.

3. Set any constraints that you want for the Screenlet in the scene.

The exact steps for configuring Web Screenlet are unique to Web Screenlet. First, you'll conform your view controller to Web Screenlet's delegate protocol.

Conforming to Web Screenlet's Delegate Protocol

To use any Screenlet, you must conform the class of the view controller that contains it to the Screenlet's delegate protocol. Web Screenlet's delegate protocol is `WebScreenletDelegate`. Follow these steps to conform your view controller to `WebScreenletDelegate`:

1. Import `LiferayScreens` and set your view controller to adopt the `WebScreenletDelegate` protocol:

```
import UIKit
import LiferayScreens

class ViewController: UIViewController, WebScreenletDelegate {...
```

2. Implement the `WebScreenletDelegate` method `onWebLoad(_:url:)`. This method is called when the Screenlet loads the page successfully. How you implement it depends on what (if anything) you want to happen upon page load. Its arguments are the `WebScreenlet` instance and the page URL. This example prints a message to the console indicating that the page was loaded:

```
func onWebLoad(_ screenlet: WebScreenlet, url: String) {
    // Called when the page is loaded
    print("\(url) was just loaded")
}
```

3. Implement the `WebScreenletDelegate` method `screenlet(_:onError:)`. This method is called when an error occurs loading the page, and therefore includes the `NSError` object. This lets you log or print the error. For example, this implementation prints a message containing the error's description:

```
func screenlet(_ screenlet: WebScreenlet, onError error: NSError) {
    print("Failed to load the page: \(error.localizedDescription)")
}
```

4. Implement the `WebScreenletDelegate` method `screenlet(_:onScriptMessageNamespace:onScriptMessage:)`. This method is called when the Screenlet's `WKWebView` sends a message. This method's arguments include the message's namespace and the message. How you implement this method depends on what you want to happen when the message is sent. For example, you could perform a segue and include the message as the segue's `sender`:

```
func screenlet(_ screenlet: WebScreenlet,
    onScriptMessageNamespace namespace: String,
    onScriptMessage message: String) {

    performSegue(withIdentifier: "detail", sender: message)
}
```

5. Get a reference to the Web Screenlet on your storyboard by using Interface Builder to create an outlet to it in your view controller. It's a best practice to name a Screenlet outlet after the Screenlet it references, or simply `screenlet`. Here's an example Web Screenlet outlet:

```
@IBOutlet weak var webScreenlet: WebScreenlet?
```

6. In the view controller's `viewDidLoad()` method, use the Web Screenlet reference you just created to set the view controller as the Screenlet's delegate. To do this, add the following line of code just below the `super.viewDidLoad()` call:

```
self.webScreenlet?.delegate = self
```

Next, you'll use the same Web Screenlet reference to set the Screenlet's parameters.

Setting Web Screenlet's Parameters

Web Screenlet has `WebScreenletConfiguration` and `WebScreenletConfigurationBuilder` objects that supply the parameters the Screenlet needs to work. These parameters include the URL of the page to load and the location of any JavaScript or CSS files that customize the page. You'll set most of these parameters via `WebScreenletConfigurationBuilder`'s methods.

Note: For a full list of `WebScreenletConfigurationBuilder`'s methods, and a description of each, see the table in the Configuration section of Web Screenlet's reference doc.

To set Web Screenlet's parameters, follow these steps in the `viewDidLoad()` method of a view controller that uses Web Screenlet:

1. Use `WebScreenletConfigurationBuilder(<url>)`, where `<url>` is the web page's URL string, to create a `WebScreenletConfigurationBuilder` object. If the page requires Liferay DXP authentication, then the user must be logged in via Login Screenlet or a `SessionContext` method, and you must provide a relative URL to the `WebScreenletConfigurationBuilder` constructor. For example, if such a page's full URL is `http://your.liferay.instance/web/guest/blog`, then the constructor's argument is `/web/guest/blog`. For any other page that doesn't require Liferay DXP authentication, you must supply the full URL to the constructor.

2. Call the `WebScreenletConfigurationBuilder` methods to set the parameters that you need.

```
**Note:** If the URL you supplied to the `WebScreenletConfigurationBuilder`
constructor is to a page that doesn't require Liferay DXP authentication, then
you must call the `WebScreenletConfigurationBuilder` method
`set(webType: .other)`. The default `WebType` is `.liferayAuthenticated`,
which is required to load Liferay DXP pages that require authentication. If
you need to set `.liferayAuthenticated` manually, call
`set(webType: .liferayAuthenticated)`.
```

---

3. Call the `WebScreenletConfigurationBuilder` instance's `load()` method, which returns a `WebScreenletConfiguration` object.

4. Set the `WebScreenletConfiguration` object to the Web Screenlet instance's `configuration` property.

5. Call the Web Screenlet instance's `load()` method.

Here's an example snippet of these steps in the `viewDidLoad()` method of a view controller in which the Web Screenlet instance is `webScreenlet`, and the `WebScreenletConfiguration` object is `webScreenletConfiguration`:

```
override func viewDidLoad() {
    super.viewDidLoad()

    self.webScreenlet?.delegate = self

    let webScreenletConfiguration =
        WebScreenletConfigurationBuilder(url: "/web/westeros-hybrid/companynews")
            .addCss(localFile: "blogs")
            .addJs(localFile: "blogs")
            .load()
    webScreenlet.configuration = webScreenletConfiguration
    webScreenlet.load()
}
```

The relative URL `/web/westeros-hybrid/companynews` supplied to the `WebScreenletConfigurationBuilder` constructor, and the lack of a `set(webType: .other)` call, indicates that this Web Screenlet instance loads a Liferay DXP page that requires authentication. The `addCss` and `addJs` calls add local CSS and JavaScript files, respectively. Both files are named `blogs`.

Great! Now you know how to use Web Screenlet in your iOS apps.

  Rendering Web Content in Your iOS App

77.23 Using Web Screenlet with Cordova in Your iOS App

By using Cordova plugins in Web Screenlet, you can extend the functionality of the web page that the Screenlet renders. This lets you tailor that page to your app's needs. You'll get started by installing Cordova.

Installing and Configuring Cordova Automatically

Follow these steps to automatically create an empty Android project configured to use Cordova. Note that you must have git, Node.js and npm, and CocoaPods installed.

1. Install `screens-cli`:

   ```
   npm install -g screens-cli
   ```

2. Create the file `.plugins.screens` in the folder you want to create your project in. In this file, add all the Cordova plugins you want to use in your app. For example, you can add plugins from Cordova or GitHub:

   ```
   https://github.com/apache/cordova-plugin-wkwebview-engine.git
   cordova-plugin-call-number
   cordova-plugin-camera
   ```

   Note that the `WKWebView` Engine plugin is mandatory in iOS.

3. In the folder containing your `.plugins.screens` file, run `screens-cli` to create your project:

   ```
   screens-cli ios <project-name>
   ```

   This creates your project in the folder `platforms/ios/<project-name>`.

4. Run the following in `platforms/ios/<project-name>`:

   ```
   pod install
   ```

5. Open the `<project-name>.xcworkspace` file with Xcode.

Installing and Configuring Cordova Manually

Follow these steps to install and configure Cordova:

1. Follow the Cordova getting started guide to install Cordova, create a Cordova project, and add the iOS platform to your Cordova project.

2. Install the Cordova `WKWebView` engine:

   ```
   cordova plugin add cordova-plugin-wkwebview-engine
   ```

3. Install any other Cordova plugins you want to use in your app. You can use `cordova plugin` to view the currently installed plugins.

4. Copy the following files and folders from your Cordova project to your iOS project's root folder:

   - `platforms/ios/<your-cordova-project>/config.xml`
   - `platforms/ios/<your-cordova-project>/Plugins`
   - `platforms/ios/www`

5. In the `config.xml` file you just copied to your iOS project's root folder, add `<allow-navigationhref="*" />` below `<access origin="*" />`.

Using Cordova in Web Screenlet

Now that you've installed and configured Cordova in your iOS project, you're ready to use it with Web Screenlet. Follow these steps to do so:

1. Insert and configure Web Screenlet in your app.

2. When you set Web Screenlet's parameters via the `WebScreenletConfigurationBuilder` object, call the `enableCordova()` method. For example, this code adds a local JavaScript file via `addJs` and then calls `enableCordova()` before loading the configuration and the Screenlet:

   ```
   let configuration = WebScreenletConfigurationBuilder(url: "url")
       .addJs(localFile: "call")
       .enableCordova()
       .load()

   webScreenlet?.configuration = configuration
   webScreenlet?.load();
   ```

That's it! Note, however, that you may also need to invoke Cordova from a JavaScript file, depending on what you're doing. For example, to use the Cordova plugin `cordova-plugin-call-number` to call a number, then you must add a JavaScript file with the following code:

```
function callNumber() {
    //This line triggers the Cordova plugin and makes a call
    window.plugins.CallNumber.callNumber(null, function(){ alert("Calling failed.") }, "900000000", true);
}

setTimeout(callNumber, 3000);
```

If you run the app containing this code and wait three seconds, the plugin activates and calls the number in the JavaScript file.

Great! Now you know how to use Web Screenlet with Cordova.

77.24 iOS Best Practices

When developing iOS projects with Liferay Screens, there are a few best practices that you should follow to ensure your code is as clean and bug-free as possible. This tutorial lists these. Note that this tutorial doesn't cover Swift coding conventions for contributing to the Liferay Screens project on GitHub. Click here to see these.

Naming Conventions

Using the naming conventions described here leads to consistency and a better understanding of the Screens library. This makes working with your Screenlets much simpler.

Screenlet Folder

Your Screenlet folder's name should indicate your Screenlet's functionality. For example, Login Screenlet's folder is named `LoginScreenlet`.

If you have multiple Screenlets that operate on the same entity, you can place them inside a folder named for that entity. For example, Asset Display Screenlet and Asset List Screenlet both work with Liferay assets. They're therefore in the Screens library's `Asset` folder.

Screenlets

Naming Screenlets properly is very important; they're the main focus of Liferay Screens. Your Screenlet should be named with its principal action first, followed by *Screenlet*. Its Screenlet class should also follow this pattern. For example, Login Screenlet's principal action is to log users into a Liferay instance. Its Screenlet class is `LoginScreenlet`.

View Models

You should place View Models in your Screenlet's root folder and name them after your Screenlet. For example, Forgot Password Screenlet's View Model is in the `ForgotPasswordScreenlet` folder and is named `ForgotPasswordViewModel`.

Interactors

You should place your Screenlet's Interactors in a folder named `Interactors` in your Screenlet's root folder. You should name each Interactor with its action first, followed by *Interactor*. For example, Rating Screenlet has three Interactors in its `Interactors` folder:

- `DeleteRatingInteractor`: Deletes an asset's ratings
- `LoadRatingsInteractor`: Loads an asset's ratings
- `UpdateRatingInteractor`: Updates an asset's ratings

Connectors

Name your Connectors with the same naming conventions as Interactors, replacing *Interactor* with *Connector*. If your Connector calls a Liferay service, precede *Connector* with *Liferay*. For example, the Connector `CommentAddLiferayConnector` adds comments to an asset in a Liferay instance. A Connector that retrieves a webpage's title from any URL would be called `GetWebsiteTitleConnector`.

Themes

Place your Screenlet's Themes in a folder named *Themes* in your Screenlet's root folder. If you're creating a group of similarly styled Themes for multiple Screenlets, however, then you can place them in a separate *Themes* folder outside of your Screenlets' root folders. This is what the Screens Library does for its Default and Flat7 Themes. The `Default` and `Flat7` folders each contain similarly styled Themes for several Screenlets. Also note that each Screenlet's Theme is in its own folder. For example, Forgot Password Screenlet's Default Theme is in the folder `Themes/Default/Auth/ForgotPasswordScreenlet`. Note that the `Auth` folder is the Screenlet's module. Creating your Screenlets and Themes in modules isn't required.

Recall that a Theme consists of an XIB file and a View class. Name these after your Screenlet, but with *View* instead of *Screenlet*. The filenames should also be suffixed with `_yourThemeName`. For example, the XIB file and View class for Forgot Password Screenlet's Default theme are `ForgotPasswordView_default.xib` and `ForgotPasswordView_default.swift`, respectively.

Avoid Hardcoded Elements

Using constants instead of hard coded elements is a simple way to avoid bugs. Constants reduce the likelihood that you'll make a typo when referring to common elements. They also gather these elements in a single location. For example, when you add an action to your Screenlet, each Screenlet action used as a `restorationIdentifier` in the View class is defined as a constant in the Screenlet class. The Screenlet class's `createInteractor` method then uses the constants to distinguish between the actions. If you instead typed each action manually in both places, a typo could break your Screenlet and would be difficult to track down. Defining the actions in one place via constants avoids this potentially maddening complication.

Screenlet attributes, like those listed in each Screenlet's reference documentation, are another good example of this. Although you can set these directly in Interface Builder, it's better to set them via constants in a `plist` file. This puts all your Screenlets' attributes in a single location that is also subject to version control. For instructions on setting attributes in a `plist` file, see the Configuring Communication with Liferay section of the tutorial on preparing iOS projects for Liferay Screens.

To retrieve these values in your code, you can use the following `LiferayServerContext` methods:

- `propertyForKey`: Get a property as an `AnyObject`
- `numberPropertyForKey`: Get a property as an `NSNumber`.
- `longPropertyForKey`: Get a property as an `Int64`.
- `intPropertyForKey`: Get a property as an `Int`.
- `booleanPropertyForKey`: Get a property as a `Bool`.
- `datePropertyForKey`: Get a property as an `NSDate`.
- `stringPropertyForKey`: Get a property as a `String`.

For example, the following code retrieves the `galleryFolderId` value and sets it to Image Gallery Screenlet's `folderId` attribute:

```
@IBOutlet weak var imageGalleryScreenlet: ImageGalleryScreenlet? {
    didSet {
        imageGalleryScreenlet?.delegate = self
        imageGalleryScreenlet?.presentingViewController = self

        imageGalleryScreenlet?.repositoryId = LiferayServerContext.groupId
        imageGalleryScreenlet?.folderId = LiferayServerContext.longPropertyForKey("galleryFolderId")
    }
}
```

Stay in Your Layer

When accessing variables that belong to other Screenlet components, you should avoid those outside your current Screenlet layer. This achieves better decoupling between the layers, which tends to reduce bugs and simplify maintenance. For an explanation of the layers in Liferay Screens, see the architecture tutorial. For example, you shouldn't directly access View variables from an Interactor. This Interactor's `start` method gets a View instance and accesses its `title` variable:

```
public class MyInteractor: Interactor {
    override func start() -> Bool {
        if let view = self.screenlet.screenletView as? MyView {
            let title = view.title
            ...
        }
    }
}
```

Instead, you should pass the variable to the Interactor's initializer. The Interactor now contains its own `title` variable, set in its initializer:

```
public class MyInteractor: Interactor {

    public let title: String

    //MARK: Initializer

    public init(screenlet: BaseScreenlet, title: String) {
        self.title = title
        super.init(screenlet: screenlet)
    }
}
```

The Screenlet class's `createInteractor` method calls this initializer when creating an instance of the Interactor. Also note that the Screenlet's View Model is used to retrieve the View's `title`. As explained in the tutorial Supporting Multiple Themes in Your Screenlet, a View Model serves as an abstraction layer for your View, which lets you use different Themes with a Screenlet:

```
public class MyScreenlet: BaseScreenlet {
    ...
    override public func createInteractor(name name: String, sender: AnyObject?) -> Interactor? {
        let interactor = MyInteractor(self, title: viewModel.title)
        ...
    }
    ...
}
```

There are, however, a few places where you can break this rule (otherwise it wouldn't be possible for layers to interact):

- The Screenlet class's `createInteractor` method. To get the user's input, this method must access the View's computed properties.

- The Interactor's `onSuccess` closure in the Screenlet class. Here, you must retrieve the Interactor's result object.
- When using a Connector, the Interactor's `completedConnector` method. In this method, you must retrieve the Connector's result object.
- The Screenlet class's View Model references. This is required for the Screenlet to communicate with the View.

Chapter 78

Using Xamarin with Liferay Screens

Liferay Screens for Android and iOS lets you use *Screenlets* to develop native mobile apps on each platform. Screenlets are complete visual components that you insert in your app to leverage Liferay DXP's content and services. As of Liferay Screens 3.0, you can use Screenlets with Xamarin to develop hybrid mobile apps for Android and iOS.

The tutorials in this section show you how to develop hybrid mobile apps using Liferay Screens and Xamarin. You'll start by preparing your Xamarin project for Screens. You'll then learn how to use Screenlets in Xamarin, customize their appearance, and more.

Note: These tutorials assume that you know how to use Xamarin. If you need assistance with Xamarin, see its documentation.

78.1 Preparing Xamarin Projects for Liferay Screens

To use Liferay Screens with Xamarin, you must install Screens in your Xamarin project. You must then configure your project to communicate with your Liferay DXP instance. Note that Liferay Screens for Xamarin is released as a NuGet package hosted in NuGet.org.

Note: After installation, you must configure Liferay Screens to communicate with your Liferay DXP instance. The last section in this tutorial shows you how to do this.

Requirements and Example Projects

Liferay Screens for Xamarin includes the bindings necessary to use all Screenlets included with Screens. The following software is required:

- Visual Studio
- Android SDK 4.1 (API Level 16) or above
- Liferay CE Portal 7.0/7.1, or Liferay DXP 7.0
- Liferay Screens NuGet package

Also note that if you get confused or stuck while using Screens for Xamarin, the official Liferay Screens repository contains two sample Xamarin projects that you can reference:

- **Showcase-Android:** An example app for Xamarin.Android containing all the currently available Screenlets.

- **Showcase-iOS:** An example app for Xamarin.iOS containing all the currently available Screenlets.

Securing JSON Web Services

Each Screenlet in Liferay Screens calls one or more of Liferay DXP's JSON web services, which are enabled by default. The Screenlet reference documentation for Android and iOS lists the web services that each Screenlet calls. To use a Screenlet, its web services must be enabled in the portal. It's possible, however, to disable the web services needed by Screenlets you're not using. For instructions on this, see the tutorial Configuring JSON Web Services. You can also use Service Access Policies for more fine-grained control over accessible services.

Install Liferay Screens in Xamarin Solutions

Follow these steps to install Liferay Screens in your Xamarin project:

1. Open your project in Visual Studio.

2. Right click your project's *Packages* folder and then select *Add packages…*.

3. Look for *LiferayScreens* and install the latest version.

4. Accept the license agreements for any dependencies. These are necessary to use Liferay Screens in Xamarin.

5. Check your configuration one of these ways:

    - Rebuild and execute your project, and import a Liferay Screens path (e.g., `Com.Liferay.Mobile.Screens.Auth.Logir`
    - In your project, select *References → From Packages* and look for the `LiferayScreens*` file. Open that file in the Assembly Browser. You should then see all the available Liferay Screens files.

Next, you'll set up communication with Liferay DXP.

Configuring Communication with Liferay DXP

Before using Liferay Screens, you must configure your project to communicate with your Liferay DXP instance. To do this, you must provide your project with the following information:

- Your Liferay DXP instance's ID.
- The ID of the Liferay DXP site your app needs to communicate with.
- Your Liferay DXP instance's version.
- Any other information required by specific Screenlets.

Fortunately, this is straightforward. Do the following in your Xamarin projects:

- For Xamarin.Android, create a new file called `server_context.xml` in the `Resources/values` folder. Add the following code to this file:

```
<?xml version="1.0" encoding="utf-8"?>
<resources>

    <!-- Change these values for your portal installation -->
    <string name="liferay_server">http://10.0.2.2:8080</string>

    <integer name="liferay_company_id">20116</integer>
    <integer name="liferay_group_id">20143</integer>

    <integer name="liferay_portal_version">70</integer>

</resources>
```

- For Xamarin.iOS, create a new file called `liferay-server-context.plist` in the `Resources` folder. Add the following code to this file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
    <key>server</key>
    <string>http://localhost:8080</string>
    <key>version</key>
    <integer>70</integer>
    <key>companyId</key>
    <real>20116</real>
    <key>groupId</key>
    <real>20143</real>
</dict>
</plist>
```

Make sure to change these values to match those of your Liferay DXP instance. The server address `http://10.0.2.2:8080` is suitable for testing with Android Studio's emulator, because it corresponds to `localhost:8080` through the emulator. If you're using the Genymotion emulator, you should, however, use `192.168.56.1` instead of `localhost`.

The `liferay_company_id` and `companyId` values are your Liferay DXP instance's ID. You can find this in your Liferay DXP instance at *Control Panel* → *Configuration* → *Virtual Instances*. The instance's ID is in the *Instance ID* column.

The `liferay_group_id` and `groupId` values are the ID of the site your app needs to communicate with. To find this value, first go to the site in your Liferay DXP instance that you want your app to communicate with. In the *Site Administration* menu, select *Configuration* → *Site Settings*. The site ID is listed at the top of the *General* tab.

The `liferay_portal_version` and `version` value `70` tells Screens that it's communicating with a Liferay CE Portal 7.0 or Liferay DXP 7.0 instance. Here are the supported values and the portal versions they correspond to:

- `71`: Liferay CE Portal 7.1 or Liferay DXP 7.1
- `70`: Liferay CE Portal 7.0 or Liferay DXP 7.0
- `62`: Liferay Portal 6.2 CE/EE

You can also configure Screenlet properties in `server_context.xml` and `liferay-server-context.plist`. The example `server_context.xml` properties listed below, `liferay_recordset_id` and `liferay_recordset_fields`, enable DDL Form Screenlet and DDL List Screenlet to interact with a Liferay DXP instance's DDLs:

```
<!-- Change these values for your portal installation -->

<integer name="liferay_recordset_id">20935</integer>
<string name="liferay_recordset_fields">Title</string>
```

For additional examples of these files, see the Showcase-Android and Showcase-iOS sample projects.

Super! Your Xamarin projects are ready for Liferay Screens.

Liferay Screens for Xamarin Troubleshooting and FAQs

78.2 Using Screenlets in Xamarin Apps

You can start using Screenlets once you've prepared your Xamarin project to use Liferay Screens. The Screenlet reference documentation describes the available Screenlets:

- Screenlets in Liferay Screens for Android
- Screenlets in Liferay Screens for iOS

Using Screenlets is very straightforward. This tutorial shows you how to insert and configure Screenlets in your Xamarin app. You'll be a Screenlet master in no time!

Xamarin.iOS

Follow these steps to insert Screenlets in your Xamarin.iOS app:

1. Insert a view (`UIView`) in your storyboard (in Visual Studio's iOS Designer or Xcode's Interface Builder). Note that if you're editing an XIB file, you must insert the view inside the XIB's parent view.

2. Set the view's class to the class of the Screenlet you want to use. For example, Login Screenlet's class is `LoginScreenlet`. If you're using Xamarin Designer for iOS in Visual Studio, you must also give the view a name so you can refer to it in your view controller's code.

   For example, the following video shows the first two steps for inserting Login Screenlet in a Xamarin Designer for iOS storyboard.

3. Configure the Screenlet's behavior in your app by implementing the Screenlet's delegate in your view controller. To configure your app to listen for events the Screenlet triggers, implement the Screenlet's delegate methods and register the view controller as the delegate. Make sure to annotate each delegate method with `[Export(...)]`. This ensures the method can be called from Objective-C, which is required for it to work in Screens. You should also set any Screenlet attributes you need. Each Liferay Screenlet's reference documentation lists its available attributes and delegate methods.

```
**Note:** In Liferay Screens for Xamarin, Screenlet delegates are prefixed
with an `I`. For example, Login Screenlet's delegate in native code is
`LoginScreenletDelegate`, while in Xamarin it's `ILoginScreenletDelegate`.
```

```
For example, here's a view controller that implements Login Screenlet's
delegate, `ILoginScreenletDelegate`. Note that the `ViewDidLoad()` method
sets the Screenlet's `ThemeName` attribute (`ThemeName` is available for all
Screenlets via `BaseScreenlet` inheritance) and registers the view
controller as the delegate. This view controller also implements the
`OnLoginResponseUserAttributes` method, which is called upon successful
login. Also note this method's `[Export(...)]` annotation:

    public partial class ViewController : UIViewController, ILoginScreenletDelegate
    {
        protected ViewController(IntPtr handle) : base(handle) {}

        public override void ViewDidLoad()
        {
            base.ViewDidLoad();

            // Set the Screenlet's attributes
            this.loginScreenlet.ThemeName = "demo";

            // Registers this view controller as the delegate
            this.loginScreenlet.Delegate = this;
        }

        ...

        // Delegate methods

        [Export("screenlet:onLoginResponseUserAttributes:")]
        public virtual void OnLoginResponseUserAttributes(BaseScreenlet screenlet,
            NSDictionary<NSString, NSObject> attributes)
        {
            ...
        }
    }
```

See the Showcase-iOS app for more examples of view controllers that use Liferay's Screenlets.

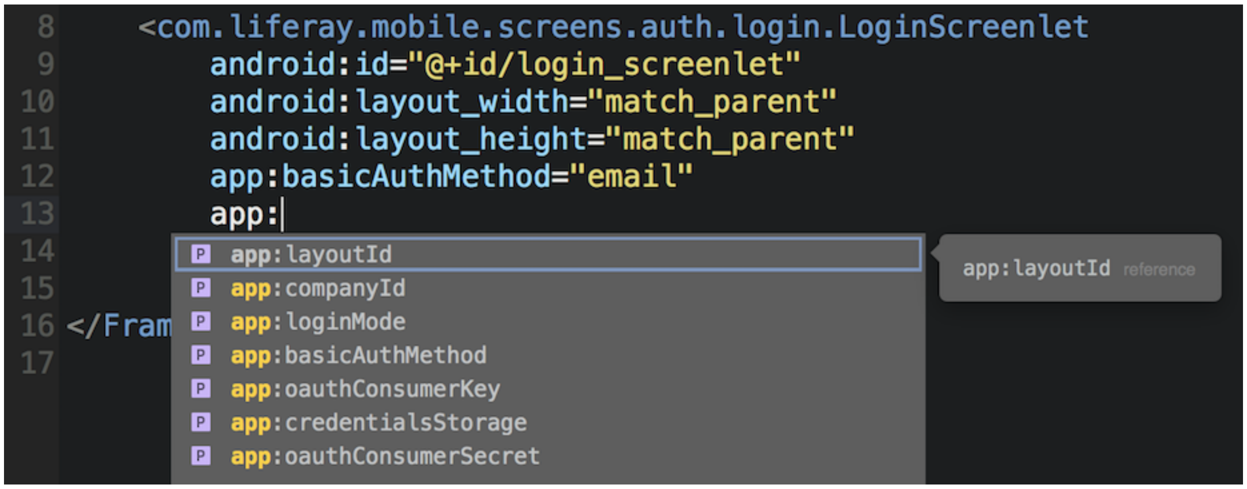
Xamarin.Android

Follow these steps to insert Screenlets in your Xamarin.Android app:

1. Open your app's layout AXML file and insert the Screenlet's XML in your activity or fragment layout. For example, here's Login Screenlet's XML in an activity's `FrameLayout`:

```
<?xml version="1.0" encoding="utf-8"?>
<FrameLayout xmlns:android="http://schemas.android.com/apk/res/android"
    xmlns:app="http://schemas.android.com/apk/res-auto"
    android:orientation="vertical"
    android:layout_width="match_parent"
    android:layout_height="match_parent">
    <com.liferay.mobile.screens.auth.login.LoginScreenlet
        android:id="@+id/login_screenlet"
        android:layout_width="match_parent"
        android:layout_height="match_parent"
        app:basicAuthMethod="email"/>
</FrameLayout>
```

2. Set the Screenlet's attributes. If it's a Liferay Screenlet, refer to the Screenlet reference documentation to learn the Screenlet's required and supported attributes. This screenshot shows Login Screenlet's attributes being set:



```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    app:basicAuthMethod="email"
    app:
</Fram
```

Figure 78.1: You can set a Screenlet's attributes via the app's layout AXML file.

3. To configure your app to listen for events the Screenlet triggers, implement the Screenlet's listener interface in your activity or fragment class. Refer to the Screenlet's reference documentation to learn its listener interface. Then register that activity or fragment as the Screenlet's listener.

```
**Note:** In Liferay Screens for Xamarin, Screenlet listeners are prefixed
with an `I`. For example, Login Screenlet's listener in native code is
`LoginListener`, while in Xamarin it's `ILoginListener`.
```

```
For example, the following activity class implements Login Screenlet's
`ILoginListener` interface, and registers itself as the Screenlet's
listener via `loginScreenlet.Listener = this`. Note that the listener
methods `OnLoginSuccess` and `OnLoginFailure` are called when login succeeds
and fails, respectively. In this case, these methods print simple toast
messages:

    [Activity]
    public class LoginActivity : Activity, ILoginListener
    {
        LoginScreenlet loginScreenlet;

        protected override void OnCreate(Bundle savedInstanceState)
        {
            base.OnCreate(savedInstanceState);
            SetContentView(Resource.Layout.LoginView);

            loginScreenlet = (LoginScreenlet) FindViewById(Resource.Id.login_screenlet);
            loginScreenlet.Listener = this;
        }

        // ILoginListener

        public void OnLoginSuccess(User p0)
        {
            Toast.MakeText(this, "Login success: " + p0.Id, ToastLength.Short).Show();
        }

        public void OnLoginFailure(Java.Lang.Exception p0)
        {
            Android.Util.Log.Debug("LoginScreenlet", $"Login failed: {p0.Message}");
        }

    }
```

See the Showcase-Android app for more examples of activities that use Liferay's Screenlets.
