Liferay Screens for Xamarin Troubleshooting and FAQs

78.3 Using Views in Xamarin.Android

You can use a Liferay Screens *View* to set a Screenlet's look and feel independent of the Screenlet's core functionality. Liferay's Screenlets come with several Views, and more are being developed by Liferay and the community. The Screenlet reference documentation lists the Views available for each Screenlet included with Screens. This tutorial shows you how to use Views in Xamarin.Android.

Views and View Sets

The concepts and components that comprise Views and View Sets in Liferay Screens for Xamarin are the same as they are in Liferay Screens for Android. For a brief description of these components, see the section on Views and View Sets in the general tutorial on using Views. For a detailed description of the View layer in Liferay Screens, see the tutorial Architecture of Liferay Screens for Android.

Using Views

Follow these steps to use a View in Xamarin.Android:

1. Copy the layout of the View you want to use from the Liferay Screens repository to your app's `res/layout` folder. Alternatively, you can create a new layout. The following links list the View layouts available in each View Set:

    - Default
    - Material
    - Westeros

    For example, this is Login Screenlet's Material View, `login_material.xml`:

    ```
    <com.liferay.mobile.screens.viewsets.material.auth.login.LoginView
        xmlns:android="http://schemas.android.com/apk/res/android"
        xmlns:liferay="http://schemas.android.com/apk/res-auto"
        android:paddingLeft="40dp"
        android:paddingRight="40dp"
        style="@style/default_screenlet">

    <LinearLayout
        android:id="@+id/basic_authentication_login"
    ```

```
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:orientation="vertical">

    <LinearLayout style="@style/material_row">

        <ImageView
            android:id="@+id/drawable_login"
            android:contentDescription="@string/user_login_icon"
            android:src="@drawable/material_email"
            style="@style/material_icon"/>

        <EditText
            android:id="@+id/liferay_login"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_marginTop="8dp"
            android:inputType="text"
            android:labelFor="@+id/liferay_login"/>

    </LinearLayout>

    <LinearLayout style="@style/material_row">

        <ImageView
            android:id="@+id/drawable_password"
            android:contentDescription="@string/password_icon"
            android:src="@drawable/material_https"
            style="@style/material_icon"/>

        <EditText
            android:id="@+id/liferay_password"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_marginTop="8dp"
            android:hint="@string/password"
            android:inputType="textPassword"/>

    </LinearLayout>

    <FrameLayout
        android:layout_width="match_parent"
        android:layout_height="wrap_content"
        android:layout_marginTop="32dp">

        <Button
            android:id="@+id/liferay_login_button"
            android:layout_width="match_parent"
            android:layout_height="match_parent"
            android:layout_margin="10dp"
            android:text="@string/sign_in"/>

        <com.liferay.mobile.screens.base.ModalProgressBar
            android:id="@+id/liferay_progress"
            android:layout_width="wrap_content"
            android:layout_height="match_parent"
            android:layout_gravity="center_vertical|left"
            android:layout_margin="10dp"
            android:theme="@style/white_theme"
            android:visibility="invisible"
            liferay:actionViewId="@id/liferay_login_button"/>
    </FrameLayout>
</LinearLayout>

<Button
    android:id="@+id/oauth_authentication_login"
    android:layout_width="match_parent"
    android:layout_height="wrap_content"
    android:text="@string/authorize_application"
    android:visibility="gone"/>

</com.liferay.mobile.screens.viewsets.material.auth.login.LoginView>
```

2. When you insert the Screenlet's XML in the layout of the activity or fragment you want the Screenlet to appear in, set the `liferay:layoutId` attribute to the View's layout. For example, here's Login Screenlet's XML with `liferay:layoutId` set to `@layout/login_material`, which specifies Login Screenlet's Material View from the previous step:

```
<com.liferay.mobile.screens.auth.login.LoginScreenlet
    android:id="@+id/login_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    liferay:layoutId="@layout/login_material"
    />
```

3. If the View you want to use is part of a View Set (e.g., the Material View is part of the Material View Set), your app or activity's theme must also inherit the theme that defines that View Set's styles. For example, the following code in an app's `Resources/values/Styles.xml` tells `AppTheme.NoActionBar` to use the Material View Set as its parent theme:

```
<resources>
    <style name="AppTheme.NoActionBar" parent="material_theme">
        <item name="colorPrimary">@color/colorPrimary</item>
        <item name="colorPrimaryDark">@color/colorPrimaryDark</item>
        <item name="colorAccent">@color/colorAccent</item>

        <item name="windowActionBar">false</item>
        <item name="windowNoTitle">true</item>
    </style>
    ...
</resources>
```

   To use the Default or Westeros View Set, inherit `default_theme` or `westeros_theme`, respectively.

Awesome! Now you know how to use Views to spruce up your Xamarin.Android Screenlets.

Creating Xamarin Views and Themes
Liferay Screens for Xamarin Troubleshooting and FAQs

78.4 Using Themes in Xamarin.iOS

Themes in Xamarin.iOS are analogous to *Views* in Xamarin.Android. Like Views, Themes let you set a Screenlet's look and feel independent of the Screenlet's core functionality. Liferay's Screenlets come with several Themes, and more are being developed by Liferay and the community. The Screenlet reference documentation lists the Themes available for each Screenlet included with Screens. This tutorial shows you how to use Themes in Xamarin.iOS.

Installing and Using Themes

Follow these steps to install and use a Theme:

1. If the Theme is packaged as a NuGet dependency, you can install it in your project via NuGet. To do so, right-click your project's *Packages* folder and then select *Add packages…*. Then search for the Theme and install it. If the Theme isn't available in NuGet, you can drag and drop the Theme's folder directly into your project.

2. To use the installed Theme, set its name to the Screenlet instance's `ThemeName` property in your view controller that implements the Screenlet's delegate. All Screenlets inherit this property from `BaseScreenlet`. For example, this code sets Login Screenlet's `ThemeName` property to the Material Theme:

   ```
   loginScreenlet.ThemeName = "material"
   ```

   If you don't set this property or enter an invalid or missing Theme, the Screenlet uses its Default Theme. Each Screenlet's available Themes are listed in the *Themes* section of the Screenlet's reference documentation.

Great, that's it! Now you know how to use Themes to dress up Screenlets in your Xamarin.iOS apps.

Liferay Screens for Xamarin Troubleshooting and FAQs

78.5 Creating Xamarin Views and Themes

Recall that Views in Xamarin.Android and Themes in Xamarin.iOS are analogous components that let you customize a Screenlet's look and feel. You can use the Views and Themes provided by Liferay Screens, or write your own. Writing your own lets you tailor a Screenlet's UI to your exact specifications. This tutorial shows you how to do this.

You can create Views and Themes from scratch, or use an existing one as a foundation. Views and Themes include a View class for implementing the Screenlet UI's behavior, a Screenlet class for notifying listeners/delegates and invoking Interactors, and an AXML or XIB file for defining the UI.

There are also different types of Views and Themes. These are discussed in the tutorials on creating Views and Themes in native code. You should read those tutorials before creating Views in Xamarin.Android or Themes in Xamarin.iOS.

First, you'll determine where to create your View or Theme.

Determining the Location of Your View or Theme

If you plan to reuse or redistribute your View or Theme, create it in a new Xamarin project as a multiplatform library for code sharing. Otherwise, create it in your app's project.

Creating a Xamarin.Android View

Creating Views for Xamarin.Android is very similar to doing so in native code. You can create the following View types:

- **Themed View:** Creating a Themed View in Xamarin.Android is identical to doing so in native code. In Xamarin.Android, however, only the Default View Set is available to extend.
- **Child View:** Creating a Child View in Xamarin.Android is identical to doing so in native code.
- **Extended View:** Creating an Extended View in Xamarin.Android differs from doing so in native code. The next section shows you how.

Extended View

To create an Extended View in Xamarin.Android, follow the steps for creating an Extended View in native code, but make sure your custom View class in the second step is the appropriate C# class. For example, here's the View class from the native code tutorial, converted to C#:

```
using System;
using Android.Content;
using Android.Util;
using Com.Liferay.Mobile.Screens.Viewsets.Defaultviews.Auth.Login;

namespace ShowcaseAndroid.CustomViews
{
    public class LoginCheckPasswordView : LoginView
    {
        public LoginCheckPasswordView(Context context) : base(context) { }

        public LoginCheckPasswordView(Context context, IAttributeSet attributes) : base(context, attributes) {}

        public LoginCheckPasswordView(Context context, IAttributeSet attributes, int defaultStyle) : base(context, attributes, defaultStyle) {}

        public override void OnClick(Android.Views.View view)
        {
            // compute password strength
            if (PasswordIsStrong) {
                base.OnClick(view);
            }
            else {
                // Present user message
            }
        }
    }
}
```

Awesome! Now you know how to create Extended Views in Xamarin.Android.

Creating a Xamarin.iOS Theme

Creating Themes for Xamarin.iOS is very similar to doing so in native code. You can create the following Theme types in Xamarin.iOS:

- **Child Theme:** presents the same UI components as its parent Theme, but lets you change their appearance and position.
- **Extended Theme:** inherits its parent Theme's functionality and appearance, but lets you add to and modify both.

First, you'll learn how to create a Child Theme in Xamarin.iOS.

Child Theme

Child Themes leverage a parent Theme's behavior and UI components, letting you modify the appearance and position of those components. Note that you can't add or remove components, and the parent Theme must be a Full Theme. The Child Theme presents visual changes with its own XIB file and inherits the parent's View class.

Follow these steps to create a Child Theme in Xamarin.iOS:

1. In Visual Studio, create a new XIB file named after the Screenlet's View class and your Theme. By convention, an XIB file for a Screenlet with a View class named `LoginView` and a Theme named `demo` should be named `LoginView_demo`. You can use content from the parent Theme's XIB file as a foundation for your new XIB file. In your new XIB, you can change the UI components' visual properties (e.g., their position and size). You mustn't change, however, the XIB file's custom class, outlet connection, or `restorationIdentifier`. These must match those of the parent XIB file.

2. In the View Controller, set the Screenlet's `ThemeName` property to the Theme's name. For example, this sets Login Screenlet's `ThemeName` property to the `demo` Theme from the first step:

   ```
   this.loginScreenlet.ThemeName = "demo";
   ```

   This causes Liferay Screens to look for the file `LoginView_demo` in all apps' bundles. If that file doesn't exist, Screens uses the Default Theme instead (`LoginView_default`).

You can see an example of `LoginView_demo` in the Showcase-iOS demo app. Fantastic! Next, you'll learn how to create an Extended Theme.

Extended Theme

An Extended Theme inherits another Theme's UI components and behavior, but lets you add to or alter both. For example, you can extend the parent Theme's View class to change the parent Theme's behavior. You can also create a new XIB file that contains new or modified UI components. An Extended Theme's parent must be a Full Theme.

Follow these steps to create an Extended Theme:

1. In Visual Studio, create a new XIB file named after the Screenlet's View class and your Theme. By convention, an XIB file for a Screenlet with a View class named `LoginView` and a Theme named `demo` should be named `LoginView_demo`. You can use the parent Theme's XIB file as a template. Make your Theme's UI changes by editing your XIB file in Visual Studio's iOS Designer or Xcode's Interface Builder.

2. Create a new View class that extends the parent Theme's View class. You should name this class after the XIB file you just created. You can add to or override functionality of the parent Theme's View class. Here's an example that extends the View class of Login Screenlet's default Theme (`LoginView_default`). Note that it changes the login button's background color and disables the progress presenter:

   ```
   using LiferayScreens;
   using System;

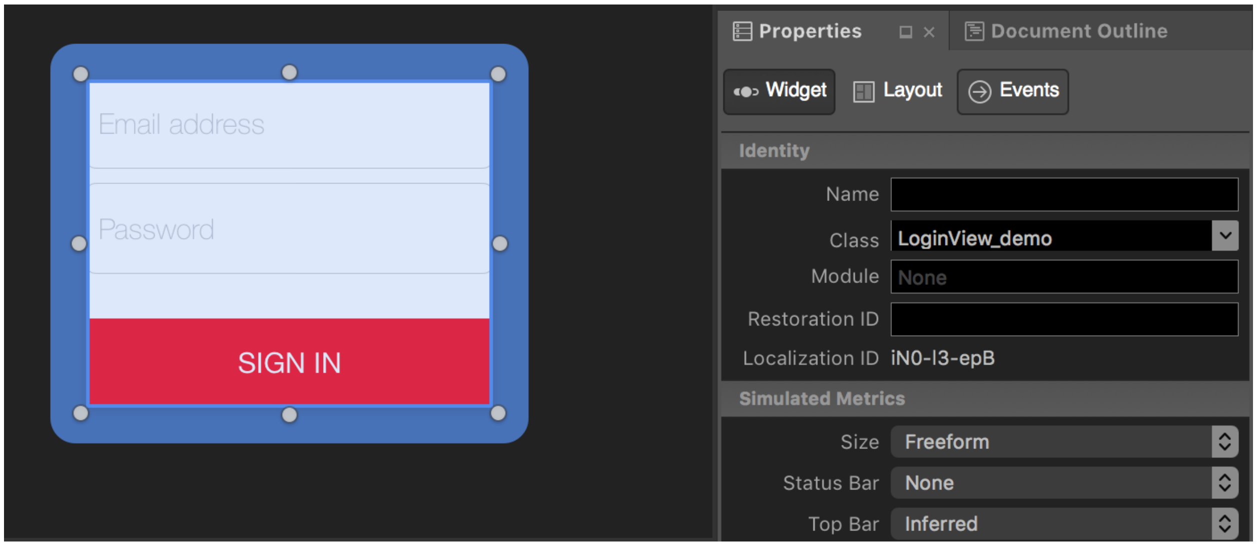
   namespace ShowcaseiOS
   {
       public partial class LoginView_demo : LoginView_default
       {
   ```

```
        public LoginView_demo (IntPtr handle) : base (handle) { }

        public override void OnCreated()
        {
            // You can change the login button color from code
            this.LoginButton.BackgroundColor = UIKit.UIColor.DarkGray;
        }

        // If you don't want a progress presenter, create an empty one
        public override IProgressPresenter CreateProgressPresenter()
        {
            return new NoneProgressPresenter();
        }
    }
}
```

3. Set your new View class as the custom class for your Theme's XIB file:



Name:
Class: LoginView_demo
Module: None
Restoration ID:
Localization ID: iN0-l3-epB
Size: Freeform
Status Bar: None
Top Bar: Inferred

Figure 78.2: Set new View class in XIB Theme file.

Well done! Now you know how to create an Extended Theme.

Liferay Screens for Xamarin Troubleshooting and FAQs

78.6 Liferay Screens for Xamarin Troubleshooting and FAQs

Even though Liferay developed Liferay Screens for Xamarin with great care, you may still run into some common issues. This tutorial lists tips and solutions for these issues, as well as answers to common questions about Screens for Xamarin.

General Troubleshooting

Before exploring specific issues, you should first make sure that you've installed the correct versions of Visual Studio and the Mono .NET framework. Each Screenlet's reference documentation (available for Android and iOS) lists these versions.

It may also help to investigate the sample Xamarin.Android and Xamarin.iOS apps developed by Liferay. Both are good examples of how to use Screenlets, Views (Android), and Themes (iOS):

- Showcase-Android
- Showcase-iOS

If you get stuck at any point, you can post your question on our forum. We're happy to assist you!

Common Issues

1. Build issues:

   Running *Clean* in Visual Studio may not be enough. Close Visual Studio, remove all the `bin` and `obj` folders that weren't removed by the clean, then rebuild your project.

2. `NSUnknownKeyException` error in Xamarin.iOS:

   This error occurs when Liferay Screens for iOS has a wrong module name in an XIB file. You must solve this in Xcode, removing the module name in the XIB file's *Custom Class* assignment in Interface Builder.

3. `The selector is already registered` error in Xamarin.iOS:

   This error occurs because one or more methods share the same name. To fix this, the binding file must be updated. Please file a ticket in our Jira or post the issue on our forum.

4. Xamarin.iOS crashes unexpectedly without any error messages in the console:

   Check the log file. On Mac OS, do this via the Console. On Windows, use the Event Viewer. In the app, you must click *User Reports* and then look for your app's name. Note that there may be more than one log file.

5. The app doesn't call delegate methods in Xamarin.iOS:

   When you implement the delegate methods in your view controller, make sure to annotate them with `[Export(...)]`. You must also set the view controller to the Screenlet instance's `Delegate` property. Here's an example of such a view controller that implements Login Screenlet's delegate, `ILoginScreenletDelegate`:

   ```
   public partial class ViewController : UIViewController, ILoginScreenletDelegate
   {
       protected ViewController(IntPtr handle) : base(handle) {}

       public override void ViewDidLoad()
   ```

```
    {
        base.ViewDidLoad();

        this.loginScreenlet.Delegate = this;
    }

    [Export("screenlet:onLoginResponseUserAttributes:")]
    public virtual void OnLoginResponseUserAttributes(BaseScreenlet screenlet,
        NSDictionary<NSString, NSObject> attributes)
    {
        ...
    }

    ...
}
```

DataType Mapping

For a better understanding of Xamarin code and example apps, see this list to compare type mapping between platforms. You must write Xamarin apps in C#, which has some differences compared to native code:

- Delegate (iOS) or listener (Android) classes:

  These classes are important because they listen for a Screenlet's events. In Liferay Screens for Xamarin, Screenlet delegates and listeners are prefixed with an I. For example, Login Screenlet's delegate in native code is `LoginScreenletDelegate`, while in Xamarin it's `ILoginScreenletDelegate`. Similarly, Login Screenlet's listener in native code is `LoginListener`, while in Xamarin it's `ILoginListener`. Use a similar naming scheme when you define a class/interface pair where the class is a standard implementation of the interface.

- Getter and setter methods:

  To get or set a value in native code, you use its getter and setter methods. In Liferay Screens for Xamarin, you should convert such methods to properties. If you have only one of these methods, you can call the method itself. For example:

```
// If you implemented a setter and a getter, call the property
loginScreenlet.Listener = this;

// Otherwise, call the method
loginScreenlet.getListener();
```

- Pascal case convention:

  C# code is usually written in Pascal case. However, you should use Camel case for protected instance fields or parameters.

Language Equivalents between Swift and C

- Protocols in Swift are analogous to interfaces in C#:

```
// Swift
protocol DoThings {
    func MyMethod() -> String
}

// C#
interface DoThings
```

```
{
    string MyMethod();
}
```

- Initializers in Swift are analogous to constructors in C#:

  ```
  // Swift
  class MyClass {
      var myVar : String = ""

      init(myVar : String) {
          self.myVar = myVar
      }
  }

  var testing = MyClass(myVar: "Test")

  // C#
  class MyClass {
      protected string myVar = "";

      public MyClass() {}

      public MyClass(string myVar) {
          this.myVar = myVar;
      }
  }

  var testing = new MyClass(myVar: "Test");
  ```

To learn more about language equivalents between Swift and C#, see this quick reference.

Language Equivalents between Java and C

To extend or implement a class or interface, Java requires that you use the `extends` or `implements` keywords. C# doesn't require this:

```
// Java
class Bird extends Vertebrate implements Actions {
    ...
}

// C#
class Bird : Vertebrate, Actions {
    ...
}
```

To learn more about language equivalents between Java and C#, see the C# for Java developers cheat sheet.

FAQs

1. Do I have to use Visual Studio?

   No, but we strongly recommend it. If you wish, however, you can use Xamarin Studio or Visual Studio Code instead.

2. What's the meaning of `[Export(...)]` above delegate method names?

   In short, this attribute makes properties and methods available in Objective-C. Xamarin's documentation explains this attribute in detail.

Chapter 79

Mobile SDK

Want to wield Liferay's power in your mobile apps? Thanks to Liferay's Mobile SDK, you can do just that. The Liferay Mobile SDK provides a way to streamline consuming Liferay core web services, Liferay utilities, and custom app web services. It's a low-level layer that wraps Liferay JSON web services, making them easy to call in native mobile apps. It takes care of authentication, makes HTTP requests (synchronously or asynchronously), parses JSON results, and handles server-side exceptions so you can concentrate on *using* the services in your app. The Liferay Mobile SDK bridges the gap between your native app and Liferay services. The official project page gives you access to the SDK releases, provides the latest SDK news, and has forums for you to engage in mobile app development discussions. The Liferay Mobile SDK is available as separate downloads for Android and iOS.

There are two different types of Mobile SDKs that you need to add to your app's project, depending on the remote services you need to call. Liferay's prebuilt Mobile SDK includes the classes required to construct remote service calls in general. It also contains the classes required to call the specific remote services of Liferay's *core* portlets. Core portlets are included with every Liferay installation (these are also referred to as out-of-the-box or built-in portlets). However, you need to build an additional Mobile SDK if you want to leverage your custom portlet's remote services. Once built, this Mobile SDK contains *only* the classes required to call those services. Therefore, you must install it in your app alongside Liferay's prebuilt Mobile SDK to leverage your custom portlet's remote services.

Note that Liferay also provides Liferay Screens for constructing mobile apps that connect to Liferay. Screens uses components called *screenlets* to leverage and abstract the Mobile SDK's low-level service calls. However, if there's not a screenlet for your use case, or you need more control over the service call, then you may want to use the Mobile SDK directly. You should read the Screens tutorials in addition to the Mobile SDK tutorials here to decide which better fits your needs.

This section's tutorials cover using the Mobile SDK in Android and iOS app development. The following tutorials introduce these topics and are followed by in-depth tutorials on each:

- Creating Android Apps that Use the Mobile SDK
- Creating iOS Apps that Use the Mobile SDK

In addition, the following tutorial covers building Mobile SDKs to support your custom portlet services:

- Building Mobile SDKs

Fasten your seatbelt–it's time to go mobile with Liferay's Mobile SDK!

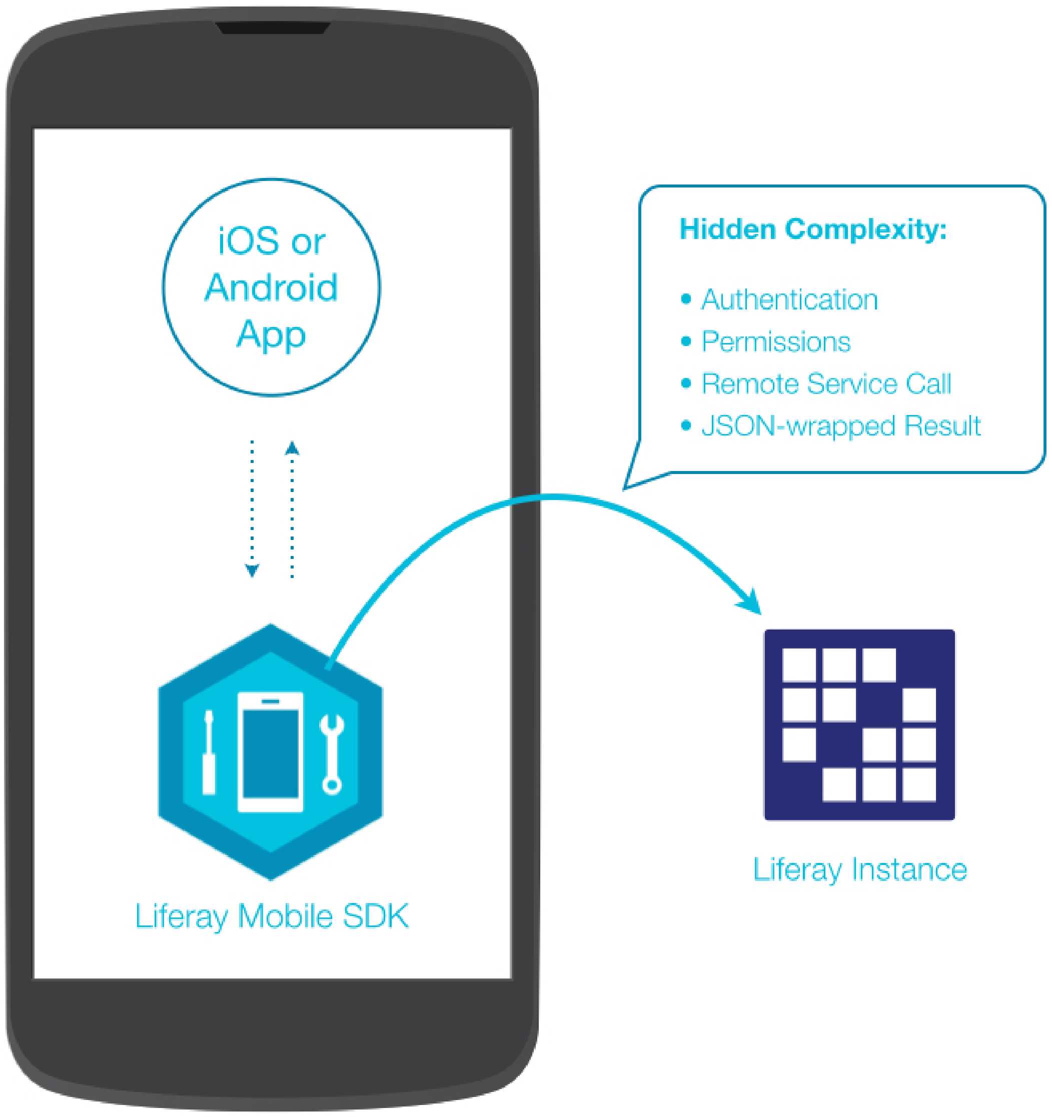

Figure 79.1: Liferay's Mobile SDK enables your native app to communicate with Liferay.

Building Mobile SDKs

79.1 Creating Android Apps that Use the Mobile SDK

The Liferay Mobile SDK provides a way to streamline the consumption of Liferay DXP's core web services and utilities, as well as those of custom apps. It wraps Liferay DXP's JSON web services, making them easy to call in native mobile apps. It handles authentication, makes HTTP requests (synchronously or asynchronously), parses JSON results, and handles server-side exceptions so you can concentrate on *using* the services in your app.

The Liferay Mobile SDK comes with the Liferay Android SDK. The official project page gives you access to the SDK releases, provides the latest SDK news, and has forums for you to engage in mobile app development discussions. Once you configure the Mobile SDK in your app, you can invoke Liferay DXP services in it.

The Android Mobile SDK app development tutorials cover these topics:

- Making Liferay and Custom Portlet Services Available in Your Android App
- Invoking Liferay Services in Your Android App
- Invoking Services Asynchronously from Your Android App
- Sending Your Android App's Requests Using Batch Processing

A great way to start is by setting up the Mobile SDK your Android project. This makes Liferay DXP's services available in your app.

Invoking Liferay Services in Your Android App
Creating iOS Apps that Use the Mobile SDK
Building Mobile SDKs

79.2 Making Liferay and Custom Portlet Services Available in Your Android App

You must install the correct Mobile SDKs in your Android project to call the remote services you need in your app. You should first install Liferay's prebuilt Mobile SDK. This is required for any app that leverages Liferay. To call your custom portlet's services, you also need to install the Mobile SDK that you built for it. For instructions on building a Mobile SDK for your custom portlet, see the tutorial Building Mobile SDKs.

This tutorial shows you how to install Liferay's prebuilt Mobile SDK, and any custom built Mobile SDKs. First, you'll learn how to use Gradle or Maven to install Liferay's prebuilt Mobile SDK. You'll then learn how to install a Mobile SDK manually, which is required for installing any custom built Mobile SDKs. Now go forth and fear no remote service!

Adding the SDK to Your Gradle Project

If your Android project is using Gradle as the build system, you can add Liferay's prebuilt Mobile SDK as a dependency to your project. All versions are available at the JCenter and Maven Central repositories. Both repositories are listed here, but you only need to have one in your app:

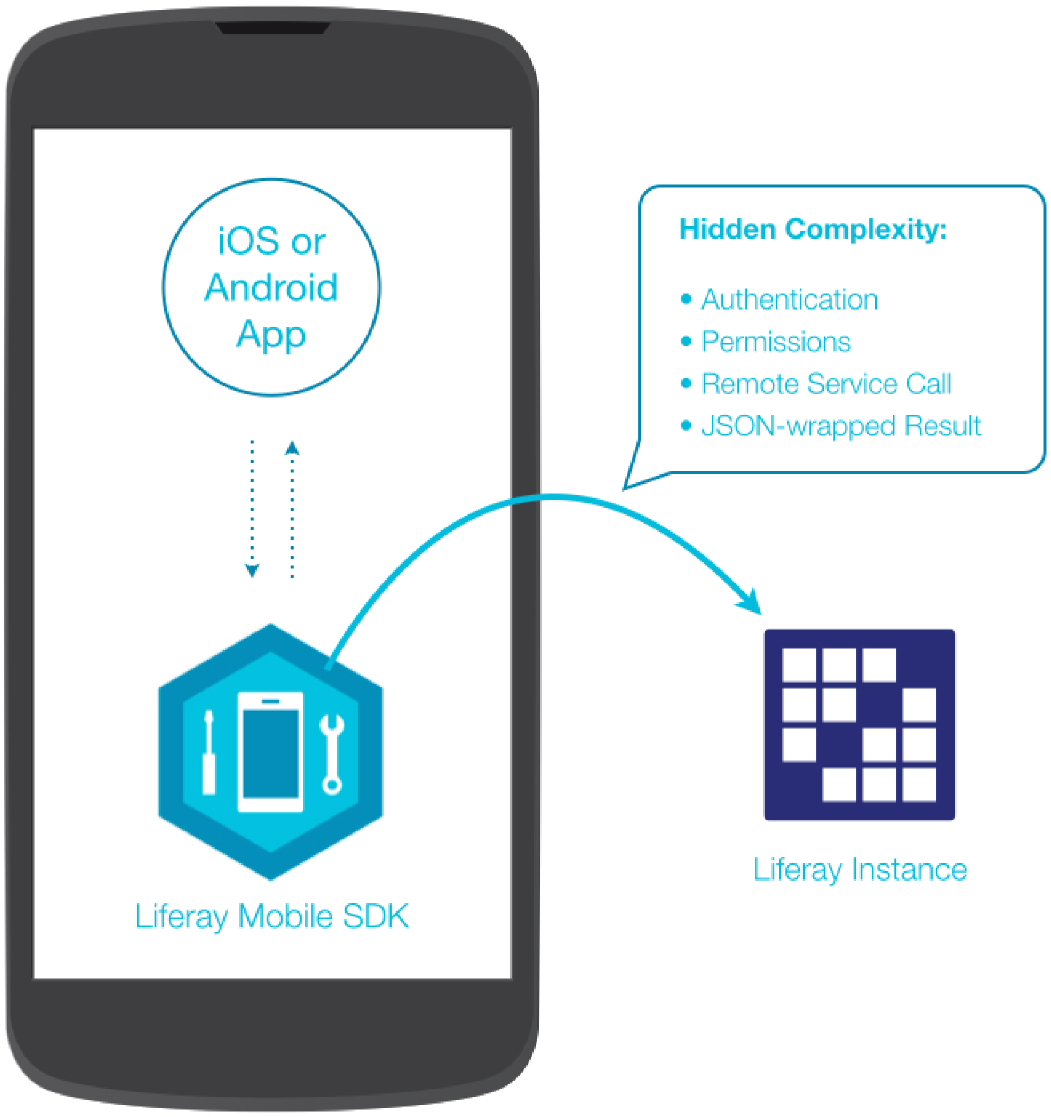

Figure 79.2: Liferay's Mobile SDK enables your native app to communicate with Liferay DXP.

```
repositories {
  jcenter()
  mavenCentral()
}

dependencies {
  compile group: 'com.liferay.mobile', name: 'liferay-android-sdk', version: '7.0.+'
}
```

If you get errors such as `Duplicate files copied in APK META-INF/NOTICE` when building with Gradle, add this to your `build.gradle` file:

```
android {
    ...
    packagingOptions {
        exclude 'META-INF/LICENSE'
        exclude 'META-INF/NOTICE'
    }
    ...
}
```

That's all there is to it! When your project syncs with your Gradle files, Liferay's prebuilt Mobile SDK downloads to your project. The instructions for doing this with Maven are shown next.

Adding the SDK to Your Maven Project

You can also add the Liferay's prebuilt Mobile SDK as a dependency to your project using Maven. To do so, add the following code to your `pom.xml` file:

```
<dependency>
    <groupId>com.liferay.mobile</groupId>
    <artifactId>liferay-android-sdk</artifactId>
    <version>LATEST</version>
</dependency>
```

Awesome! However, what if you're not using Gradle or Maven? What if you want to install a custom built Mobile SDK? No problem! The next section shows you how to install a Mobile SDK manually.

Manually Adding the SDK to Your Android Project

Use the following steps to manually set up a Mobile SDK in your Android project:

1. To install Liferay's prebuilt Mobile SDK, first download the latest version of `liferay-android-sdk-[version].jar`. If you built your own Mobile SDK, find its JAR file on your machine. This is detailed in the Building Mobile SDKs tutorial.

2. Copy the JAR into your Android project's `/libs` folder.

3. If you're manually installing Liferay's prebuilt Mobile SDK, you also need to download and copy these dependencies to your Android Project's `/libs` folder: `httpclient-android-4.3.3.jar` and `httpmime-4.3.3.jar`.

4. Start using it!

Great! Now you know how to manually install a Mobile SDK in your Android apps.

Making Custom Portlet Services Available in Your Android App

If you want to invoke remote web services for your custom portlet, then you need to generate its client libraries by building an Android Mobile SDK yourself. Building an SDK is covered in the tutorial Building Mobile SDKs. Once you build an SDK to a JAR file, you can install it using the manual installation steps above (make sure to use the JAR file you built instead of Liferay's prebuilt JAR file). Note that because your custom built SDKs contain *only* the client libraries for calling your custom portlet services, you must install them alongside Liferay's prebuilt SDK. Liferay's prebuilt SDK contains additional classes that are required to construct any remote service call.

Super! Now that the remote services you need are available in your app, you're ready to call them.

Creating iOS Apps that Use the Mobile SDK

Building Mobile SDKs

79.3 Invoking Liferay Services in Your Android App

Once the appropriate Mobile SDKs are set up in your Android project, you can access and invoke Liferay DXP services in your app. This tutorial takes you through the steps you must follow to invoke these services:

1. Create a session.
2. Import the Liferay DXP services you need to call.
3. Create a service object and call the service methods.

Since some service calls require special treatment, this tutorial also shows you how to handle them. But first, you'll learn about securing Liferay DXP's JSON web services in the portal.

Securing JSON Web Services

The Liferay Mobile SDK calls Liferay DXP's JSON web services, which are enabled by default. The web services you call via the Mobile SDK must remain enabled for those calls to work. It's possible, however, to disable the web services that you don't need to call. For instructions on this, see the tutorial Configuring JSON Web Services. You can also use Service Access Policies for more fine-grained control over accessible services.

Step 1: Create a Session

A session is a conversion state between the client and server, that consists of multiple requests and responses between the two. You need a session to pass requests between your app and the Mobile SDK. In most cases, sessions need to be created with user authentication. The imports and code required to create a session are shown here:

```
import com.liferay.mobile.android.auth.basic.BasicAuthentication;
import com.liferay.mobile.android.service.Session;
import com.liferay.mobile.android.service.SessionImpl;
...
Session session = new SessionImpl("http://10.0.2.2:8080",
    new BasicAuthentication("test@example.com", "test"));
```

The arguments to `SessionImpl` are used to create the session. The first parameter is the URL of the Liferay instance you're connecting to. If you're running your app on Android Studio's emulator, `http://10.0.2.2:8080` is equivalent to `http://localhost:8080`. Be sure to replace this with the correct address for your server.

Warning: Be careful when using administrator credentials on a production Liferay instance, as you'll have permission to call any service. Make sure not to modify data by accident. Of course, the default administrator credentials should be disabled on a production Liferay instance.

The second parameter creates a new `BasicAuthentication` object containing the user's credentials. Depending on the authentication method used by your Liferay instance, you need to provide the user's email address, screen name, or user ID. You also need to provide the user's password. The `BasicAuthentication` object tells the session to use Basic Authentication to authenticate each service call. The Mobile SDK also supports OAuth authentication, as long as the OAuth Provider portlet is deployed to your Liferay instance. To learn how to use OAuth authentication with the Mobile SDK, see the OAuth sample app. Also, note that the OAuth Provider portlet is only available to customers with an active Liferay subscription.

If you're building a sign in view for your app, you can use the `SignIn` utility class to check if the credentials given by the user are valid.

```
import com.liferay.mobile.android.auth.SignIn;
...
SignIn.signIn(session, new JSONObjectAsyncTaskCallback() {

    @Override
    public void onSuccess(JSONObject userJSONObject) {
        System.out.println("Successful sign-in, user details: " + userJSONObject)
    }

    @Override
    public void onFailure(Exception e) {
        e.printStackTrace();
    }

});
```

Note that the Mobile SDK doesn't keep a persistent connection or session with the server. Each request is sent with the user's credentials (except when using OAuth). However, the `SignIn` class provides a way to return user information after a successful sign-in.

Next, you're shown how to create an unauthenticated session in the limited cases where this is possible.

Creating an Unauthenticated Session

In some cases, it's possible to create a `Session` instance without user credentials. However, most Liferay remote methods don't accept unauthenticated remote calls. Making a call with an unauthenticated session generates an `Authentication access required` exception in most cases.

Unauthenticated service calls only work if the remote method in the Liferay instance or your plugin has the `@AccessControlled` annotation. This is shown here for the hypothetical class `FooServiceImpl` and its method `bar`:

```
import com.liferay.portal.security.ac.AccessControlled;
...
public class FooServiceImpl extends FooServiceBaseImpl {
...
    @AccessControlled(guestAccessEnabled = true)
    public void bar() { ... }
...
```

To make such a call, you need to use the constructor that accepts the server URL only:

```
Session session = new SessionImpl("http://10.0.2.2:8080");
```

Fantastic! Now that you have a session, you can use it to call Liferay's services.

Step 2: Import the Liferay Services You Need

First, you should determine the Liferay services you need to call. You can find the available services at `http://localhost:8080/api/jsonws`. Be sure to replace `http://localhost:8080` in this URL with your server's address.

Add the imports for the services you need to call. For example, if you're building a blogs app, you can import `BlogsEntryService`:

```
import com.liferay.mobile.android.v62.blogsentry.BlogsEntryService;
```

Note that the Liferay version (`.v62`) is used in the package namespace. Since the Mobile SDK is built for a specific Liferay version, service classes for different Liferay versions are separated by their package names. In this example, the Mobile SDK classes use the `.v62` package, which means this Mobile SDK is compatible with Liferay 6.2. Mobile SDK classes compatible with Liferay 7.0 use the `v7` package. This namespacing lets your app support multiple Liferay versions.

Step 3: Create a Service Object and Call its Service Methods

Once you have a session and the required imports, you're ready to make the service call. This is done by creating a service object for the service you want to call, and then calling its service methods. For example, if you're creating a blogs app, you need to use `BlogsEntryService` to get all the blogs entries from a site. This is demonstrated by the following code:

```
BlogsEntryService service = new BlogsEntryService(session);

JSONArray jsonArray = service.getGroupEntries(10184, 0, 0, -1, -1);
```

This fetches all blog entries from the *Guest* site. In this example, the *Guest* site's `groupId` is `10184`. Note that many service methods require `groupId` as a parameter. You can get the user's groups by calling the `getUserSites()` method from `GroupService`.

Service method return types can be `void`, `String`, `JSONArray`, or `JSONObject`. Primitive type wrappers can be `Boolean`, `Integer`, `Long`, or `Double`.

This `BlogsEntryService` call is a basic example of a synchronous service call; the method only returns after the request finishes. However, Android doesn't allow network communication from an app's main UI thread. Service calls issued from the main UI thread need need to be asynchronous. For instructions on doing this, see the tutorial Invoking Services Asynchronously from Your Android App.

Great! Now you're familiar with the basics of accessing Liferay services through the Mobile SDK. However, there are some special cases you may run into when making service calls from your app. These are discussed in the following sections.

Non-Primitive Arguments

There are some special cases in which a service method's arguments aren't primitives. In these cases, you should use JSONObjectWrapper. For example:

```
JSONObjectWrapper wrapper = new JSONObjectWrapper(new JSONObject());
```

You must pass a JSON containing the object properties and their values. On the server side, your object is instantiated and setters for each property are called with the values from the JSON you passed.

There are other cases in which service methods require interfaces or abstract classes as arguments. Since it's impossible for the SDK to guess which implementation you want to use, you must initialize JSONObjectWrapper with the class name. For example:

```
JSONObjectWrapper wrapper = new JSONObjectWrapper(className, new JSONObject());
```

The server looks for the class name in its classpath and instantiates the object for you. It then calls setters, as in the previous example. The abstract class OrderByComparator is a good example of this. This is discussed next.

OrderByComparator

On the server side, OrderByComparator is an abstract class. You must therefore pass the name of a class that implements it. For example:

```
String className = "com.liferay.portlet.bookmarks.util.comparator.EntryNameComparator";

JSONObjectWrapper orderByComparator = new JSONObjectWrapper(className, new JSONObject());
```

If the service you're calling accepts null for a comparator argument, pass null to the service call.

You may want to set the ascending property for a comparator. Unfortunately, as of Liferay 6.2, most Liferay OrderByComparator implementations don't have a setter for this property and it isn't possible to set from the Mobile SDK. Future Liferay versions may address this. However, you may have a custom OrderByComparator that has a setter for ascending. In this case, you can use the following code:

```
String className = "com.example.MyOrderByComparator";

JSONObject jsonObject = new JSONObject();
jsonObject.put("ascending", true);

JSONObjectWrapper orderByComparator = new JSONObjectWrapper(className, jsonObject);
```

For more examples, see the test case OrderByComparatorTest.java.

ServiceContext

Another non-primitive argument is ServiceContext. It requires special attention because most Liferay service methods require it. However, you aren't required to pass it to the SDK; you can pass null instead. The server then creates a ServiceContext instance for you, using default values.

If you need to set properties for ServiceContext, you can do so by adding them to a new JSONObject and then passing it as the ServiceContext argument:

```
JSONObject jsonObject = new JSONObject();
jsonObject.put("addGroupPermissions", true);
jsonObject.put("addGuestPermissions", true);

JSONObjectWrapper serviceContext = new JSONObjectWrapper(jsonObject);
```

For more examples, see the test case ServiceContextTest.java.

Binaries

Some Liferay services require argument types such as byte arrays (`byte[]`) and Files (`java.io.File`).

The Mobile SDK converts byte arrays to strings before sending the POST request. For example, `"hello".getBytes("UTF-8")` becomes a JSON array such as `"[104,101,108,108,111]"`. The Mobile SDK does this for you so you don't have worry about it; you only need to pass the byte array to the method.

However, you need to be careful when using such methods. This is because you're allocating memory for the whole byte array, which may cause memory issues if the content is large.

Other Liferay service methods require `java.io.File` as an argument. In these cases, the Mobile SDK requires `InputStreamBody` instead. To accomodate this, you need to create an `InputStream` and pass it to the `InputStreamBody` constructor, along with the file's mime type and name. For example:

```
InputStream is = context.getAssets().open("file.png");
InputStreamBody file = new InputStreamBody(is, "image/png", "file.png");
```

The Mobile SDK sends a multipart form request to the Liferay instance. On the server side, a `File` instance is created and sent to the service method you're calling.

It's also possible to cancel or monitor service calls that upload data to Liferay. Every service that uploads data returns an `AsyncTask` instance. You can use it to cancel the upload if needed. If want to listen for upload progress to create a progress bar, you can create an `UploadProgressAsyncTaskCallback` callback and set it to the current `Session` object. Its `onProgress` method is called for each byte chunk sent. It passes the total number of uploaded bytes so far. For example:

```
session.setCallback(

    new UploadProgressAsyncTaskCallback<JSONObject>() {

        (...)

        public void onProgress(int totalBytes) {
            // This method will be called for each byte chunk sent.
            // The totalBytes argument will contain the total number
            // of uploaded bytes, from 0 to the total size of the
            // request.
        }

        (...)

    }
);
```

For more examples on this subject, see the `addFileEntry*` methods in `DLAppServiceTest.java`

As you can see, the Mobile SDK does a great deal of work for you even when special service method arguments are required.

Invoking Services Asynchronously from Your Android App

Building Mobile SDKs

Creating iOS Apps that Use the Mobile SDK

79.4 Invoking Services Asynchronously from Your Android App

Android doesn't allow synchronous HTTP requests to be made from the main UI thread. You can use Android's `AsyncTask` to make synchronous requests from threads other than the main UI thread. If you don't want to use

AsyncTask, you can make asynchronous requests through the Mobile SDK. To do so, you need to implement and instantiate a callback class, and then set it to the session. When the Mobile SDK makes your service calls for that session, it then makes them asynchronously. To make synchronous calls again, set null as the session's callback.

With the following steps, this tutorial shows you how to implement asynchronous requests in your Android app:

1. Implement and instantiate your callback class.
2. Set the callback on the session.
3. Call Liferay services.

Now go ahead and get started!

Implementing and Instantiating Your Callback Class

Before implementing and instantiating your callback class, you should add the required imports. The imports you add depend on the return type of the service method you're calling. For example, if you need to call the service method getGroupEntries to retrieve blog entries from a site's Blogs portlet, you need to import the Mobile SDK's AsyncTaskCallback and JSONArrayAsyncTaskCallback:

```
import com.liferay.mobile.android.task.callback.AsyncTaskCallback;
import com.liferay.mobile.android.task.callback.typed.JSONArrayAsyncTaskCallback;
```

This is because the getGroupEntries returns a JSONArray. There are multiple AsyncTaskCallback implementations, one for each method return type:

- JSONObjectAsyncTaskCallback
- JSONArrayAsyncTackCallback
- StringAsyncTaskCallback
- BooleanAsyncTaskCallback
- IntegerAsyncTaskCallback
- LongAsyncTaskCallback
- DoubleAsyncTaskCallback

It's also possible to use a generic AsyncTaskCallback implementation called GenericAsyncTaskCallback. To do so, you must implement a transform method and handle JSON parsing yourself.

If you still don't want to use any of these callbacks, you can implement AsyncTaskCallback directly. However, you should be careful when doing so. You should always get the first element of the JSONArray passed as a parameter to the onPostExecute(JSONArray jsonArray) method (for example, jsonArray.get(0)).

Next, implement and instantiate your callback class. When implementing your callback class, you need to implement its onFailure and onSuccess methods. These methods respectivley determine what your app does when the request fails or succeeds. The onFailure() method is called if an exception occurs during the request. This could be triggered by a connection exception (e.g., a request timeout) or a ServerException. If a ServerException occurs, it's because something went wrong on the server side. For example, if you pass a groupId that doesn't exist, the Liferay instance complains about it, and the Mobile SDK wraps the error message with ServerException.

The onSuccess method is called on the main UI thread after the request finishes. Since the request is asynchronous, the service call immediately returns a null object. The service delivers the service's real return value to the callback's onSuccess() method, instead.

Example code is shown here for AsyncTaskCallback and JSONArrayAsyncTaskCallback:

```
AsyncTaskCallback callback = new JSONArrayAsyncTaskCallback() {

    public void onFailure(Exception exception) {
        // Implement exception handling code
    }

    public void onSuccess(JSONArray result) {
        // Called after request has finished successfully
    }

};
```

Now that you have your callback class, you can set it to the session.

Setting the Callback to the Session

Once you've implemented and instantiated your callback class, you're ready to set it to the session. If you haven't created a session yet, do so now. The tutorial Invoking Liferay Services in Your Android App shows you how to create a session. Now you're ready to set the callback to the session. For example, this is done here for `AsyncTaskCallback`:

```
session.setCallback(callback);
```

Pretty simple! Now you're ready to make the service call.

Making the Service Call

Last but certainly not least, make the service call. This is done the same as calling any other service: create a service object from the session and use it to make the service call. This is also described in the tutorial Invoking Liferay Services in Your Android App. An example service call that gets all the blog entries from a site's Blogs portlet is shown here:

```
service.getGroupEntries(10184, 0, 0, -1, -1);
```

The example code from the above sections is shown together here:

```
import com.liferay.mobile.android.task.callback.AsyncTaskCallback;
import com.liferay.mobile.android.task.callback.typed.JSONArrayAsyncTaskCallback;

...

AsyncTaskCallback callback = new JSONArrayAsyncTaskCallback() {

    public void onFailure(Exception exception) {
        // Implement exception handling code
    }

    public void onSuccess(JSONArray result) {
        // Called after request has finished successfully
    }

};

// create a session first
session.setCallback(callback);

// create a service object first
service.getGroupEntries(10184, 0, 0, -1, -1);
```

Great! Now you know how to invoke services asynchronously from your Android app.

Creating iOS Apps that Use the Mobile SDK
Building Mobile SDKs

79.5 Sending Your Android App's Requests Using Batch Processing

The Mobile SDK also allows sending requests in batch. This can be much more efficient than sending separate requests. For example, suppose you want to delete ten blog entries in a site's Blogs portlet at the same time. Instead of making a request for each deletion, you can create a batch of calls and send them all together.

This tutorial shows you how to implement batch processing for your Android app. It's assumed that you already know how to invoke Liferay services from your Android app. If you don't, see the tutorial Invoking Liferay Services in Your Android App. Now get ready to whip up a fresh batch of service calls!

Implementing Batch Processing

Making service calls in batch only requires two extra steps over making them one at a time:

- Create a batch session with `BatchSessionImpl`.
- Make the batch service calls with the `invoke` method of `BatchSessionImpl`.

The rest of the steps are the same as making other service calls. You still need a service object, and you still need to call its service methods. As an example, here's a code snippet from an app that deletes a Blogs portlet's blog entries synchronously in batch:

```
import com.liferay.mobile.android.service.BatchSessionImpl;

BatchSessionImpl batch = new BatchSessionImpl(session);
BlogsEntryService service = new BlogsEntryService(batch);

service.deleteEntry(1);
service.deleteEntry(2);
service.deleteEntry(3);

JSONArray jsonArray = batch.invoke();
```

So what's going on here? After the import, `BatchSessionImpl` is used with a pre-existing session to create a batch session. Note that the `BatchSessionImpl` constructor takes either credentials or a session. Passing a session to the constructor is useful when you already have a `Session` object and want to reuse the same credentials. After creating the service object, several `deleteEntry` service calls are created. Since the service object is created with a batch session, these calls aren't made immediately; they return `null` instead. The calls aren't made until issued in batch by calling the `invoke()` method on the batch session object. It returns a `JSONArray` containing the results for each service call. Since this example contains three `deleteEntry` calls, the `jsonArray` contains three objects. The results are ordered the same as the service calls.

Great! But what if you want to make batch calls asynchronously? No problem! Set the callback as a `BatchAsyncTaskCallback` instance:

```
import com.liferay.mobile.android.task.callback.BatchAsyncTaskCallback;

batch.setCallback(new BatchAsyncTaskCallback() {

    public void onFailure(Exception exception) {
    }
    public void onSuccess(JSONArray results) {
        // The result is always a JSONArray
    }

});
```

This is similar to the procedure for making asynchronous calls as described in the tutorial Invoking Services Asynchronously from Your Android App. Awesome! Now you know how to make efficient service calls in batch!

Invoking Liferay Services in Your Android App
Invoking Services Asynchronously from Your Android App
Creating iOS Apps that Use the Mobile SDK

79.6 Creating iOS Apps that Use the Mobile SDK

The Liferay Mobile SDK provides a way to streamline the consumption of Liferay DXP's core web services and utilities, as well as those of custom apps. It wraps Liferay DXP's JSON web services, making them easy to call in native mobile apps. It handles authentication, makes HTTP requests (synchronously or asynchronously), parses JSON results, and handles server-side exceptions so you can concentrate on *using* the services in your app.

The Liferay Mobile SDK comes with the Liferay iOS SDK. The official project page gives you access to the SDK releases, provides the latest SDK news, and has forums for you to engage in mobile app development discussions. Once you configure the Mobile SDK in your app, you can invoke Liferay DXP services in it.

The iOS Mobile SDK app development tutorials cover these topics:

- Making Liferay and Custom Portlet Services Available in Your iOS App
- Invoking Liferay Services in Your iOS App
- Invoking Services Asynchronously from Your iOS App
- Sending Your iOS App's Requests Using Batch Processing

A great way to start is by setting up the Mobile SDK in your iOS project. This makes Liferay DXP's services available in your app.

Invoking Liferay Services in Your iOS App
Building Mobile SDKs
Creating Android Apps that Use the Mobile SDK

79.7 Making Liferay and Custom Portlet Services Available in Your iOS App

Your iOS app is no doubt pretty great, or at least off to a great start. Now you want it to access Liferay services. How do you accomplish this? Use Liferay's iOS Mobile SDK, of course! You must install the correct Mobile SDKs in your iOS project to call the remote services you need in your app. You should first install Liferay's prebuilt Mobile SDK. This is required for any app that leverages Liferay. To call your custom portlet's services,

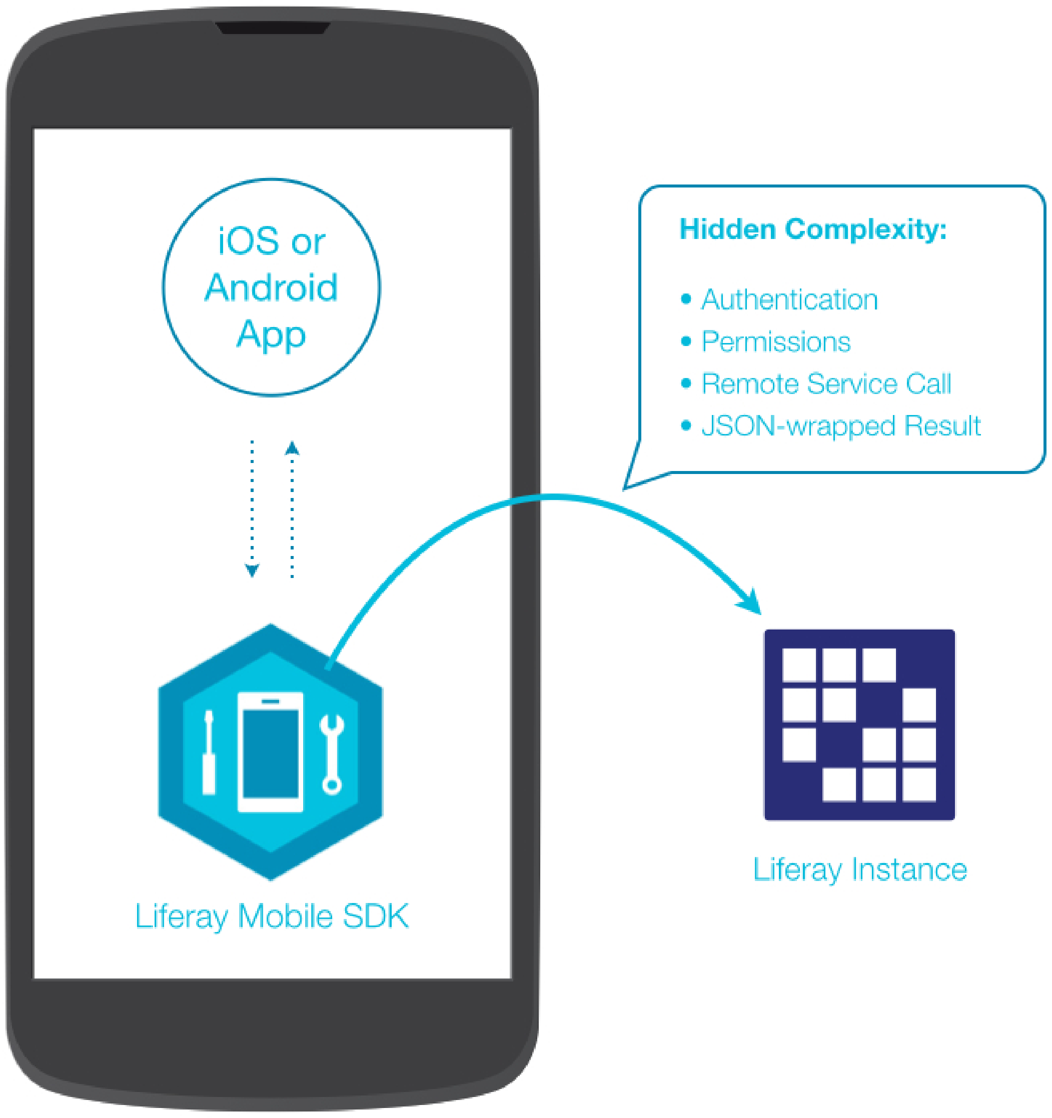

Figure 79.3: Liferay's Mobile SDK enables your native app to communicate with Liferay DXP.

you also need to install the Mobile SDK that you built for it. For instructions on building a Mobile SDK for your custom portlet, see the tutorial Building Mobile SDKs.

This tutorial shows you how to install Liferay's prebuilt Mobile SDK, and any custom built Mobile SDKs. First, you'll learn how to use CocoaPods to install Liferay's prebuilt Mobile SDK. You'll then learn how to install a Mobile SDK manually, which is required for installing any custom built Mobile SDKs. Now go forth and fear no remote service!

Installing the SDK Using CocoaPods

Using CocoaPods is the simplest way to install Liferay's prebuilt Mobile SDK. The steps for doing so are shown here:

1. Make sure you have CocoaPods installed.
2. Create a file called `Podfile` in your project. Add the following line in this file:

   ```
   pod 'Liferay-iOS-SDK'
   ```

3. Run `pod install` from your project's directory. This downloads the latest version of the Liferay iOS Mobile SDK and creates a `.xcworkspace` file. CocoaPods also downloads all the necessary dependencies and configures your workspace. Note that you may have to run `pod repo update` before running `pod install`; this ensures you have the latest version of the CocoaPods repository on your machine.
4. Use the `.xcworkspace` file to open your project in Xcode.
5. If you're importing dependencies as frameworks (`use_frameworks!` in your Podfile), you need to import the `LRMobileSDK` module:

   ```
   @import LRMobileSDK; // (Objective-C)
   import LRMobileSDK // (Swift)
   ```

For more information on how CocoaPods works, see their documentation. Next, you'll learn how to install a Mobile SDK manually.

Installing an iOS SDK Manually

You can also install Mobile SDKs manually. This is required if you built one for your custom portlet's services. You can also install install Liferay's prebuilt Mobile SDK manually if you don't want to use CocoaPods.

1. To install Liferay's prebuilt Mobile SDK, first download the latest version of the Liferay iOS Mobile SDK ZIP file. If you built your own Mobile SDK, find its ZIP file on your machine. This is detailed in the Building Mobile SDKs tutorial.
2. Unzip the file into your Xcode project.
3. Within Xcode, right-click on your project and click *Add Files to 'Project Name'*.
4. Add the `core` and `v7` folders. Note the `v7` folder's name can change for each Liferay version. In this example, the SDK is built for Liferay 7.0.
5. If you're manually installing Liferay's prebuilt Mobile SDK, it also requires AFNetworking 2.6.3. Add its source code to your project.

Great! Now you know how to manually install a Mobile SDK in your iOS apps.

Understanding Liferay and iOS Compatibility

Each Liferay Mobile SDK is designed to work with a specific Liferay version. The Liferay Mobile SDK version number reflects this. The first two digits of each Mobile SDK's version number correspond to the compatible Liferay version. For example, a Mobile SDK version `6.2.*` is compatible with Liferay 6.2, while a Mobile SDK version `7.0.*` is compatible with Liferay 7.0. Any digits after the first two correspond to the internal Liferay Mobile SDK build.

The Mobile SDK's service class names are also suffixed with the Mobile SDK's version number. This lets your app support several Liferay versions. For example, you can add Mobile SDK versions `6.2.0.22` and `7.0.3` to the same project. The Mobile SDK service classes supporting Liferay versions 6.2 and 7.0 end in `_v62.m` and `_v7.m`, respectively. To find out the Liferay versions your app connects to, use the `[LRPortalVersionUtil getPortalVersion:...]` method.

The Liferay iOS Mobile SDK is compatible with iOS versions 7.0 and up. Older iOS versions may work, but compatibility is untested.

Making Custom Portlet Services Available in Your iOS App

If you want to invoke remote web services for your custom portlet, then you need to generate its client libraries by building an iOS Mobile SDK yourself. Building an SDK is covered in the tutorial Building Mobile SDKs. Once you build an SDK to a ZIP file, you can install it using the manual installation steps above (make sure to use the ZIP file you built instead of Liferay's prebuilt ZIP file). Note that because your custom built SDKs contain *only* the client libraries for calling your custom portlet services, you must install them alongside Liferay's prebuilt SDK. Liferay's prebuilt SDK contains additional classes that are required to construct any remote service call.

Building Mobile SDKs

Creating Android Apps that Use the Mobile SDK

79.8 Invoking Liferay Services in Your iOS App

Once the appropriate Mobile SDKs are set up in your iOS project, you can access and invoke Liferay DXP services in your app. This tutorial takes you through the steps you must follow to invoke these services:

1. Create a session.
2. Import the Liferay DXP services you need to call.
3. Create a service object and call the service methods.

Since some service calls require special treatment, this tutorial also shows you how to handle them. Note that the code snippets in this tutorial are written in Objective-C.

First, you'll learn about securing Liferay DXP's JSON web services in the portal.

Securing JSON Web Services

The Liferay Mobile SDK calls Liferay DXP's JSON web services, which are enabled by default. The web services you call via the Mobile SDK must remain enabled for those calls to work. It's possible, however, to disable the web services that you don't need to call. For instructions on this, see the tutorial Configuring JSON Web Services. You can also use Service Access Policies for more fine-grained control over accessible services.

Step 1: Create a Session

A session is a conversion state between the client and server, consisting of multiple requests and responses between the two. You need a session to pass requests between your app and the Mobile SDK. In most cases, sessions need to be created with user authentication. The imports and code required to create a session are shown here:

```
#import "LRBasicAuthentication.h"
#import "LRSession.h"

LRSession *session = [[LRSession alloc] initWithServer:@"http://localhost:8080"
    authentication:[[LRBasicAuthentication alloc] initWithUsername:@"test@example.com" password:@"test"]];
```

The `LRSession` object is created with initializers specifying the Liferay instance to connect to and the credentials of the user to authenticate. The `initWithServer` parameter sets the URL of the Liferay instance you're connecting to. In this case, the Liferay instance is running on `http://localhost:8080`. The iOS emulator is also running on the same machine. Next, the `authentication` parameter takes an `LRBasicAuthentication` instance with the credentials of the user to authenticate. Depending on the authentication method used by your Liferay instance, you need to provide the user's email address, screen name, or user ID to the `initWithUsername` parameter. You also need to provide the user's password to the `password` parameter.

Using `LRBasicAuthentication` tells the session to authenticate each service call with Basic Authentication. The Mobile SDK also supports OAuth authentication, as long as the OAuth Provider app is deployed to your Liferay DXP instance. To learn how to use OAuth authentication with the Mobile SDK, see the OAuth sample app. Also, note that the OAuth Provider app is only available to customers with an active Liferay subscription.

Warning: Be careful when using administrator credentials on a production portal instance, as you'll have permission to call any service. Make sure not to modify data accidentally. Of course, the default administrator credentials should be disabled on a production portal instance.

If you're building a sign in view for your app, you can use the `LRSignIn` utility class to check if the credentials given by the user are valid:

```
#import "LRSignIn.h"

[session
    onSuccess:^(id result) {
        user = result;
        [monitor signal];
    }
    onFailure:^(NSError *e) {
        error = e;
        [monitor signal];
    }
];

[LRSignIn signInWithSession:session callback:session.callback error:&error];
```

The Mobile SDK doesn't keep a persistent connection or session with the server. Each request is sent with the user's credentials (except when using OAuth). However, the `SignIn` class provides a way to return user information after a successful sign-in.

You can persist credentials with `LRCredentialStorage`. It safely saves the username and password in the keychain:

```
[LRCredentialStorage storeCredentialForServer:@"http://localhost:8080"
    username:@"test@example.com" password:@"test"];
```

After credentials are stored, you can retrieve them with:

```
NSURLCredential *credential = [LRCredentialStorage getCredential];
```

Alternatively, you can create an LRSession instance directly with:

```
LRSession *session = [LRCredentialStorage getSession];
```

For more examples of this, see CredentialStorageTest.m.

Next, you're shown how to create an unauthenticated session in the limited cases where this is possible.

Creating an Unauthenticated Session

In some cases, it's possible to create an LRSession instance without user credentials. However, most Liferay remote methods don't accept unauthenticated remote calls. Making a call with an unauthenticated session generates an Authentication access required exception in most cases.

Unauthenticated service calls only work if the remote method in the Liferay instance or your plugin has the @AccessControlled annotation. This is shown here for the hypothetical class FooServiceImpl and its method bar:

```
import com.liferay.portal.security.ac.AccessControlled;
...
public class FooServiceImpl extends FooServiceBaseImpl {
...
    @AccessControlled(guestAccessEnabled = true)
    public void bar() { ... }
...
```

To make such a call, you need to use the constructor that accepts the server URL only:

```
LRSession *session = [[LRSession alloc] initWithServer:@"http://localhost:8080"];
```

Fantastic! Now that you have a session, you can use it to call Liferay's services.

Step 2: Import the Service

First, you should determine the Liferay services you need to call. You can find the available services at http://localhost:8080/api/jsonws. Be sure to replace http://localhost:8080 in this URL with your server's address.

Once you determine the services you need to call, add their imports. For example, if you're building a blogs app, you can import LRBlogsEntryService:

```
#import "LRBlogsEntryService_v62.h"
```

Note that the Liferay version (_v62) is used in the service class's name. This corresponds to the Liferay version it's compatible with. In this example, _v62 is used, which means this Mobile SDK class is compatible with Liferay 6.2. Mobile SDK classes compatible with Liferay 7.0 use _v7 instead. Because service class names contain the Liferay version they're compatible with, you can use several Mobile SDKs simultaneously to support different Liferay versions in the same app.

Step 3: Calling the Service

Once you have a session and have imported the service class, you're ready to make the service call. This is done by creating a service object for the service you want to call, and then calling its service methods. For example, if you're creating a blogs app, you need to use `LRBlogsEntryService` to get all the blogs entries from a site. This is demonstrated by the following code.

```
LRBlogsEntryService_v62 *service = [[LRBlogsEntryService_v62 alloc] initWithSession:session];

NSError *error;
NSArray *entries = [service getGroupEntriesWithGroupId:10184 status:0 start:-1 end:-1 error:&error];
```

This fetches all blog entries from the *Guest* site. In this example, the *Guest* site's `groupId` is `10184`. Note that many service methods require `groupId` as a parameter. You can get the user's groups by calling `[LRGroupService_v62 getUserSites:&error]`.

Service method return types can be `void`, `NSString`, `NSArray`, `NSDictionary`, `NSNumber`, and `BOOL`.

This `LRBlogsEntryService` call is a basic example of a synchronous service call. The method in a synchronous service call returns only after the request is finished.

Non-Primitive Arguments

There are some special cases in which service method arguments aren't primitives. In these cases, you should use `LRJSONObjectWrapper`. For example:

```
LRJSONObjectWrapper *wrapper = [[LRJSONObjectWrapper alloc]
    initWithJSONObject:[NSDictionary dictionary]];
```

You must pass a dictionary containing the object's properties and their values. On the server side, your object is instantiated and setters for each property are called with the values from the dictionary.

There are some other cases in which service methods require interfaces or abstract classes as arguments. Since it's impossible for the SDK to guess which implementation you want to use, you must initialize `LRJSONObjectWrapper` with the class name. For example:

```
LRJSONObjectWrapper *wrapper = [[LRJSONObjectWrapper alloc]
    initWithClassName:@"com.example.MyClass" jsonObject:[NSDictionary dictionary]];
```

The server looks for the class name in its classpath and instantiates the object for you. It then calls setters, as in the previous example. The abstract class `OrderByComparator` is a good example of this. This is discussed next.

OrderByComparator

On the server side, `OrderByComparator` is an abstract class. You must therefore pass the name of a class that implements it. For example:

```
NSString *className = @"com.liferay.portlet.bookmarks.util.comparator.EntryNameComparator";

LRJSONObjectWrapper *orderByComparator = [[LRJSONObjectWrapper alloc] initWithClassName:className jsonObject:[NSDictionary dictionary]];
```

If the service you're calling accepts `null` for a comparator argument, pass `nil` to the service call.

You may want to set the ascending property for a comparator. Unfortunately, as of Liferay 6.2, most Liferay `OrderByComparator` implementations don't have a setter for this property and it isn't possible to set from the Mobile SDK. Future Liferay versions may address this. However, you may have a custom `OrderByComparator` that has a setter for ascending. In this case, you can use the following code:

```
NSString *className = @"com.example.MyOrderByComparator";

NSDictionary *jsonObject = @{
    @"ascending": @(YES)
};

LRJSONObjectWrapper *orderByComparator = [[LRJSONObjectWrapper alloc]
    initWithClassName:className jsonObject:jsonObject];
```

For more examples, see the test case `OrderByComparatorTest.m`.

ServiceContext

Another non-primitive argument is `ServiceContext`. It requires special attention because most Liferay service methods require it. However, you aren't required to pass it to the SDK; you can pass `nil` instead. The server then creates a `ServiceContext` instance for you, using default values.

If you need to set properties for `ServiceContext`, you can do so by adding them to a new `NSDictionary` and then passing it as the `ServiceContext` argument:

```
NSDictionary *jsonObject = @{
    @"addGroupPermissions": @(YES),
    @"addGuestPermissions": @(YES)
};

LRJSONObjectWrapper *serviceContext = [[LRJSONObjectWrapper alloc] initWithJSONObject:jsonObject];
```

For more examples, see the test case `ServiceContextTest.m`.

Binaries

Some Liferay services require binary argument types like `NSData` or `LRUploadData`. The Mobile SDK converts `NSData` instances to `NSString` before sending the POST request. For example, `[@"hello" dataUsingEncoding:NSUTF8StringEncoding]` becomes a JSON array such as `"[104,101,108,108,111]"`. The Mobile SDK does this for you, so you don't have worry about it; you only need to pass the `NSData` instance to the method.

However, you need to be careful when using such methods. This is because you're allocating memory for the whole `NSData`, which may cause memory issues if the content is large.

Other Liferay service methods require `java.io.File` as an argument. In these cases the Mobile SDK requires `LRUploadData` instead. Here are two examples of creating `LRUploadData` instances:

```
LRUploadData *upload = [[LRUploadData alloc]
    initWithData:data fileName:@"file.png" mimeType:@"image/png"];

LRUploadData *upload = [[LRUploadData alloc]
    initWithInputStream:is length:length fileName:@"file.png" mimeType:@"image/png"];
```

The first constructor accepts an `NSData` argument, while the second accepts `NSInputStream`. As you can see, you also need to pass the file's mime type and name. The `length` is the size in bytes of the content being sent. The SDK sends a multipart form request to the Liferay instance. On the server side, a `File` instance is created and sent to the service method you're calling.

It's also possible to monitor service calls that upload data to Liferay. If want to listen for upload progress to create a progress bar, you can create a `LRProgressDelegate` delegate and set it to an `LRUploadData` object. Its `onProgressBytes` method is called for each byte chunk sent. It passes the bytes that were sent, the total number of bytes sent so far, and the total request size. For example:

```
@interface ProgressDelegate : NSObject <LRProgressDelegate>

@end

@implementation ProgressDelegate

- (void)onProgressBytes:(NSUInteger)bytes sent:(long long)sent
    total:(long long)total {

        // bytes contains the byte values that were sent.
        // sent will contain the total number of bytes sent.
        // total will contain the total size of the request in bytes.

}

@end
```

For more examples of this, see the test case `FileUploadTest.m`.

79.9 Invoking Services Asynchronously from Your iOS App

The main drawback of using synchronous requests from your app is that each request must terminate before another can begin. If you're sending a large number of synchronous requests, performance suffers as a bottleneck forms while each one waits to be processed. Fortunately, Liferay's iOS SDK allows *asynchronous* HTTP requests. To do so, you need to set a callback to the session object. If you want to make synchronous requests again, you can set the callback to `nil`.

With the following steps, this tutorial shows you how to implement asynchronous requests in your iOS app:

1. Implement your callback class.
2. Instantiate your callback class and set it to the session.
3. Call Liferay services.

Objective-C is used in the code snippets that follow. Let the requesting begin!

Implementing Your Callback Class

To configure asynchronous requests, first create a class that conforms to the `LRCallback` protocol. When implementing this callback class, you need to implement its `onFailure` and `onSuccess` methods. These methods respectively determine what your app does when the request fails or succeeds. If a server side exception or a connection error occurs during the request, the `onFailure` method is called with an `NSError` instance that contains information about the error. Note that the `onSuccess` result parameter doesn't have a specific type. When deciding what to cast it to, you need to check the type in the service method signature.

The example code here implements a callback class for an app that retrieves blog entries from a Blogs portlet. The service method for this call is `getGroupEntriesWithGroupId`, which returns an `NSArray` instance. The `onSuccess` method's result parameter is therefore cast to this type:

```
#import "LRCallback.h"

@interface BlogsEntriesCallback : NSObject <LRCallback>

@end

#import "BlogsEntriesCallback.h"

@implementation BlogsEntriesCallback

- (void)onFailure:(NSError *)error {
    // Implement error handling code
}

- (void)onSuccess:(id)result {
    // Called after request has finished successfully
    NSArray *entries = (NSArray *)result;
}

@end
```

Awesome! Now you have a callback class that you can use with the session.

Set the Callback to the Session

Next, create an instance of this callback and set it to the session. If you haven't created a session yet, do so now. The tutorial Invoking Liferay Services in Your iOS App shows you how to create a session. Now you're ready to set the callback to the session. For example, this is done here for `BlogsEntriesCallback`:

```
BlogsEntriesCallback *callback = [[BlogsEntriesCallback alloc] init];

[session setCallback:callback];
```

Pretty simple! Now you're ready to make the service call.

Making the Service Call

Last but certainly not least, make the service call. This is done the same as calling any other service: create a service object from the session and use it to make the service call. This is also described in the tutorial Invoking Liferay Services in Your iOS App. Here, an example service call that gets all the blog entries from a site's Blogs portlet is shown:

```
[service getGroupEntriesWithGroupId:10184 status:0 start:-1 end:-1 error:&error];
```

Since the request is asynchronous, `getGroupEntriesWithGroupId` immediately returns `nil`. Once the request finishes successfully, the `onSuccess` method of your callback is invoked with the results on the main UI thread.

Great! Now you know how to make asynchronous requests in your iOS apps. However, there's another way to accomplish the same thing. This is discussed next.

Using Blocks as Callbacks

Instead of implementing a separate callback class, you can use an Objective-C block as a callback. An example of this is shown here for an asynchronous call that retrieves a user's sites. Note that this includes all the code required to make the call:

```
LRSession *session = [[LRSession alloc]
    initWithServer:@"http://localhost:8080" username:@"test@example.com" password:@"test"];

[session
    onSuccess:^(id result) {
        // Called after request has finished successfully
    }
    onFailure:^(NSError *e) {
        // Implement error handling code
    }
];

LRGroupService_v62 *service = [[LRGroupService_v62 alloc] initWithSession:session];

NSError *error;
[service getUserSites:&error];
```

When using a block as a callback, take care not to also set an `LRCallback` instance to the session. If you do, it gets overridden. Otherwise, support for blocks works the same way as described in the previous sections.

Super! Now you know two different ways to make asynchronous service requests in your iOS apps.

Creating Android Apps that Use the Mobile SDK

79.10 Sending Your iOS App's Requests Using Batch Processing

The Mobile SDK also allows sending requests in batch. This can be much more efficient than sending separate requests. For example, suppose you want to delete ten blog entries in a site's Blogs portlet at the same time. Instead of making a request for each deletion, you can create a batch of calls and send them all together.

This tutorial shows you how to implement batch processing for your iOS app. It's assumed that you already know how to invoke Liferay services from your iOS app. If you don't, see the tutorial Invoking Liferay Services in Your iOS App. Objective-C is used in the code snippets that follow. Now it's time to whip up a fresh batch of requests!

Implementing Batch Processing

Making service calls in batch only requires two extra steps over making them one at a time:

- Create a batch session with `LRBatchSession`.
- Make the batch service calls with the `invoke` method of `LRBatchSession`.

The rest of the steps are the same as making other service calls. You still need a service object, and you still need to call its service methods. As an example, here's a code snippet from an app that deletes a Blogs portlet's blog entries synchronously in batch:

```
#import "LRBatchSession.h"

LRBatchSession *batch = [[LRBatchSession alloc]
    initWithServer:@"http://localhost:8080" username:@"test@example.com" password:@"test"];
LRBlogsEntryService_v62 *service = [[LRBlogsEntryService_v62 alloc] initWithSession:batch];
NSError *error;

[service deleteEntryWithEntryId:1 error:&error];
[service deleteEntryWithEntryId:2 error:&error];
```

```
[service deleteEntryWithEntryId:3 error:&error];

NSArray *entries = [batch invoke:&error];
```

So what's going on here? After the import, `LRBatchSession` is used with a Liferay instance's URL and a user's credentials to create a batch session. You can alternatively pass a pre-existing `session` to the constructor. This is useful when you already have a session object and want to reuse the same credentials. Next, the service calls are made as usual (in this case, `deleteEntryWithEntryId`). With asynchronous calls, these methods return `nil` right away. Finally, call `[batch invoke:&error]`. This returns an `NSArray` containing the results for each service call (the return type for batch calls is always `NSArray`). Since there are three `deleteEntryWithEntryId` calls, the `entries` array contains three objects. The order of the results matches the order of the service calls.

If you want to make batch calls asynchronously, set the callback to the session as usual.

```
[batch setCallback:callback];
```

Great! Now you know how to utilize batch processing to speed up your app's requests.

Invoking Liferay Services in Your iOS App

Creating Android Apps that Use the Mobile SDK

79.11 Building Mobile SDKs

The Liferay Mobile SDK lets you connect your Android and iOS apps to a Liferay DXP instance. By accessing built-in portal services through Liferay's prebuilt Mobile SDK, your apps can access the out-of-the-box functionality in a Liferay DXP instance. But what if you want to call custom services that belong to a custom portlet? No problem! In this case, you need to build your own Mobile SDK that can call these custom portlet services.

Note that when you build a Mobile SDK for a portlet, it contains *only* the classes needed to call that portlet's remote services. You still need to install Liferay's prebuilt Mobile SDK in your app. It contains the framework required to construct remote service calls in general.

The Liferay Mobile SDK project contains a Mobile SDK Builder that generates a custom Mobile SDK for the Android and iOS platforms. The Mobile SDK Builder does this by generating client libraries that let your native mobile apps invoke a custom portlet's remote web services. Think of the Mobile SDK Builder as a Service Builder on the client side.

This tutorial covers how to build a custom Mobile SDK for Android and iOS. You'll begin by making sure the remote services are configured for any custom portlets you have.

Configuring Your Portlet's Remote Services

For the Mobile SDK Builder to discover a portlet's remote services, the services must be available and accompanied by a Web Service Deployment Descriptor (WSDD). For instructions on creating a portlet's remote services and building its WSDD, click here.

Next, you'll download the Liferay Mobile SDK's source code.

Downloading the Liferay Mobile SDK

To build a Mobile SDK for your custom portlet's services, you need to have the Liferay Mobile SDK's source code on your local machine. This code also contains the Mobile SDK Builder. You can get this code by cloning the Mobile SDK project via Git, or by downloading it from GitHub. To clone the Mobile SDK project with Git, open a terminal and navigate to the directory on your machine in which you want to put the Mobile SDK. Then run this command:

```
git clone git@github.com:liferay/liferay-mobile-sdk.git
```

Since the Mobile SDK changes frequently, you should check out the latest stable release for your chosen mobile platform (Android or iOS). Click here to see the list of available stable releases. Stable releases correspond to tags in GitHub that begin with the mobile platform and end with the Liferay Mobile SDK version. For example, the `android-7.0.6` tag corresponds to version 7.0.6 of the Liferay Mobile SDK for Android. To check out this tag in a new branch of the same name, you can use this command:

```
git checkout tags/android-7.0.6 -b android-7.0.6
```

Alternatively, you can download the ZIP or TAR.GZ file listed under each tag on GitHub.

Now you're ready to build the Mobile SDK!

Building a Liferay Mobile SDK

After you've downloaded the Mobile SDK's source code, you must build the module in which you'll build your custom portlet's Mobile SDK. The Mobile SDK Builder comes with a command line wizard that helps you build this module. To start the wizard, run the following command in the Mobile SDK source code's root folder:

```
./gradlew createModule
```

This starts the wizard with the most commonly required properties it needs to generate code for your portlet. If you need more control over these properties, run the same command with the `all` argument:

```
./gradlew createModule -P=all
```

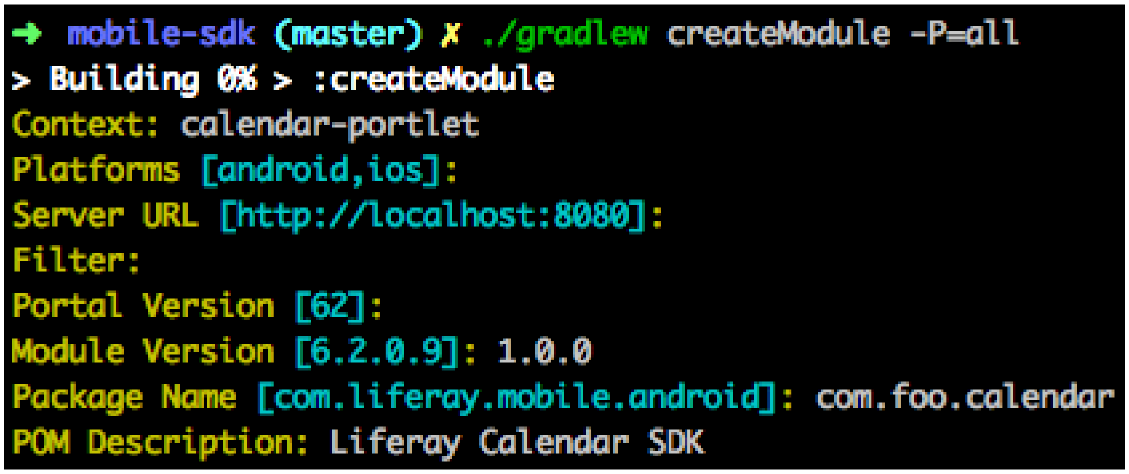
The wizard should look similar to this screenshot. Note that default values are in square brackets with blue text:

So what properties are available, and what do they do? Fantastic question! You can set the following properties during or after running `createModule`. If you want or need to set these properties after running `createModule`, you can do so in your module's `gradle.properties` file. The values in parentheses are the keys used in `gradle.properties`:

- `Context (context)`: Your portlet's web context. For example, if you're generating a Mobile SDK for Liferay DXP's Calendar portlet, which is generally deployed to the `calendar` context, then you should set the context value to `calendar`. If there are no services available at the specified context, you may have forgotten to generate your portlet's WSDD.

- `Platforms (platforms)`: The platforms to build the Mobile SDK for. By default, you can generate code for Android and iOS (`android,ios`).

- `Server URL (url)`: Your Liferay DXP instance's URL. To discover your services, the Mobile SDK Builder tries to connect to this instance at the specified context.



```
➜  mobile-sdk (master) ✗ ./gradlew createModule -P=all
> Building 0% > :createModule
Context: calendar-portlet
Platforms [android,ios]:
Server URL [http://localhost:8080]:
Filter:
Portal Version [62]:
Module Version [6.2.0.9]: 1.0.0
Package Name [com.liferay.mobile.android]: com.foo.calendar
POM Description: Liferay Calendar SDK
```

Figure 79.4: The Mobile SDK Builder's wizard lets you specify property values for building your module.

- `Filter (filter)`: Specifies the portlet entities the Mobile SDK can access. A blank value specifies all portlet entity services. For example, the Calendar portlet's entities include `CalendarBooking` and `CalendarResource`. To generate a Mobile SDK for only the `CalendarBooking` entity, set the filter's value to `calendarbooking` (all lowercase).

- `Module Version (version)`: The version number appended to your Mobile SDK's JAR (Android) and ZIP files (iOS). The sections on packaging your Mobile SDK explain this further.

- `Package Name (packageName)`: On Android, this is the package your Mobile SDK's classes are written to (iOS doesn't use packages). Note that the Liferay DXP version is appended to the end of the package name. For example, if you're using Liferay Portal 7.0 or Liferay DXP Digital Enterprise 7.0, and specify `com.liferay.mobile.android` as the package name, the Mobile SDK Builder appends v7 to the package name, yielding `com.liferay.mobile.android.v7`. This prevents collisions between classes with the same name, which lets you use Mobile SDKs for more than one portal version in the same app. You can use the `Portal Version` property to change the portal version.

- `POM Description (description)`: Your POM file's description.

Note that there's also a `destination` property that can only be set in the `gradle.properties` file. This property specifies the destination for the generated source files. You won't generally need to change this.

After you set the properties you need, the Mobile SDK Builder generates your module in the folder `modules/${your_portlet_context}`.

Now you can build your Mobile SDK. To do this, navigate to your module and run this command:

```
../../gradlew generate
```

By default, the builder writes the source files to `android/src/gen/java` and `ios/Source` in your module's folder.

If you update your portlet's remote services on the server side and need to update your Mobile SDK, simply run `../../gradlew generate` again.

Awesome! Now you know how to create and regenerate a Mobile SDK for your custom portlet's remote services. Next, you'll finish by packaging your Mobile SDK for the Android and iOS.

Packaging Your Mobile SDK for Android

To package your Mobile SDK in a JAR file for use in an Android project, run the following command from your module's folder:

```
../../gradlew jar
```

This packages your Mobile SDK in the following file:

- `modules/${your_portlet_context}/build/libs/liferay-${your_portlet_context}-android-sdk-${version}.jar`

To call your portlet's remote services, you must first install this file in your Android project. To do so, copy the file into your Android app's `app/libs` folder. Note that you must also install Liferay's prebuilt Mobile SDK in your app. Click here for instructions on doing this.

Also note that if you regenerate your Mobile SDK to include new functionality, you can update your module's version in its `gradle.properties` file. For example, if you added or changed a service method in the Mobile SDK you initially built, you could update it's version by setting `version=1.1` in your module's `gradle.properties` file.

To learn how to use the Mobile SDK in your Android app, see the rest of the Android Mobile SDK documentation. You can also use your Mobile SDK to create custom Screenlets in Liferay Screens.

Packaging Your Mobile SDK for iOS

To package your Mobile SDK in a ZIP file for use in an iOS project, run the following command from your module's folder:

```
../../gradlew zip
```

This packages your Mobile SDK in the following file:

- `modules/${your_portlet_context}/build/liferay-${your_portlet_context}-ios-sdk-${version}.zip`

To call your portlet's remote services, you must first install this file in your Xcode project. To do so, simply unzip it and add its files to your Xcode project.

To learn how to use the Mobile SDK in your iOS app, see the rest of the iOS Mobile SDK documentation. You can also use your Mobile SDK to create custom Screenlets in Liferay Screens.

Chapter 80

Service Builder

An application without reliable business logic or persistence isn't much of an application at all. Unfortunately, writing your own persistence code often takes a great deal of time. Fortunately, Liferay provides the Liferay Service Builder to generate it for you. You might now be thinking, "What?! I hate code generators!" Not to fear; you can still write your own persistence code if you wish. And if you choose to use Service Builder, you can edit and customize the code it generates. Regardless of how you produce your persistence code, you can then use it to implement your app's business logic.

This section of tutorials shows you how to use Service Builder to generate your persistence framework and implement your business logic. You're also shown how to use Spring in your app.

80.1 What is Service Builder?

Service Builder is a model-driven code generation tool built by Liferay that allows developers to define custom object models called entities. Service Builder generates a service layer through object-relational mapping (ORM) technology that provides a clean separation between your object model and code for the underlying database. This frees you to add the necessary business logic for your application. Service Builder takes an XML file as input and generates the necessary model, persistence, and service layers for your application. These layers provide a clean separation of concerns. Service Builder generates most of the common code needed to implement create, read, update, delete, and find operations on the database, allowing you to focus on the higher level aspects of service design. In this section, you'll learn some of the main benefits of using Service Builder:

- Integration with Liferay
- Automatically generated model, persistence, and service layers
- Automatically generated local and remote services
- Automatically generated Hibernate and Spring configurations
- Support for generating finder methods for entities and finder methods that account for permissions
- Built-in entity caching support
- Support for custom SQL queries and dynamic queries
- Saved development time

Liferay uses Service Builder to generate all of its internal database persistence code. In fact, all of Liferay's services, both local and remote, are generated by Service Builder. Additionally, the service modules in Liferay are generated by Service Builder. Service Builder's use in Liferay Portal demonstrates it to be a robust and reliable tool. Service Builder is easy to use and can save developers *lots* of development time. Although the number of files Service Builder generates can seem intimidating at first, developers only need to work with a few files in order to make customizations to their applications and add business logic.

Note: You don't have to use Service Builder for Liferay application development. It's entirely possible to develop Liferay plugins by writing custom code for database persistence using your persistence framework of choice. If you so choose, you can work directly with JPA or Hibernate.

One of the main ways Service Builder saves development time is by completely eliminating the need to write and maintain database access code. To generate a basic service layer, you only need to create a `service.xml` file and run Service Builder. This generates a new service `.jar` file for your project. The generated service `.jar` file includes a model layer, a persistence layer, a service layer, and related infrastructure. These distinct layers represent a healthy separation of concerns. The model layer is responsible for defining objects to represent your project's entities, the persistence layer is responsible for saving entities to and retrieving entities from the database, and the service layer is responsible for exposing CRUD and related methods for your entities as an API. The code Service Builder generates is database-agnostic, as is Liferay itself.

Each entity generated by Service Builder contains a model implementation class. Each entity also contains a local service implementation class, a remote service implementation class, or both, depending on how you configure Service Builder in your `service.xml` file. Customizations and business logic can be implemented in these three classes; in fact, these are the only classes generated by Service Builder that are intended to be customized. Ensuring that all customizations take place in only a few classes makes Service Builder projects easy to maintain. The local service implementation class is responsible for calling the persistence layer to retrieve and store data entities. Local services contain the business logic and access the persistence layer. They can be invoked by client code running in the same Java Virtual Machine. Remote services usually have additional code for permission checking and are meant to be accessible from anywhere over the Internet or your local network. Service Builder automatically generates the code necessary to allow access to the remote services. The remote services generated by Service Builder include SOAP utilities and can be accessed via SOAP or JSON.

Another way Service Builder saves development time is by providing Spring and Hibernate configurations for your project. Service Builder uses Spring dependency injection for making service implementation classes available at runtime and uses Spring AOP for database transaction management. Service Builder also uses the Hibernate persistence framework for object-relational mapping. As a convenience to developers, Service Builder hides the complexities of using these technologies. Developers can take advantage of Dependency Injection (DI), Aspect Oriented Programming (AOP), and Object-Relational Mapping (ORM) in their projects without having to manually set up a Spring or Hibernate environment or make any configurations.

Another benefit of using Service Builder is that it provides support for generating finder methods. Finder methods retrieve entity objects from the database based on specified parameters. You just need to specify the kinds of finder methods to be generated in the `service.xml` configuration file and Service Builder does the rest. The generated finder methods allow you, for example, to retrieve a list of all entities associated with a certain site or a list of all entities associated with a certain site *and* a certain user. Service Builder not only provides support for generating these kinds of simple finder methods but also for finder methods that take Liferay's permissions into account. For example, if you are using Liferay's permissions system to protect access to your entities, Service Builder can generate a different kind of finder method that only returns entities that the logged-in user has permission to view.

Service Builder also provides built-in caching support. Liferay caches objects at three levels: *entity*, *finder*, and *Hibernate*. By default, Liferay uses Ehcache as an underlying cache provider for each of these cache levels. However, this is configurable via portal properties. All you have to do to enable entity and finder caching for an entity in your project is to set the `cache-enabled=true` attribute of your entity's `<entity>` element in your `service.xml` configuration file. Please refer to the Distributed Caching documentation for more details about Liferay caching.

Service Builder is a flexible tool. It automates many of the common tasks associated with creating database persistence code but it doesn't prevent you from creating custom SQL queries or custom finder methods. Service Builder allows developers to define custom SQL queries in an XML file and to implement custom finder methods to run the queries. This could be useful, for example, for retrieving specific pieces of information from multiple tables via an SQL join. Service Builder also supports retrieving database information via dynamic query. Liferay's dynamic query API leverages Hibernate's criteria API.

In summary, we encourage developers to use Service Builder for portlet and plugin development because it's a proven solution used by many Liferay plugins and by Liferay Portal itself. It generates distinct model, persistence, and service layers, local and remote services, Spring and Hibernate configurations, and related infrastructure without requiring any manual intervention by developers. It also allows basic SQL queries and finder methods to be generated and ones that filter results, taking Liferay's permissions into account. Service Builder also provides support for entity and query caching. Each of these features can save lots of development time, both initial development time and time that would have to be spent maintaining, extending, or customizing a project. Finally, Service Builder is not a restrictive tool: it allows custom SQL queries and finder methods to be added and it also supports dynamic query.

Service Builder supports Liferay 7's modular application development style. When you configure Service Builder in a Liferay 7 OSGi module, this module functions as a *service* module and its a convention to append `service` to the module's name. Liferay includes a Service Builder plugin and a build tool-specific plugins such as the Gradle Service Builder plugin. The Gradle Service Builder plugins includes Liferay's Service Builder plugin as a dependency. The `basic-api`, `basic-service`, `basic-web` modules in the Service Builder Blade Sample project serve as example Service Builder projects.

Chapter 81

Service Builder Persistence

Liferay's Service Builder can generate your project's persistence layer by automating the creation of interfaces and classes. Your application's persistence layer persists data represented by your configured entities to a database. In fact, your local service implementation classes are responsible for calling the persistence layer to retrieve and store your application's data. So instead of taking the time-consuming route of writing your own persistence layer, you can use Liferay's Service Builder to quickly define your entities and generate the layer instantaneously.

In this section of tutorials, you'll learn how to define an object-relational map and generate your persistence layer from that map. You'll also learn about the local and remote services Service Builder generates, and how you can use them for your own application. You'll also discuss how to use the `ServiceContext` class, model hints, SQL queries, and Hibernate's criteria API.

81.1 Defining an Object-Relational Map with Service Builder

In this tutorial, you'll learn how to define an object relational map for your application so that it can persist data. As an example, you'll examine the existing Liferay Bookmarks application that uses Service Builder.

The Bookmarks application is an example portlet project that an organization can use to bookmark assets in Liferay. The application defines two entities, or model types, to represent an organization's bookmarks and their folders. These entities are called *bookmark entries* and *bookmark folders*. Since a bookmark must have a folder (even if it's a root folder), the entry entity references a folder entity as one of its attributes.

You can design your application's modules anyway you like, but for the Bookmarks application, its Java sources reside in the `bookmarks-api`, `bookmarks-service`, and `bookmarks-web` modules. Notice the `BookmarksAdminPortlet.java` and `BookmarksPortlet.java` files in the `com.liferay.bookmarks.web.portlet` package in the `bookmarks-web` module. These portlet classes extend Liferay's `MVCPortlet` class. They act as the controllers in the MVC pattern. These classes contain the business logic that invokes the Service Builder generated bookmarks services that you'll learn how to create in this section. The application's view layer is implemented in the JSPs in the `bookmarks-web/src/main/resources/META-INF/resources` folder.

You can learn how to generate a generic modular application from scratch that includes the `*api`, `*service`, and `*web` modules by default in the Modularizing an Existing Portlet tutorial. This tutorial assumes you've assembled your application's modules similarly to the linked tutorial above. Be sure to also visit the Fundamentals tutorial for additional info on the `*api`, `*service`, and `*web` modules.

The first step in using Service Builder is to define your model classes and their attributes in a `service.xml` file. This file's location typically resides in the root folder of the `*-service` module, although you can configure your build tool to recognize it from other directories. In Service Builder terminology, your model classes are called entities. For example, the Bookmarks application has two entities: `BookmarksEntry` and `BookmarksFolder`. The requirements for each of these entities are defined in the `bookmarks-service` module's service.xml listed in the `<column />` elements.

Once Service Builder reads the `service.xml` file, you can define your entities. Liferay @ide@ makes it very easy to define entities in your application's `service.xml` file. To define a custom entity, follow these steps:

1. Create the `service.xml` file in your project's `*-service` module. It resides in the root folder of that module, if one does not already exist there.

2. Define global information for the service.

3. Define service entities.

4. Define the columns (attributes) for each service entity.

5. Define relationships between entities.

6. Define a default order for the entity instances to be retrieved from the database.

7. Define finder methods that retrieve objects from the database based on specified parameters.

You'll examine these steps in detail next, starting with creating a `service.xml` file.

Step 1: Creating the service.xml File

To define a service for your portlet project, you must create a `service.xml` file. The DTD (Document Type Declaration) file http://www.liferay.com/dtd/liferay-service-builder_7_0_0.dtd specifies the format and requirements of the XML to use. You can create your `service.xml` file manually, following the DTD, or you can use Liferay @ide@. @ide@ helps you build the `service.xml` file piece-by-piece, taking the guesswork out of creating XML that adheres to the DTD.

If a default `service.xml` file already exists in your `*-service` module folder, check to see if it has an `<entity />` element named *Foo*. If it has the Foo entity, remove the entire `<entity name="Foo" ...> ... </entity>` element. The Liferay @ide@ project wizard creates the Foo entity as an example. It has no practical use for you.

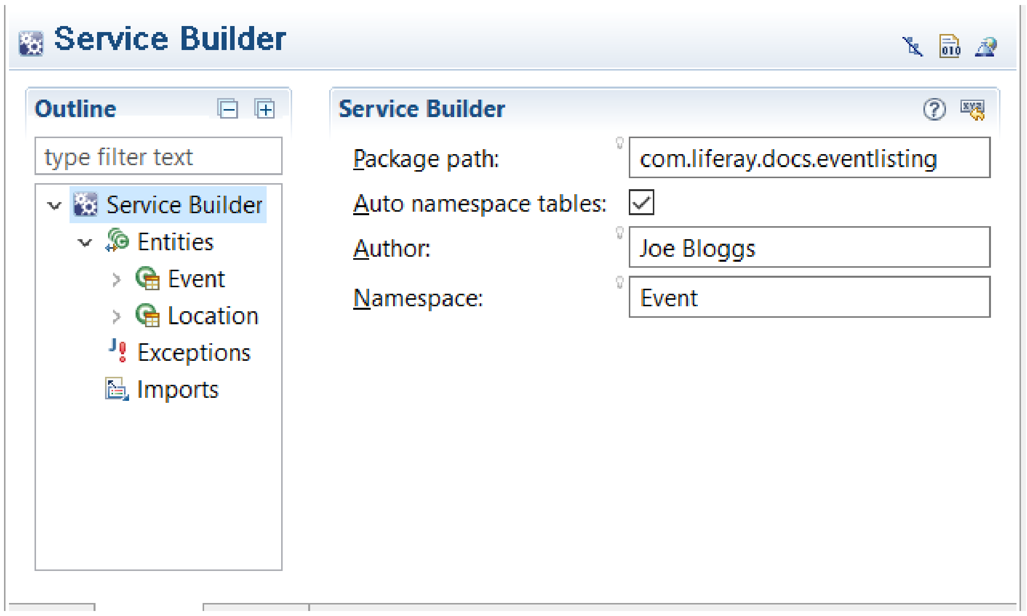
If you don't already have a `service.xml` file, create one in your `*-service` module. Once it's created, open it. Liferay @ide@ provides a Diagram mode and a Source mode to give you different perspectives of the service information in your `service.xml` file. Diagram mode is helpful for creating and visualizing relationships between service entities. Source mode brings up the `service.xml` file's raw XML content in the editor. You can switch between these modes as you wish.

Next, you can start filling out the global information for your service.

Step 2: Defining Global Service Information

A service's global information applies to all of its entities, so it's a good place to start. In Liferay @ide@, select the *Service Builder* node in the upper left corner of the Overview mode of your `service.xml` file. The main section of the view now shows the Service Builder form in which you can enter your service's global information. The fields include the service's package path, author, and namespace options.

The package path specifies the package in which the service and persistence classes are generated. The package path defined above ensures that the service classes are generated in the `com.liferay.docs.eventlisting` package in the `*-api` module. The persistence classes are generated



Package path: com.liferay.docs.eventlisting
Auto namespace tables: ✓
Author: Joe Bloggs
Namespace: Event

Figure 81.1: This is the Service Builder form from a fictitious Event Listing application's `service.xml`.

in a package of the same name in the `*-service` module. For examples, you can look in the Bookmarks application's bookmarks-api and bookmarks-service modules to see an example of how these are automatically generated for you. Refer to the Running Service Builder and Understanding the Generated Code tutorial for a description of the contents of these packages.

Service Builder uses the service namespace in naming the database tables it generates for the service. For example, *Event* could serve as the namespace for an Event Listing portlet service.

```
<namespace>Event</namespace>
```

Service Builder uses the namespace in the following SQL scripts it generates in your `src/main/resources/META-INF/sql` folder:

- `indexes.sql`
- `sequences.sql`
- `tables.sql`

Note: The folder location for holding your generated SQL scripts is configurable. For example, if you're using Ant can configure an argument in your `build.xml` similar to this:

```
 <arg value="service.sql.dir=${basedir}/../sql"/>
```

If you're using Gradle, you can define the `sqlDir` setting in the project's `build.gradle` file or Maven `pom.xml` file, the same way the `databaseNameMaxLength` setting is applied in the examples below.

Liferay DXP uses these scripts to create database tables for all the entities defined in the `service.xml` file. Service Builder prepends the namespace to the database table names. Since the namespace value above is `Event`, the names of the database tables created for the entities start with `Event_` as their prefix. The namespace for each Service Builder project must be unique. Separate plugins should use separate namespaces and should not use a namespace already used by Liferay (such as `Users` or `Groups`). Check the table names in Liferay's database if you're wondering which namespaces are already in use.

Warning: Use caution when assigning namespace values. Some databases have strong restrictions on database table and column name lengths. The Service Builder Gradle and Maven plugin parameter `databaseNameMaxLength` sets the maximum length you can use for your table and column names. Here are paraphrased examples of setting `databaseNameMaxLength` in build files:

Gradle `build.gradle`

```
buildService {
    ...
    databaseNameMaxLength = 64
    ...
}
```

Maven `pom.xml`

```
<configuration>
    ...
    <databaseNameMaxLength>64</databaseNameMaxLength>
    ...
</configuration>
```

As the last piece of global information, enter your name as the service's *author* in your `service.xml` file. Service Builder adds `@author` annotations with the specified name to all of the generated Java classes and interfaces. Save your `service.xml` file to preserve the information you added. Next, you'll add entities for your service's events and locations.

Step 3: Defining Service Entities

Entities are the heart and soul of a service. Entities represent the map between the model objects in Java and the fields and tables in your database. Once your entities are defined, Service Builder handles the mapping automatically, giving you a facility for taking Java objects and persisting them. For the Bookmarks application, two entities are created according to its service.xml –one for bookmark entries and one for bookmark folders.

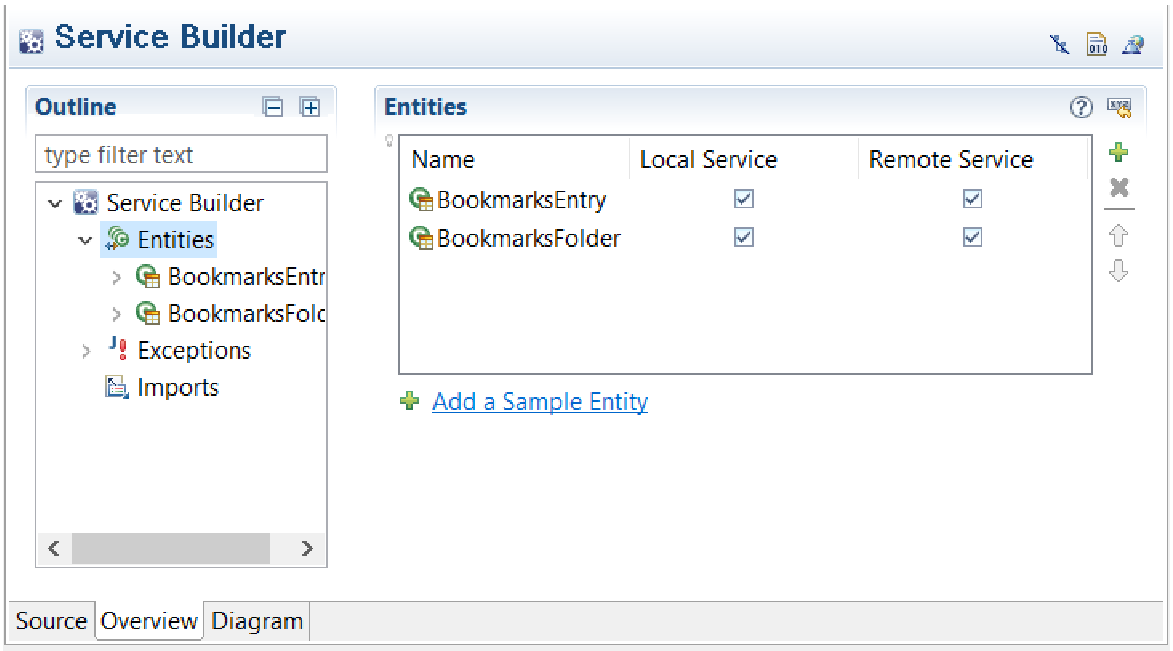
Here's a summary of the information used for the BookmarksEntry entity:

- **Name:** *BookmarksEntry*
- **Local service:** *yes*
- **Remote service:** *yes*

And here's what was used for the BookmarksFolder entity:

- **Name:** *BookmarksFolder*
- **Local service:** *yes*
- **Remote service:** *yes*

To create your entities using Liferay @ide@, select the *Entities* node under the Service Builder node in the outline on the left side of the `service.xml` editor in Overview mode. In the main part of the view, notice that the Entities table is empty. Create an entity by clicking on the *Add Entity* icon (✚) to the right of the table. Enter your entity's name and if you'd like to generate local and remote services for that entity. Add as many entities as you need.



Name	Local Service	Remote Service
BookmarksEntry	✓	✓
BookmarksFolder	✓	✓

Figure 81.2: Adding service entities is easy with Liferay @ide@'s *Overview* mode of your `service.xml` file.

An entity's name is used to name the database table for persisting instances of the entity. The actual name of the database table is prefixed with the namespace; the Bookmarks example creates one database table named `Bookmarks_BookmarksEntry` and another named `Bookmarks_BookmarksFolder`.

Setting the *local service* attribute to `true` instructs Service Builder to generate local interfaces for the entity's services. The default value for local service is `false`. Local services can only be invoked from the Liferay server on which they're deployed. Therefore, if your application will be deployed to Liferay, the service will be local from your Liferay server's point of view.

Setting the *remote service* attribute to `true` instructs Service Builder to generate remote interfaces for the service. The default value for remote service is `true`. You could build a fully-functional application without generating remote services. In that case, you could set local service to `true` and remote service to `false` for your entities. If, however, you want to enable remote access to your application's services, you should set both local service and remote service to `true`.

Tip: Suppose you have an existing DAO service for an entity built using some other framework such as JPA. You can set local service to `false` and remote service to `true` so that the methods of your remote `-Impl` class can call the methods of your existing DAO. This enables your entity to integrate with Liferay's permission-checking system and provides access to the web service APIs generated by Service Builder. This is a very handy, quite powerful, and often used feature of Liferay.

Now that you've seen how to create your application's entities, you'll learn how to describe their attributes using entity *columns*.

Step 4: Defining the Columns (Attributes) for Each Service Entity

Each entity is described by its columns, which represent an entity's attributes. These attributes map on the one side to fields in a table and on the other side to attributes of a Java object. To add attributes for your entity, you need to drill down to its columns in the Overview mode outline of the `service.xml` file. From the outline, expand the *Entities* node and expand an entity node. Then select the *Columns* node. Liferay @ide@ displays a table of the entity's columns.

Service Builder creates a database field for each column you add to the `service.xml` file. It maps a database field type appropriate to the Java type specified for each column, and it does this across all the databases Liferay supports. Once Service Builder runs, it generates a Hibernate configuration that handles the object-relational mapping. Service Builder automatically generates getter/setter methods in the model class for these attributes. The column's Name specifies the name used in the getters and setters that are created for the entity's Java field. The column's Type indicates the Java type of this field for the entity. If a column's Primary (i.e., primary key) attribute value is set to `true`, then the column becomes part of the primary key for the entity. An entity's primary key is a unique identifier for the entity. If only one column has Primary set to `true`, then that column represents the entire primary key for the entity. This is the case in the Event Listing example. However, it's possible to use multiple columns as the primary key for an entity. In this case, the combination of columns makes up a compound primary key for the entity.

Note: Each Service Builder generated `*LocalServiceImpl` class has a `CounterLocalService` field for generating unique entity instance primary keys. For details, see Creating Local Services.

Note: On deploying a `*service` module, Service Builder automatically generates indexes for all entity primary keys.

Similar to the way you used the form table for adding entities, add attribute columns for each of your entities. Create each attribute by clicking on the Add icon (➕). Then fill in the name of the attribute, select its type, and specify whether it is a primary key for the entity. While your cursor is in a column's *Type* field, an option icon appears. Click this icon to select the appropriate type for the column. Create a column for each attribute of your entity or entities.

In addition to columns for your entity's primary key and attributes, it's recommended to add columns for portal instance ID and site ID. They allow your portlet to support the multi-tenancy features of Liferay, so that each portal instance and each site in a portal instance can have independent sets of portlet data. To hold the site's ID, add a column called `groupId` of type `long`. To hold the portal instance's ID, add a column called `companyId` of type `long`. If you'd like to add these columns to your entities, follow the table below.

Portal and site scope columns

Name	Type	Primary
`companyId`	long	no
`groupId`	long	no

You'll also want to know who owns each entity instance. To keep track of that, add a column called `userId` of type `long`.

User column

Name	Type	Primary
`userId`	long	no

Lastly, you can add columns to help audit your entities. For example, you could create a column named `createDate` of type `Date` to note the date an entity instance was created. And add a column named `modifiedDate` of type `Date` to track the last time an entity instance was modified.

Audit columns

Name	Type	Primary
`userId`	long	no
`createDate`	Date	no
`modifiedDate`	Date	no

Great! Your entities are set with the columns that not only represent their attributes, but also support multi-tenancy and entity auditing. Next, you'll learn how to specify the relationship service entities.

Step 5: Defining Relationships Between Service Entities

Often you'll want to reference one type of entity in the context of another entity. That is, you'll want to *relate* the entities. Liferay's Bookmarks application defines a relationship between an entry and its folder.

As mentioned earlier, each bookmark must have a folder. Therefore, each `BookmarksEntry` entity must relate to a `BookmarksFolder` entity. Liferay @ide@'s Diagram mode for `service.xml` makes relating entities easy. First, select Diagram mode for the `service.xml` file. Then select the *Relationship* option under *Connections* in the palette on the right side of the view. This relationship tool helps you draw relationships between entities in the diagram. Click your first entity and move your cursor over to the entity you'd like to relate it with. Liferay @ide@ draws a dashed line from your selected entity to the cursor. Click the second entity to complete drawing the relationship. Liferay IDE turns the dashed line into a solid line, with an arrow pointing to the second entity. Save the `service.xml` file.

Congratulations! You've related two entities. Their relationship should show in Diagram mode and look similar to that of the figure below.

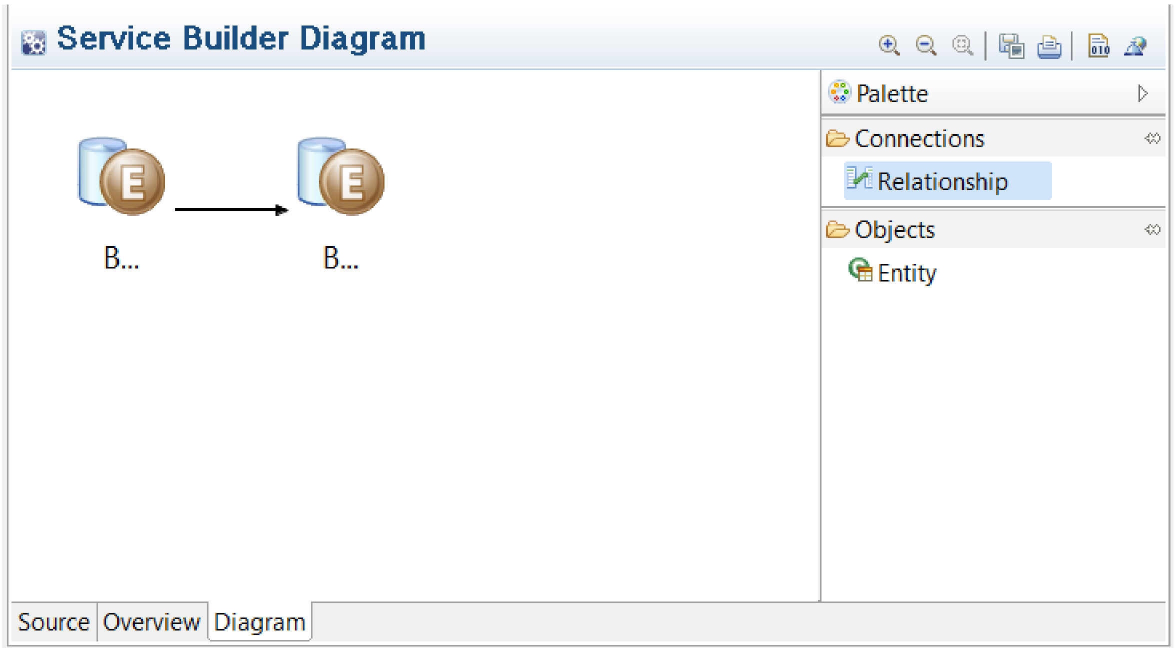


Figure 81.3: Relating entities is a snap in Liferay @ide@'s *Diagram* mode for `service.xml`.

Switch to *Source* mode in the editor for your `service.xml` file and note that Liferay @ide@ created a column element in the first selected entity to hold the ID of the corresponding entity instance reference. For example:

```
<column name="folderId" type="long" />
```

Now that your entity columns are in place, you can specify the default order in which the entity instances are retrieved from the database.

Step 6: Defining Ordering of Service Entity Instances

Often, you want to retrieve multiple instances of a given entity and list them in a particular order. Liferay lets you specify the default order of the entities in your `service.xml` file.

Suppose you want to return `BookmarksEntry` entities alphabetically by name. It's easy to specify these default orderings using Liferay @ide@. Switch back to *Overview* mode in the editor for your `service.xml` file. Then select the *Order* node under the entity node in the outline on the left side of the view. The IDE displays a form for ordering the chosen entity. Check the *Specify ordering* checkbox to show the form for specifying the ordering. Create an order column by clicking the *Add* icon ( ) to the right of the table. Enter the column name (e.g., *name*, *date*, etc.) to use in ordering the entity. Click the *Browse icon* ( ) to the right of the *By* field and choose the *asc* or *desc* option. This orders the entity in ascending or descending order.

Now that you know how to order your service entities, the last thing to do is to define the finder methods for retrieving entity instances from the database.

Step 7: Defining Service Entity Finder Methods

Finder methods retrieve entity objects from the database based on specified parameters. You'll probably want to create at least one finder method for each entity you create in your services. Service Builder generates several methods based on each finder you create for an entity. It creates methods to fetch, find, remove, and count entity instances based on the finder's parameters.

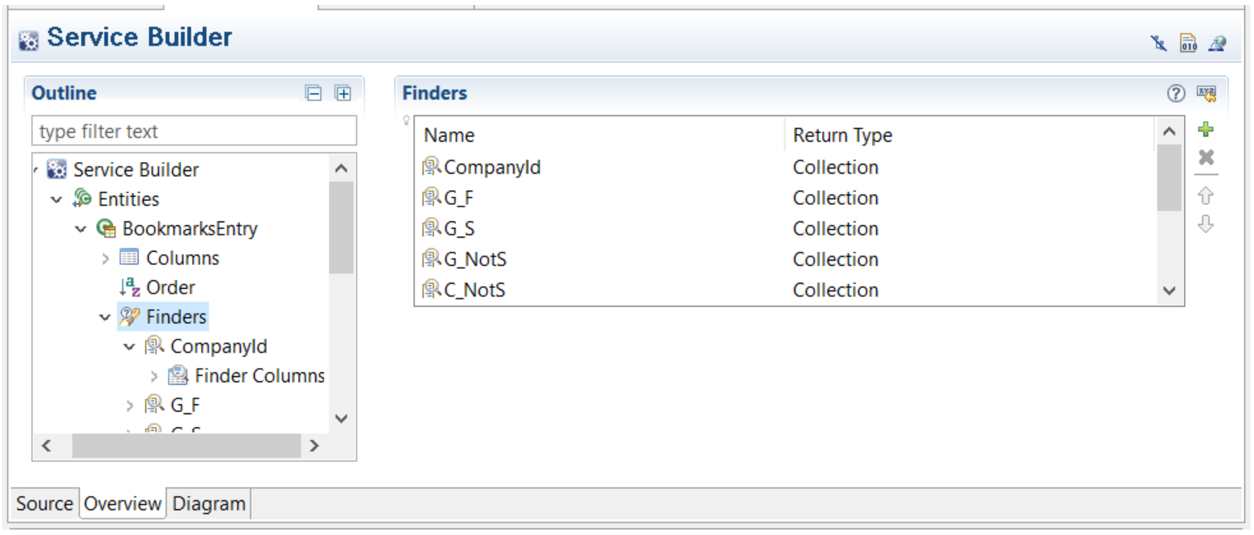
For many applications, it's important to be able to find its entities per site. You can specify these finders using Liferay @ide@'s Overview mode of `service.xml`. Select the *Finders* node under the entity node in the Outline on the left side of the screen. The IDE displays an empty *Finders* table in the main part of the view. Create a new finder by clicking the *Add* icon ( ) to the right of the table. Give your finder a name and return type. Use the Java camel-case naming convention when naming finders since the finder's name is used to name the methods that Service Builder creates. The IDE creates a new finder sub-node under the *Finders* node in the outline. Next, you'll learn how to specify the finder column for this node.

Important: DO NOT create finders that use entity primary key as parameters. They're unnecessary as Service Builder automatically generates `findByPrimaryKey` and `fetchByPrimaryKey` methods for all entity primary keys. On deploying a `*service` module, Service Builder creates indexes for all entity primary key columns and finder columns. Adding finders that use entity primary keys results in attempts to create multiple indexes for the same columns—Oracle DB, for example, reports these attempts as errors.

Under the new finder node, the IDE created a *Finder Columns* node. Select the *Finder Columns* node to specify the columns for your finder's parameters. Create a new finder column by clicking the *Add* icon and specifying the column's name. Keep in mind that you can specify multiple parameters (columns) for a finder.

If you're creating site-scoped entities (entities whose data should be unique to each site), you should follow the steps described above to create finders by `groupId` for retrieving your entities. Remember to save your `service.xml` file after editing it to preserve the finders you define.

When you run Service Builder, it generates finder-related methods (e.g., `fetchByGroupId`, `findByGroupId`, `removeByGroupId`, `countByGroupId`) for the your entities in the `*Persistence` and `*PersistenceImpl` classes.



Name	Return Type
CompanyId	Collection
G_F	Collection
G_S	Collection
G_NotS	Collection
C_NotS	Collection

Figure 81.4: Creating Finder entities is easy with Liferay @ide@.

The first of these classes is the interface; the second is its implementation. For example, Liferay's Bookmarks application generates its entity finder methods in the `-Persistence` classes found in the `/bookmarks-api/src/main/java/com/liferay/bookmarks/service/persistence` folder and the `-PersistenceImpl` classes in the `/bookmarks-service/src/main/java/com/liferay/bookmarks/service/persistence/impl` folder.

Now you know to configure Service Builder to create finder methods for your entity. Terrific!

Now that you've specified the service for your project, you're ready to *build* the service by running Service Builder. To learn how to run Service Builder and to learn about the code that Service Builder generates, please refer to the Running Service Builder and Understanding the Generated Code tutorial.

Running Service Builder and Understanding the Generated Code

81.2 Running Service Builder and Understanding the Generated Code

This tutorial explains how to run Service Builder and provides an overview of the code that Service Builder generates. If you'd like to use Service Builder in your application but haven't yet created a `service.xml` file, visit the Defining an Object-Relational Map with Service Builder tutorial and then come back to this one.

Running Service Builder

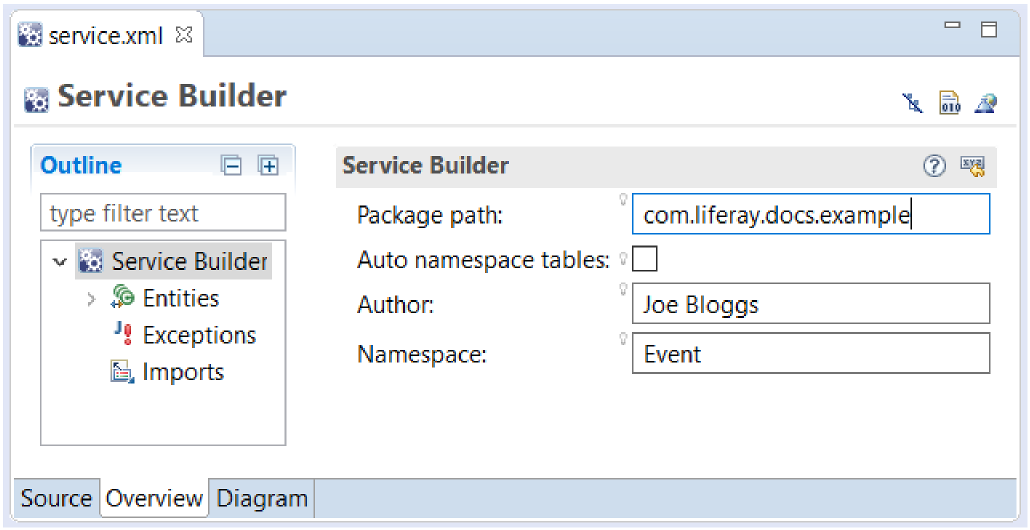
To build a service from a `service.xml` file, you can use Liferay @ide@ or a terminal window. In this tutorial, you'll refer to the Event Listing example project that's referenced throughout the Liferay Service Builder tutorials.

Now let's learn how to run Service Builder.

Using Liferay @ide@

From the Package Explorer, open the `service.xml` file from your `*-service` module's root folder. By default, the file opens up in the Service Builder Editor. Make sure you are in Overview mode. Then click the *Build Services* button ( ) near the top-right corner of the view.

Make sure to click the *Build Services* button and not the *Build WSDD* button ( ) that appears next to it. Building the WSDDs won't hurt anything, but you'll generate files for the remote service instead of the local one. For information about WSDDs (web service deployment descriptors), please refer to the SOAP Web Services tutorial.



Service Builder

Package path: com.liferay.docs.example

Auto namespace tables: ☐

Author: Joe Bloggs

Namespace: Event

Figure 81.5: The *Overview* mode in the editor provides a nested outline which you can expand, a form for editing basic Service Builder attributes, and buttons for building services or building web service deployment descriptors.

Another simple way to run Service Builder is to right-click on your project's name in the Package Explorer and then select *Liferay* → *build-service*.

After running Service Builder, your generated files are available. More information about the generated files appears below.

Using the Terminal

Open a terminal window and navigate to your module project's root folder, which should be located in your Liferay Workspace's `modules` directory. To learn more about creating your module project in a Liferay Workspace, visit the Creating Modules with Blade CLI tutorial. You can leverage the Service Builder Template to create your own predefined Service Builder project.

Liferay Workspace offers a Gradle or Maven build environment; this tutorial shows how to use both. Liferay is tool agnostic, however, and you can use other tools, as well.

For Gradle projects, enter the following command in your module project's root folder to build your services:

```
gradlew buildService
```

Note: Liferay Workspaces provide the Gradle Wrapper script for usage, if you don't have Gradle installed globally in your classpath. It is located in the workspace's root folder, so you can call it from your module project's root folder, if necessary (e.g., `../../gradlew buildService`).

If your module project uses Maven, you can build services running the following command from the module project's root folder:

```
mvn service-builder:build
```

Important: The `mvn service-builder:build` command only works if you're using the `com.liferay.portal.tools.service.bu`
plugin version 1.0.145+. Maven projects using an earlier version of the Service Builder plugin should update their POM accordingly. See the Using Service Builder in a Maven Project tutorial for more information on using Maven to run Service Builder.

When the service has been successfully generated, a `BUILD SUCCESSFUL` message appears in your terminal window. You should also see that a large number of files have been generated in your project. These files include a model layer, service layer, and persistence layer. Don't worry about the number of generated files–you'll never have to customize more than three of them. To review the code that Service Builder generates for your entities, see the next section.

Understanding the Code Generated by Service Builder

Now you'll examine the files Service Builder generated for your entity. Note that the files listed under Local Service and Remote Service below are only generated for an entity that has both `local-service` and `remote-service` attributes set to `true`. Service Builder generates services for these entities in two locations in your project. These locations use the package path that you specified in your `service.xml` file. For Liferay's Bookmarks application, for example, these two locations are the following ones:

- `/bookmarks-api/src/main/java/com/liferay/bookmarks`
- `/bookmarks-service/src/main/java/com/liferay/bookmarks`

The `bookmarks-api` module contains the API for the Bookmarks project. All the classes and interfaces in the `*-api` module are packaged in a `.jar` file called `PROJECT_NAME-api.jar` in the module's `build/libs` folder. This `.jar` file is generated whenever you compile and deploy your module. When deploying this JAR to Liferay, the necessary interfaces to *define* the service API are available.

The `bookmarks-service` module contains the implementation of the interfaces defined in the `bookmarks-api` module. These interfaces provide OSGi services for the portal instance to which your application is deployed. Service Builder generates classes and interfaces belonging to the persistence layer, service layer, and model layer in the `/bookmarks-api/src/main/java/com/liferay/bookmarks` and `/bookmarks-service/src/main/java/com/liferay/bookmarks` packages.

Now you'll look at the classes and interfaces generated for the entities you specified. Each entity has similar classes generated for it, depending on what you specfied for them in the `service.xml`. You won't have to customize more than three classes for each entity. These customizable classes are `*LocalServiceImpl`, `*ServiceImpl`, and `*Impl`.

- Persistence

    - `[ENTITY_NAME]Persistence`: Persistence interface that defines CRUD methods for the entity such as `create`, `remove`, `countAll`, `find`, `findAll`, etc.
    - `[ENTITY_NAME]PersistenceImpl`: Persistence implementation class that implements `[ENTITY_NAME]Persistence`.

  - `[ENTITY_NAME]Util`: Persistence utility class that wraps `[ENTITY_NAME]PersistenceImpl` and provides direct access to the database for CRUD operations. This utility should only be used by the service layer; in your portlet classes, use `[ENTITY_NAME]LocalServiceUtil` or `[ENTITY_NAME]ServiceUtil` instead.

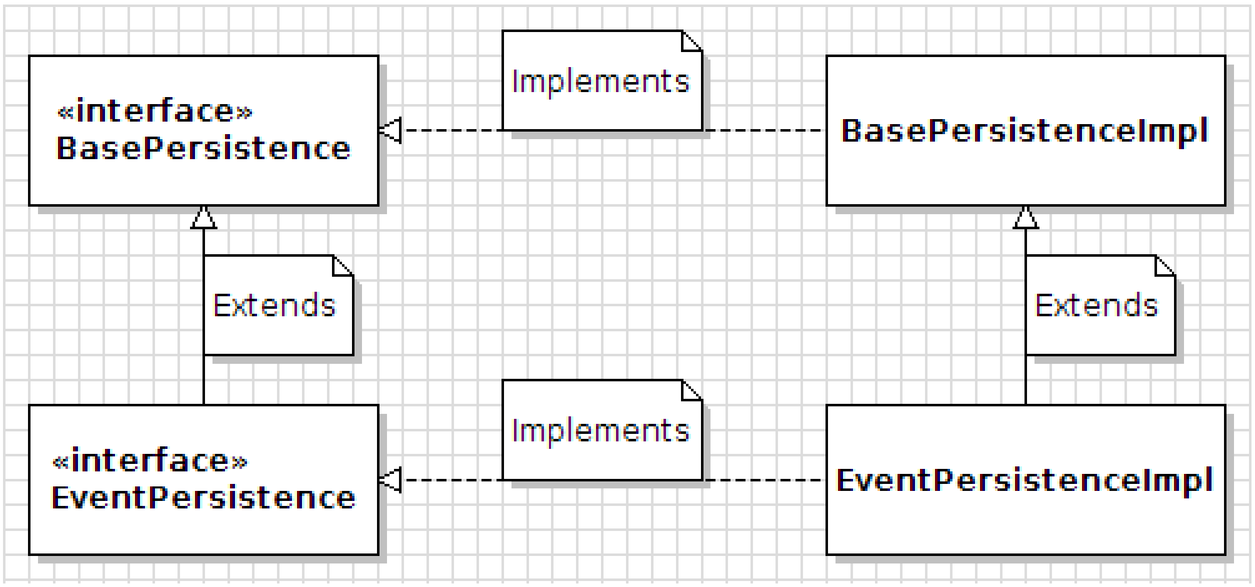


Figure 81.6: Service Builder generates these persistence classes and interfaces. You shouldn't (and you won't need to) customize any of these classes or interfaces.

- Local Service (generated for an entity only if an entity's `local-service` attribute is set to `true` in `service.xml`)

  - `[ENTITY_NAME]LocalService`: Local service interface.
  - `[ENTITY_NAME]LocalServiceImpl` (**LOCAL SERVICE IMPLEMENTATION**): Local service implementation. This is the only class in the local service that you should modify manually. You can add custom business logic here. For any custom methods added here, Service Builder adds corresponding methods to the `[ENTITY_NAME]LocalService` interface the next time you run it.
  - `[ENTITY_NAME]LocalServiceBaseImpl`: Local service base implementation. This is an abstract class. Service Builder injects a number of instances of various service and persistence classes into this class. `@abstract`
  - `[ENTITY_NAME]LocalServiceUtil`: Local service utility class which wraps `[ENTITY_NAME]LocalServiceImpl` and serves as the primary local access point to the service layer.
  - `[ENTITY_NAME]LocalServiceWrapper`: Local service wrapper which implements `[ENTITY_NAME]LocalService`. This class is designed to be extended and it allows developers to customize the entity's local services.

- Remote Service (generated for an entity only if an entity's `remote-service` attribute is *not* set to `false` in `service.xml`)

  - `[ENTITY_NAME]Service`: Remote service interface.
  - `[ENTITY_NAME]ServiceImpl` (**REMOTE SERVICE IMPLEMENTATION**): Remote service implementation. This is the only class in the remote service that you should modify manually.

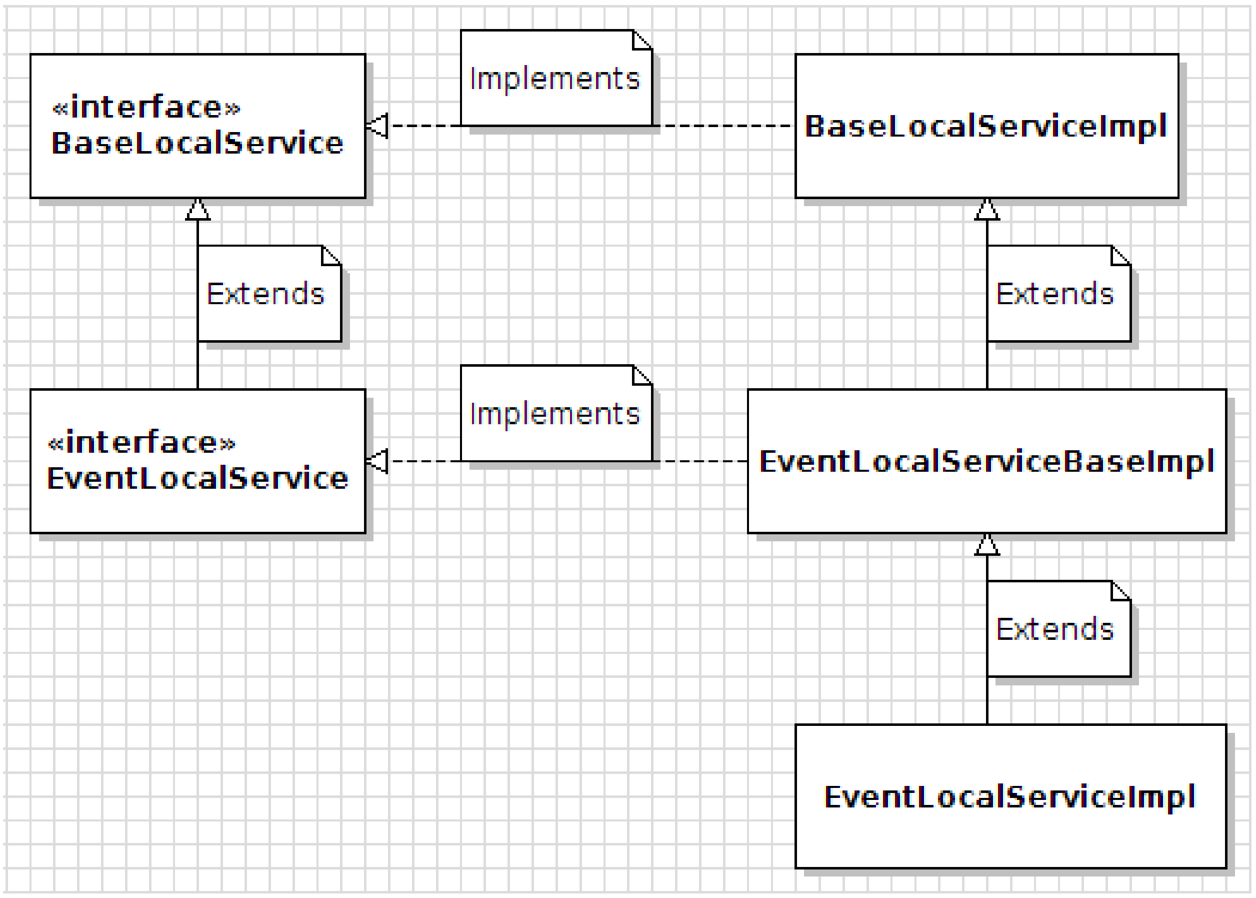

Figure 81.7: Service Builder generates these service classes and interfaces. Only EventLocalServiceImpl allows custom methods to be added to the service layer.

Here, you can write code that adds additional security checks and invokes the local services. For any custom methods added here, Service Builder adds corresponding methods to the `[ENTITY_NAME]Service` interface the next time you run it.

- `[ENTITY_NAME]ServiceBaseImpl`: Remote service base implementation. This is an abstract class. `@abstract`
- `[ENTITY_NAME]ServiceUtil`: Remote service utility class which wraps `[ENTITY_NAME]ServiceImpl` and serves as the primary remote access point to the service layer.
- `[ENTITY_NAME]ServiceWrapper`: Remote service wrapper which implements `[ENTITY_NAME]Service`. This class is designed to be extended and it allows developers to customize the remote entity's services.
- `[ENTITY_NAME]ServiceSoap`: SOAP utility which the remote `[ENTITY_NAME]ServiceUtil` remote service utility can access.
- `[ENTITY_NAME]Soap`: SOAP model, similar to `[ENTITY_NAME]ModelImpl`. `[ENTITY_NAME]Soap` is serializable; it does not implement `[ENTITY_NAME]`.

• Model

- `[ENTITY_NAME]Model`: Base model interface. This interface and its `[ENTITY_NAME]ModelImpl` implementation serve only as a container for the default property accessors generated by Service Builder. Any helper methods and all application logic should be added to `[ENTITY_NAME]Impl`.

- `[ENTITY_NAME]ModelImpl`: Base model implementation.
- `[ENTITY_NAME]`: [ENTITY_NAME] model interface which extends `[ENTITY_NAME]Model`.
- `[ENTITY_NAME]Impl`: (**MODEL IMPLEMENTATION**) Model implementation. You can use this class to add helper methods and application logic to your model. If you don't add any helper methods or application logic, only the auto-generated field getters and setters are available. Whenever you add custom methods to this class, Service Builder adds corresponding methods to the `[ENTITY_NAME]` interface the next time you run it.
- `[ENTITY_NAME]Wrapper`: Wrapper, wraps `[ENTITY_NAME]`.

Note: `*Util` classes are generated for backwards compatibility purposes only. Your module applications should avoid calling the util classes.

Each file that Service Builder generates is assembled from an associated FreeMarker template. You can find Service Builder's FreeMarker templates in the portal-tools-service-builder module. For example, if you want to find out how a `*ServiceImpl.java` file is generated, just look at the service_impl.ftl template.

Of all the classes generated by Service Builder, only three should be manually modified: `*LocalServiceImpl`, `*ServiceImpl` and `*Impl`. If you manually modify the other classes, your changes are overwritten the next time you run Service Builder. Whenever you add methods to, remove methods from, or change a method signature of a `*LocalServiceImpl` class, `*ServiceImpl` class, or `*Impl` class, you should run Service Builder again to regenerate the affected interfaces and the service JAR.

Congratulations! You've generated your application's initial model, persistence, and service layers and you understand the generated code.

Understanding Service Context

Creating Local Services

81.3 Iterative Development

During the course of development, you're likely to need to add fields to your database. This is a normal process of iterative development: you get an idea for a new feature, or it's suggested to you, and that feature requires additional data in the database. It's important to note, then, that **new fields added to `service.xml` are not automatically added to the database.** To add the fields, you must do one of two things:

1. Write an upgrade process to modify the tables and preserve the data, or

2. Run the `cleanServiceBuilder` Gradle task (also supported on Maven and Ant), which drops your tables so they get re-created the next time your app is deployed. See the Maven DB Support Plugin reference article for instructions on how to run this command from a Maven project.

Use the first option when you have a released application and you must preserve your users' data. Use the second option when you're in the middle of development and you're adding new columns during that process.

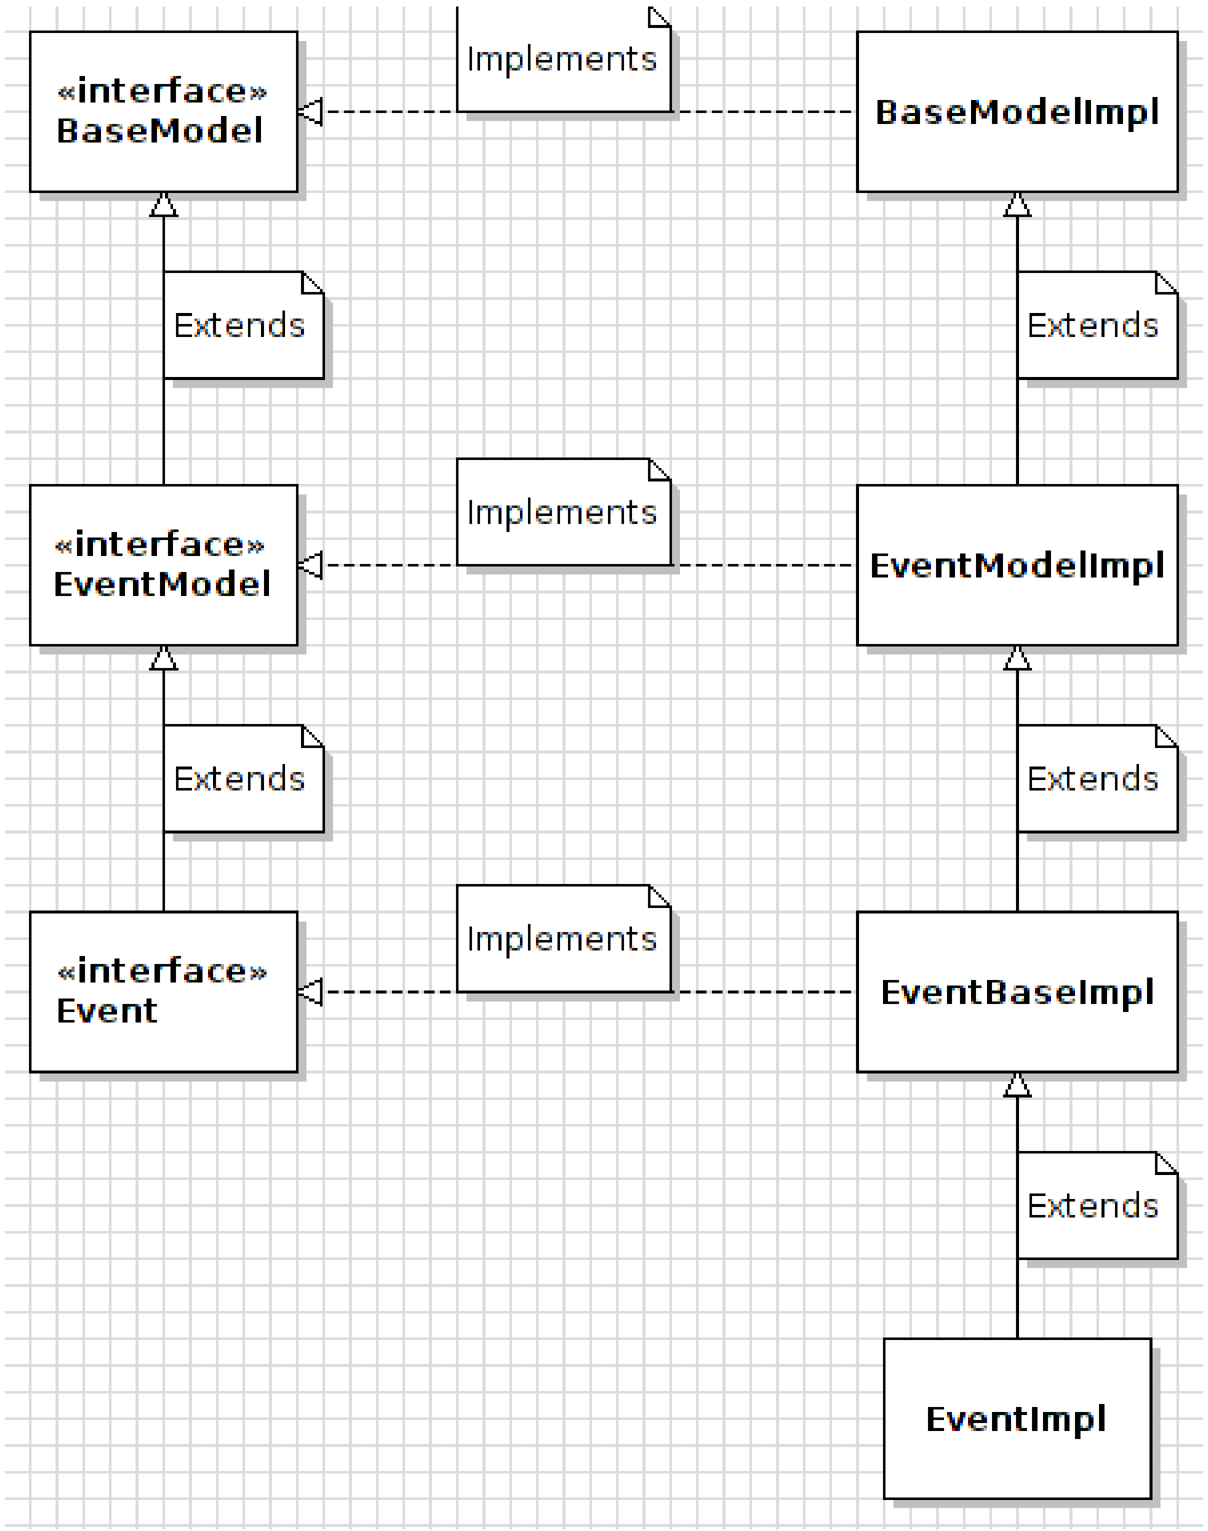

Figure 81.8: Service Builder generates these model classes and interfaces. Only `EventImpl` allows custom methods to be added to the service layer.

81.4 Understanding ServiceContext

The `ServiceContext` class is a parameter class used for passing contextual information for a service. Using a parameter class lets you consolidate many different methods with different sets of optional parameters into a single, easier-to-use method. The class also aggregates information necessary for features used throughout Liferay's core portlets, such as permissions, tagging, categorization, and more.

In this section, you'll examine the Service Context fields, learn how to create and populate a Service Context, and learn to access Service Context data. First, you'll look at the fields of the `ServiceContext` class.

Service Context Fields

The `ServiceContext` class has many fields. The best field descriptions are found in the Javadoc: @platform-ref@/7.0-latest/javadocs/portal-kernel/com/liferay/portal/kernel/service/ServiceContext.html. Here, you can review a categorical listing of the fields:

- Actions:
    - `_command`
    - `_workflowAction`
- Attributes:
    - `_attributes`
    - `_expandoBridgeAttributes`
- Classification:
    - `_assetCategoryIds`
    - `_assetTagNames`
- Exception
    - `_failOnPortalException`
- IDs and Scope:
    - `_companyId`
    - `_portletPreferencesIds`
    - `_plid`
    - `_scopeGroupId`
    - `_userId`
    - `_uuid`
- Language:

    - `_languageId`

- Miscellaneous:
    - `_headers`
    - `_signedIn`
- Permissions:
    - `_addGroupPermissions`
    - `_addGuestPermissions`
    - `_deriveDefaultPermissions`
    - `_modelPermissions`
- Request
    - `_request`
- Resources:
    - `_assetEntryVisible`
    - `_assetLinkEntryIds`
    - `_assetPriority`
    - `_createDate`
    - `_formDate`
    - `_indexingEnabled`
    - `_modifiedDate`
    - `_timeZone`
- URLs, paths and addresses:
    - `_currentURL`
    - `_layoutFullURL`
    - `_layoutURL`
    - `_pathMain`
    - `_pathFriendlyURLPrivateGroup`
    - `_pathFriendlyURLPrivateUser`
    - `_pathFriendlyURLPublic`
    - `_portalURL`
    - `_remoteAddr`
    - `_remoteHost`
    - `_userDisplayURL`

Are you wondering how the `ServiceContext` fields get populated? Good! You'll learn about that next.

Creating and Populating a Service Context

Although all the ServiceContext class fields are optional, services that store any kind of scopeable data need to at least specify the scope group ID. Here's a simple example of creating a ServiceContext instance and passing it as a parameter to a Liferay service API using Java:

```
ServiceContext serviceContext = new ServiceContext();
serviceContext.setScopeGroupId(myGroupId);

...

_blogsEntryService.addEntry(..., serviceContext);
```

If you invoke the service from a servlet, a Struts action, or any other front-end end class which has access to the PortletRequest, use one of the ServiceContextFactory.getInstance(...) methods. These methods create a ServiceContext object from the request and automatically populate its fields with all the values specified in the request. The above example looks different if you invoke the service from a servlet:

```
ServiceContext serviceContext =
    ServiceContextFactory.getInstance(BlogsEntry.class.getName(), portletRequest);

...

_blogsEntryService.addEntry(..., serviceContext);
```

You can see an example of populating a ServiceContext with information from a request object in the code of the ServiceContextFactory.getInstance(...) methods. The methods demonstrate how to set parameters like *scope group ID*, *company ID*, *language ID*, and more. They also demonstrate how to access and populate more complex context parameters like *tags*, *categories*, *asset links*, *headers*, and the *attributes* parameter. By calling ServiceContextFactory.getInstance(String className, PortletRequest portletRequest), you can assure that your Expando bridge attributes are set on the ServiceContext. Expandos are the back-end implementation of custom fields for entities in Liferay.

Creating and Populating a Service Context in JavaScript

Liferay's API can be invoked in languages other than Java. Some methods of Liferay's API require or allow a ServiceContext parameter. If you're invoking such a method via Liferay's JSON web services, you might want to create and populate a ServiceContext object in JavaScript. Creating a ServiceContext object in JavaScript is no different from creating any other object in JavaScript.

Before examining a JSON web service invocation that uses a ServiceContext object, it helps to see a simple JSON web service example in JavaScript:

```
Liferay.Service(
    '/user/get-user-by-email-address`,
    {
        companyId: Liferay.ThemeDisplay.getCompanyId(),
        emailAddress: 'test@example.com`
    },
    function(obj) {
        console.log(obj);
    }
);
```

If you run this code, the *test@example.com* user (JSON object) is logged to the JavaScript console.

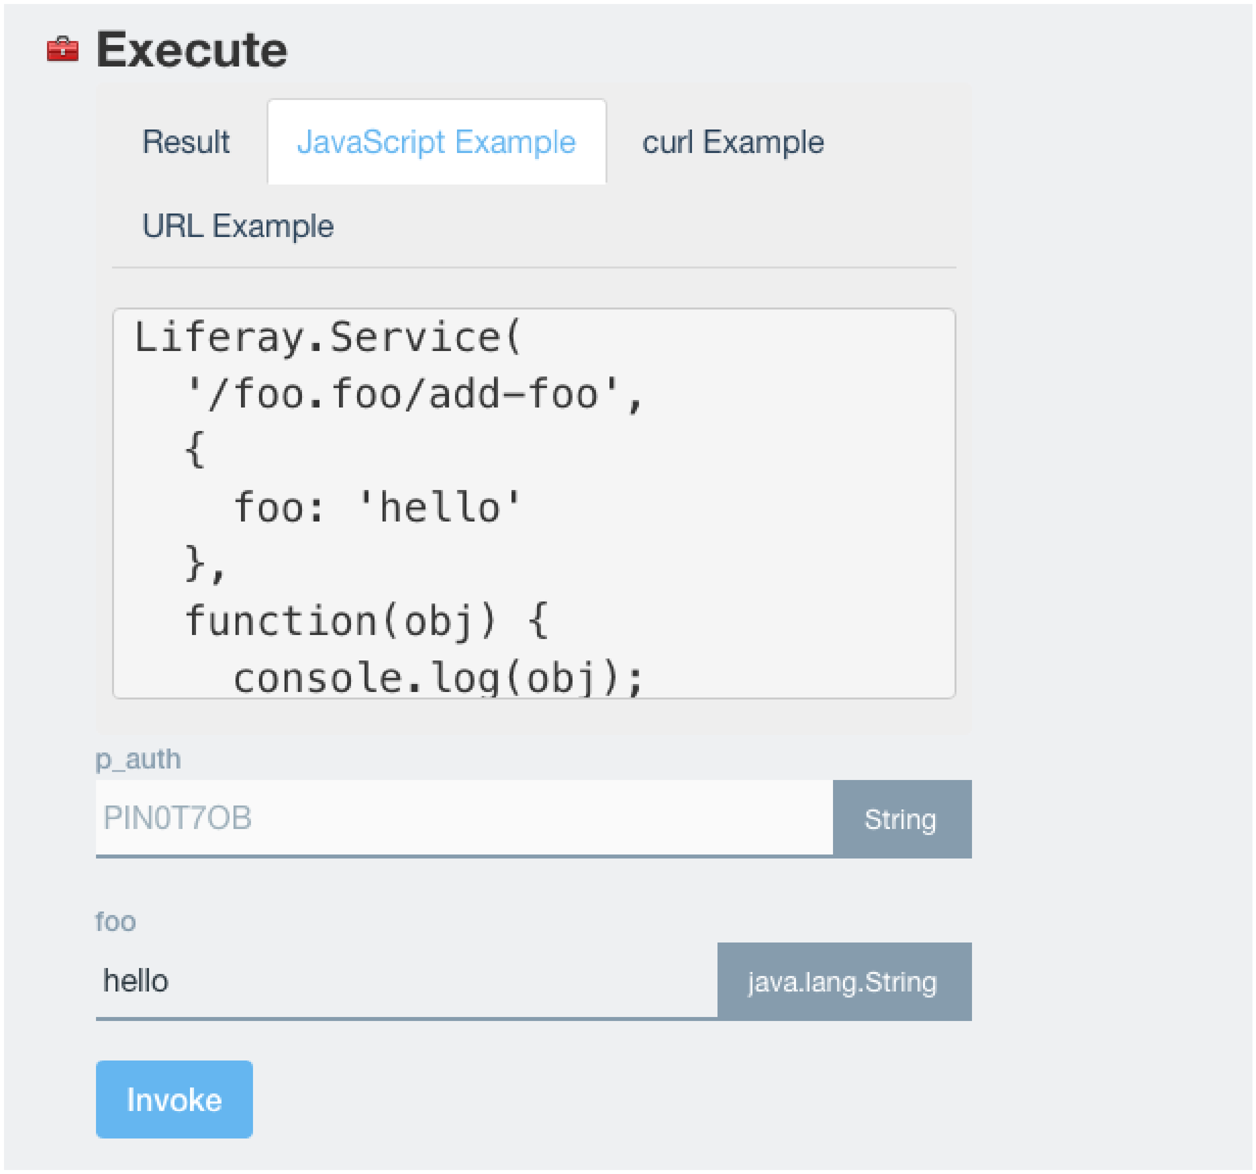
The Liferay.Service(...) function takes three arguments:

1. A string representing the service being invoked

2. A parameters object
3. A callback function

The callback function takes the result of the service invocation as an argument.

The Liferay JSON web services page (its URL is localhost:8080/api/jsonws if you're running Liferay locally on port 8080) generates example code for invoking web services. To see the generated code for a particular service, click on the name of the service, enter the required parameters, and click *Invoke*. The JSON result of your service invocation appears. There are multiple ways to invoke Liferay's JSON web services: click on *JavaScript Example* to see how to invoke the web service via JavaScript, click on *curl Example* to see how to invoke the web service via curl, or click on *URL example* to see how to invoke the web service via a URL.



```
Liferay.Service(
  '/foo.foo/add-foo',
  {
    foo: 'hello'
  },
  function(obj) {
    console.log(obj);
```

Figure 81.9: When you invoke a service from Liferay's JSON web services page, you can view the result of your service invocation as well as example code for invoking the service via JavaScript, curl, or URL.

To learn more about Liferay's JSON web services, see the JSON Web Services tutorial.

Next, you'll learn how to access information from a ServiceContext object.

Accessing Service Context Data

In this section, you'll find code snippets from BlogsEntryLocalServiceImpl.addEntry(..., ServiceContext). This code demonstrates how to access information from a ServiceContext and provides an example of how the context information can be used.

As mentioned above, services for scopeable entities need to get a scope group ID from the ServiceContext object. This is true for the Blogs entry service because the scope group ID provides the scope of the Blogs entry (the entity being persisted). For the Blogs entry, the scope group ID is used in the following way:

- It's used as the groupId for the BlogsEntry entity.
- It's used to generate a unique URL for the blog entry.
- It's used to set the scope for comments on the blog entry.

Here are the corresponding code snippets:

```
long groupId = serviceContext.getScopeGroupId();

...

entry.setGroupId(groupId);

...

entry.setUrlTitle(getUniqueUrlTitle(entryId, groupId, title));

...

// Message boards

if (PropsValues.BLOGS_ENTRY_COMMENTS_ENABLED) {
    mbMessageLocalService.addDiscussionMessage(
        userId, entry.getUserName(), groupId,
        BlogsEntry.class.getName(), entryId,
        WorkflowConstants.ACTION_PUBLISH);
}
```

Can ServiceContext be used to access the UUID of the blog entry? Absolutely! Can you use ServiceContext to set the time the blog entry was added? You sure can. See here:

```
entry.setUuid(serviceContext.getUuid());
...
entry.setCreateDate(serviceContext.getCreateDate(now));
```

Can ServiceContext be used in setting permissions on resources? You bet! When adding a blog entry, you can add new permissions or apply existing permissions for the entry, like this:

```
// Resources

if (serviceContext.isAddGroupPermissions() ||
    serviceContext.isAddGuestPermissions()) {

    addEntryResources(
        entry, serviceContext.isAddGroupPermissions(),
        serviceContext.isAddGuestPermissions());
}
else {
    addEntryResources(
        entry, serviceContext.getGroupPermissions(),
        serviceContext.getGuestPermissions());
}
```

ServiceContext helps apply categories, tag names, and the link entry IDs to asset entries too. Asset links are the back-end term for related assets in Liferay.

```
// Asset

updateAsset(
    userId, entry, serviceContext.getAssetCategoryIds(),
    serviceContext.getAssetTagNames(),
    serviceContext.getAssetLinkEntryIds());
```

Does ServiceContext also play a role in starting a workflow instance for the blogs entry? Must you ask?

```
// Workflow

if ((trackbacks ≠ null) && (trackbacks.length > 0)) {
    serviceContext.setAttribute("trackbacks", trackbacks);
}
else {
    serviceContext.setAttribute("trackbacks", null);
}

_workflowHandlerRegistry.startWorkflowInstance(
    user.getCompanyId(), groupId, userId, BlogsEntry.class.getName(),
    entry.getEntryId(), entry, serviceContext);
```

The snippet above also demonstrates the trackbacks attribute, a standard attribute for the blogs entry service. There may be cases where you need to pass in custom attributes to your blogs entry service. Use Expando attributes to carry custom attributes along in your ServiceContext. Expando attributes are set on the added blogs entry like this:

```
entry.setExpandoBridgeAttributes(serviceContext);
```

You can see that the ServiceContext can be used to transfer lots of useful information for your services. Understanding how ServiceContext is used in Liferay helps you determine when and how to use ServiceContext in your own Liferay application development.

81.5 Customizing Model Entities With Model Hints

If you've already used Service Builder to define your model entities and have implemented business logic for creating and modifying those entities, you might have some ideas for helping users to submit valid model entity data. For example, suppose you're working on a calendar app where users can select a date for a calendar event. How can you specify that only future dates are selectable? Easy! Use portlet model hints! Liferay Service Builder's model hints provide a single place in your application where you can specify entity data restrictions. Model hints are specified in a single file called portlet-model-hints.xml in your project. If your project is comprised of an API module, a service module, and a web module, as is common for 7.0 applications, portlet-model-hints.xml should go in the service module. For example, in Liferay's Bookmarks application, the portlet-model-hints.xml file goes in the bookmarks-service/src/main/resources/META-INF/ folder. Model hints are referred to as such because they suggest how entities should be presented to users. Model hints let you to configure how the AlloyUI tag library, aui, shows model fields. As Liferay displays form fields in your application, it first checks the model hints you specified and customizes the form's input fields based on these hints. Model hints can also be used to specify the size of the database columns used to store the entities and to specify other entity details.

Note: Service Builder generates a number of XML configuration files in your service module's `src/main/resources/META-INF` folder. Service Builder uses most of these files to manage Spring and Hibernate configurations. Don't modify the Spring or Hibernate configuration files; your changes will be overwritten the next time Service Builder runs. However, you can safely edit the `portlet-model-hints.xml` file.

As an example, consider the Bookmarks app's model hints file:

```
<?xml version="1.0"?>

<model-hints>
    <model name="com.liferay.bookmarks.model.BookmarksEntry">
        <field name="uuid" type="String" />
        <field name="entryId" type="long" />
        <field name="groupId" type="long" />
        <field name="companyId" type="long" />
        <field name="userId" type="long" />
        <field name="userName" type="String" />
        <field name="createDate" type="Date" />
        <field name="modifiedDate" type="Date" />
        <field name="resourceBlockId" type="long" />
        <field name="folderId" type="long" />
        <field name="treePath" type="String">
            <hint name="max-length">4000</hint>
        </field>
        <field name="name" type="String">
            <hint name="max-length">255</hint>
        </field>
        <field name="url" type="String">
            <hint-collection name="URL" />
            <validator name="required" />
            <validator name="url" />
        </field>
        <field name="description" type="String">
            <hint-collection name="TEXTAREA" />
        </field>
        <field name="visits" type="int" />
        <field name="priority" type="int">
            <hint name="display-width">20</hint>
        </field>
        <field name="lastPublishDate" type="Date" />
        <field name="status" type="int" />
        <field name="statusByUserId" type="long" />
        <field name="statusByUserName" type="String" />
        <field name="statusDate" type="Date" />
    </model>
    <model name="com.liferay.bookmarks.model.BookmarksFolder">
        ...
    </model>
</model-hints>
```

The root-level element is `model-hints`. All the model entities are represented by `model` sub-elements of the `model-hints` element. Each `model` element must have a `name` attribute specifying the fully-qualified model class name. Each model has `field` elements representing its model entity's columns. Lastly, each `field` element must have a name and a type. Each `field` element's names and types correspond to the names and types specified for each entity's columns in the service module's `service.xml` file. Service Builder generates all these elements for you, based on `service.xml`.

To add hints to a field, add a `hint` tag inside its `field` tag. For example, you can add a `display-width hint` to specify the pixel width used to display the field. The default pixel width is 350. To show a `String` field with 50 pixels, you could nest a `hint` element named `display-width` and give it a value of `50`.

To see the effect of a hint on a field, you must run Service Builder again and redeploy your project. Note that changing `display-width` doesn't limit the number of characters a user can enter into the `name` field; it only controls the field's width in the AlloyUI input form.

To configure the maximum size of a model field's database column (i.e., the maximum number of characters that can be saved for the field), use the `max-length` hint. The default `max-length` value is 75 characters. If you want the `name` field to persist up to 100 characters, add a `max-length` hint to that field:

```
<field name="name" type="String">
    <hint name="display-width">50</hint>
    <hint name="max-length">100</hint>
</field>
```

Remember to run Service Builder and redeploy your project after updating the `portlet-model-hints.xml` file.

So far, you've seen a few different hints. The following table describes the portlet model hints available for use.

Model Hint Values and Descriptions

Name	Value Type	Description	Default
`auto-escape`	boolean	sets whether text values should be escaped via `HtmlUtil.escape`	true
`autoSize`	boolean	displays the field in a for scrollable text area	false
`day-nullable`	boolean	allows the day to be null in a date field	false
`default-value`	String	sets the default value of the form field rendered using the aui taglib	(empty String)
`display-height`	integer	sets the display height of the form field rendered using the aui taglib	15
`display-width`	integer	sets the display width of the form field rendered using the aui taglib	350
`editor`	boolean	sets whether to provide an editor for the input	false
`max-length`	integer	sets the maximum column size for SQL file generation	75
`month-nullable`	boolean	allows the month to be null in a date field	false
`secret`	boolean	sets whether to hide the characters input by the user	false
`show-time`	boolean	sets whether to show the time along with the date	true
`upper-case`	boolean	converts all characters to upper case	false
`year-nullable`	boolean	allows a date field's year to be null	false
`year-range-delta`	integer	specifies the number of years to display from today's date in a date field rendered with the aui taglib	5
`year-range-future`	boolean	sets whether to include future dates	true
`year-range-past`	boolean	sets whether to include past dates	true

Note that Liferay has its own `portal-model-hints.xml` file. This file contains many hint examples, so you can reference it when customizing your `portlet-model-hints.xml` file.

You can use the `default-hints` element to define a list of hints to apply to every field of a model. For example, adding the following element inside a model element applies a `display-width` of 300 to each field:

```
<default-hints>
    <hint name="display-width">300</hint>
</default-hints>
```

You can define `hint-collection` elements inside the `model-hints` root-level element to define a list of hints to apply together. A hint collection must have a name. For example, Liferay's `portal-model-hints.xml` defines the following hint collections:

```
<hint-collection name="CLOB">
    <hint name="max-length">2000000</hint>
</hint-collection>
<hint-collection name="EDITOR">
    <hint name="editor">true</hint>
    <hint name="max-length">2000000</hint>
</hint-collection>
<hint-collection name="SEARCHABLE-DATE">
    <hint name="month-nullable">true</hint>
    <hint name="day-nullable">true</hint>
    <hint name="year-nullable">true</hint>
    <hint name="show-time">false</hint>
</hint-collection>
<hint-collection name="TEXTAREA">
    <hint name="display-height">105</hint>
    <hint name="display-width">500</hint>
    <hint name="max-length">4000</hint>
</hint-collection>
<hint-collection name="URL">
    <hint name="max-length">4000</hint>
</hint-collection>
```

You can apply a hint collection to a model field by referencing the hint collection's name. For example, if you define a `SEARCHABLE-DATE` collection like the one above in your `model-hints` element, you can apply it to your model's date field by using a `hint-collection` element that references the collection by its name:

```
<field name="date" type="Date">
    <hint-collection name="SEARCHABLE-DATE" />
</field>
```

As always, remember to run Service Builder and redeploy your project after updating your `portlet-model-hints.xml` file.

For example, suppose you want to use a couple of model hints in your project. Start by providing users with an editor for filling in their comment fields. To apply the same hint to multiple entities, define it as a hint collection. Then reference the hint collection in each entity.

To define a hint collection, add a `hint-collection` element inside the `model-hints` root element in your `portlet-model-hints.xml` file. For example:

```
<hint-collection name="COMMENT-TEXTAREA">
    <hint name="display-height">105</hint>
    <hint name="display-width">500</hint>
    <hint name="max-length">4000</hint>
</hint-collection>
```

To reference a hint collection for a specific field, add the `hint-collection` element inside the field's `field` element:

```
<field name="comment" type="String">
    <hint-collection name="COMMENT-TEXTAREA" />
</field>
```

After defining hint collections and adding hint collection references, rebuild your services using Service Builder, redeploy your project, and check that the hints defined in your hint collection have taken effect.

Nice work! You've learned the art of persuasion through Liferay's model hints. Now you can not only influence how your model's input fields are displayed, but you can also can set its database table column sizes. You can organize hints, insert individual hints directly into your fields, apply a set of default hints to all of a model's fields, or define collections of hints to apply at either of those scopes. You've picked up the "hints" on how Liferay model hints specify how to display app data!

81.6 Custom SQL

Service Builder creates finder methods that retrieve entities by their attributes: their column values. When you add a column as a parameter for the finder in your `service.xml` file and run Service Builder, it generates the finder method in your persistence layer and adds methods to your service layer that invoke the finder. If your queries are simple enough, consider using Dynamic Query to access Liferay's database. If you want to do something more complicated like JOINs, you can write your own custom SQL queries. You'll learn how in this tutorial.

Say you have a Guestbook application with two tables, one for guestbooks and one for guestbook entries. The entry entity's foreign key to its guestbook is the guestbook's ID. That is, the entry entity table, `GB_Entry`, tracks an entry's guestbook by its long integer ID in the table's `guestbookId` column. If you want to find a guestbook entry based on its name, message, and guestbook name, you must access the *name* of the entry's guestbook. Of course, with SQL you can join the entry and guestbook tables to include the guestbook name. Service Builder lets you do this by specifying the SQL as *Liferay custom SQL* and invoking it in your service via a *custom finder method*.

Liferay custom SQL is a Service Builder-supported method for performing custom, complex queries against the database by invoking custom SQL from a finder method in your persistence layer. Service Builder helps you generate the interfaces to your finder method. It's easy to do by following these steps:

1. Specify your custom SQL.
2. Implement your finder method.
3. Access your finder method from your service.

Next, using the Guestbook application as an example, you'll learn how to accomplish these steps.

Step 1: Specify Your Custom SQL

After you've tested your SQL, you must specify it in a particular file for Liferay to access it. `CustomSQLUtil` class (from module `com.liferay.portal.dao.orm.custom.sql`) retrieves SQL from a file called `default.xml` in your service module's `src/main/resources/META-INF/custom-sql/` folder. You must create the `custom-sql` folder and create the `default.xml` file in that `custom-sql` folder. The `default.xml` file must adhere to the following format:

```
<custom-sql>
    <sql id="[fully-qualified class name + method]">
    SQL query wrapped in <![CDATA[...]]>
    No terminating semi-colon
    </sql>
</custom-sql>
```

Create a `custom-sql` element for every SQL query you want in your application, and give each query a unique ID. The recommended convention to use for the ID value is the fully-qualified class name of the finder followed by a dot (`.`) character and the name of the finder method. More detail on the finder class and finder methods is provided in Step 2.

For example, in the Guestbook application, you could use the following ID value to specify a query:

```
com.liferay.docs.guestbook.service.persistence.\
EntryFinder.findByEntryNameEntryMessageGuestbookName
```

Custom SQL must be wrapped in character data (CDATA) for the sql element. Importantly, do not terminate the SQL with a semi-colon. Following these rules, the default.xml file of the Guestbook application specifies an SQL query that joins the GB_Entry and GB_Guestbook tables:

```
<?xml version="1.0" encoding="UTF-8"?>
<custom-sql>
    <sql id="com.liferay.docs.guestbook.service.persistence.EntryFinder.findByEntryNameEntryMessageGuestbookName">
        <![CDATA[
            SELECT GB_Entry.*
            FROM GB_Entry
            INNER JOIN
                GB_Guestbook ON GB_Entry.guestbookId = GB_Guestbook.guestbookId
            WHERE
                (GB_Entry.name LIKE ?) AND
                (GB_Entry.message LIKE ?) AND
                (GB_Guestbook.name LIKE ?)
        ]]>
    </sql>
</custom-sql>
```

Now that you've specified some custom SQL, the next step is to implement a finder method to invoke it. The method name for the finder should match the ID you just specified for the sql element.

Step 2: Implement Your Finder Method

Next, implement the finder method in your persistence layer to invoke your custom SQL query. Service Builder generates the interface for the finder in your API module but you must create the implementation.

The first step is to create a *FinderImpl class in the service persistence package. For the Guestbook application, you could create a EntryFinderImpl class in the com.liferay.docs.guestbook.service.persistence.impl package. Your class should extend BasePersistenceImpl<Entry>.

Run Service Builder to generate the *Finder interface based on the *FinderImpl class. Modify your *FinderImpl class to make it a component (annotated with @Component) that implements the *Finder interface you just generated:

```
@Component(service = EntryFinder.class)
public class EntryFinderImpl extends BasePersistenceImpl<Event>
    implements EntryFinder {

}
```

Now you can create a finder method in your EntryFinderImpl class. Add your finder method and static field to the *FinderImpl class. For example, here's how you could write the EntryFinderImpl class:

```
public List<Entry> findByEntryNameEntryMessageGuestbookName(
    String entryName, String entryMessage, String guestbookName,
    int begin, int end) {

    Session session = null;
    try {
        session = openSession();

        String sql = CustomSQLUtil.get(
            getClass(),
            FIND_BY_ENTRYNAME_ENTRYMESSAGE_GUESTBOOKNAME);

        SQLQuery q = session.createSQLQuery(sql);
        q.setCacheable(false);
        q.addEntity("GB_Entry", EntryImpl.class);

        QueryPos qPos = QueryPos.getInstance(q);
        qPos.add(entryName);
        qPos.add(entryMessage);
        qPos.add(guestbookName);

        return (List<Entry>) QueryUtil.list(q, getDialect(), begin, end);
    }
    catch (Exception e) {
        try {
            throw new SystemException(e);
        }
        catch (SystemException se) {
            se.printStackTrace();
        }
    }
    finally {
        closeSession(session);
    }

    return null;
}

public static final String FIND_BY_ENTRYNAME_ENTRYMESSAGE_GUESTBOOKNAME =
    EntryFinder.class.getName() +
        ".findByEntryNameEntryMessageGuestbookName";
```

The custom finder method opens a new Hibernate session and uses Liferay's `com.liferay.portal.dao.orm.custom.sql.Cust` `clazz, String id)` method to get the custom SQL to use for the database query. The `FIND_BY_ENTRYNAME_ENTRYMESSAGE_GUESTBOO` static field contains the custom SQL query's ID. The `FIND_BY_EVENTNAME_EVENTDESCRIPTON_LOCATIONNAME` string is based on the fully-qualified class name of the `*Finder` interface (`EventFinder`) and the name of the finder method (`findByEntryNameEntryMessageGuestbookName`).

Awesome! Your custom SQL is in place and your finder method is implemented. Next, you'll call the finder method from your service.

Step 3: Access Your Finder Method from Your Service

So far, you've created a `*FinderImpl` class, generated the `*Finder` interface, and created a custom finder method that gets your custom SQL. Your last step is to add a service method that calls your finder.

When you ran Service Builder after defining your custom finder method, the `*Finder` interface was generated (e.g., `GuestbookFinder`). Your portlet class, however, should not call the `*Finder` interface: only a local or remote service implementation (i.e., `*LocalServiceImpl` or `*ServiceImpl`) in your service module should invoke the `*Finder` class. This encourages a proper separation of concerns: the portlet classes in your application's web module invoke the business logic of the services published from your application's service module. The services, in turn, access the data model using the persistence layer's finder classes.

So you'll add a method in the `*LocalServiceImpl` class that invokes the finder method implementation via the `*Finder` class. Then you'll rebuild your application's service layer so that the portlet classes and JSPs in your web module can access the services.

For example, for the Guestbook application, you'd add the following method to the `EntryLocalServiceImpl` class:

```
public List<Entry> findByEntryNameGuestbookName(String entryName,
    String guestbookName) throws SystemException {

    return entryFinder.findByEntryNameGuestbookName(String entryName,
        String guestbookName);
}
```

After you've added your `findBy-` method to your `*LocalServiceImpl` class, run Service Builder to generate the interface and make the finder method available in the `EntryLocalService` class.

Now you can indirectly call the finder method from your portlet class or a JSP in your web module. For example, to call the finder method in the Guestbook application, just call `entryLocalService.findByEntryNameEntryMessageGuestb`

Congratulations on developing a custom SQL query and custom finder for your application!

81.7 Dynamic Query

Liferay lets you use custom SQL queries to retrieve data from the database. However, it's sometimes more convenient to build queries dynamically at runtime than it is to invoke predefined SQL queries. Liferay allows you to build queries dynamically using its DynamicQuery API, which wraps Hibernate's Criteria API. Using Liferay's DynamicQuery API allows you to build queries without writing a single line of SQL. The DynamicQuery API helps you think in terms of objects and member variables instead of in terms of tables and columns. Complex queries constructed via Hibernate's Criteria API can be significantly easier to understand and maintain than the equivalent custom SQL (or HQL) queries. While you technically don't need to know SQL to construct queries via Hibernate's Criteria API, you still need to take care to construct efficient queries. For information on Hibernate's Criteria API, please see Hibernate's manual. In this tutorial, you'll learn how to create custom finders for Liferay applications using Service Builder and Liferay's Dynamic Query API.

To use Liferay's Dynamic Query API, you need to create a finder implementation for your model entity. You can define model entities in `service.xml` and run Service Builder to generate model, persistence, and service layers for your application. See the Running Service Builder and Understanding the Generated Code learning path for more information on using Service Builder. This tutorial assumes that you're creating a Liferay application that consists of a service module, an API module, and a web module. Once you've used Service Builder to generate model, persistence, and service layers for your application, you can call custom finders using Liferay's Dynamic Query API by following these steps:

1. Create a custom `-FinderImpl` class and define a `findBy-` finder method in this class. Run Service Builder to generate the required interfaces and utility classes.

2. Implement your finder method using Liferay's Dynamic Query API.

3. Add a method to your `-LocalServiceImpl` class that invokes your finder method. Run Service Builder to add the required method to the service interface.

Once you've taken these steps, you can access your custom finder as a service method. Note: You can create multiple or overloaded `findBy-` finder methods in your `-FinderImpl` class. Next, let's examine these steps in more detail.

Step 1: Defining a Custom Finder Method

To define any custom query, either by specifying custom SQL or by defining a dynamic query, you need a finder class. Create a `[Entity]FinderImpl` class in the generated `[package path].service.persistence.impl` package of your service module's `src/main/java` folder. Recall that you specify the package path in `service.xml`. Here's an example:

```
<service-builder package-path="com.liferay.docs.guestbook">
    ...
</service-builder>
```

Then define a `findBy-` finder method in the class you created. Make sure to add any required arguments to your finder method's method signature.

For example, consider a fictitious Guestbook application. In this application, there are two entities: guestbooks and entries. Each entry belongs to a guestbook so the entry entity has a `guestbookId` field as a foreign key. Suppose you need to create a custom finder to search for guestbook entries by the entry name and the guestbook name. In this case, you'd add a custom finder method to `GuestbookFinderImpl` and name it something like `findByEntryNameGuestbookName`. The full method signature would appear as `findByEntryNameGuestbookName(String entryName, String guestbookName)`.

Once you've created a finder method with the appropriate method signature in your finder class, run Service Builder to generate the appropriate interface in the `[package path].service.persistence` package in the `service` folders of your API and service modules.

For example, after adding `findByEntryNameGuestbookName(String entryName, String guestbookName)` to `GuestbookFinderImpl` and running Service Builder, the interface `com.liferay.docs.guestbook.service.persistence.GuestbookF` is generated.

Once the finder interface has been generated, make sure that the finder class implements the interface. For example, the class declaration should look like this:

```
public class GuestbookFinderImpl extends BasePersistenceImpl<Guestbook> implements GuestbookFinder
```

Your next step is to actually define your query in your custom finder method using the Dynamic Query API.

Step 2: Implementing Your Custom Finder Method Using Dynamic Query

Your first step in implementing your custom finder method in your `-FinderImpl` class is to open a new Hibernate session. Since your `-FinderImpl` class extends `BasePersistenceImpl<Entity>`, and `BasePersistenceImpl<Entity>` contains a session factory object and an `openSession` method, you can simply invoke the `openSession` method of your `-FinderImpl`'s parent class to open a new Hibernate session. The basic structure of your finder method should look like this:

```
public List<Entity> findBy-(...) {

    Session session = null;
    try {
            /*
            Try to open a new Hibernate session and create a dynamic
            query to retrieve and return the desired list of entity
            objects
            */
    }
    catch (Exception e) {
            // Exception handling
    }
    finally {
            closeSession(session);
    }

    return null;
    /*
    Return null only if there was an error returning the
    desired list of entity objects in the try block
    */

}
```

For example, in the case of the Guestbook application, you could write the following finder method to retrieve a list of Guestbook entries that have a specific name and that also belong to a Guestbook of a specific name:

```
public List<Event> findByEntryNameGuestbookName(String entryName, String guestbookName) {

    Session session = null;
    try {
        session = openSession();

        ClassLoader classLoader = getClass().getClassLoader();

        DynamicQuery guestbookQuery = DynamicQueryFactoryUtil.forClass(Guestbook.class, classLoader)
            .add(RestrictionsFactoryUtil.eq("name", guestbookName))
            .setProjection(ProjectionFactoryUtil.property("guestbookId"));

        Order order = OrderFactoryUtil.desc("modifiedDate");

        DynamicQuery entryQuery = DynamicQueryFactoryUtil.forClass(Entry.class, classLoader)
            .add(RestrictionsFactoryUtil.eq("name", entryName))
            .add(PropertyFactoryUtil.forName("guestbookId").in(guestbookQuery))
            .addOrder(order);

        List<Event> entries = EventLocalServiceUtil.dynamicQuery(entryQuery);

        return entries;
    }
    catch (Exception e) {
        try {
            throw new SystemException(e);
        }
        catch (SystemException se) {
            se.printStackTrace();
        }
    }
    finally {
        closeSession(session);
    }
```

Notice that in Liferay, you don't create criteria objects directly from the Hibernate session. Instead, you create dynamic query objects using Liferay's DynamicQueryFactoryUtil service. Thus, instead of

```
Criteria entryCriteria = session.createCriteria(Entry.class);
```

you use

```
DynamicQuery entryQuery = DynamicQueryFactoryUtil.forClass(Entry.class,
    classLoader);
```

Most features of Hibernate's Criteria API, including restrictions, projections, and orders, can be used on Liferay's dynamic query objects. Restrictions in Hibernate's Criteria API roughly correspond to the `where` clause of an SQL query: they offer a variety of ways to limit the results returned by the query. You can use restrictions, for example, to cause a query to return only results where a certain field has a particular value, or a value in a certain range, or a non-null value, etc.

Projections in Hibernate's Criteria API let you modify the kind of results returned by a query. For example, if you don't want your query to return a list of entity objects (the default), you can set a projection on a query so that only a list of the values of a certain entity field, or fields, is returned. You can also use projections on a query to return the maximum or minimum value of an entity field, or the sum of all the values of a field, or the average, etc. For more information on restrictions and projections, please refer to Hibernate's documentation.

Orders, another feature of Hibernate's Criteria API, let you control the order of the elements in the list returned by a query. You can choose the property or properties to which an order should be applied and you can choose for the properties to appear in ascending or descending order in the list.

Like Hibernate criteria, Liferay's dynamic queries are *chainable*. This means that you can add criteria to, set projections on, and add orders to Liferay's dynamic query objects just by appending the appropriate method calls to the query object. For example, the following snippet demonstrates chaining the addition of a restriction criterion and a projection to a dynamic query object declaration:

```
DynamicQuery guestbookQuery = DynamicQueryFactoryUtil.forClass(Guestbook.class, classLoader)
    .add(RestrictionsFactoryUtil.eq("name", guestbookName))
    .setProjection(ProjectionFactoryUtil.property("guestbookId"));
```

When you need to add restrictions to a dynamic query in Liferay, don't call Hibernate's `Restrictions` class directly. Instead, use the methods of Liferay's RestrictionsFactoryUtil service. You'll find the same methods in Liferay's `RestrictionsFactoryUtil` service class that you're used to from Hibernate's `Restrictions` class: `in`, `between`, `like`, `eq`, `ne`, `gt`, `ge`, `lt`, `le`, etc.

Thus, instead of

```
entryCriteria.add(Restrictions.eq("name", guestbookName));
```

to specify that a guestbook must have a certain name, you use

```
entryQuery.add(RestrictionsFactoryUtil.eq("name", guestbookName));
```

Similarly, to set projections, you create properties via Liferay's PropertyFactoryUtil service instead of through Hibernate's `Property` class. Thus, instead of

```
entryCriteria.setProjection(Property.forName("guestbookId"));
```

you use

```
entryQuery.setProjection(PropertyFactoryUtil.forName("guestbookId"));
```

Notice that in the custom `findByGuestbookNameEntryName` finder method, there are two distinct dynamic queries. The first query retrieves a list of guestbook IDs corresponding to guestbook names that match the `guestbookName` parameter of the finder method. The second query retrieves a list of guestbook entries with entry names that match the `entryName` parameter and have `guestbookId` foreign keys belonging to the list returned by the first query.

Here's the first query:

```
DynamicQuery guestbookQuery = DynamicQueryFactoryUtil.forClass(Guestbook.class, classLoader)
    .add(RestrictionsFactoryUtil.eq("name", guestbookName))
    .setProjection(ProjectionFactoryUtil.property("guestbookId"));
```

By default, `DynamicQueryFactoryUtil.forClass(Guestbook.class, classLoader)` returns a query that retrieves a list of all guestbook entities. Adding the `.add(RestrictionsFactoryUtil.eq("name", guestbookName))` restriction limits the results to only those guestbooks whose guestbook names match the `guestbookName` parameter. The `.setProjection(ProjectionFactoryUtil.property("guestbookId"))` projection changes the result set from a list of guestbook entries to a list of guestbook IDs. This is useful since guestbook IDs are much less expensive to retrieve than full guestbook entities and the guestbook IDs are all that the guestbook entry query requires.

Next is an order which applies to the list of entries returned by the `findByEntryNameGuestbookName` finder method:

```
Order order = OrderFactoryUtil.desc("modifiedDate");
```

When this order is applied to a query, the list of results returned by the query are arranged in descending order of the query entity's `modifiedDate` attribute. Thus the most recently modified entities (guestbook entries, in our example) appear first and the least recently modified entities appear last.

Here's the second query:

```
DynamicQuery eventQuery = DynamicQueryFactoryUtil.forClass(Entry.class, classLoader)
    .add(RestrictionsFactoryUtil.eq("name", entryName))
    .add(PropertyFactoryUtil.forName("guestbookId").in(guestbookQuery))
    .addOrder(order);

List<Event> entries = _eventLocalService.dynamicQuery(entryQuery);
```

By default, `DynamicQueryFactoryUtil.forClass(Entry.class, classLoader)` returns of list of all guestbook entry entities. The `.add(RestrictionsFactoryUtil.eq("name", entryName))` restriction limits the results to only those guestbook entries whose names match the `entryName` parameter of the finder method. PropertyFactoryUtil is a Liferay utility class with the method `forName(String propertyName)`, which returns the specified property. This property can be passed to another Liferay dynamic query. This is exactly what happens in the following line of our example:

```
.add(PropertyFactoryUtil.forName("guestbookId").in(guestbookQuery))
```

Here, the code makes sure that the guestbook IDs (foreign keys) of the entry entities in the `entityQuery` must belong to the list of guestbook IDs returned by the `guestbookQuery`. Declaring that an entity property in one query must belong to the result list of another query is a way to use Liferay's dynamic query API to create complex queries, similar to SQL joins.

Lastly, you apply the order defined earlier to the entries returned by the `findByEntryNameGuestbookName` finder method:

```
.addOrder(order);
```

This orders the list of guestbook entities by the `modifiedDate` attribute, from most recent to least recent.

Note: Service Builder not only generates a `public List dynamicQuery(DynamicQuery dynamicQuery)` method in `-LocalServiceBaseImpl` but it also generates `public List dynamicQuery(DynamicQuery dynamicQuery, int start, int end)` and `public List dynamicQuery(DynamicQuery dynamicQuery, int start, int end, OrderByComparator orderByComparator)` methods. You can go back to step 1 and either modify your custom finder method or create overloaded versions of your custom finder method to take advantage of these extra methods and their parameters. The `int start` and `int end` parameters are useful when paginating a result list. `start` is the lower bound of the range of model entity instances and `end` is the upper bound. The `OrderByComparator orderByComparator` is the comparator by which to order the results.

To use the overloaded `dynamicQuery` methods of your `-LocalServiceBaseImpl` class in the (optionally overloaded) custom finders of your `-FinderImpl` class, just choose the appropriate methods for running the dynamic queries: `EventLocalService.dynamicQuery(eventQuery)`, or `EventLocalService.dynamicQuery(eventQuery, start, end)` or `EventLocalService.dynamicQuery(eventQuery, start, end, orderByComparator)`.

Great! You've now created a custom finder method using Liferay's Dynamic Query API. Your last step is to add a service method that calls your finder.

Step 3: Accessing Your Custom Finder Method from the Service Layer

So far, you've created a `-FinderImpl` class, defined a custom `findBy-` finder method in that class, and implemented the custom finder method using Dynamic Query. Now how do you call your custom finder method from the service layer?

When you ran Service Builder after defining your custom finder method, the `-Finder` interface was generated (e.g., `GuestbookFinder`). Your portlet class, however, should not call the `-Finder` interface: only a local or remote service implementation (i.e., `-LocalServiceImpl` or `-ServiceImpl`) in your service module should invoke the `-Finder` class. This encourages a proper separation of concerns: the portlet classes in your application's web module invoke the business logic of the services published from your application's service module. The services, in turn, access the data model using the persistence layer's finder classes.

Note: In previous versions of Liferay Portal, your finder methods were accessible via `-FinderUtil` utility classes. Finder methods are now injected into your app's local services, removing the need to call finder utilities.

So you'll add a method in the `-LocalServiceImpl` class that invokes the finder method implementation via the `-Finder` class. Then you'll rebuild your application's service layer so that the portlet classes and JSPs in your web module can access the services.

For example, for the Guestbook application, you'd add the following method to the `EntryLocalServiceImpl` class:

```
public List<Entry> findByEntryNameGuestbookName(String entryName,
    String guestbookName) throws SystemException {

    return entryFinder.findByEntryNameGuestbookName(String entryName,
        String guestbookName);
}
```

After you've added your `findBy-` method to your `-LocalServiceImpl` class, run Service Builder to generate the interface and make the finder method available in the `EntryLocalService` class.

Now you can indirectly call the finder method from your portlet class or from a JSP by calling `EntryLocalService.findByEntryNameGuestbookName(...)`!

Congratulations on following the three step process of developing a dynamic query in a custom finder and exposing it as a service for your portlet!

Actionable Dynamic Queries

Suppose you have over a million users on your portal, and you want to perform some kind of mass update to a large portion of them. One approach might be to use a dynamic query to retrieve the list of users in question. Once loaded into memory, you could loop through the list and update each user. However, with over a million users, the memory cost of such an operation would be too great. In general, if you have very large numbers of service builder entities, it can be too expensive in terms of memory and speed to run a dynamic query to retrieve a list of such entities in order to do some processing on them.

Liferay provides actionable dynamic queries to solve this kind of situation. An actionable dynamic query does not return a list of service builder entities like a regular dynamic query. Instead, it uses a pagination strategy to load only small numbers of service builder entities into memory at a time and performs some processing (i.e., performs an *action*) on each entity. So instead of trying to use a dynamic query to load a million users into memory and then perform some processing on each of them, a much better strategy is to use an actionable dynamic query to process them. This way, only small numbers of users are loaded into memory at a time, but you still process all the users.

When you run Service Builder, it includes actionable dynamic query support in the generated API and service modules. For example, consider the API module of the BLADE service builder example project.

The FooLocalService interface in the API module contains these methods:

```
@Transactional(propagation = Propagation.SUPPORTS, readOnly = true)
public ActionableDynamicQuery getActionableDynamicQuery();

public DynamicQuery dynamicQuery();

@Transactional(propagation = Propagation.SUPPORTS, readOnly = true)
public ExportActionableDynamicQuery getExportActionableDynamicQuery(
    PortletDataContext portletDataContext);

@Transactional(propagation = Propagation.SUPPORTS, readOnly = true)
public IndexableActionableDynamicQuery getIndexableActionableDynamicQuery();
```

The FooLocalServiceBaseImpl class in the service module implements each of these methods. See here and here for details.

The implementation of FooLocalService.dynamicQuery() uses DynamicQueryFactoryUtil to obtain new (regular) dynamic query instance for the Foo entity. This is the pattern shown earlier.

You can use FooLocalService.getActionableDynamicQuery() to obtain a new actionable dynamic query instance for the Foo entity. Once you have the instance, you can use chaining to build up the query using any of the techniques described above for regular dynamic queries, such as restrictions or projections. But the point of using an *actionable* dynamic query is to specify an action to perform on each entity that results from the query. To specify such an action, use the ActionableDynamicQuery.setPerformActionMethod<PerformActionMethod<?> method. Once the query has been defined and an action has been specified, use the ActionableDynamicQuery.performActions to perform the action on each entity that results from the query.

Here's an example from a test for Liferay DXP's Bookmarks application:

```
ActionableDynamicQuery actionableDynamicQuery = BookmarksEntryLocalServiceUtil.getActionableDynamicQuery();

actionableDynamicQuery.setPerformActionMethod(new ActionableDynamicQuery.PerformActionMethod<BookmarksEntry>() {
        @Override
        public void performAction(BookmarksEntry bookmarksEntry) {
            Assert.assertNotNull(bookmarksEntry);

            count.increment();
        }
    });

actionableDynamicQuery.performActions();
```

You can see the full context here.

Consider the FooLocalService from the BLADE service builder API project again. For most of your actionable dynamic query use cases, the actionable query returned by FooLocalService.getActionableDynamicQuery will suffice. This actionable dynamic query is an instance of the concrete class DefaultActionableDynamicQuery. However, in addition to FooLocalService.getActionableDynamicQuery, there are two additional methods related to actionable dynamic queries: FooLocalService.getExportActionableDynamicQuery and FooLocalService.getIndexableActionableDynamicQuery. These methods return instances of concrete classes (either IndexableActionableDynamicQuery or ExportActionableDynamicQuery) that extend DefaultActionableDynamicQuery. IndexableActionableDynamicQuery contains methods designed to facilitate processing that involves search indexing and ExportActionableDynamicQuery contains methods designed to facilitate processing that involves export / import functionality.

To see examples of configuring indexer and export actionable dynamic queries, see the Bookmarks application here and here. To see an example invocation of an indexable actionable dynamic query, see the `reindexEntries` method of the Bookmarks application's indexer here.

Invoking Local Services

81.8 Configuring service.properties

In this tutorial, you'll learn how to use and edit the `service.properties` file. You'll also learn about the properties included in this file and how to set them to fit your needs.

Service Builder generates a `service.properties` file in your `*-service` module's `src/main/resources` folder. Liferay DXP uses the properties in this file to alter your service's database schema. You should not modify this file, but rather make any necessary overrides in a `service-ext.properties` file in that same folder.

Here are some of the properties included in the `service.properties` file:

- `build.namespace`: This is the namespace you defined in your `service.xml`. Liferay distinguishes different plugins from each other using their namespaces.
- `build.number`: Liferay distinguishes different builds of your plugin. Each time a distinct build of your plugin is deployed to Liferay, Liferay increments this number.
- `build.date`: This is the time of the latest build of your plugin.
- `include-and-override`: The default value of this property defines `service-ext.properties` as an override file for `service.properties`.

Note: The `build.auto.upgrade` property is available for WAR-style Service Builder applications. This property determines whether or not Liferay should automatically apply changes to the database model when a new version of the plugin is deployed. This is `true` by default. This property is not necessary for module-style applications.

It's sometimes useful to override the `build.auto.upgrade` property in legacy projects from `service.properties`. Setting `build.auto.upgrade=false` in your `service-ext.properties` file prevents Liferay from trying automatically to apply any changes to the database model when a new version of the plugin is deployed. This is needed in projects to manually manage the changes to the database (recommended) or in which the SQL schema has intentionally been modified manually after generation by Service Builder.

Awesome! You now have all the tools necessary to set up your own `service-ext.properties` file.

Creating Local Services

81.9 Connecting Service Builder to External Data Sources

Sometimes you want to use a data source other than Liferay DXP's. To do this, the data source must be defined in `portal-ext.properties` or configured as a JNDI data source on Liferay DXP's app server. This tutorial shows how to connect Service Builder to a data source.

Note: All entities defined in a Service Builder module's `service.xml` file are bound to the same data source. Binding different entities to different data sources requires defining the entities in separate Service Builder modules and configuring each of the modules to use a different data source.

Here are the steps:

1. If Liferay DXP's application server defines the data source using JNDI, skip this step. Otherwise, specify the data source in a `portal-ext.properties` file. Distinguish it from Liferay DXP's default data source by giving it a prefix other than `jdbc.default.`. This example uses prefix `jdbc.ext.`:

```
jdbc.ext.driverClassName=org.mariadb.jdbc.Driver
jdbc.ext.password=userpassword
jdbc.ext.url=jdbc:mariadb://localhost/external?useUnicode=true&characterEncoding=UTF-8&useFastDateParsing=false
jdbc.ext.username=yourusername
```

2. Create a Spring bean that points to the data source. To do this, create an `ext-spring.xml` file in your Service Builder module's `src/main/resources/META-INF/spring` folder or in your traditional portlet's `WEB-INF/src/META-INF` folder. Define the following elements:

   - A data source factory Spring bean for the data source. It's different based on the type:

     - **JNDI**: Specify an arbitrary property prefix and prepend the prefix to a JNDI name property key. Here's an example:

```
<bean class="com.liferay.portal.dao.jdbc.spring.DataSourceFactoryBean"
    id="liferayDataSourceFactory">
    <property name="propertyPrefix" value="custom." />
    <property name="properties">
        <props>
            <prop key="custom.jndi.name">jdbc/externalDataSource</prop>
        </props>
    </property>
</bean>
```

     - **Portal Properties**: Specify a property prefix that matches the prefix (e.g., `jdbc.ext.`) you used in `portal-ext.properties`.

```
<bean class="com.liferay.portal.dao.jdbc.spring.DataSourceFactoryBean"
    id="liferayDataSourceFactory">
    <property name="propertyPrefix" value="jdbc.ext." />
</bean>
```

   - A Liferay DXP data source bean that refers to the data source factory Spring bean.
   - An alias for the Liferay DXP data source bean.

   Here's an example `ext-spring.xml` that points to a JNDI data source:

```
<?xml version="1.0"?>

<beans default-destroy-method="destroy" default-init-method="afterPropertiesSet"
   xmlns="http://www.springframework.org/schema/beans" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.springframework.org/schema/beans http://www.springframework.org/schema/beans/spring-beans-
3.0.xsd">

   <!-- To define an external data source, the liferayDataSource Spring bean
       must be overridden. Other default Spring beans like liferaySessionFactory
       and liferayTransactionManager may optionally be overridden.

       liferayDataSourceFactory refers to the data source configured on the
       application server. -->
   <bean class="com.liferay.portal.dao.jdbc.spring.DataSourceFactoryBean"
       id="liferayDataSourceFactory">
       <property name="propertyPrefix" value="custom." />
       <property name="properties">
           <props>
               <prop key="custom.jndi.name">jdbc/externalDataSource</prop>
           </props>
       </property>
   </bean>

   <!-- The data source bean refers to the factory to access the data source.
   -->
   <bean
       class="org.springframework.jdbc.datasource.LazyConnectionDataSourceProxy"
       id="liferayDataSource">
       <property name="targetDataSource" ref="liferayDataSourceFactory" />
   </bean>

   <!-- In service.xml, we associated our entity with the extDataSource. To
       associate the extDataSource with our overridden liferayDataSource, we define
       this alias. -->
   <alias alias="extDataSource" name="liferayDataSource" />
</beans>
```

The `liferayDataSourceFactory` above refers to a JNDI data source named `jdbc/externalDataSource`. If the data source was specified via data source properties in a `portal-ext.properties` file, the bean would require only a `propertyPrefix` property that matches the data source property prefix.

The data source bean `liferayDataSource` is overridden with one that refers to the `liferayDataSourceFactory` bean. The override affects this bundle (module or Web Application Bundle) only.

The alias `extDataSource` refers to the `liferayDataSource` data source bean.

```
**Note**: To use an external data source in multiple Service Builder
bundles, you must override the `liferayDataSource` bean in each bundle.
```

---

2. In your Service Builder module's `service.xml` file, set your entity's data source to the `liferayDataSource` alias you specified in your `ext-spring.xml` file. Here's an example:

```
<?xml version="1.0"?>
<!DOCTYPE service-builder PUBLIC "-//Liferay//DTD Service Builder 7.0.0//EN"
    "http://www.liferay.com/dtd/liferay-service-builder_7_0_0.dtd">

<service-builder package-path="com.liferay.example" >
    <namespace>TestDB</namespace>
    <entity local-service="true" name="Foo" table="testdata" data-source="extDataSource"
```

```
            remote-service="false" uuid="false">
           <column name="id" db-name="id" primary="true" type="long" />
           <column name="foo" db-name="foo" type="String" />
           <column name="bar" db-name="bar" type="long" />
    </entity>
</service-builder>
```

Note the example's `<entity>` tag attributes:

- `data-source`: The `liferayDataSource` alias `ext-spring.xml` specifies.
- `table`: Your entity's database table.

Also note that your entity's `<column>`s must have a `db-name` attribute set to the column name.

3. Run Service Builder.

Now your Service Builder services use the data source. You can use the services in your business logic as you always have regardless of the underlying data source.

Business Logic with Service Builder

Once you've defined your application's entities and ran Service Builder to generate your service and persistence layers, you can begin adding business logic. Each entity generated by Service Builder contains a model implementation, local service implementation, and optionally a remote service implementation class. Your application's business logic can be implemented in these classes. The generated service layer contains default methods for CRUD operations, but often times it's necessary to implement additional methods. Once you've added your business logic, running Service Builder again regenerates your application's interfaces and makes your new logic available for invocation.

In this section of tutorials, you'll learn about creating and invoking your application's local services, finding and invoking Liferay's services, and customizing Liferay services.

82.1 Creating Local Services

The heart of your service is its `*LocalServiceImpl` class. This class is your entity's local service extension point. Local services can be invoked within your application or by other Liferay applications running on the same Liferay instance as your application. Remote services differ from local services in that remote services can be invoked from any application that can access your Liferay instance (e.g., over the Internet) and has permission to do so. All of your application's core business logic for working with your entity model (or models) should be added as methods of your `*LocalServiceImpl` class. Before adding any custom service methods, however, you should review the initial service classes that Service Builder generated during its initial run.

Best Practice: If your application needs both local and remote services, determine the service methods that your application needs for working with your entity model. Add these service methods to `*LocalServiceImpl`. Then create corresponding remote services methods in `*ServiceImpl`. Add permission checks to the remote service methods and make the remote service methods invoke the local service methods. The remote service methods can have the same names as the local service methods that they call. Within your application, only call the remote services. This ensures that your service methods are secured and that you don't have to duplicate permissions code.

Note that Service Builder creates a `*LocalService` class which is the interface for the local service. It contains the signatures of every method in `*LocalServiceBaseImpl` and `*LocalServiceImpl`. `*LocalServiceBaseImpl` contains some automatically generated methods that provide functionality that's common to all local services. Since the `*LocalService` class is generated, you should never modify it. If you do, your changes will be overwritten the next time you run Service Builder. All custom code should be placed in *LocalServiceImpl, where it will not be overwritten.

For example, the Bookmarks application's BookmarksEntryLocalServiceImpl class demonstrates the kinds of service methods that applications commonly need for working with an entity model. Click on the class's link to view some of its local service methods.

In order to add an entity to the database, you need an ID for the entity. Liferay provides a counter service which you call to obtain a unique ID for each new entity. It's possible to use the increment method of Liferay's CounterLocalService class, but Service Builder already makes a CounterLocalService instance available to your app's *LocalServiceBaseImpl. The CounterLocalService instance is injected into a module as an OSGi service:

```
@ServiceReference(type=com.liferay.counter.kernel.service.CounterLocalService.class)
protected com.liferay.counter.kernel.service.CounterLocalService counterLocalService;
```

If you're creating local services in Liferay's core, the CounterLocalService instance is injected as a Spring bean:

```
@BeanReference(type=com.liferay.counter.kernel.service.CounterLocalService.class)
protected com.liferay.counter.kernel.service.CounterLocalService counterLocalService;
```

Since your *LocalServiceImpl class extends *LocalServiceBaseImpl, you can access this CounterLocalService instance. See your app's *LocalServiceBaseImpl for a list of all the Spring beans/OSGi services you have available for use.

You can use either the injected class's increment method or you can call Liferay's CounterLocalService's increment method directly. For example, a bookmarks entry is assigned a unique ID like this:

```
long entryId = counterLocalService.increment();
```

The Bookmarks application uses the generated entryId as the ID for the new BookmarksEntry:

```
BookmarksEntry entry = bookmarksEntryPersistence.create(entryId);
```

bookmarksEntryPersistence is one of the OSGi services injected into EventLocalServiceBaseImpl by Service Builder.

Next, the Bookmarks application sets the attribute fields that were specified for the BookmarksEntry entity in the service.xml. These attributes include the groupId, userId, name, url, serviceContext, etc. Lastly, a Bookmarks folder ID must be associated to the entry.

It's also important to assign values to the audit fields. In the Bookmarks application, the group of the entity is set first. An entity's group determines its scope. In this example, the group is the site. The company and user are specified after the group is set. The company represents the portal instance and the user is the user who created the bookmark. The Bookmarks application sets the createDate and modifiedDate of the Event to the current time. After that, the generated addEntry method of BookmarksEntryLocalServiceBaseImpl is called to add the bookmark to the database. Lastly, the bookmark is added as a resource so that permissions can be applied to it later. To view the addEntry method in its entirety, see the BookmarksEntryLocalServiceImpl class.

The Bookmarks application creates local services for BookmarksFolder entities as well as for BookmarksEntry entities. Take a look at the custom service methods available in the BookmarksFolderLocalServiceImpl class for a better understanding of services available for bookmark folders.

Before you can use any custom methods that you added to your *LocalServiceImpl class, you must run Service Builder again. Running Service Builder again adds the method signatures of your custom service methods to your *LocalService interface and updates your *LocalServiceUtil class. For more information on running Service Builder see the Running Service Builder and Understanding the Generated Code tutorial.

Service Builder looks through your *LocalServiceImpl class and automatically copies the signatures of each method into the corresponding *LocalService interface. After running Service Builder, you can test that your services are working as intended by invoking one of the methods that Service Builder added to your *LocalService class. For example, if you were developing the Bookmarks application, you could make the following service invocation to make sure that your service was working as intended:

```
BookmarksEntryLocalService.addBookmarksEntry(bookmarksEntry);
```

In addition to all of the Java classes and interfaces, Service Builder also generates a service.properties file. To learn about the service.properties file and how to configure it, please refer to the Configuring service.properties tutorial. To learn how to invoke local services, please refer to the Invoking Local Services tutorial.

82.2 Invoking Local Services

In this tutorial, you'll learn about the differences between local and remote services, and when you should invoke local services rather than their remote service counterparts.

Once Service Builder has generated your module project's services, you can call them from anywhere in your application. When invoking a local service, you should call one of the service methods of a *LocalService class. You should never call the service methods of an *Impl class directly. Local services in your project are generated automatically when using Service Builder. To do this, set the local-service attribute to true for an entity in the service.xml file. Service Builder generates methods that call existing services, but you can create new methods in the *LocalServiceImpl class that can be generated into new exposed methods in your module's services (*LocalService, *LocalServiceUtil, etc.).

Many of Liferay's module applications use their generated remote services for important calls in their controller layer, for example, because they offer conveniences like configured permissions checking. Remote services perform a permission check and then invoke the corresponding local service. However, there are many services you'd like to expose only to your local project, and do not want other applications to have access to.

In the Bookmarks application, for example, the BookmarksEntryLocalService interface provides the openEntry method, which opens a bookmark for viewing. The remote service interface BookmarksEntryService, however, does not provide this method. Why could this be?

There are many services that you don't want to expose to other applications in Liferay. In the example mentioned above, Bookmarks are configured to only open locally, meaning that other apps do not have access to open and view a bookmark entry. This should only be done by the Bookmarks application. Therefore, in certain cases, you'll need to invoke local services instead of remote services. For more information on invoking remote services, see the Invoking Remote Services tutorial.

To see how you could call a local service from a portlet action class, you'll examine the EditOrganizationMVCActionCommand class. Notice that this class has a private instance variable called _dlAppLocalService. The _dlAppLocalService instance variable of type DLAppLocalService gets an instance of DLAppLocalService at runtime via dependency injection. The instance variable is set like this:

```
@Reference(unbind = "-")
protected void setDLAppLocalService(DLAppLocalService dlAppLocalService) {
    _dlAppLocalService = dlAppLocalService;
}
```

This tutorial demonstrated how you can call the local services generated by Service Builder in your project. To learn how to call Liferay services, see the Service Security Layers and Finding and Invoking Liferay Services tutorials.

82.3 Finding and Invoking Liferay Services

In this tutorial, you'll learn how to search for portal services and portlet services. You can find Liferay's services by searching for them in the Javadocs: @platform-ref@/7.0-latest/javadocs/.

First, you'll learn how to find a portal service using Liferay's Javadocs.

Finding Liferay Portal Services

Searching for Liferay Portal services is easy and intuitive. The first two options, `portal-impl` and `portal-kernel`, are the most popular options when searching for Liferay's Javadocs. In summary, the `portal-kernel` directory provides interfaces and utils, and the `portal-impl` directory provides service implementations that implement those interfaces. The remaining options are miscellaneous util and test classes that are used in Liferay DXP.

Liferay's Javadocs are easy to browse and well-organized. Here's how to find the *Organization* services, for example:

1. In your browser, open up the Javadocs: @platform-ref@/7.0-latest/javadocs/ You're offered several options, which were discussed earlier. Select *portal-kernel*.
2. Under *Portal Kernel*, click on the link for the `com.liferay.portal.kernel.service` package, since the services for the Organization entity belong to the *Portal* scope.
3. Find and click on the `*LocalService` class (in this case, `OrganizationLocalService`) in the *Class Summary* table or the *Classes* list at the bottom of the page.

That was easy! What if you want to find module services?

Finding Liferay Module Services

Searching for Liferay module services is also easy. The Javadocs for modules are hosted on Liferay's Nexus repository, and can be viewed by downloading and extracting the module's `*javadoc.jar` file. You can learn move about how a module's Java API is organized by reading the Java APIs section.

Here's an example of how to find services for a bookmarks entry:

1. Navigate to Liferay's Nexus repository and select `com.liferay.bookmarks.api`. Then select the appropriate version.

2. Select the com.liferay.bookmarks.api-[VERSION]-javadoc.jar link, which downloads that JAR file. Extract the JAR file, once downloaded.

3. Open the extracted contents and select the index.html file.

4. Select the com.liferay.bookmarks.service package from the main view, and then select the BookmarksEntryLocalService class in the *Class Summary* table or the *Classes* list.

Awesome! You've successfully located the bookmark entry's services.

Another easy way to search for services in module projects is by importing them into your IDE. For Liferay @ide@, you can right-click in the Package Explorer and navigate to *Import → Liferay Module Project(s)*. Then browse for your module, select the build type, and click *Finish*. Now you can peruse your module services from Liferay @ide@.

Now you're ready to invoke Liferay services.

Invoking Liferay Services Locally

Every Liferay service provides a local interface to clients running in the same JVM as Liferay Portal. Many local services (e.g., *LocalService classes) are called by remote services (e.g., *Service classes). The remote classes mask the complexity of the local service implementations and include permission checks. The core Liferay services that are provided as part of Liferay Portal were generated by the same Service Builder tool that you can use in your applications. You can invoke a remote Liferay service by calling the appropriate *LocalService or *Service class. The following code found in the journal-content-web module demonstrates how to retrieve the portal instance's group by calling Liferay's GroupLocalService:

```
Group group = _groupLocalService.getCompanyGroup(companyId);
```

By Liferay convention, the _groupLocalService instance variable is created and set for usage in the class it's called from:

```
private GroupLocalService _groupLocalService;

@Reference(unbind = "-")
protected void setGroupLocalService(GroupLocalService groupLocalService) {
    _groupLocalService = groupLocalService;
}
```

The @Reference(unbind="-") annotation retrieves a reference to a service of type GroupLocalService, and ignores how this service has been published and who published it.

Besides the services Service Builder made available for your application, you can also access any service published within the OSGi Registry. This means the following services are available:

- Beans defined in Liferay's core
- Beans created in other module app contexts
- Services declared using Declarative Service
- Services registered using the OSGi low level API

Some types of portlets don't have access to the OSGi Registry using Declarative Services (e.g., Spring MVC and JSF). You can call OSGi services in these portlets by using Service Trackers.

You'll learn more about referencing OSGi services next.

Referencing OSGi Services

All the services created within your Service Builder application are wired using an internal Spring Application Context. This uses AOP proxies to give your services the ability to deal with transactions, indexing, and security.

In many cases, however, you'll need to reference an external service (i.e., something that is not defined within your Spring Application Context). Liferay has included the ability to reference OSGi services from your Spring beans using the `@ServiceReference` annotation.

You'll step through a simple example next.

Suppose you're building an application with a simple entity defined in your `service.xml` file. The application needs to send an SMS every time a new entity is created, and the `SMSService` is provided by a module installed in the system.

How would you get a reference from the `-LocalServiceImpl` (Spring bean) to an *external* service? You can do this by using the `@ServiceReference` annotation:

```
@ServiceReference
private SMSService _smsService;
```

Using this annotation lets you retrieve a reference to an OSGi service from a regular Spring bean. This provides some nice benefits. If the `SMSService` is not available, the whole Spring context is not created until the service is available. Likewise, if the `SMSService` suddenly disappears, the whole Spring Application Context is destroyed. This makes our Spring apps much more robust and versatile.

Fortunately, Service Builder generates this kind of code every time you have a reference to an entity which is not defined in your `service.xml` file. For example, imagine that your entity has a reference provided in your `service.xml` file, to the Group entity:

```
<reference entity="Group" package-path="com.liferay.portal" />
```

The generated code for this entity would look like the following:

```
@ServiceReference(type = com.liferay.portal.kernel.service.GroupLocalService.class)
protected com.liferay.portal.kernel.service.GroupLocalService groupLocalService;
```

Great! You know how to find Liferay's core and module services, and can invoke them from your application. You also learned about referencing OSGi services.

Chapter 83

Data Access

Liferay DXP's data can be retrieved using its APIs. It's important, however, to understand how data is used amid all of Liferay DXP's constructs. At a basic level, all the data is represented by an object model. This is retrieved from the database and automatically mapped from SQL to the model by Service Builder. Using Model Listeners, you can listen for events on these models and take action when they are stored or retrieved.

All data in Liferay DXP is scoped to a context: a site, a page, or global. When storing data in your application, you should therefore take advantage of scope so your application integrates well with the system and users can add your application in whatever scope they need it.

Read on to learn how to do both of these things.

83.1 Data Scopes

Apps in Liferay DXP can restrict their data to specific scopes. Scopes provide a context for the application's data. For example, a site-scoped app can display its data across a single site. For a detailed explanation of scopes, see the user guide article Application Scope. To give your applications scope, you must manually add support for it. This tutorial shows you how.

Scoping Your Entities

In your service layer, your entities must have a `companyId` attribute of type `long` to enable scoping by portal instance and a `groupId` attribute of type `long` to enable scoping by site. Using Service Builder is the simplest way to do this. For instructions on this, see the tutorial series Service Builder Persistence and Business Logic with Service Builder.

Enabling Scoping

To enable scoping in your app, set the property `"com.liferay.portlet.scopeable=true"` in your portlet class's `@Component` annotation. For example, this property is set to `true` in the `@Component` annotation of Web Content Display Portlet's portlet class:

```
@Component(
    immediate = true,
    property = {
        ...
        "com.liferay.portlet.scopeable=true",
        ...,
    },
    service = Portlet.class
)
public class JournalContentPortlet extends MVCPortlet {...
```

That's it! You can now access your app's scope in your code. The next section shows you how.

Accessing Your App's Scope

Users can typically set an app's scope to a page, a site, or the entire portal. To handle your app's data, you must access it in its current scope. Liferay DXP gives you techniques to do this. Your app's scope is available:

1. Via the `scopeGroupId` variable that is injected in your JSPs whenever you use the `<liferay-theme:defineObjects />` tag. This variable contains your app's current scope. For example, Liferay's Bookmarks app uses `scopeGroupId` in its `view.jsp` to retrieve the bookmarks and total number of bookmarks in the current scope:

   ```
   ...
   total = BookmarksEntryServiceUtil.getGroupEntriesCount(scopeGroupId, groupEntriesUserId);

   bookmarksSearchContainer.setTotal(total);
   bookmarksSearchContainer.setResults(BookmarksEntryServiceUtil.getGroupEntries(scopeGroupId, groupEntriesUserId, bookmarksSearchContainer.getStart()
   ...
   ```

2. By calling the `getScopeGroupId()` method on the request's `ThemeDisplay` instance. This method returns your app's current scope. For example, the `EditEntryMVCActionCommand` class in Liferay's Blogs app does this in its `subscribe` and `unsubscribe` methods:

   ```
   protected void subscribe(ActionRequest actionRequest) throws Exception {
       ThemeDisplay themeDisplay = (ThemeDisplay)actionRequest.getAttribute(
           WebKeys.THEME_DISPLAY);

       _blogsEntryService.subscribe(themeDisplay.getScopeGroupId());
   }

   protected void unsubscribe(ActionRequest actionRequest) throws Exception {
       ThemeDisplay themeDisplay = (ThemeDisplay)actionRequest.getAttribute(
           WebKeys.THEME_DISPLAY);

       _blogsEntryService.unsubscribe(themeDisplay.getScopeGroupId());
   }
   ```

   If you know your app always needs the portal instance ID, use `themeDisplay.getCompanyId()`.

3. By calling the `getScopeGroupId()` method on a `ServiceContext` object. You can find more information on this, and an example, in the tutorial Understanding `ServiceContext`. If you know your app always needs the portal instance ID, use the `getCompanyId()` method on a `ServiceContext` object.

Awesome! Now you know how to get your app's scope. Next, you'll learn about a special use case: getting the site scope for entities that belong to a different app.

Accessing the Site Scope Across Apps

There may be times when you need to access a different app's site-scoped data, even though your app may be scoped to a page or the portal. For example, web content articles can be created in the page, site, or portal scope. Structures and Templates for such articles, however, can only exist in the site scope. If you use the above techniques to retrieve the app's current scope, you won't always get the site scope required for Structures and Templates. You might get the page or portal scope instead, if that's how the user configured your app. What a pickle! Never fear, the `ThemeDisplay` method `getSiteGroupId()` is here! This method always gets the site scope, no matter your app's current scope. For example, the Web Content app's `edit_feed.jsp` uses this method to get the site ID needed to retrieve Structures:

...

```
ddmStructure = DDMStructureLocalServiceUtil.fetchStructure(themeDisplay.getSiteGroupId(),
    PortalUtil.getClassNameId(JournalArticle.class), ddmStructureKey, true);
```

...

Great! Now you know how to scope your apps, access their scope, and even get the site scope of entities that belong to other apps. Now that's minty-fresh breath!

Chapter 84

Web Services

Generating and invoking web services is a central part of the Liferay development experience. After all, what good is it if you can't generate remote services for an app you're developing, or call Liferay's built-in remote services? It's no good at all! Liferay without web services would be like a luxury car without wheels. Fortunately, Liferay comes with full set of JSON and SOAP web services that you can invoke until your heart's content. Liferay also provides Service Builder to generate local and remote services for your apps.

The tutorials that follow show you how to work with web services in Liferay. You'll learn how to use Service Builder to generate remote services for your apps. You'll also learn how to invoke those services, and any other Liferay web services.

Chapter 85

Service Builder Web Services

Liferay's Service Builder can generate local and remote services for your Liferay apps. The section of tutorials on Service Builder gives a general introduction to Service Builder, as well as instructions on generating your app's local services. But what if you want to use Service Builder to generate your app's remote services? And how should you invoke remote services generated by Service Builder? No sweat! That's exactly what the tutorials here cover. This section shows you how to use Service Builder to create JSON and SOAP web services, and how to invoke those services. Because Liferay's own developers use Service Builder to generate JSON and SOAP web services, knowing how to invoke these services is especially important. This section includes the following tutorials:

- Creating Remote Services: Use Service Builder to generate your app's JSON and SOAP web services.
- Invoking Remote Services: Learn the basics of invoking JSON and SOAP web services in Liferay.
- Service Security Layers: Learn how Liferay secures web services, and how to invoke them with proper authentication.
- Registering JSON Web Services: Learn some of the details behind how Service Builder generates JSON web services, and how you can tailor this process to your needs.
- Invoking JSON Web Services: Learn how to invoke Liferay's JSON web services API via URL. This includes information on passing URL parameters, troubleshooting, and more.
- JSON Web Services Invoker: Learn how to use Liferay's JSON Web Services Invoker to optimize your JSON web service calls.
- JSON Web Services Invocation Examples: See examples of how to invoke Liferay's JSON web services via JavaScript, URL, and cURL.
- Configuring JSON Web Services: Learn which properties you can use to control how JSON web services behave in your Liferay instance.
- SOAP Web Services: Learn how SOAP web services work in Liferay.

85.1 Creating Remote Services

Many default Liferay DXP services are available as web services. Liferay DXP exposes its web services via JSON and SOAP web services. If you're running the portal locally on port 8080, visit the following URL to browse Liferay DXP's default JSON web services:

```
http://localhost:8080/api/jsonws/
```

To browse Liferay DXP's default SOAP web services, visit this URL:

```
http://localhost:8080/api/axis
```

These web services APIs can be accessed by many different kinds of clients, including non-portlet and even non-Java clients. You can use Service Builder to generate similar remote services for your projects' custom entities. When you run Service Builder with the `remote-service` attribute set to `true` for an entity, all the classes, interfaces, and files required to support both SOAP and JSON web services are generated for that entity. Service Builder generates methods that call existing services, but it's up to you to implement the methods that are exposed remotely. In this tutorial, you'll learn how to generate remote services for your application. When you're done, your application's remote service methods can be called remotely via JSON and SOAP web services.

Using Service Builder to Generate Remote Services

Remember that you should implement your application's local service methods in `*LocalServiceImpl`. You should implement your application's remote service methods in `*ServiceImpl`.

Best Practice: If your application needs both local and remote services, determine the service methods that your application needs for working with your entity model. Add these service methods to `*LocalServiceImpl`. Then create corresponding remote services methods in `*ServiceImpl`. Add permission checks to the remote service methods and make the remote service methods invoke the local service methods. The remote service methods can have the same names as the local service methods that they call. Within your application, only call the remote services. This ensures that your service methods are secured and that you don't have to duplicate permissions code.

As an example, consider Liferay DXP's Blogs app. Articles are represented by the `JournalArticle` entity. This entity is declared in the `journal-service` module's `service.xml` file with the `remote-service` attribute set to `true`. Service Builder therefore generates the remote service class `JournalArticleServiceImpl` to hold the remote service method implementations. If you were developing this app from scratch, this class would initially be empty; you must use it to implement the entity's remote service methods. Also, note that the remote service method implementations in `JournalArticleServiceImpl` follow best practice by checking permissions and calling the corresponding local service method. For example, each `addArticle` method in `JournalArticleServiceImpl` checks permissions via the custom permissions class `JournalFolderPermission` and then calls the local service's matching `addArticle` method:

```
@Override
public JournalArticle addArticle(...)
    throws PortalException {

    JournalFolderPermission.check(
        getPermissionChecker(), groupId, folderId, ActionKeys.ADD_ARTICLE);

    return journalArticleLocalService.addArticle(...);
}
```

You'll also need to develop custom permissions classes for each entity you need to perform permissions checks on. Also note that the local service is called via the `journalArticleLocalService` field. This is a Spring bean of type `JournalArticleLocalServiceImpl` that's injected into `JournalArticleServiceImpl` by Service Builder. See the class `JournalArticleServiceBaseImpl` for a complete list of Spring beans available in `JournalArticleServiceImpl`.

After you've finished adding remote service methods to your `*ServiceImpl` class, save it and run Service Builder again. After running Service Builder, deploy your project and check the Liferay DXP JSON web services URL http://localhost:8080/api/jsonws/ to make sure that your remote services appear when you select your application's context path.

Nice work! You've successfully used Service Builder to generate your app's remote services. To make these services available via SOAP, however, you must build and deploy your app's Web Service Deployment Descriptor (WSDD). The next section shows you how to do this. If you don't need to generate SOAP web services, you can move on to the tutorial Invoking Remote Services.

Generating Your App's WSDD

Liferay DXP uses Apache Axis to make SOAP web services available. Since Axis requires a WSDD to make an app's remote services available via SOAP, you must build and deploy a WSDD for your app. To create your WSDD, you must install Liferay's WSDD Builder Gradle plugin in your app's project. How you do this, however, depends on what kind of project you have. For multi-module projects like a Service Builder project in a Liferay Workspace, you'll install the plugin via the workspace's `settings.gradle` file. This applies the WSDD Builder plugin to every module in the workspace that uses Service Builder (typically the `*-api` and `*-service` modules). If you have a standalone `*-service` module that uses Service Builder, however, you'll install the WSDD Builder plugin in the module's `build.gradle` file.

The next section shows you how to install the WSDD builder in a multi-module project. If you have a standalone module project, skip ahead to the section *Installing the WSDD Builder Plugin in a Standalone Module Project*.

Installing the WSDD Builder Plugin in a Multi-module Project

To install the WSDD Builder plugin in a multi-module project like a Service Builder project in a Liferay Workspace, do the following in the workspace's `settings.gradle` file:

1. Add the `ServiceBuilderPlugin` and `WSDDBuilderPlugin` imports to the top of the file:

   ```
   import com.liferay.gradle.plugins.service.builder.ServiceBuilderPlugin
   import com.liferay.gradle.plugins.wsdd.builder.WSDDBuilderPlugin
   ```

2. In the `repositories` block, add the Liferay CDN repository via Maven:

   ```
   repositories {
       maven {
           url "https://repository-cdn.liferay.com/nexus/content/groups/public"
       }
   }
   ```

   This repository hosts the WSDD Builder library, its transitive dependencies, and other Liferay libraries. Note that if you created your Service Builder project with the `service-builder` template in Blade CLI or Liferay @ide@, then your `settings.gradle` file should already contain this.

3. Add this code to the end of the file:

```
gradle.beforeProject {
    project ->

    project.plugins.withType(ServiceBuilderPlugin) {
        project.apply plugin: WSDDBuilderPlugin
    }
}
```

This is the code that applies the WSDD Builder plugin in every module in the Liferay Workspace that uses Service Builder. Your `settings.gradle` file should now look something like this:

```
import com.liferay.gradle.plugins.service.builder.ServiceBuilderPlugin
import com.liferay.gradle.plugins.wsdd.builder.WSDDBuilderPlugin

buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.workspace", version: "1.2.0"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.workspace"

gradle.beforeProject {
    project ->

    project.plugins.withType(ServiceBuilderPlugin) {
        project.apply plugin: WSDDBuilderPlugin
    }
}
```

4. Refresh the Liferay Workspace's Gradle project. Close and restart Liferay @ide@ if you're using it.

Now that you've installed the WSDD Builder plugin, you're ready to build and deploy the WSDD. For instructions on this, proceed to the section *Building and Deploying the WSDD*.

Installing the WSDD Builder Plugin in a Standalone Module Project

To install the WSDD Builder plugin in a standalone `*-service` module that uses Service Builder, do the following in the module's `build.gradle` file:

1. Add the plugin as a dependency in your `buildscript`.
2. Add the Liferay CDN repository via Maven.
3. Apply the plugin to your project.

For example, the following part of an example `build.gradle` file in a standalone `*-service` module includes the WSDD Builder plugin and applies it to the project:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.wsdd.builder", version: "1.0.9"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.portal.tools.wsdd.builder"
```

Now you're ready to build and deploy the WSDD. The next section shows you how to do this.

Building and Deploying the WSDD

To build the WSDD, you must run the `buildWSDD` Gradle task in your `*-service` module. Exactly how you do this depends on your development tools:

- **Liferay @ide@:** From the Liferay Workspace perspective's *Gradle Tasks* pane (typically on the right), open your `*-service` module's *build* folder and double-click *buildWSDD*.
- **Command Line:** Navigate to your `*-service` module and run `../../../gradlew buildWSDD`. Note that the exact location of the Gradle wrapper (`gradlew`) may vary. For Liferay Workspace projects, it's typically in the root workspace folder.

So what should you do if `buildWSDD` fails? A common cause of `buildWSDD` failures is failing to satisfy the dependencies needed by the WSDD Builder for your `*-service` module. Note that these dependencies vary depending on your project's code–there's no standard set. That said, the following are often required for portlet development:

```
compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
compileOnly group: "com.liferay", name: "com.liferay.registry.api", version: "1.0.0"
```

Click here for more information on finding and configuring dependencies for your apps.

In your `*-service` project's `build/libs` folder, the `buildWSDD` task generated a `*-service-wsdd-[version].jar` file that contains your WSDD. Deploy this JAR to your Liferay DXP instance. Your SOAP web services are then available at a URL that uses the following pattern:

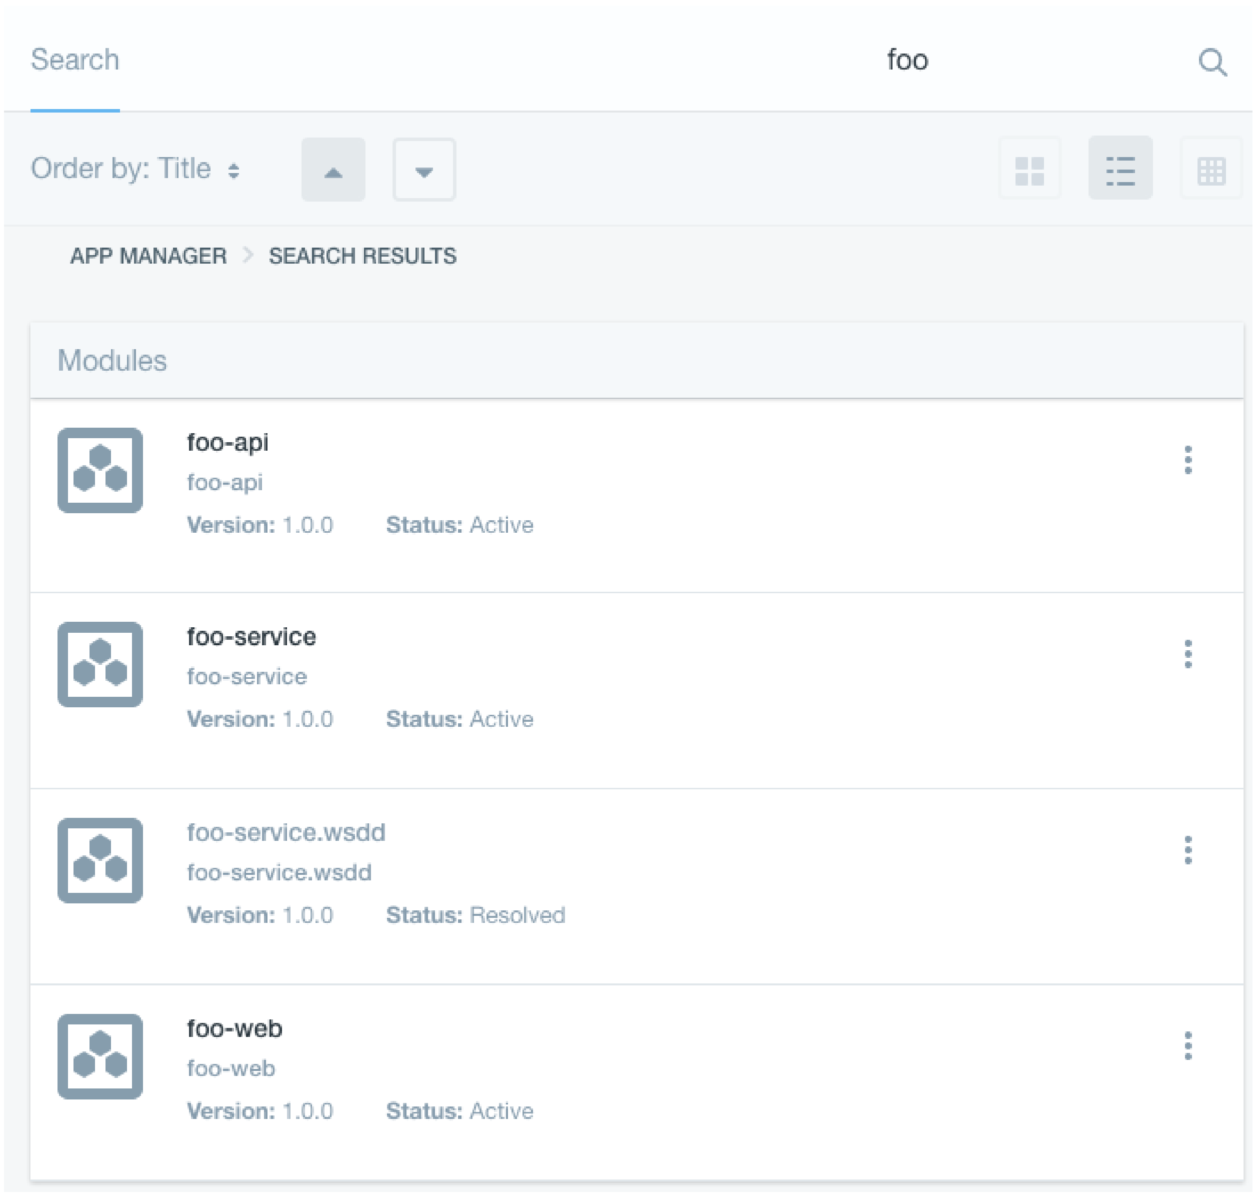
```
yourportaladdress/o/your.apps.service.module.context/api/axis
```

For example, if an app called *Foo* consists of the modules `foo-api`, `foo-service`, and `foo-web`, then the app's service module context is `foo-service`. If this app is deployed to a local Liferay DXP instance running at `http://localhost:8080`, you could access its SOAP services at:

```
http://localhost:8080/o/foo-service/api/axis
```

If you don't know an app's `*-service` module context, you can find it by searching for the app in the App Manager of the Liferay DXP instance in which the app is running. For example, the following screenshot shows the Foo app's modules in the App Manager. The name of the `*-service` module in the App Manager, `foo-service`, is also its context. Also note that the app's WSDD module is grayed out and listed as Resolved instead of Active. This is normal. WSDD modules are OSGi fragments, which can't be activated. They still work as intended, though.

Next, you'll learn how to build the WSDD module for Liferay DXP's built-in apps that don't include a WSDD by default. If you don't need to do this, you can move on to the tutorial Invoking Remote Services.



Search foo

Order by: Title

APP MANAGER > SEARCH RESULTS

Modules

foo-api
foo-api
Version: 1.0.0 Status: Active

foo-service
foo-service
Version: 1.0.0 Status: Active

foo-service.wsdd
foo-service.wsdd
Version: 1.0.0 Status: Resolved

foo-web
foo-web
Version: 1.0.0 Status: Active

Figure 85.1: To find your app's modules, including its WSDD module, search for your app in the App Manager. The `*-service` module's name in the App Manager is also the module's context.

Building the WSDD for Built-in Liferay DXP Apps

Liferay DXP doesn't provide WSDD modules for built-in apps that exist outside of the portal context. This means that by default you can't access SOAP web services for apps like Bookmarks or Blogs. To make SOAP web services available for such an app, you must build and deploy its WSDD from the `liferay-portal` GitHub repository. The apps are in the `liferay-portal/modules/apps` folder. Note that to build WSDDs for these apps, you must first download the `liferay-portal` source code to your machine. You'll run the WSDD build from your local `liferay-portal` copy.

When you build an app's WSDD, make sure to use `gradlew` in `liferay-portal` instead of the `gradle` on your machine. After building, you can find the WSDD JAR in the `tools/sdk/dist` folder of your local `liferay-portal` copy. Otherwise, building an app's WSDD is the same as in the preceding section.

For example, to build the WSDD for the Bookmarks app, first navigate to the `liferay-portal/modules/apps/collaboration/` `service` folder in your terminal. Then run the following command:

```
../../../../../gradlew buildWSDD
```

Next, deploy the `liferay-portal/tools/sdk/dist/com.liferay.bookmarks.service-wsdd-[version].jar` to your Liferay DXP instance. If your instance is running locally on `localhost:8080`, you should then be able to view the Bookmarks app's SOAP services at http://localhost:8080/o/com.liferay.bookmarks.service/api/axis.

Fantastic! Once you've created remote web services, you'll want to know how to invoke them. To learn how, see the tutorial Invoking Remote Services.

What is Service Builder?

85.2 Invoking Remote Services

You can invoke the remote services of any installed Liferay application the same way that you invoke your local services. Doing so could be described as "invoking remote services locally." One reason to invoke a remote service instead of the corresponding local service might be to take advantage of the remote service's permission checks. Consider the following common scenario:

- Both a local service implementation and a remote service implementation have been created for a particular service.
- The remote service performs a permission check and then invokes the corresponding local service.

In the above scenario, it's a best practice to invoke the remote service instead of the local service. Doing so ensures that you don't need to duplicate permission checking code. This is the practice followed by the services in Liferay's Blogs app.

Of course, the main reason for creating remote services is to invoke them remotely. Service Builder can expose your project's remote web services both via a JSON API and via SOAP. By default, running Service Builder with `remote-service` set to `true` for your entities generates a JSON web services API for your project. You can access your project's JSON-based RESTful services via a convenient web interface.

Invoking Liferay Services Remotely

Many default Liferay services are available as web services. Liferay exposes its web services via SOAP and JSON web services. If you're running Liferay locally on port 8080, visit the following URL to browse Liferay's default SOAP web services:

```
http://localhost:8080/api/axis
```

To browse Liferay's default JSON web services, visit this URL:

```
http://localhost:8080/api/jsonws/
```

By default, the context path is set to / which means that core Liferay services are listed. By default, the *http://localhost:8080/api/jsonws/* page shows the JSON web services in the `portal` context. You can select a different context in the *Context Name* selector menu. For example, selecting `journal` in *Context Name* shows you the JSON web services in Liferay's Web Content app (this app's entities all begin with `Journal*`). You can also access a context's JSON web services via a direct URL. For example, the URL for the Web Content app's JSON web services is http://localhost:8080/api/jsonws?contextName=journal.

Important: To invoke Liferay services remotely, your Liferay instance must be configured to allow remote web service access. Please see the Understanding Liferay's Service Security Model tutorial for details.

Each entity's available service methods are listed in the left column of the JSON web services page. To view details about a service method, click it. The full package path to the service's `*Impl` class is displayed along with the method's parameters, return type, and possible exceptions. You can also invoke the service from this page. For example, in the `portal` context click the `AnnouncementsEntry` entity's `get-entry` method. This brings up that service method's details page, where you can also invoke the service:

The only parameter required to invoke the `get-entry` method is an `entryId`. To invoke this web service, you could enter an announcement entry's ID in the `entryId` field and then click *Invoke*. Liferay returns feedback from each invocation that indicates, for example, whether the service invocation succeeded or failed. Invoking remote services in this manner is a great way to test your app's remote services.

Service Builder can also make your project's web services available via SOAP using Apache Axis. After you've built your `*-service` project's WSDD (web service deployment descriptor) and deployed your project's modules, its services are available on your Liferay server. You can view your Liferay instance's and app's SOAP services in a browser as described in the tutorial Creating Remote Services.

When viewing your SOAP services in a browser, Liferay lists the services available for all your entities and provides links to their WSDL documents. For example, clicking on the WSDL link for the User service takes you to the following URL:

```
http://localhost:8080/api/axis/Portal_UserService?wsdl
```

This WSDL document lists the entity's SOAP web services. Once the web service's WSDL is available, any SOAP web service client can access it. To see examples of SOAP web service client implementations, see the tutorial SOAP Web Services.

Liferay web services are designed to be invoked by client applications. Liferay's web services APIs can be accessed by many different kinds of clients, including non-portlet and even non-Java clients. For information on how to develop client applications that can access Liferay's JSON web services, please see the Invoking JSON Web Services tutorial. For information on how to develop client applications that access Liferay's SOAP web services, please see the SOAP Web Services tutorial. To learn how to create remote web services for your own application, please refer to the Creating Remote Services tutorial.

For more information on Liferay services, see the Liferay Portal CE Javadocs at @platform-ref@/7.0-latest/javadocs/.

85.3 Service Security Layers

Liferay's remote services are secured by default. They sit behind a layer of security that allows only local connections. To invoke Liferay services from a remote client, you must take deliberate steps to enable such access. Liferay's core web services require user authentication and verification. Regardless of whether you call the remote service from the same machine or via a web service, Liferay's standard security model performs its function. The user invoking a web service must have the proper permissions (as defined by Liferay's permissions system) for the remote service invocation to complete successfully. This tutorial explains these processes.

The first layer of security that a client encounters when calling a remote service is called *invoker IP filtering*. Imagine that you have have a batch job that runs on another machine in your network. This job polls a shared folder on your network and uses Liferay's web services to upload documents to your Liferay site's *Documents and Media* app on a regular basis. To get your batch job through the IP filter, you must grant web service access to the machine the batch job is running on. For example, if your batch job uses Liferay's SOAP web services to upload the documents, you must add the IP address of the machine where the batch job runs to the `axis.servlet.hosts.allowed` property. A typical entry might look like this:

```
axis.servlet.hosts.allowed=192.168.100.100, 127.0.0.1, [SERVER_IP]
```

If the IP address of the machine where the batch job runs is listed as an authorized host for the service, the machine is allowed to connect to Liferay's web services, pass in the appropriate user credentials, and upload the documents.

Note: The `portal.properties` file resides on the Liferay instance's host machine and is controlled by the instance administrator. Instance administrators can configure security settings for the Axis Servlet, the Liferay Tunnel Servlet, the Spring Remoting Servlet, the JSON Servlet, the JSON Web Service Servlet, and the WebDAV Servlet. The `portal.properties` file (online version is available at @platform-ref@/7.0-latest/propertiesdoc/portal.properties.html) describes these properties.

Next, if you invoke the remote service via web services (e.g., JSON WS, old JSON, Axis, REST, etc.), a two step process of authentication and authentication verification takes place. Each call to a Liferay web service must be accompanied by a user authentication token: `p_auth`. It's up to the web service caller to produce the token (e.g., through Liferay's utilities or through some third-party software). Liferay verifies that there is a Liferay user matching the token. If the credentials are invalid, the web service invocation is aborted. Otherwise, processing enters Liferay's user permission layer.

Liferay's user permission layer is the last Liferay security layer triggered when services are invoked remotely. It's used for every object in the Liferay instance, regardless of whether a local or remote service is involved. The user ID associated with a web service invocation must possess the proper permission to operate on the objects it's trying to access. A remote exception is thrown if the user ID doesn't possess the required permissions. An instance administrator can grant users access to these resources. For example, suppose you created a Documents and Media Library folder called *Documents* in a site, created a role called *Document Uploaders*, and granted this role the rights to add documents to your new folder. If your batch job accesses Liferay's web services to upload documents into the folder, you must call the web service using a user ID of a member of this role (or using the user ID of a user with individual rights to add documents to this folder, such as an instance administrator). If you don't, Liferay denies you access to the web service.

When invoking remote Liferay services from a non-browser client, you can specify the user credentials using HTTP basic authentication. For security reasons, you must be logged in and supply a valid `p_auth` authentication token to invoke a Liferay web service via a browser. Since you should never pass credentials over the network unencrypted, we recommend using HTTPS whenever accessing Liferay services on an untrusted network. Most HTTP clients (e.g., cURL) let you specify the basic authentication credentials in the URL–this is very handy for testing.

Important: To invoke a Liferay web service via your browser, you must be logged in to Liferay. You must also supply an authentication token (the `p_auth` parameter). If you navigate to your Liferay instance's JSON web services API page (localhost:8080/api/jsonws, by default) and click on a remote service method, you'll see the `p_auth` token for your browser session. This token is automatically supplied when you invoke a Liferay web service via the JSON web services API page or via JavaScript using `Liferay.Service(...)`.

Use the following syntax to call the Axis web service using credentials.

```
http://" + emailAddressOrScreenNameOrUserIdAsString + ":" + password + "@[server.com]:\
[port]/api/axis/" + serviceName
```

The `emailAddressOrScreenNameOrUserIdAsString` should be the user's email address, screen name, or user ID. The Liferay instance's authentication type setting determines which one to use. A user can find his or her ID by logging in as the user and accessing *My Account → Account Settings* from the User Menu. On this interface, the user ID appears below the user's profile picture and above the birthday field.

Suppose that your Liferay instance is set to authenticate by user ID, and that there's a user with an ID of `2` and a password of `test`. You can access Liferay's remote Organization service with the following URL:

```
http://2:test@localhost:8080/api/axis/Portal_OrganizationService
```

Note that if an email address appears in the URL path, it must be URL-encoded (e.g. `test@example.com` becomes `test%40liferay.com`).

Suppose that your Liferay instance is now set to authenticate by email address. To call the same web service for the same user, change the URL to this:

```
http://test%40liferay.com:test@localhost:8080/api/axis/Portal_OrganizationService
```

As mentioned, the authentication type specified for your Liferay instance dictates the authentication type you'll use to access your web service. The instance administrator can set the instance's authentication type to email address, screen name, or user ID.

You can set the authentication type via the Control Panel or via the `portal-ext.properties` file. To set the authentication type via the Control Panel, navigate to *Control Panel → Configuration → Instance Settings*, and select the *General* tab under *Authentication*. Choose your authentication type in the *How do users authenticate?* menu. To set the authentication type via properties file, add the following lines to your Liferay instance's `portal-ext.properties` file and uncomment the line for the appropriate authentication type:

```
#company.security.auth.type=emailAddress
#company.security.auth.type=screenName
#company.security.auth.type=userId
```

You should also review your Liferay instance's password policies, since they'll be enforced on your administrative user as well. If the instance enforces password policies on its users (e.g., requires them to change their passwords on a periodic basis), an administrative user accessing Liferay's web services in a batch job will have his or her password expire too.

To prevent a password from expiring, an instance administrator can add a new password policy that doesn't enforce password expiration, and then add a specific administrative user to the policy. Then your batch job can run as many times as you need it to, without your administrative user's password expiring.

To summarize, accessing Liferay remotely requires you to pass the following layers of security checks:

- *IP permission layer*: The IP address must be pre-configured in the server's portal properties.
- *Authentication/verification layer (web services only)*: Liferay verifies that the caller's authorization token can be associated with an instance user.

- *User permission layer*: The user needs permission to access the related resources.

If you'd like to develop client applications that can invoke Liferay's web services, make sure that your Liferay instance's web service security settings have been configured to allow access.

85.4 Registering JSON Web Services

Liferay's developers use a tool called *Service Builder* to build services. When you build services with Service Builder, all remote-enabled services (i.e., `service.xml` entities with the property `remote-service="true"`) are exposed as JSON web services. When each `*Service.java` interface is created for a remote-enabled service, the `@JSONWebService` annotation is added to that interface at the class level. All of the public methods of that interface become registered and available as JSON web services.

The `*Service.java` interface source file should never be modified by the user. If you need more control over its methods (e.g., if you need to hide some methods while exposing others), you can configure the `*ServiceImpl` class. When the service implementation class (`*ServiceImpl`) is annotated with the `@JSONWebService` annotation, the service interface is ignored and the service implementation class is used for configuration in its place. In other words, `@JSONWebService` annotations in the service implementation override any JSON web service configuration in the service interface.

That's it! Liferay scans all OSGi bundles registered with the `@Component` annotation or in a `*BundleActivator` class for remote services. Each class that uses the `@JSONWebService` annotation is examined and its methods become exposed via the JSON web services API. As explained previously, the `*ServiceImpl` configuration overrides the `*Service` interface configuration during registration.

Note: Liferay's developers use *Service Builder* to expose their services via JSON automatically. If you haven't used Service Builder before, please see the Service Builder section of tutorials.

Next, you'll see how you can register your application's remote services as JSON web services. Keep in mind that Liferay uses this same mechanism. This is why Liferay's remote services are exposed as JSON web services out-of-the-box.

Registering an App's JSON Web Services

As an example, say you have an app named `SupraSurf` that has some services, and you decide to expose them as remote services. After enabling the `remote-service` attribute on its `SurfBoard` entity, you rebuild the services. Service Builder regenerates the `SurfBoardService` interface, adding the `@JSONWebService` annotation to it. This annotation tells Liferay that the interface's public methods are to be exposed as JSON web services, making them a part of the app's JSON API. Start up your Liferay instance if it isn't running, and then deploy your app to Liferay.

To get some feedback from your Liferay instance on registering your application's services, configure the instance to log the application's informational messages (i.e., its `INFO ...` messages). See the tutorials on Liferay's logging system for details.

To test Liferay's JSON web service registration process, add a simple method to your app's services. Edit your `*ServiceImpl` class and add the following method:

```
public String helloWorld(String worldName) {
    return "Hello world: " + worldName;
}
```

Rebuild the services and re-deploy your app's modules. You can now invoke this service method via JSON. For instructions on doing this, see the JSON invocation tutorials listed in this section of tutorials.

This same mechanism registers Liferay's own services. They're conveniently enabled by default, so you don't have to configure them.

Next, you'll learn how to form a mapped URL for the remote service so you can access it.

Mapping and Naming Conventions

You can form the mapped URL of an exposed service by following the naming convention below:

```
http://[server]:[port]/api/jsonws/[context-path].[service-class-name]/[service-method-name]
```

Look at the last three bracketed items more closely:

- `context-name` is the app's context name (e.g., `suprasurf` in the previous example). Its value is specified via the `json.web.service.context.path` property in the `@OSGiBeanProperties` annotation. For example, for Liferay web content articles, Liferay's `JournalArticleService` class includes the following annotation (among others):

  ```
  @OSGiBeanProperties(property =  {
      "json.web.service.context.name=journal", "json.web.service.context.path=JournalArticle"}, service = JournalArticleService.class)
  ```

- `service-class-name` is generated from the service's class name in lower case, minus its `Service` or `ServiceImpl` suffix. For example, specify `surfboard` as the `app-context-name` for the `SurfBoardService` class.

- `service-method-name` is generated from the service's method name by converting its camel case to lower case and using dashes (-) to separate words.

The following example demonstrates these naming conventions by mapping a service method's URL using the naming conventions both on a custom service and on a Liferay service.

For the custom service method, the URL looks like:

```
http://localhost:8080/api/jsonws/suprasurf.surfboard/hello-world
```

Note the context name part of the URL. For Liferay, it's similar. Here's a Liferay service method:

```
@JSONWebService
public interface UserService {
    public com.liferay.portal.model.User getUserById(long userId) {...}
```

Here's that Liferay service method's URL:

```
http://localhost:8080/api/jsonws/user/get-user-by-id
```

Each service method is bound to one HTTP method type. Any method with a name starting with `get`, `is`, or has is assumed to be a read-only method and is mapped as a *GET HTTP* method by default. All other methods are mapped as *POST HTTP* methods.

Recall that you can see a list of your Liferay instance's JSON web services at http://localhost:8080/api/jsonws. When you select a method on this page, the part of its HTTP method URL that follows `http://[server]:[port]/api/jsonws` is listed at the top of the screen.

Conveniently, remote service requests can leverage the authentication credentials associated with the user's current Liferay session. Next, you'll learn how to prevent a method from being exposed as a service.

Ignoring a Method

To keep a method from being exposed as a service, annotate the method with the following option:

```
@JSONWebService(mode = JSONWebServiceMode.IGNORE)
```

Methods with this annotation don't become part of the JSON Web Service API. Next, you'll learn how to define custom HTTP method and URL names.

HTTP Method and URL Names

At the method level, you can define custom HTTP method names and URL names. Just use an annotation like this one:

```
@JSONWebService(value = "add-board-wow", method = "PUT")
public boolean addBoard(
```

In this example, the application's service method `addBoard` is mapped to URL method name `add-board-wow`. Its complete URL is now `http://localhost:8080/api/jsonws/suprasurf.surfboard/add-board-wow` and can be accessed using the HTTP PUT method.

If the URL method name in a JSON web service annotation starts with a slash character (`/`), only the method name is used to form the service URL; the class name is ignored:

```
@JSONWebService("/add-something-very-specific")
public boolean addBoard(
```

Similarly, you can change the class name part of the URL, by setting the value in a class-level annotation:

```
@JSONWebService("sbs")
public class SurfBoardServiceImpl extends SurfBoardServiceBaseImpl {
```

This maps all of the service's methods to a URL class name `sbs` instead of the default class name `surfboard`.

Next, you'll learn a different approach to exposing your methods via manual registration.

Manual Registration Mode

Up to now, it's assumed that you want to expose most of your service methods, while hiding some specific methods (the *blacklist* approach). Sometimes, however, you want the opposite: to explicitly specify only the methods you want to expose (the *whitelist* approach). This is possible by specifying *manual mode* on the class-level annotation. Then it's up to you to annotate only those methods you want to expose. For example:

```
@JSONWebService(mode = JSONWebServiceMode.MANUAL)
public class SurfBoardServiceImpl extends SurfBoardServiceBaseImpl{
    ...
    @JSONWebService
    public boolean addBoard(
```

Now only the `addBoard` method and any other method annotated with `@JSONWebService` are part of the JSON Web Service API; all of this service's other methods are excluded from the API.

JSON Web Services Invocation Examples

85.5 Invoking JSON Web Services

If you know the URL and are connected to the internet, invoke Liferay's JSON web service API in any language you want or directly with the URL or cURL. Additionally, Liferay provides a handy JSON web services page that allows you to browse and invoke service methods.

If you're running Liferay locally on port 8080, you can find the JSON web services page at http://localhost:8080/api/jsonws. You can use this page to generate example code for invoking web services. When you invoke a service on this page as described in the tutorial Invoking Remote Services, the JSON result of your service invocation appears. Click on the *JavaScript Example*, *curl Example*, or *URL Example* tabs to see different ways of invoking the web service.

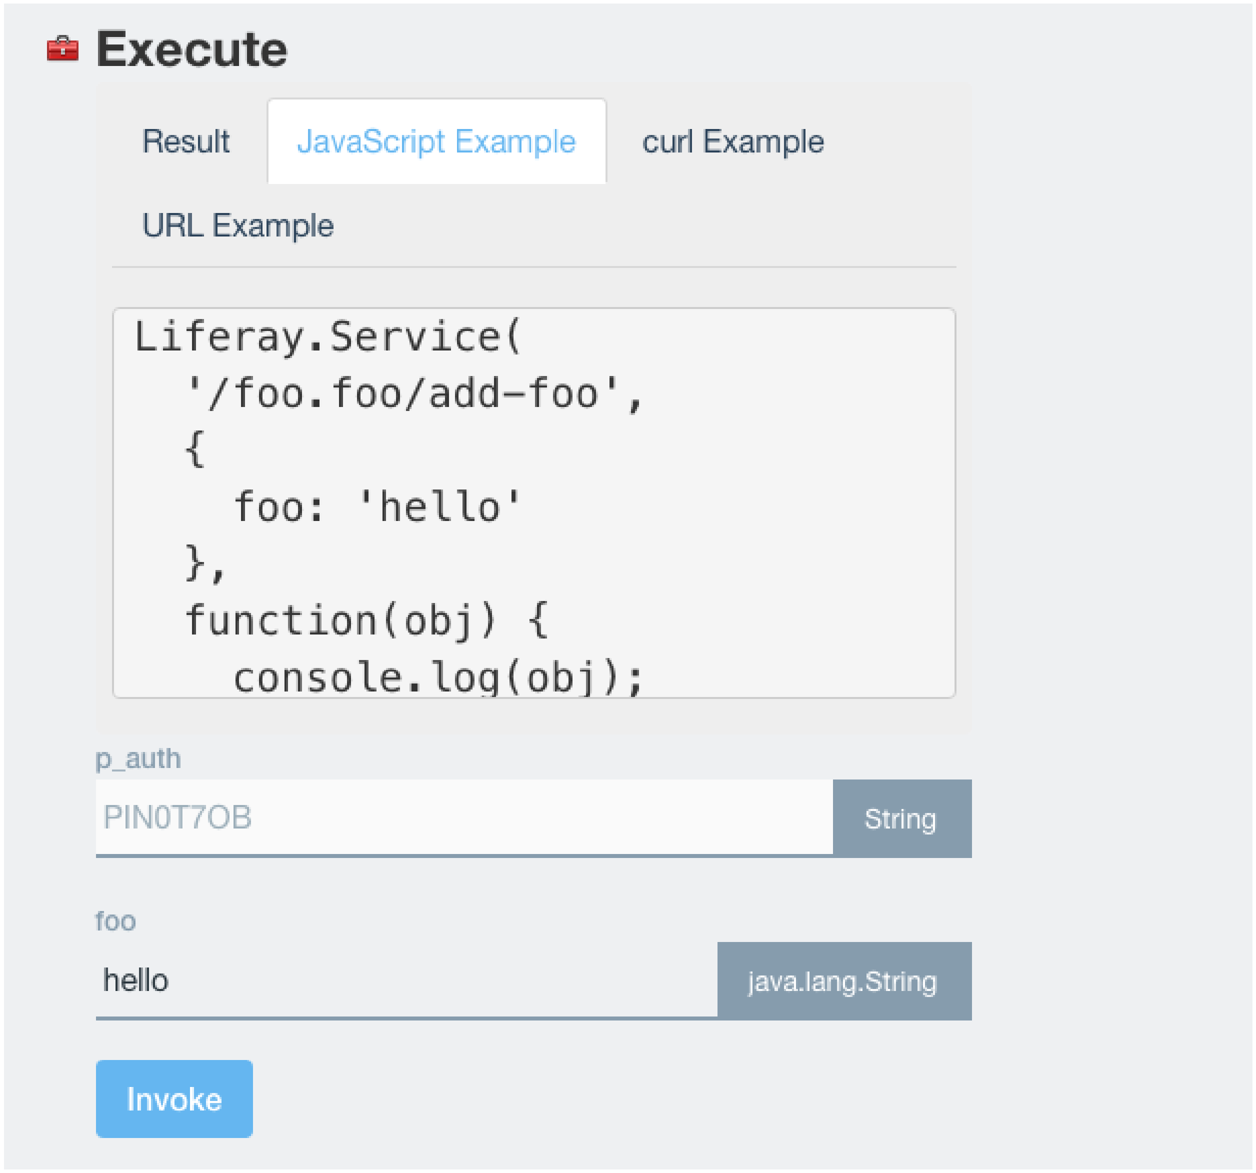
This tutorial explains general techniques for working with JSON web services and includes details about invoking them via URL. For examples of invoking Liferay's JSON web services via JavaScript, URL, and cURL, see the JSON Web Services Invocation Examples tutorial.

There are multiple ways to invoke a JSON web service since there are different ways to supply parameters. In this tutorial, you'll learn how to include parameters in web service invocations. First, you must understand how your invocation is matched to a method, especially in the case of overloaded service methods.

The general rule is that you provide the service method's name and *all* the service method's parameters–even if you only provide `null` values. It's important to provide all parameters, but it doesn't matter *how* you do it (e.g., as part of the URL line, as request parameters, etc.). The order of the parameters doesn't matter either.

Note: An authentication related token (p_auth) must accompany each Liferay web service invocation. For details, see the Service Security Layers tutorial. Also, see the note in the following section to learn how to find the `p_auth` token value that corresponds to your Liferay session.

Exceptions abound in life, and there's an exception to the rule that *all* parameters are required. When using numeric *hints* to match methods, not all of the parameters are required. You'll learn to use hints next.



```
Liferay.Service(
  '/foo.foo/add-foo',
  {
    foo: 'hello'
  },
  function(obj) {
    console.log(obj);
```

p_auth: PIN0T7OB (String)

foo: hello (java.lang.String)

Figure 85.3: When you invoke a service from Liferay's JSON web services page, you can view the result of your service invocation as well as example code for invoking the service via JavaScript, curl, or URL.

Using Hints When Invoking a Service via URL

Adding numeric hints lets you specify how many method arguments a service has. If you don't specify an argument for a parameter, it's automatically passed in as `null`. Syntactically, you can add hints as numbers separated by a dot in the method name. Here's an example:

```
/foo/get-bar.2/param1/123/-param2
```

Here, the `.2` is a numeric hint specifying that only service methods with two arguments are matched; others will be ignored for matching.

There's an important distinction to make between matching with hints and matching without hints. When a hint is specified, you don't have to specify all of the parameters. Any missing arguments are treated as `null`. The previous example may be called like this:

```
/foo/get-bar.2/param1/123
```

In this example, `param2` will automatically be set to `null`.

Here's a real Liferay example:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/add-folder.4/parent-folder-id/0/name/News?p_auth=[value]
```

In this example, the hint number is `4` because there are four parameters: `parentFolderId`, `name`, `description`, and `p_auth`. Since the `description` parameter is omitted, its value is assumed to be `null`. If you try to invoke this web service with another hint number such as `3` or `5`, you'll get an exception since there is no `bookmarks/add-folder` method that takes that number of parameters. The authentication parameter `p_auth` is associated with your Liferay session. See below for more information.

Important: When invoking a Liferay web service by entering a URL into your browser, you must be logged into Liferay with an account that has permission to invoke the web service. You must also supply an authentication token as a URL parameter. This authentication token is associated with your browser session and is called `p_auth`. Using this authentication token helps prevent CSRF attacks.

Here are two easy ways to find the `p_auth` token:

1. Go to Liferay's JSON web services page and click on any service method. The value of the `p_auth` token appears under the Execute heading.

2. If you're working from a JavaScript context and have access to the `Liferay` object, invoking `Liferay.authToken` provides the value of the `p_auth` parameter.

For example, if your `p_auth` parameter's value is `n35K1pb2`, you could invoke the preceding URL examples like this:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/add-folder.4/parent-folder-id/0/name/News?p_auth=n35K1pb2
```

For simplicity, the remainder of this tutorial omits the `p_auth` parameter from the example URLs for invoking web services. Remember that you must include it if you want to invoke services from your browser!

Next, you'll learn how to pass parameters as part of the URL path.

Passing Parameters as Part of a URL Path

To pass method parameters as part of the URL path, specify them in name-value pairs after the service URL. Parameter names must be formed from method argument names by converting them from camel case to names that use all lower case, dash-separated words. For example, this returns all top-level bookmark folders from the specified site:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/get-folders/group-id/20181/parent-folder-id/0
```

You can pass parameters in any order; it's not necessary to follow the order in which the arguments are specified in the method signatures.

When a method name is overloaded, the *best match* will be used. The method that contains the least number of undefined arguments is chosen and invoked for you.

You can also pass parameters in a URL query. The next section shows you how to do this.

Passing Parameters as a URL Query

To pass in parameters as request parameters, specify them as-is (camel case) and set them equal to their argument value. For example:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/add-folder?parentFolderId=0&name=News&description=news
```

As with passing parameters as part of a URL path, the parameter order is not important and the best match rule applies for overloaded methods.

Now you know a few different ways to pass parameters. It's also possible to pass URL parameters in a mixed way. For example, some can be part of the URL path while others can be specified as request parameters.

Parameter values are sent as strings using the HTTP protocol. Before a matching Java service method is invoked, each parameter value is converted from a `String` to its target Java type. Liferay uses a third party open source library to convert each object to its appropriate common type. Although it's possible to add or change the conversion for certain types, this tutorial only covers the standard conversion process.

Conversion for common types (e.g., `long`, `String`, `boolean`) is straightforward. Dates can be given in milliseconds. Locales can be passed as locale names (e.g. `en` and `en_US`). To pass in an array of numbers, send a string of comma-separated numbers (e.g. the string `4,8,15,16,23,42` can be converted to `long[]` type). You get the picture!

In addition to the common types, arguments can be of type `List` or `Map`. To pass a `List` argument, send a JSON array. To pass a `Map` argument, send a JSON object. These types of conversions are performed in two steps:

- *Step 1–JSON deserialization*: JSON arrays are converted into `List<String>`, and JSON objects are converted to `Map<String, String>`. For security reasons, it's forbidden to instantiate any type within JSON deserialization.
- *Step 2–Generification*: Each `String` element of the `List` and `Map` is converted to its target type (the argument's generic Java type specified in the method signature). This step is only executed if the Java argument type uses generics.

As an example, consider the conversion of a `String` array `[en,fr]` as JSON web service parameters for a `List<Locale>` Java method argument type:

- *Step 1–JSON deserialization*: The JSON array is deserialized to a `List<String>` containing `String`s `en` and `fr`.

- *Step 2–Generification*: Each `String` is converted to the `Locale` (the generic type), resulting in the `List<Locale>` Java argument type.

Next, you'll learn how to specify an argument as `null`.

Sending Null Values

To pass a `null` value for an argument, prefix the parameter name with a dash. Here's an example:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/add-folder/parent-folder-id/0/name/News/-description
```

Here's the equivalent example using URL query parameters instead of URL path parameters:

```
http://localhost:8080/api/jsonws/bookmarks.bookmarksfolder/add-folder?parentFolderId=0&name=News&-description
```

The `description` parameter is interpreted as `null`. Note that this parameter doesn't have to be last in the URL.

Null parameters don't have specified values. When a null parameter is passed as a request parameter, its value is ignored and `null` is used instead:

```
<input type="hidden" name="-description" value=""/>
```

When using JSON-RPC (see the JSON-RPC section below), you can send null values explicitly, even without a prefix. Here's an example:

```
"description":null
```

Next, you'll learn about encoding parameters.

Encoding Parameters

There's a difference between URL encoding and query (i.e., request parameters) encoding. The difference lies in how the space character is encoded. When the space character is part of the URL path, it's encoded as `%20`; when it's part of the query it's encoded as a plus sign (`+`).

All these encoding rules apply to ASCII and international (non-ASCII) characters. Since Liferay works in UTF-8 mode, parameter values must be encoded as UTF-8 values. Liferay doesn't decode request URLs and request parameter values to UTF-8 itself; it relies on the web server layer. When accessing services through JSON-RPC, encoding parameters to UTF-8 isn't enough–you need to send the encoding type in a Content-Type header (e.g. `Content-Type : "text/plain; charset=utf-8"`).

For example, suppose you want to pass the value "Супер" ("Super" in Cyrillic) to a JSON web service method. This name first has to be converted to UTF-8 (resulting in an array of 10 bytes) and then encoded for URLs or request parameters. The resulting value is the string `%D0%A1%D1%83%D0%BF%D0%B5%D1%80` that can be passed to your service method. When received, this value is first translated to an array of 10 bytes (URL decoded), and then converted to a UTF-8 string of the 5 original characters.

Next, you'll learn how to send files as arguments.

Sending Files as Arguments

Files can be uploaded using multi-part forms and requests. Here's an example:

```
<form
 action="http://localhost:8080/api/jsonws/dlapp/add-file-entry"
 method="POST"
 enctype="multipart/form-data">
    <input type="hidden" name="repositoryId" value="10172"/>
    <input type="hidden" name="folderId" value="0"/>
    <input type="hidden" name="title" value="test.jpg"/>
    <input type="hidden" name="description" value="File upload example"/>
    <input type="hidden" name="changeLog" value="v1"/>
    <input type="file" name="file"/>
    <input type="submit" value="addFileEntry(file)"/>
</form>
```

This is a common upload form that invokes the `DLAppService` class's `addFileEntry` method.
Now you'll learn how to invoke JSON web services using JSON-RPC.

JSON-RPC

You can invoke JSON Web Service using JSON-RPC. Most of the JSON-RPC 2.0 specification is supported in Liferay JSON web services. One important limitation is that parameters must be passed in as *named* parameters. Positional parameters aren't supported, as there are too many overloaded methods for convenient use of positional parameters.

Here's an example of invoking a JSON web service using JSON-RPC:

```
POST http://localhost:8080/api/jsonws/dlapp
{
    "method":"get-folders",
    "params":{"repositoryId":10172, "parentFolderId":0},
    "id":123,
    "jsonrpc":"2.0"
}
```

Next, you'll learn about parameters that are made available to secure JSON web services by default.

Default Parameters

When accessing secure JSON web services (i.e., services for which the user must be authenticated), some parameters are made available to the web services by default. All of Liferay's web services are secured by default. Unless you want to change the available parameters' values to something other than their defaults, you don't have to specify them explicitly.

Here are the available default parameters:

- `userId`: The primary key of the authenticated user
- `user`: The full user object
- `companyId`: The primary key of the user's company
- `serviceContext`: The empty service context object

Next, you'll learn about object parameters.

Object Parameters

Most services accept simple parameters like numbers and strings. However, sometimes you might need to provide an object (a non-simple type) as a service parameter.

To create an instance of an object parameter, prefix the parameter with a plus sign, + and don't assign it any other parameter value. This is similar to specifying a null parameter by prefixing the parameter with a dash symbol, -.

Here's an example:

```
/jsonws/foo/get-bar/zap-id/10172/start/0/end/1/+foo
```

To create an instance of an object parameter as a request parameter, make sure you encode the + symbol:

```
/jsonws/foo/get-bar?zapId=10172&start=0&end=1&%2Bfoo
```

Here's an alternative syntax:

```
<input type="hidden" name="+foo" value=""/>
```

If a parameter is an abstract class or an interface, it can't be instantiated as such. Instead, a concrete implementation class must be specified to create the argument value. You can do this by specifying the + prefix before the parameter name, followed by specifying the concrete implementation class. Here's an example:

```
/jsonws/foo/get-bar/zap-id/10172/start/0/end/1/+foo:com.liferay.impl.FooBean
```

Here's another way of doing it:

```
<input type="hidden" name="+foo:com.liferay.impl.FooBean" value=""/>
```

The examples above specify that a `com.liferay.impl.FooBean` object, presumed to implement the class of the parameter named `foo`, is created.

You can also set a concrete implementation as a value. Here's an example:

```
<input type="hidden" name="+foo" value="com.liferay.impl.FooBean"/>
```

In JSON-RPC, here's what it looks like:

```
"+foo" : "com.liferay.impl.FooBean"
```

All the preceding examples specify a concrete implementation for the `foo` service method parameter.

Once you pass in an object parameter, you might want to populate the object. Find out how next.

Inner Parameters

When you pass in an object parameter, you'll often need to populate its inner parameters (i.e., fields). Consider a default parameter `serviceContext` of type `ServiceContext`. To make an appropriate call to JSONWS, you might need to set the `serviceContext` parameter's `addGroupPermissions` and `scopeGroupId` fields.

You can pass inner parameters by using dot notation to specify them. Just append the name of the parameter with a dot (i.e., a period, .), followed by the inner parameter's name. For the `ServiceContext` inner parameters mentioned previously, you'll specify `serviceContext.addGroupPermissions` and `serviceContext.scopeGroupId`. These are recognized as inner parameters and their values are injected into existing parameters before the API service method is executed.

Inner parameters aren't counted as regular parameters for matching methods and are ignored during matching.

Tip: Use inner parameters with object parameters to set inner contents of created object parameter instances!

Next, let's see what values are returned when a JSON web service is invoked.

Returned Values

No matter how a JSON web service is invoked, it returns a JSON string that represents the service method result. Returned objects are *loosely* serialized to a JSON string and returned to the caller.

Now you'll look at some values returned from service calls. You'll create a `UserGroup` as in the SOAP web service client examples. To make it easy, you'll use the test form provided with the JSON web service in our browser.

1. Sign in to a local Liferay instance as an administrator and then point your browser to the JSON web service method that adds a `BookmarksFolder`:

   ```
   http://localhost:8080/api/jsonws?contextName=bookmarks&signature=%2Fbookmarks.bookmarksfolder%2Fadd-folder-4-parentFolderId-
   name-description-serviceContext
   ```

   Alternatively, navigate to it by starting at `http://localhost:8080/api/jsonws` and then scrolling down to the section for *BookmarksFolder*. Then click *add-folder*.

2. In the `parentFolderId` field, enter `0`. Top-level bookmarks folders have a `parentFolderId` value of `0`. Set the name to an arbitrary value like *News*. Set the description to something like *Created via JSON WS*.

3. Click *Invoke* and you'll get a result similar to the following:

   ```
   {
     "companyId": "20202",
     "createDate": 1459969296960,
     "description": "Created via JSON WS",
     "folderId": "31001",
     "groupId": "20233",
     "lastPublishDate": null,
     "modifiedDate": 1459969297005,
     "name": "News",
     "parentFolderId": "0",
     "resourceBlockId": "1",
     "status": 0,
     "statusByUserId": "0",
     "statusByUserName": "",
   ```

```
  "statusDate": null,
  "treePath": "/31001/",
  "userId": "20250",
  "userName": "Joe Bloggs",
  "uuid": "0682170c-f9d7-f295-aa67-26ceea37a6e5"
}
```

The returned `String` represents the `BookmarksFolder` object you just created, serialized into a JSON string. To find out more about JSON strings, go to json.org.

Common JSON Web Service Errors

While working with JSON web services, you may encounter errors. Some common errors are listed here:

- *Authenticated access required*

  If you see this error, it means you don't have permission to invoke the remote service. Double-check that you're signed in as a user with the appropriate permissions. If necessary, sign in as an administrator to invoke the remote service.

- *Missing value for parameter*

  If you see this error, you didn't pass a parameter value along with the parameter name in your URL path. The parameter value must follow the parameter name, like in this example:

  ```
  /api/jsonws/user/get-user-by-id/userId
  ```

  The path above specifies a parameter named `userId`, but doesn't specify the parameter's value. You can resolve this error by providing the parameter value after the parameter name:

  ```
  /api/jsonws/user/get-user-by-id/userId/173
  ```

- *No JSON web service action associated*

  This is error means no service method could be matched with the provided data (method name and argument names). This can be due to various reasons. For example, arguments may be misspelled, the method name may be formatted incorrectly, and so on. Since JSON web services reflect the underlying Java API, any changes in the respective Java API are automatically propagated to the JSON web services. For example, if a new argument is added to a method or an existing argument is removed from a method, the parameter data must match that of the new method signature.

- *Unmatched argument type*

  This error appears when you try to instantiate a method argument using an incompatible argument type.

85.6 JSON Web Services Invoker

To use JSON web services, you send a request that defines a service method and parameters, and you receive the result as a JSON object. As straightforward as this seems, it can be improved. In this tutorial, you'll learn how to use JSON web services more efficiently and pragmatically.

Consider the following example. You're working with two related objects: a `User` and its corresponding `Contact`. With simple JSON web service calls, you first call the user service to get the user object, and then you use that object's contact ID to call the contact service. You end up sending two HTTP requests to get two JSON objects that aren't even bound together. There's no contact information in the user object (i.e. no `user.contact`). This approach is suboptimal with respect to performance (sending two HTTP calls) and usability (manually managing the relationship between two objects). It'd be nicer if you had a tool to address these inefficiencies. Fortunately, the JSON Web Service Invoker does just that!

Liferay's JSON Web Service Invoker helps optimize your JSON Web Services use. In the following sections, you'll learn how.

Simple Invoker Calls

The Invoker is accessible from the following fixed address:

```
http://[address]:[port]/api/jsonws/invoke
```

It only accepts a `cmd` request parameter–this is the Invoker's command. If the command request parameter is missing, the request body is used as the command. So you can specify the command by either using the request parameter `cmd` or the request body.

The Invoker command is a plain JSON map that describes how JSON web services are called and how the results are managed. Here's an example of how to call a simple service using the Invoker:

```
{
    "/user/get-user-by-id": {
        "userId": 123,
        "param1": null
    }
}
```

The service call is defined as a JSON map. The key specifies the service URL (i.e. the service method to be invoked) and the key's value specifies a map of service parameter names (i.e. `userId` and `param1`) and their values. In the example above, the retrieved user is returned as a JSON object. Since the command is a JSON string, null values can be specified either by explicitly using the `null` keyword or by placing a dash before the parameter name and leaving the value empty (e.g. `"-param1": ''`).

The example Invoker calls functions exactly the same way as the following standard JSON Web Service call:

```
/user/get-user-by-id?userId=123&-param1
```

Next, suppose that you're running Liferay locally on port `8080`. Consider the following example of a real Liferay JSON web service invoker call. Suppose that you're signed in to Liferay as the default admin user whose email address is `test@example.com` and whose user ID is `20127`. And suppose that the value of your `p_auth` authentication token is `htXjvt5d`. You can then invoke the following URL to obtain a JSON representation of your user object:

```
http://localhost:8080/api/jsonws/invoke?cmd={%22/user/get-user-by-id%22:{%22userId%22:20172}}&p_auth=htXjvt5d
```

This URL uses the following JSON map. Note that it's supplied in the URL by using the cmd URL parameter:

```
{
    "/user/get-user-by-id": {
        "userId": 20172
    }
}
```

Note in the URL that the double quotes are URL-encoded. Also, if you're not sure what your user ID is, you can find it in the User Menu under *My Account → Account Settings*. If you're not sure what the value of your p_auth authentication token is, navigate to Liferay's JSON web services API page and click on any method in the list. The value of your p_auth token appears under the Execute heading along with any other parameters of the selected API method.

You can use JSON syntax for supplying values for objects and arrays that you need to supply as parameters. To supply a value for an object, use curly brackets: { and }. To supply a value for an array, use square brackets: [and]. Suppose as before that you're signed in to Liferay as an admin user and that the value of your p_auth authentication token is htXjvt5d. Furthermore, suppose that two vocabularies have been created with vocabulary IDs of 20783 and 20784. Here's a Liferay JSON web service invoker example that demonstrates how to pass an array as a parameter:

```
http://localhost:8080/api/jsonws/invoke?cmd={%22/assetvocabulary/get-vocabularies%22:{%22vocabularyIds%22:[20783,20784]}}&p_auth=htXjvt5d
```

This URL uses the following JSON map:

```
{
    "/assetvocabulary/get-vocabularies": {
        "vocabularyIds": [20783,20784]
    }
}
```

As before, the double quotes in the URL are URL-encoded. Also, the vocabularyIds parameter is an array, so its value is supplied as a JSON array.

Finally, here's one more Liferay JSON web service invoker example that demonstrates how to pass an object containing an array as a parameter:

```
http://localhost:8080/api/jsonws/invoke?cmd={%22/user/add-user%22:{%22companyId%22:20127,%22autoPassword%22:false,%22password1%22:%22test%22,%22password2%22
```

This URL uses the following JSON map:

```
{
    "/user/add-user": {
        "companyId": 20127,
        "autoPassword": false,
        "password1": "test",
        "password2": "test",
        "autoScreenName": false,
        "screenName": "joe.bloggs",
        "emailAddress": "joe.bloggs@example.com",
        "facebookId": 0,
        "openId": "",
        "locale": "en_US",
        "firstName": "Joe",
        "middleName": "T",
        "lastName": "Bloggs",
        "prefixId": 0,
        "suffixId": 0,
        "male": true,
        "birthdayMonth": 1,
        "birthdayDay": 1,
        "birthdayYear": 1970,
        "jobTitle": "Tester",
        "groupIds": null,
        "organizationIds": null,
        "roleIds": null,
        "userGroupIds": null,
        "sendEmail": false,
        "serviceContext": {"assetTagNames":["test"]}
    }
}
```

The `serviceContext` is the object containing an array in this example. It contains the array `assetTagNames`.

Of course, the JSON Web Service Invoker handles calls to plugin methods as well:

```
{
    "/suprasurf/hello-world": {
        "worldName": "Mavericks"
    }
}
```

The code above calls the (fictitious) SupraSurf application's remote service.

You can use variables to reference objects returned from service calls. Variable names must start with a dollar sign, `$`. In the previous example, the service call returned a user object you can assign to a variable:

```
{
    "$user = /user/get-user-by-id": {
        "userId": 123,
    }
}
```

The `$user` variable holds the returned user object. You can reference the user's contact ID using the syntax `$user.contactId`.

Next, see how you can use nested service calls to join information from two related objects.

Nesting Service Calls

With nested service calls, you can bind information from related objects together in a JSON object. You can call other services within the same HTTP request and nest returned objects in a convenient way. Here's a nested service call in action:

```
{
    "$user = /user/get-user-by-id": {
        "userId": 123,
        "$contact = /contact/get-contact-by-id": {
            "@contactId": "$user.contactId"
        }
    }
}
```

This command defines two service calls: the contact object returned from the second service call is nested in (i.e. injected into) the user object, as a property named `contact`. Now you can bind the user and his or her contact information together!

Now you'll see what the Invoker does in the background when using a single HTTP request to make the preceding nested service call:

- First, the Invoker calls the Java service mapped to `/user/get-user-by-id`, passing in a value for the `userId` parameter.

- Next, the resulting user object is assigned to the variable `$user`.
- The nested service calls are invoked.
- The Invoker calls the Java service mapped to `/contact/get-contact-by-id` by using the `contactId` parameter, with the `$user.contactId` value from the object `$user`.
- The resulting contact object is assigned to the variable `$contact`.
- Lastly, the Invoker injects the contact object referenced by `$contact` into the user object's property named `contact`.

Note: You must flag parameters that take values from existing variables. To flag a parameter, insert the `@` prefix before the parameter name.

Next, you'll learn about filtering object properties so that only the properties you need are returned when you invoke a service.

Filtering Results

Many of Liferay's model objects are rich with properties. If you only need a handful of an object's properties for your business logic, making a web service invocation that returns all of an object's properties is a waste of network bandwidth. With the JSON Web Service Invoker, you can define a whitelist of properties: only the specific properties you request in the object are returned from your web service call. Here's how you whitelist the properties you need:

```
{
    "$user[firstName,emailAddress] = /user/get-user-by-id": {
        "userId": 123,
        "$contact = /contact/get-contact-by-id": {
            "@contactId": "$user.contactId"
        }
    }
}
```

In this example, the returned user object has only the `firstName` and `emailAddress` properties (it still has the `contact` property, too). To specify whitelist properties, you simply place the properties in square brackets (e.g., `[whiteList]`) immediately following the name of your variable.

Next, you'll learn about making calls in batch.

Making Batch Calls

When nesting service calls, the intent is to invoke multiple services with a single HTTP request. Using a single request for multiple service calls is helpful for gathering related information from the service call results, but it can also be advantageous to use a single request to invoke multiple unrelated service calls. The Invoker lets you batch service calls together to improve performance. It's simple: just pass in a JSON array of commands using the following format:

```
[
    {/* first command */},
    {/* second command */}
]
```

The result is a JSON array populated with results from each command. The commands are collectively invoked in a single HTTP request, one after another.

Great! Now you know how to use Liferay's JSON Web Service Invoker to simplify your JSON calls to Liferay.

85.7 JSON Web Services Invocation Examples

This tutorial provides examples of invoking Liferay's JSON web services via JavaScript, URL, and cURL. To illustrate the differences between these, the same two use cases (getting a user and adding a user) are shown in each example. This tutorial also includes an example of using JavaScript to invoke Liferay's JSON web services from a portlet.

Loading AlloyUI

Liferay web pages use the AlloyUI JavaScript framework. Among the JavaScript objects created for each Liferay page is a `Liferay` object. This object includes a `Service` function that you can use to invoke Liferay's API. To invoke Liferay web services via `Liferay.Service(...)`, your JavaScript context must include the AlloyUI JavaScript framework. Liferay uses AlloyUI 3.0. If you're working in a JSP, you can load the AlloyUI taglib and wrap your JavaScript code in an `<aui:script>` tag. Here's the required import:

```
<%@ taglib uri="http://alloy.liferay.com/tld/aui" prefix="aui" %>
```

By default, the `<aui:script>` tag includes the base AUI module. To load specific AUI modules, specify them via the use attribute. For example, to use the AUI `node` and `event` modules, wrap your code like this:

```
<aui:script use="node, event">
    // Liferay service invocation here
</aui:script>
```

If you're not working in a JSP, you won't have access to taglibs. In this case, create an AUI context manually. For example, use the following HTML fragment to load the AUI seed and CSS files:

```
<script src="http://cdn.alloyui.com/3.0.0/aui/aui-min.js"></script>
<link href="http://cdn.alloyui.com/3.0.0/aui-css/css/bootstrap.min.css" rel="stylesheet"></link>
```

Then you can create an AUI context like this:

```
AUI().use('aui-base', function(A){
    // Liferay service invocation here
});
```

Now you're ready to invoke Liferay's JSON web services.

Get User JSON Web Service Invocation via JavaScript

First, examine the following JSON web service invocation, written in JavaScript:

```
Liferay.Service(
    '/user/get-user-by-email-address',
    {
        companyId: Liferay.ThemeDisplay.getCompanyId(),
        emailAddress: 'test@example.com`
    },
    function(obj) {
        console.log(obj);
    }
);
```

If you run this code, the test@example.com user (JSON object) is logged to the JavaScript console. The `Liferay.Service(...)` function takes three arguments:

1. A string representing the service to invoke
2. A parameters object
3. A callback function

The callback function takes the result of the service invocation as an argument.

Add User JSON Web Service Invocation via JavaScript

Here's an example JSON web service invocation, also written in JavaScript, that adds a new user. It requires many more parameters than the one for retrieving a user!

```
Liferay.Service(
    '/user/add-user',
    {
        companyId: Liferay.ThemeDisplay.getCompanyId(),
        autoPassword: false,
        password1: 'test',
        password2: 'test',
        autoScreenName: false,
        screenName: 'joe.bloggs',
        emailAddress: 'joe.bloggs@example.com',
        facebookId: 0,
        openId: '',
        locale: 'en_US',
        firstName: 'Joe',
        middleName: 'T',
        lastName: 'Bloggs',
        prefixId: 0,
        suffixId: 0,
        male: true,
        birthdayMonth: 1,
        birthdayDay: 1,
        birthdayYear: 1970,
        jobTitle: 'Tester',
        groupIds: null,
        organizationIds: null,
        roleIds: null,
        userGroupIds: null,
        sendEmail: false,
        serviceContext: {assetTagNames: ['test']}
    },
    function(obj) {
        console.log(obj);
    }
);
```

The `serviceContext` object assigns the `test` tag to the newly created user. Note that you can use JSON syntax to supply values for objects and arrays. For example, to supply a value for the `serviceContext` object, you use curly brackets: { and }. To supply a value for the `assetTagNames` array, you use square brackets: [and]. Thus, the line `serviceContext: {assetTagNames: ['test']}` indicates that `serviceContext` is an object containing an array named `assetTagNames`, which contains the string `test`.

Invoking JSON Web Services via JavaScript in a Application

You can adapt the example from the previous section for use in a Liferay app. For example, the JSP page below creates a form that lets the user specify a first name, middle name, last name, screen name, and email address. When the user clicks the *Add User* button, the app uses these values to create a new user.

```
<%@ taglib uri="http://alloy.liferay.com/tld/aui" prefix="aui" %>
<%@ taglib uri="http://java.sun.com/portlet_2_0" prefix="portlet" %>

<portlet:defineObjects />

<portlet:renderURL var="successURL">
    <portlet:param name="mvcPath" value="/success.jsp"/>
</portlet:renderURL>

<portlet:renderURL var="failureURL">
    <portlet:param name="mvcPath" value="/failure.jsp"/>
</portlet:renderURL>

<aui:form method="GET" name="<portlet:namespace />fm">
    <aui:fieldset>
        <aui:input label="First Name" name="first-name"></aui:input>
        <aui:input label="Middle Name" name="middle-name"></aui:input>
        <aui:input label="Last Name" name="last-name"></aui:input>
        <aui:input label="Screen Name" name="screen-name"></aui:input>
        <aui:input label="Email Address" name="email-address"></aui:input>
    </aui:fieldset>

        <p>Click the button below to add a new user by invoking Liferay's JSON web services.</p>

        <aui:button-row>
            <aui:button id="add-user" value="Add User">
            </aui:button>
        </aui:button-row>
</aui:form>

<aui:script use="node, event">
var addUserButton = A.one('#add-user');

var firstNameNode = A.one('#<portlet:namespace />first-name');
var middleNameNode = A.one('#<portlet:namespace />middle-name');
var lastNameNode = A.one('#<portlet:namespace />last-name');
var screenNameNode = A.one('#<portlet:namespace />screen-name');
var emailAddressNode = A.one('#<portlet:namespace />email-address');

addUserButton.on('click', function(event) {
        var firstName = firstNameNode.get('value');
        var middleName = middleNameNode.get('value');
        var lastName = lastNameNode.get('value');
        var screenName = screenNameNode.get('value');
        var emailAddress = emailAddressNode.get('value');

    var user = Liferay.Service(
        '/user/add-user',
        {
            companyId: Liferay.ThemeDisplay.getCompanyId(),
            autoPassword: false,
            password1: 'test',
            password2: 'test',
            autoScreenName: false,
            screenName: screenName,
            emailAddress: emailAddress,
            facebookId: 0,
            openId: '',
            locale: 'en_US',
            firstName: firstName,
            middleName: middleName,
            lastName: lastName,
            prefixId: 0,
            suffixId: 0,
            male: true,
            birthdayMonth: 1,
            birthdayDay: 1,
            birthdayYear: 1970,
            jobTitle: 'Tester',
            groupIds: null,
            organizationIds: null,
            roleIds: null,
            userGroupIds: null,
            sendEmail: false,
            serviceContext: {assetTagNames: ['test']}
        },
        function(obj) {
            console.log(obj);

            if (obj.hasOwnProperty('createDate')) {
                window.open('<%= successURL %>', '_self');
            }
            else {
                window.open('<%= failureURL %>', '_self');
            }
        }
    );
});
</aui:script>
```

In this example, it's assumed that the JSP page is part of a web module with a portlet class that extends Liferay's `MVCPortlet` class. This is required since the code uses the `mvcPath` URL parameter. It's also assumed that the JSP code is in a file named `view.jsp`, and that there are also `success.jsp` and `failure.jsp` files in the same directory.

Get User JSON Web Service Invocation via URL

Here's a simple JSON web service invocation via URL that returns the user with the specified email address:

```
http://localhost:8080/api/jsonws/user/get-user-by-email-address/company-id/20154/email-address/test%40liferay.com?p_auth=[value]
```

This web service invocation returns the test@example.com user. After invoking a service via Liferay's JSONWS API page, the URL provided when you click on the *URL Example* tab omits the `p_auth` URL query parameter. It's assumed that you'll add this parameter yourself. Remember that you must be logged in as a user with the required permission to invoke a web service. To find the `p_auth` token that corresponds to your session, see the Invoking JSON Web Services tutorial.

If you read that tutorial, you know that you can supply parameters as either URL path parameters or URL query parameters. In the preceding example, the company ID and email address are supplied as URL path parameters. Here's an equivalent example using URL query parameters:

```
http://localhost:8080/api/jsonws/user/get-user-by-email-address?companyId=20154&emailAddress=test@example.com&p_auth=[value]
```

Next, you'll consider an example that requires many more parameters!

Add User JSON Web Service Invocation via URL

Here's an example JSON web service invocation via URL that adds a new user with the specified attributes:

```
http://localhost:8080/api/jsonws/user/add-user/company-id/20154/auto-password/false/password1/test/password2/test/auto-screen-
name/false/screen-name/joe.bloggs/email-address/joe.bloggs%40liferay.com/facebook-id/0/-open-id/locale/en_US/first-name/Joe/middle-
name/T/last-name/Bloggs/prefix-id/0/suffix-id/0/male/true/birthday-month/1/birthday-day/1/birthday-year/1970/job-title/Tester/-group-
ids/-organization-ids/-role-ids/-user-group-ids/send-email/false?p_auth=[value]
```

And here's the same example using URL query parameters instead of URL path parameters:

```
http://localhost:8080/api/jsonws/user/add-user?companyId=20154&autoPassword=false&password1=test&password2=test&autoScreenName=false&screenName=joe.bloggs&e
openId&locale=en_US&firstName=Joe&middleName=T&lastName=Bloggs&prefixId=0&suffixId=0&male=true&birthdayMonth=1&birthdayDay=1&birthdayYear=1970&jobTitle=Test
groupIds&-organizationIds&-roleIds&-userGroupIds&sendEmail=false&p_auth=[value]
```

Get User JSON Web Service Invocation via cURL

Here's an example JSON web service invocation via the cURL tool that returns the user with the specified email address:

```
curl http://localhost:8080/api/jsonws/user/get-user-by-email-address \
  -u test@example.com:test \
  -d companyId=20154 \
  -d emailAddress='test@example.com'
```

Note that cURL is a command line tool. You can execute this command from a terminal or command prompt.

Add User JSON Web Service Invocation via cURL

Here's an example JSON web service invocation via the cURL tool that adds the user with the specified attributes:

```
curl http://localhost:8080/api/jsonws/user/add-user \
  -u test@example.com:test \
  -d companyId=20154 \
  -d autoPassword=false \
  -d password1='test' \
  -d password2='test' \
  -d autoScreenName=false \
  -d screenName='joe.bloggs' \
  -d emailAddress='joe.bloggs@example.com' \
  -d facebookId=0 \
  -d openId='0' \
  -d locale=en_US \
  -d firstName='Joe' \
  -d middleName='T' \
  -d lastName='Bloggs' \
  -d prefixId=0 \
  -d suffixId=0 \
  -d male=true \
  -d birthdayMonth=1 \
  -d birthdayDay=1 \
  -d birthdayYear=1970 \
  -d jobTitle='Tester' \
  -d groupIds= \
  -d organizationIds= \
  -d roleIds= \
  -d userGroupIds= \
  -d sendEmail=false
```

Great! Now you've seen how to invoke Liferay's JSON web services from JavaScript, URL, and cURL.

    Invoking Remote Services

85.8 Configuring JSON Web Services

JSON web services are enabled in Liferay by default. If you need to disable them, specify this portal property setting in a `portal-ext.properties` file:

```
json.web.service.enabled=false
```

This tutorial presents other such properties that you can use to fine-tune exactly how JSON web services work in your Liferay instance. You can find these, and other properties, in the portal properties reference documentation. As with the preceding property, you should set portal properties in a `portal-ext.properties` file.

First, you'll learn about setting whether JSON web services are discoverable via the API page.

Discoverability

By default, JSON web services are discoverable via the API page at `http://[address]:[port]/api/jsonws`. To disable this, set the following property:

```
jsonws.web.service.api.discoverable=false
```

Next, you'll learn how to disable HTTP methods.

Disabling HTTP Methods

When strict HTTP method mode is enabled, you can filter web service access based on HTTP methods used by the services. For example, you can set your Liferay instance's JSON web services to work in read-only mode by disabling HTTP methods other than `GET`. For example:

```
jsonws.web.service.invalid.http.methods=DELETE,POST,PUT
```

With this setting, all requests that use `DELETE`, `POST`, or `PUT` HTTP methods are ignored.

Next, you'll learn how to restrict public access to exposed JSON APIs.

Strict HTTP Methods

All JSON web services are mapped to either `GET` or `POST` HTTP methods. If a service method name starts with `get`, `is` or `has`, the service is assumed to be read-only and is bound to the `GET` method. Otherwise, it's bound to `POST`.

By default, Liferay doesn't check `HTTP` methods when invoking a service call; it works in non-strict http method mode, where services may be invoked using any HTTP method. If you need the strict mode, you can set it as follows:

```
jsonws.web.service.strict.http.method=true
```

When using strict mode, you must use the correct HTTP methods to calll service methods. When strict HTTP mode is enabled, you still might need to disable HTTP methods. You'll learn how next.

Controlling Public Access

Each service method knows whether a given user has permission to invoke the chosen action. If you're concerned about security, you can restrict access to exposed JSON APIs by explicitly permitting or restricting certain JSON web service paths.

The property `jsonws.web.service.paths.includes` denotes patterns for JSON web service action paths that are allowed. Set a blank pattern to allow any service action path.

The property `jsonws.web.service.paths.excludes` denotes patterns for JSON web service action paths that aren't allowed even if they match one of the patterns set in `jsonws.web.service.paths.includes`.

Note that these properties support wildcards. For example, if you set `jsonws.web.service.paths.includes=get*,has*,is*`, Liferay makes all read-only JSON methods publicly accessible. All other JSON methods are secured. To disable access to all exposed methods, you can leave the right side of the = symbol empty. To enable access to all exposed methods, specify *. Remember that if a path matches both the `jsonws.web.service.paths.includes` and `jsonws.web.service.paths.excludes` properties, the `jsonws.web.service.paths.excludes` property takes precedence.

Invoking Remote Services

85.9 SOAP Web Services

You can access Liferay's web services via Simple Object Access Protocol (SOAP) over HTTP. The packaging protocol is SOAP, and the transport protocol is HTTP.

Note: An authentication token must accompany each Liferay web service invocation. For details, see the tutorial on Service Security Layers.

As an example, consider some example SOAP web service clients for Liferay's `Company`, `User`, and `UserGroup` services that perform these tasks:

1. List each user group the user with the screenname *test* belongs to.
2. Add a new user group named *MyGroup*.
3. Add your Liferay instance's administrative user to the new user group. For demonstration purposes, you'll use an administrative user whose email address is `test@example.com`.

You'll use these SOAP related classes:

```
import com.liferay.portal.kernel.model.CompanySoap;
import com.liferay.portal.kernel.model.CompanySoap;
import com.liferay.portal.kernel.model.UserGroupSoap;
import com.liferay.portal.kernel.model.UserGroupSoap;
import com.liferay.portal.service.http.CompanyServiceSoap;
import com.liferay.portal.service.http.CompanyServiceSoapServiceLocator;
import com.liferay.portal.service.http.UserGroupServiceSoap;
import com.liferay.portal.service.http.UserGroupServiceSoapServiceLocator;
import com.liferay.portal.service.http.UserServiceSoap;
import com.liferay.portal.service.http.UserServiceSoapServiceLocator;
```

Can you see the naming convention for SOAP related classes? These classes have either `-ServiceSoapServiceLocator`, `-ServiceSoap`, or `-Soap` as suffixes. The `-ServiceSoapServiceLocator` class finds the `-ServiceSoap` class via the service's URL you provide. The `-ServiceSoap` class is the interface to the services specified in the Web Services Definition Language (WSDL) file for each service. The `-Soap` classes are the serializable implementations of the models.

So how do you determine the URLs for these services? This is a most excellent question! You can see a list of the services deployed on your Liferay instance by opening your browser to the following URL:

```
http://[host]:[port]/api/axis
```

Note that this URL only lists services in the portal context. To learn how to find services in other contexts in your Liferay instance, see the SOAP sections in the tutorial Creating Remote Services.

Regardless of the context you're viewing SOAP services in, each web service is listed with its name, operations, and a link to its WSDL file. For example, here's the list of secure web services listed for `UserGroup`:

- `Portal_UserGroupService` (wsdl)
  - `addGroupUserGroups`
  - `addTeamUserGroups`
  - `addUserGroup`
  - `deleteUserGroup`
  - `fetchUserGroup`
  - `getUserGroup`
  - `getUserGroups`
  - `getUserUserGroups`
  - `unsetGroupUserGroups`
  - `unsetTeamUserGroups`
  - `updateUserGroup`

Note that some of these methods are overloaded.

Liferay uses Service Builder to automatically generate JSON and SOAP web service interfaces. If you haven't used Service Builder before, see its introductory tutorial.

The WSDL file is written in XML and provides a model for describing and locating the web service. Here's a WSDL excerpt of the `addUserGroup` operation of `UserGroup`:

```
<wsdl:operation name="addUserGroup" parameterOrder="name description">
    <wsdl:input message="intf:addUserGroupRequest" name="addUserGroupRequest"/>
    <wsdl:output message="intf:addUserGroupResponse" name="addUserGroupResponse"/>
</wsdl:operation>
```

To use the service, you pass in the WSDL URL along with your login credentials to the SOAP service locator for your service. The next section shows you an example of this.

SOAP Java Client

Now you'll learn how to invoke Liferay's SOAP web services. As an example, you'll do this by setting up a Java web services client in Eclipse. You can use Eclipse's Web Service Client wizard to either create a new web service client project or add a client to an existing project. You must add a new web service client to your project for each service that you want to consume in your client code. For this example, you'll build a web service client to invoke Liferay's `Company`, `User`, and `UserGroup` services.

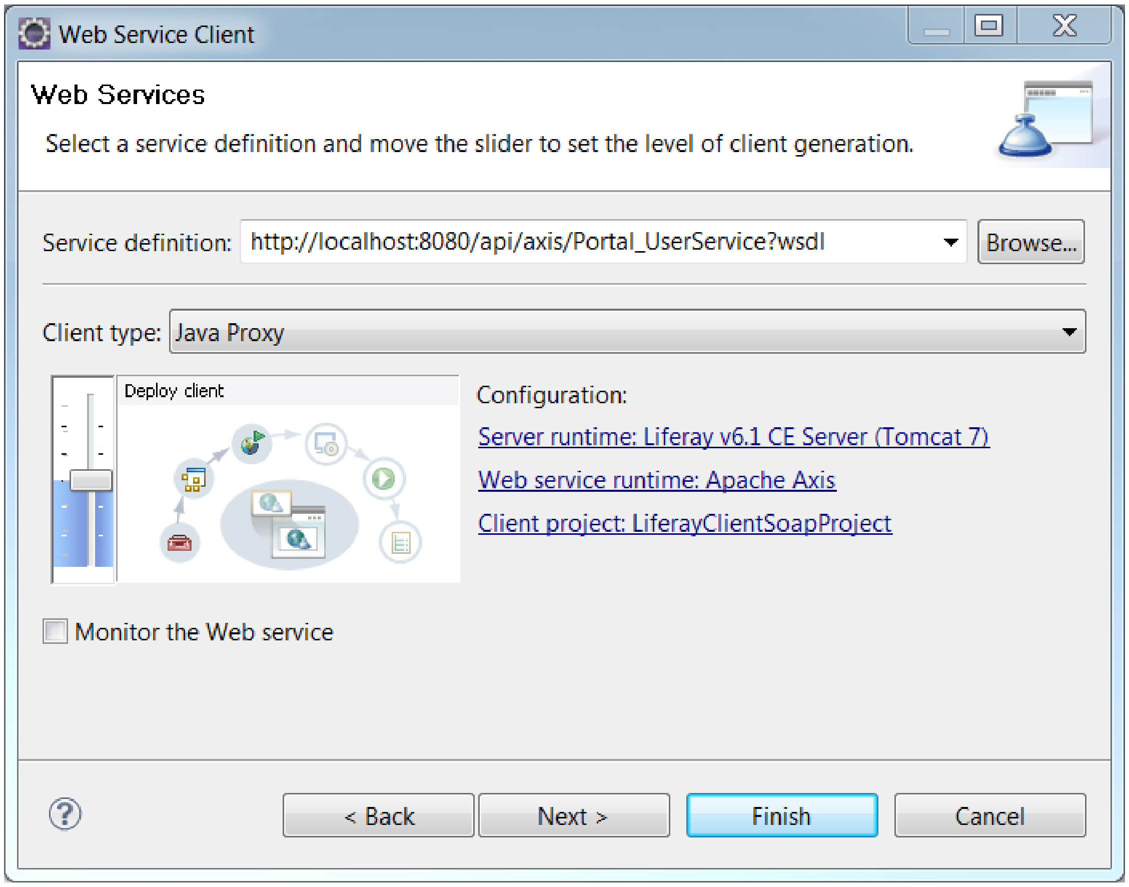
To create a new web service client project in Eclipse, click *File → New → Other...*, then expand the *Web Services* category. Select *Web Service Client*.

For each client you create, you're prompted to enter the service definition (WSDL) for the desired service. Since your example web service client needs Liferay's `Company`, `User`, and `UserGroup` services, enter the following WSDLs:

```
http://localhost:8080/api/axis/Portal_CompanyService?wsdl
```

```
http://localhost:8080/api/axis/Portal_UserService?wsdl
```

```
http://localhost:8080/api/axis/Portal_UserGroupService?wsdl
```



Web Service Client

Web Services

Select a service definition and move the slider to set the level of client generation.

Service definition: http://localhost:8080/api/axis/Portal_UserService?wsdl

Client type: Java Proxy

Configuration:

Server runtime: Liferay v6.1 CE Server (Tomcat 7)

Web service runtime: Apache Axis

Client project: LiferayClientSoapProject

Monitor the Web service

Figure 85.4: Service Definition

When you specify a WSDL, Eclipse automatically adds the auxiliary files and libraries required to consume that web service. After you've created your web service client project using one of the above WSDLs, you need to create additional clients in the project using the remaining WSDLs. To create an additional client in an existing project, right-click on the project and select *New → Other → Web Service Client*. Click *Next*, enter the WSDL, and complete the wizard.

The following code locates and invokes operations to create a new user group named MyUserGroup and add a user with the screen name *test* to it. Create a LiferaySoapClient.java file in your web service client project and add this code to it. If you create this class in a package other than the one that's specified in this code, replace the package with your package. To run the client from Eclipse, make sure that your Liferay server is running, right-click the LiferaySoapClient.java class, and select *Run as Java application*. Check your console to check that your service calls succeeded.

```
package com.liferay.test;

import java.net.URL;

import com.liferay.portal.kernel.model.CompanySoap;
import com.liferay.portal.kernel.model.UserGroupSoap;
import com.liferay.portal.service.http.CompanyServiceSoap;
import com.liferay.portal.service.http.CompanyServiceSoapServiceLocator;
import com.liferay.portal.service.http.UserGroupServiceSoap;
import com.liferay.portal.service.http.UserGroupServiceSoapServiceLocator;
import com.liferay.portal.service.http.UserServiceSoap;
import com.liferay.portal.service.http.UserServiceSoapServiceLocator;
```

```
public class LiferaySoapClient {

    public static void main(String[] args) {

        try {
            String remoteUser = "test";
            String password = "test";
            String virtualHost = "localhost";

            String groupName = "MyUserGroup";

            String serviceCompanyName = "Portal_CompanyService";
            String serviceUserName = "Portal_UserService";
            String serviceUserGroupName = "Portal_UserGroupService";

            long userId = 0;

            // Locate the Company
            CompanyServiceSoapServiceLocator locatorCompany =
                new CompanyServiceSoapServiceLocator();

            CompanyServiceSoap soapCompany =
                locatorCompany.getPortal_CompanyService(
                    _getURL(remoteUser, password, serviceCompanyName,
                            true));

            CompanySoap companySoap =
                soapCompany.getCompanyByVirtualHost(virtualHost);

            // Locate the User service
            UserServiceSoapServiceLocator locatorUser =
                new UserServiceSoapServiceLocator();
            UserServiceSoap userSoap = locatorUser.getPortal_UserService(
                _getURL(remoteUser, password, serviceUserName, true));

            // Get the ID of the remote user
            userId = userSoap.getUserIdByScreenName(
                companySoap.getCompanyId(), remoteUser);
            System.out.println("userId for user named " + remoteUser +
                    " is " + userId);

            // Locate the UserGroup service
            UserGroupServiceSoapServiceLocator locator =
                new UserGroupServiceSoapServiceLocator();
            UserGroupServiceSoap usergroupsoap =
                locator.getPortal_UserGroupService(
                    _getURL(remoteUser, password, serviceUserGroupName,
                            true));

            // Get the user's user groups
            UserGroupSoap[] usergroups = usergroupsoap.getUserUserGroups(
                    userId);

            System.out.println("User groups for userId " + userId + " ...");
            for (int i = 0; i < usergroups.length; i++) {
                System.out.println("\t" + usergroups[i].getName());
            }

            // Adds the user group if it does not already exist
            String groupDesc = "My new user group";
            UserGroupSoap newUserGroup = null;

            boolean userGroupAlreadyExists = false;
            try {
                newUserGroup = usergroupsoap.getUserGroup(groupName);
                if (newUserGroup ≠ null) {
                    System.out.println("User with userId " + userId +
                        " is already a member of UserGroup " +
                                newUserGroup.getName());
                    userGroupAlreadyExists = true;
                }
            } catch (Exception e) {
                // Print cause, but continue
                System.out.println(e.getLocalizedMessage());
            }

            if (!userGroupAlreadyExists) {
                newUserGroup = usergroupsoap.addUserGroup(
                        groupName, groupDesc);
                System.out.println("Added user group named " + groupName);

                long users[] = {userId};
                userSoap.addUserGroupUsers(newUserGroup.getUserGroupId(),
                        users);
            }

            // Get the user's user groups
            usergroups = usergroupsoap.getUserUserGroups(userId);

            System.out.println("User groups for userId " + userId + " ...");
            for (int i = 0; i < usergroups.length; i++) {
                System.out.println("\t" + usergroups[i].getName());
            }
        }
        catch (Exception e) {
            e.getLocalizedMessage();
        }
    }

        private static URL _getURL(String remoteUser, String password,
                        String serviceName, boolean authenticate)
                        throws Exception {

                // Unauthenticated url
                String url = "http://localhost:8080/api/axis/" + serviceName;

                // Authenticated url
                if (authenticate) {
                        url = "http://" + remoteUser + ":" + password
                                        + "@localhost:8080/api/axis/"
                                        + serviceName;
                }

                return new URL(url);
        }

}
```

Running this client should produce output like this:

```
userId for user named test is 10196
User groups for user 10196 ...
java.rmi.RemoteException: No UserGroup exists with the key {companyId=10154,
name=MyUserGroup}
Added user group named
Added user to user group named MyUserGroup
User groups for user 10196 ...
    MyUserGroup
```

The output tells you the user had no groups, but was added to the user group `MyUserGroup`.

You might be thinking, "But an error was thrown! Something is wrong!" Yes, an error is thrown (`java.rmi.RemoteException:`), but you can sit here as cool as an ice cream sandwich all the same. The exception is thrown because the `UserGroup` check is invoked before the `UserGroup` is created. Because the very next line of the output says `Added user group named...`, you're okay. The SOAP web service invocations worked!

Here are a few things to note about this example:

- Authentication is done using HTTP Basic Authentication, which isn't appropriate for a production environment since the password is unencrypted. It's simply used for convenience in this example. In production, you should use SSL. Refer to Liferay's `portal.properties` file and look up the `company.security.auth.requires.https` and `web.server.protocol` properties for more information.
- The screen name and password are passed in the URL as credentials.
- The name of the service (e.g. `Portal_UserGroupService`) is specified at the end of the URL. Remember that the service name can be found in the web service listing.

The operations `getCompanyByVirtualHost()`, `getUserIdByScreenName()`, `getUserUserGroups()`, `addUserGroup()` and `addUserGroupUsers()` are specified for the `-ServiceSOAP` classes `CompanyServiceSoap`, `UserServiceSoap` and `UserGroupServiceSoap` in the WSDL files. Information on parameter types, parameter order, request type, response type, and return type are conveniently specified in the WSDL for each Liferay web service. It's all there for you!

Next, you'll learn how to implement a web service client in PHP.

SOAP PHP Client

You can write your client in any language that supports web services invocation. The following example code invokes the same operations as before, but uses PHP and a PHP SOAP client instead of Java:

```
<?php
    $userGroupName = "MyUserGroup2";
    $userName = "test";
    $clientOptions = array('login' => $userName, 'password' => 'test');

    // Add user group
    $userGroupClient = new
        SoapClient(
            "http://localhost:8080/api/axis/Portal_UserGroupService?wsdl",
            $clientOptions);
    $userGroup = $userGroupClient->addUserGroup($userGroupName,
        "This user group was created by the PHP client! ");
    print ("User group ID is $userGroup->userGroupId ");

    // Add user to user group
    $companyClient = new SoapClient(
        "http://localhost:8080/api/axis/Portal_CompanyService?wsdl",
        $clientOptions);
    $company = $companyClient->getCompanyByVirtualHost("localhost");
    $userClient = new SoapClient(
        "http://localhost:8080/api/axis/Portal_UserService?wsdl",
        $clientOptions);
    $userId = $userClient->getUserIdByScreenName($company->companyId,
        $userName);
    print ("User ID for $userName is $userId ");
    $users = array($userId);
    $userClient->addUserGroupUsers($userGroup->userGroupId, $users);

    // Print the user groups to which the user belongs
    $userGroups = $userGroupClient->getUserUserGroups($userId);
    print ("User groups for user $userId ... ");
    foreach($userGroups as $ug)
        print ("$ug->name, $ug->userGroupId ")
?>
```

Remember, you can implement a web service client in any language that supports SOAP web services.

85.10 JAX-WS and JAX-RS

Liferay supports JAX-WS and JAX-RS via the Apache CXF implementation. Apps can publish JAX web services to the CXF endpoints defined in your Liferay instance. CXF endpoints are effectively context paths the JAX web services are deployed to and accessible from. To publish any kind of JAX web service, one or more CXF endpoints must be defined in your Liferay instance. To access JAX web services, an *extender* must also be configured in your Liferay instance. Extenders specify where the services are deployed and whether they are augmented with handlers, providers, and so on. There are two types of extenders:

1. **SOAP Extenders:** Required to publish JAX-WS web services. Each SOAP extender can deploy the services to one or more CXF endpoints and can use a set of JAX-WS handlers to augment the services.
2. **REST Extenders:** Required to publish JAX-RS web services. REST extenders for JAX-RS services are analogous to SOAP extenders for JAX-WS services. To create JAX-RS services that can work across different JAX-RS implementations, you must provide an implementation of `javax.ws.rs.core.Application` to the OSGi framework. You can do this by registering an instance of this implementation as an OSGi service via `BundleContext` or the Declarative Services `@Component` annotation. The JAX-RS application encompasses the services that represent JAX-RS endpoints and the services that represent JAX-RS providers. By specifying OSGi filters in a REST extender, you can also dynamically add endpoints or JAX-RS providers to a JAX-RS application.

SOAP extenders and REST extenders are subsystems that track the services the app developer registers in OSGi (those matching the provided OSGi filters), and deploy them under the specified CXF endpoints. For example, if you create the CXF endpoints `/soap` and `/rest`, you could later create a REST extender for `/rest` that publishes REST applications, and a SOAP extender for `/soap` that publishes SOAP services. Of course, this is only a rough example: you can fine tune things to your liking.

CXF endpoints and both types of extenders can be created programmatically or with Liferay's Control Panel. This tutorial shows you how to do both, and then shows you how to publish JAX-WS and JAX-RS web services. The following topics are covered:

- Configuring Endpoints and Extenders with the Control Panel
  - CXF Endpoints
  - SOAP Extenders
  - REST Extenders
- Configuring Endpoints and Extenders Programmatically
- Publishing JAX-WS Web Services
- Publishing JAX-RS Web Services

Configuring Endpoints and Extenders with the Control Panel

Liferay's Control Panel lets administrators configure endpoints and extenders for JAX web services. Note that you must be an administrator in your Liferay instance to access the settings here. First, you'll learn how to create CXF endpoints.

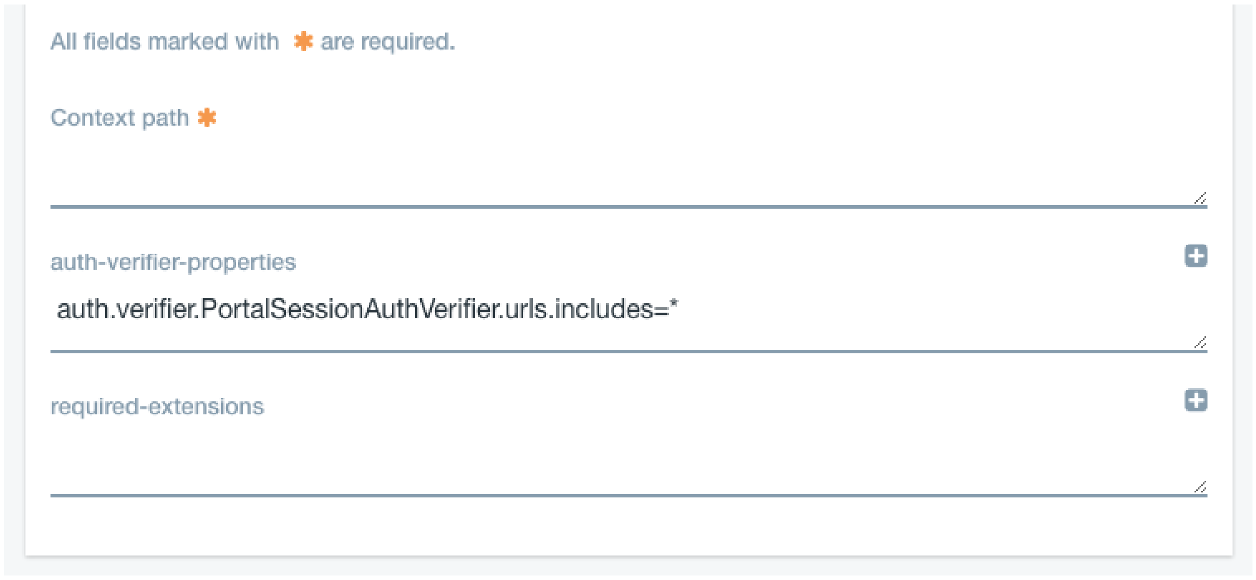
CXF Endpoints

To configure a CXF endpoint with the Control Panel, first go to *Control Panel* → *Configuration* → *System Settings* → *Foundation*. Then select *CXF Endpoints* from the table. If there are any existing CXF endpoints, they're shown here. To add a new one, select the *Add* button (+) in the lower right-hand corner. The form that appears lets you configure a new CXF endpoint by filling out these fields:

- **Context path:** The path the JAX web services are deployed to on the Liferay server. For example, if you define the context path `/web-services`, any services deployed there are available at `http://your-server:your-port/o/web-services`.

- **`AuthVerifier` properties:** Any properties defined here are passed as-is to the `AuthVerifier` filter. See the `AuthVerifier` documentation for more details.

- **Required extensions:** CXF normally loads its default extension classes, but in some cases you can override them to replace the default behavior. In most cases, you can leave this field blank: overriding extensions isn't common. By specifying custom extensions here via OSGi filters, Liferay waits until those extensions are registered in the OSGi framework before creating the CXF servlet and passing the extensions to the servlet.



All fields marked with * are required.

Context path *

auth-verifier-properties

auth.verifier.PortalSessionAuthVerifier.urls.includes=*

required-extensions

Figure 85.5: Fill out this form to create a CXF endpoint.

Next, you'll learn how to use the Control Panel to create SOAP extenders for JAX-WS web services.

SOAP Extenders

For an app to deploy JAX-WS web services, you must configure a SOAP extender. To configure a SOAP extender with the Control Panel, first go to *Control Panel* → *Configuration* → *System Settings* → *Foundation*. Then select *SOAP Extenders* from the table. If there are any existing SOAP extenders, they're shown here. To add a new one, select the *Add* button (+) in the lower right-hand corner. The form that appears lets you configure a new SOAP extender by filling out these fields:

- **Context paths:** Specify at least one CXF endpoint here. This is where the services affected by this extender are deployed. In the preceding CXF endpoint example, this would be `/web-services`. Note that you can specify more than one CXF endpoint here.

- **jax.ws.handler.filters:** Here you can specify a set of OSGi filters that select certain services registered in the OSGi framework. The selected services should implement JAX-WS handlers and augment the JAX-WS services specified in the *jax.ws.service.filters* property. These JAX-WS handlers apply to each service selected in this extender.

- **jax.ws.service.filters:** Here you can specify a set of OSGi filters that select the services registered in the OSGi framework that will be deployed to the CXF endpoints. These OSGi services must be proper JAX-WS services.

- **soap.descriptor.builder:** Leave this option empty to use JAX-WS annotations to describe the SOAP service. To use a different way to describe the SOAP service, you can provide an OSGi filter here that selects an implementation of `com.liferay.portal.remote.soap.extender.SoapDescriptorBuilder`.

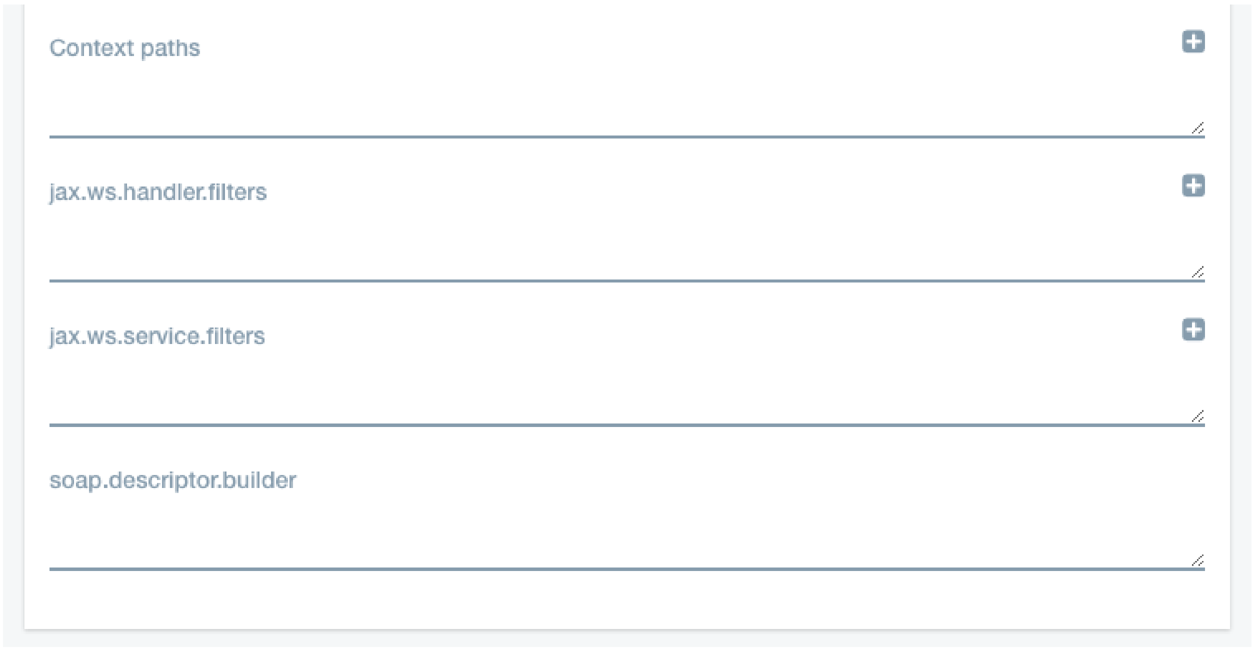


Figure 85.6: Fill out this form to create a SOAP extender.

Next, you'll learn how to use the Control Panel to create REST extenders for JAX-RS web services.

REST Extenders

To configure a REST extender with the Control Panel, first go to *Control Panel* → *Configuration* → *System Settings* → *Foundation*. Then select *REST Extender* from the table. If there are any existing REST extenders, they're shown here. To add a new one, select the *Add* button (+) in the lower right-hand corner. The form that appears lets you configure a new REST extender by filling out these fields:

- **Context paths:** Specify at least one CXF endpoint here. This is where the services affected by this extender are deployed. In the preceding CXF endpoint example, this would be `/web-services`. Note that you can specify more than one CXF endpoint here. This works the same way as the *Context paths* setting in SOAP Extenders.

- **jax.rs.application.filters:** Here you can specify a set of OSGi filters that select services that implement `javax.ws.rs.core.Application`. These JAX-RS applications are deployed to the CXF endpoints specified in the *Context paths* property.

- **jsx.rs.provider.filters:** Here you can specify a set of OSGi filters that select services registered in the OSGi framework. The selected services should implement any of the interfaces supported by JAX-RS for providers. These JAX-RS providers are added to the JAX-RS application as if they had been returned by the `getSingletons()` method of `javax.ws.rs.core.Application`. The following links list some of the supported JAX-RS providers:

  - JAX-RS Entity Providers
  - Filters and Interceptors

- **jax.rs.service.filters:** Here you can specify a set of OSGi filters that selects services registered in the OSGi framework that are valid JAX-RS endpoints. These endpoints are added to the JAX-RS application as if they had been returned by the `getSingletons()` method of `javax.ws.rs.core.Application`.

Next, you'll learn how to configure endpoints and extenders programmatically.

Configuring Endpoints and Extenders Programmatically

To configure endpoints or extenders programmatically, you must use Liferay's configurator extender. The configurator extender provides a way for OSGi modules to deploy default configuration values. Modules that use the configurator extender must provide a `ConfigurationPath` header that points to the configuration files' location inside the module. For example, the following configuration sets the `ConfigurationPath` to `src/main/resources/configuration`:

```
Bundle-Name: Liferay Export Import Service JAX-WS
Bundle-SymbolicName: com.liferay.exportimport.service.jaxws
Bundle-Version: 1.0.0
Liferay-Configuration-Path: /configuration
Include-Resource: configuration=src/main/resources/configuration
Liferay-Releng-Module-Group-Description:
Liferay-Releng-Module-Group-Title: Data Management
```

Note: If you're using any version before Liferay CE GA4 or Liferay DXP Fixpack 22, the `Liferay-Configuration-Path` directive above is `Configuration-Path`. As of LPS-62571, Liferay-specific Bnd instructions are prefixed with `Liferay` to avoid conflicts.

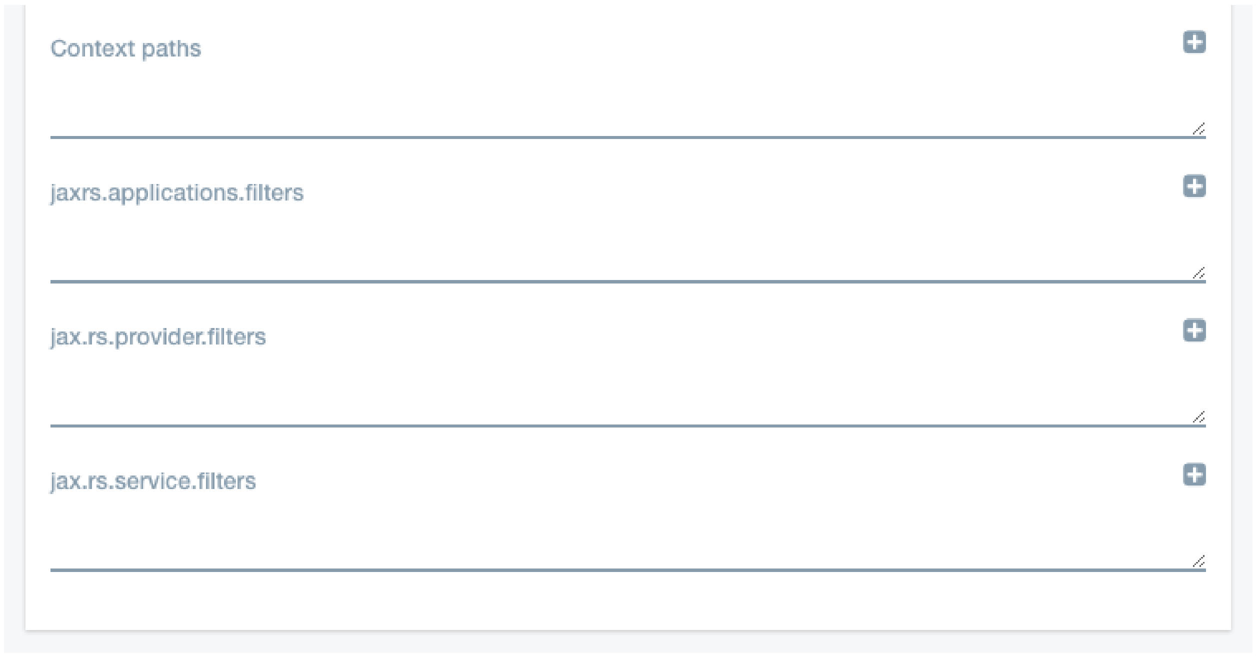

Figure 85.7: Fill out this form to create a REST extender.

There are two different configuration types in OSGi's `ConfigurationAdmin`: single, and factory. Factory configurations can have several configuration instances per factory name. Liferay DXP uses factory configurations. You must provide a factory configuration's default values in a `*.properties` file. In this properties file, use a suffix on the end of the PID (persistent identifier) and then provide your settings. For example, the following code uses the `-staging` suffix on the PID and creates a CXF endpoint at the context path `/staging-ws`:

```
com.liferay.portal.remote.cxf.common.configuration.CXFEndpointPublisherConfiguration-staging.properties:

contextPath=/staging-ws
```

As another example, the following code uses the suffix `-stagingjaxws` on the PID and creates a SOAP extender at the context path `/staging-ws`. This code also includes settings for the configuration fields `jaxWsHandlerFilterStrings` and `jaxWsServiceFilterStrings`:

```
com.liferay.portal.remote.soap.extender.configuration.SoapExtenderConfiguration-stagingjaxws.properties:

contextPaths=/staging-ws
jaxWsHandlerFilterStrings=(staging.jax.ws.handler=true)
jaxWsServiceFilterStrings=(staging.jax.ws.service=true)
```

You must then use these configuration fields in the configuration class. For example, the `SoapExtenderConfiguration` interface below contains the configuration fields `contextPaths`, `jaxWsHandlerFilterStrings`, and `jaxWsServiceFilterStrings`:

```
@ExtendedObjectClassDefinition(
    category = "foundation", factoryInstanceLabelAttribute = "contextPaths"
)
@Meta.OCD(
    factory = true,
    id = "com.liferay.portal.remote.soap.extender.configuration.SoapExtenderConfiguration",
    localization = "content/Language", name = "soap.extender.configuration.name"
)
public interface SoapExtenderConfiguration {

    @Meta.AD(required = false)
    public String[] contextPaths();

    @Meta.AD(name = "jax.ws.handler.filters", required = false)
    public String[] jaxWsHandlerFilterStrings();

    @Meta.AD(name = "jax.ws.service.filters", required = false)
    public String[] jaxWsServiceFilterStrings();

    @Meta.AD(name = "soap.descriptor.builder", required = false)
    public String soapDescriptorBuilderFilter();

}
```

You can use similar techniques to create REST extenders. For example, see the `RestExtenderConfiguration` interface in Liferay's source code.

Next, you'll learn how to publish JAX-WS web services.

Publishing JAX-WS Web Services

To publish JAX-WS web services via SOAP in a 7.0 module, annotate the class and its methods with standard JAX-WS annotations, and then register it as a service in the OSGi framework. For example, the following class uses the `@WebService` annotation for the class and `@WebMethod` annotations for its methods. You must also set the `jaxws` property to true in the OSGi `@Component` annotation:

```
import javax.jws.WebMethod;
import javax.jws.WebService;

import org.osgi.service.component.annotations.Component;

@Component(
    immediate = true, property = "jaxws=true", service = Calculator.class
)
@WebService
public class Calculator {

    @WebMethod
    public int divide(int a, int b) {
        return a / b;
    }

    @WebMethod
    public int multiply(int a, int b) {
        return a * b;
    }

    @WebMethod
    public int subtract(int a, int b) {
        return a - b;
    }

    @WebMethod
    public int sum(int a, int b) {
        return a + b;
    }

}
```

You should also make sure that you include `org.osgi.core` and `org.osgi.service.component.annotations` as dependencies to your project.

Next, you'll learn how to publish JAX-RS web services.

Publishing JAX-RS Web Services

You can publish JAX-RS web services in a Liferay module the same way you would outside of Liferay. You must also, however, register the class in the OSGi framework. Note that the services must match the OSGi filters provided in the respective extenders. This is how the instances that become services are selected. There's no classpath scanning or other automatic mechanism at work here: it's the developer's responsibility to register the services in the OSGi framework.

The following example registers an OSGi component that publishes a JAX-RS web service at `/application-path/hello`. Get requests to this web service return a simple *"Hello!"*:

```
import org.osgi.service.component.annotations.Component;

import javax.ws.rs.ApplicationPath;
import javax.ws.rs.GET;
import javax.ws.rs.Path;
import javax.ws.rs.Produces;
import javax.ws.rs.core.Application;
import java.util.Collections;
import java.util.Set;

@Component(immediate = true, service = Application.class)
@ApplicationPath("/application-path")
public class RestEndpoint extends Application {

    public Set<Object> getSingletons() {
        return Collections.<Object>singleton(this);
    }

    @GET
    @Path("/hello")
    @Produces("text/text")
    public String sayHello() {
        return "Hello!";
    }
}
```

Nice work! Now you know how JAX-WS and JAX-RS works in Liferay.

Service Builder Web Services

85.11 Liferay WebSocket Whiteboard

Modern web apps exchange large amounts of data with clients. The WebSockets specification lets this exchange occur over a full-duplex connection that remains open, therefore enabling real-time communication. This approach is more efficient than techniques like long polling, which open two connections to emulate a full-duplex connection. Click here for more information on WebSockets.

Since WebSockets are ubiquitous throughout the web and in all modern browsers, you need a way to register new WebSocket endpoints in Liferay DXP. The *Liferay WebSocket Whiteboard* lets you define new WebSocket endpoints as regular OSGi services. This tutorial shows you how to do this. Onward!

Configuring a Non-Liferay OSGi Container

There may be instances where you want to use a Liferay OSGi module in a non-Liferay OSGi container, and need to define a WebSocket endpoint. To do this, you must register a `javax.servlet.ServletContext` service with the property `websocket.active` set to `true`:

```
Dictionary<String, Object> servletContextProps = new Hashtable<String, Object>();
servletContextProps.put("websocket.active", Boolean.TRUE);

bundleContext.registerService(ServletContext.class, servletContext, servletContextProps);
```

You must also configure the `javax.websocket-api`'s `ServiceLoader`. You can do this by creating your own module as a `javax.websocket-api` fragment. Here's an example of a manifest for such a module:

```
Fragment-Host: javax.websocket-api

Require-Capability:\
    osgi.serviceloader;\

filter:='(osgi.serviceloader=javax.websocket.server.ServerEndpointConfig$Configurator)';\
        cardinality:=multiple,\
    osgi.extender;\
        filter:='(osgi.extender=osgi.serviceloader.processor)'
```

Next, you'll learn how to define a new WebSocket server endpoint in a Liferay OSGi container.

Configuring a Liferay OSGi Container

Defining a new WebSocket server endpoint in Liferay DXP is straightforward. Follow these steps:

1. If you're running Liferay Portal 7.0.2 GA3 or Liferay Digital Enterprise 7.0 Fix Pack 7 or earlier, add the following property to your `portal-ext.properties` file. Otherwise, you can skip this and move on to the next step.

   ```
   module.framework.system.packages.extra=\
       com.ibm.crypto.provider,\
       com.ibm.db2.jcc,\
       com.microsoft.sqlserver.jdbc,\
       com.mysql.jdbc,\
       com.p6spy.engine.spy,\
       com.sun.security.auth.module,\
       com.sybase.jdbc4.jdbc,\
       oracle.jdbc,\
       org.postgresql,\
       org.apache.naming.java,\
       org.hsqldb.jdbc,\
       org.mariadb.jdbc,\
       sun.misc,\
       sun.net.util,\
       sun.security.provider,\
       javax.websocket;version="1.1.0",\
       javax.websocket.server;version="1.1.0"
   ```

2. Deploy the Liferay WebSocket Whiteboard module (`com.liferay.websocket.whiteboard`) to your Liferay DXP instance. You can download this module from JCenter or Maven Central by clicking the respective link:

   - JCenter

- Maven Central

3. In your module's build file, add a dependency to the Liferay WebSocket Whiteboard:

   ```
   com.liferay:com.liferay.websocket.whiteboard:1.0.1
   ```

4. In your module, define a WebSocket server endpoint as you normally would. Note, however, that Liferay DXP doesn't currently support the annotation-driven approach; only the interface-driven approach is supported. To create a WebSocket server endpoint, register an OSGi Service for `javax.websocket.Endpoint.class` with the following properties:

   - `org.osgi.http.websocket.endpoint.path`: the WebSocket's path (required)
   - `org.osgi.http.websocket.endpoint.decoders`: the WebSocket's decoders (optional)
   - `org.osgi.http.websocket.endpoint.encoders`: the WebSocket's encoders (optional)
   - `org.osgi.http.websocket.endpoint.subprotocols`: the WebSocket's subprotocols (optional)

For example, the following steps show you how to define a WebSocket endpoint in a portlet. For the purposes of this example, the portlet also contains a client that communicates with the endpoint. This example portlet, Echo Portlet, uses WebSocket functionality to echo a simple message the client sends to the server.

Although the following steps show only code snippets, you can click here to see the complete example code.

Use these steps to define a WebSocket endpoint:

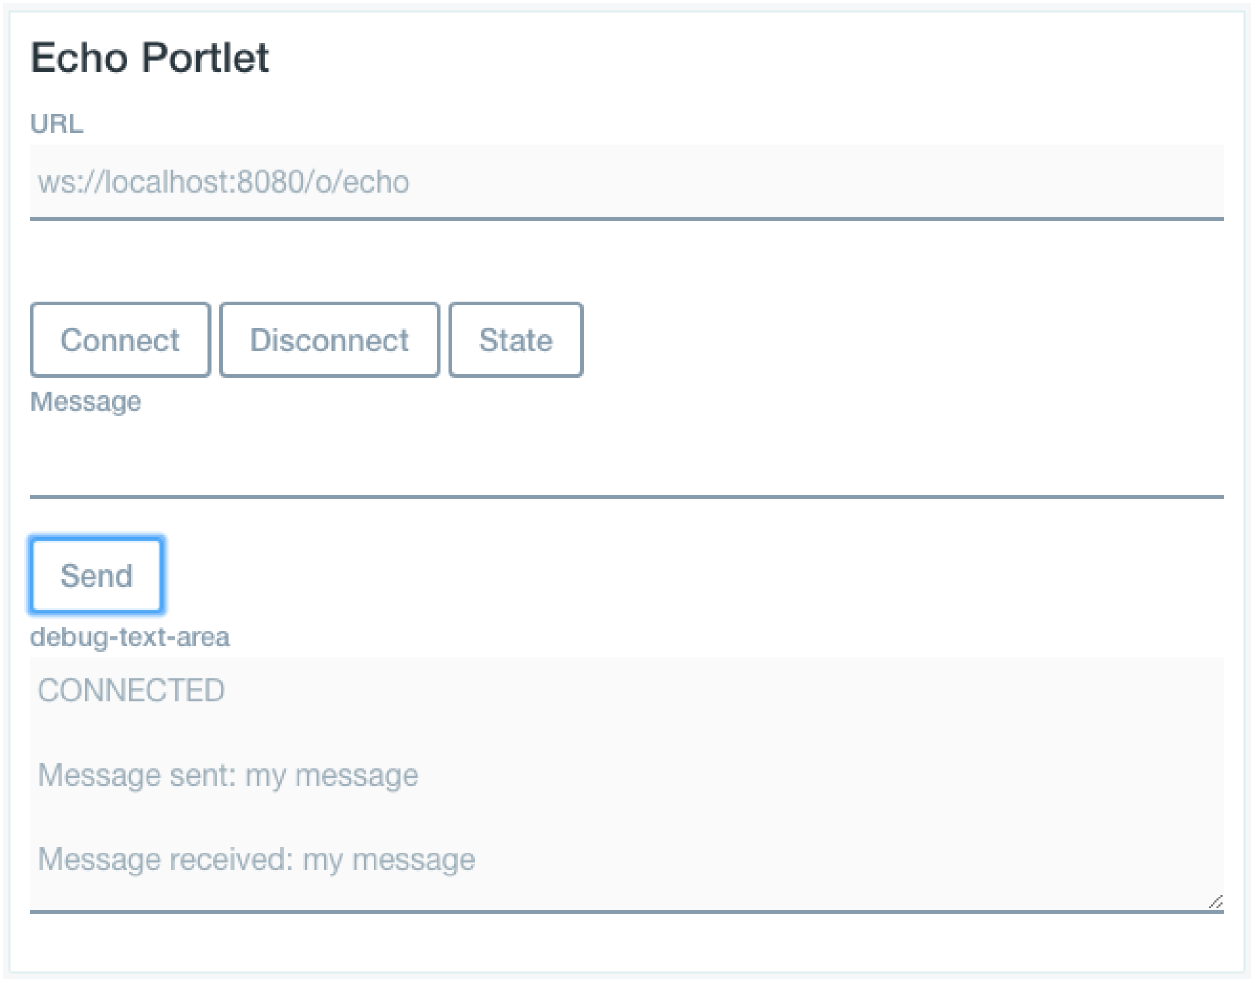
1. Add the WebSocket dependency to your module's build file. For example, here's the dependency in a `build.gradle` file:

   ```
   javax.websocket:javax.websocket-api:1.1
   ```

2. Create the WebSocket endpoint. Note that the `@Component` annotation contains the required property `org.osgi.http.websocket.endpoint.path`, which defines the endpoint `/o/echo`. Also note that `service = Endpoint.class` in the `@Component` annotation registers this class as an `Endpoint` service in Liferay DXP's OSGi framework. Otherwise, there's nothing special about the `EchoWebSocketEndpoint` class's code; it resembles that of any other WebSocket endpoint:

   ```
   @Component(
       immediate = true,
       property = {"org.osgi.http.websocket.endpoint.path=/o/echo"},
       service = Endpoint.class
   )
   public class EchoWebSocketEndpoint extends Endpoint {

       @Override
       public void onOpen(final Session session, EndpointConfig endpointConfig) {
           session.addMessageHandler(
               new MessageHandler.Whole<String>() {
               @Override
               public void onMessage(String text) {
                   try {
                       RemoteEndpoint.Basic remoteEndpoint =
                           session.getBasicRemote();
                       remoteEndpoint.sendText(text);
                   }
   ```



CONNECTED

Message sent: my message

Message received: my message

Figure 85.8: The example Echo portlet sends and receives a simple message via a WebSocket endpoint.

```
                    catch (IOException ioe) {
                        throw new RuntimeException(ioe);
                    }
                }
            });
        }
    }
```

3. Write your client code. In this example, the Echo portlet's `view.jsp` defines a WebSocket client. Again, there's nothing special about this code; it resembles that of other WebSocket clients:

```
<%@ include file="/init.jsp" %>

<div id="content">
    <div id="left_col">
        <strong>Websocket URL:</strong>
        <br />
        <input id="urlInputText" type="text" readonly />
        </br>
        </br>
        <button onClick="initWebSocket();">Connect</button>
        <button onClick="stopWebSocket();">Disconnect</button>
        <button onClick="checkSocket();">State</button>
        <br />
        <br />
        <strong>Message:</strong>
        <br />
        <input id="inputText" onkeydown="if(event.keyCode==13)sendMessage();" type="text" />
         <button onClick="sendMessage();">Send</button>
     </div>

     <div id="right_col">
         <strong>Log:</strong>
         <br />
         <textarea id="debugTextArea" style="width:400px;height:200px;" readonly></textarea>
     </div>
</div>

<script type="text/javascript">
    var debugTextArea = document.getElementById("debugTextArea");

    var wsUri = "ws://localhost:8080/o/echo";

    urlInputText.value=wsUri;

    resizeUrlInputText(urlInputText.value);

    function resizeUrlInputText(message) {
        urlInputText.size=message.length;
    }

    function debug(message) {
        debugTextArea.value += message + "\n\n";
        debugTextArea.scrollTop = debugTextArea.scrollHeight;
    }

    function sendMessage() {
        var msg = document.getElementById("inputText").value;
        if ( websocket != null ) {
            document.getElementById("inputText").value = "";
            websocket.send(msg);
            debug("Message sent: " + msg);
            console.log( "string sent :", '"'+msg+'"' );
        }
        else {
            debug("Can't sent message, the connection is not open");
        }
    }

    var websocket = null;

    function initWebSocket() {
        try {
            if (typeof MozWebSocket == 'function')
                WebSocket = MozWebSocket;
            if ( websocket && websocket.readyState == 1 )
                websocket.close();
            websocket = new WebSocket( wsUri );
            websocket.onopen = function(evt) {
                debug("CONNECTED");
            };
            websocket.onclose = function(evt) {
                debug("DISCONNECTED");
            };
            websocket.onmessage = function(evt) {
                console.log( "Message received: ", evt.data );
                debug( "Message received: " + evt.data );
            };
            websocket.onerror = function(evt) {
                debug('ERROR: ' + evt.data);
            };
        }
        catch (exception) {
            debug('ERROR: ' + exception);
        }
    }

    function stopWebSocket() {
        if (websocket) {
            websocket.close();
        }
    }

    function checkSocket() {
        if (websocket != null) {
            var stateStr;
            switch (websocket.readyState) {
                case 0: {
                    stateStr = "CONNECTING";
                    break;
                }
                case 1: {
                    stateStr = "OPEN";
                break;
            }
            case 2: {
                stateStr = "CLOSING";
                break;
            }
            case 3: {
                stateStr = "CLOSED";
                break;
            }
            default: {
                stateStr = "UNKNOW";
                break;
            }
        }
        debug("WebSocket state = " + websocket.readyState + " ( " + stateStr + " )");
        } else {
            debug("WebSocket is null");
        }
    }
</script>
```

That's it! Now you know how to create WebSocket endpoints in Liferay DXP.

Chapter 86

Asset Framework

Liferay's asset framework is a system that allows you to add core Liferay features to your application. For example, if you've built an event management application that displays a list of upcoming events, you can use the asset framework to let users add tags, categories, or comments to make entries more self-descriptive.

Tags, categories, and comments are just a few of the features in Liferay's asset framework. You'll also find it easy to use: you'll be infusing your application with these features in no time.

As background, the term *asset* refers to any type of content in the portal. This could be text, a file, a URL, an image, documents, blog entries, bookmarks, wiki pages, or anything you create in your applications.

The asset framework tutorials assume that you've used Liferay's Service Builder to generate your persistence layer, that you've implemented permissions on the entities that you're persisting, and that you've enabled them for search and indexing. You can learn more about Liferay's Service Builder and how to use it in the Service Builder tutorial section.

If you've yet to do any of those things, you can see how each is done in respective tutorials Generating the Back-end, Using Resources and Permissions, and Leveraging Search. Lastly, the Learning Path Assets: Integrating with Liferay's Framework takes you through the fundamentals of enabling an example application's custom entities to use the asset framework. If you haven't traveled through that Learning Path, we recommend you do so before continuing with the tutorials in this section.

The tutorials that follow in this section explore the details of leveraging the asset framework's various features. Here are some features that you'll give your users as you implement them in your app:

- Extensively render your assets.
- Associate tags to custom content types. Users can create and assign new tags or use existing tags.
- Associate categories to custom content types.
- Manage tags from the Control Panel. Administrators can even merge tags.
- Manage categories from the Control Panel. This includes the ability to create category hierarchies.
- Relate assets to one another.

At this point, you might be saying, "Liferay's asset framework sounds great, but how do I leverage all of its awesome features?" Excellent question, and perfect timing!

Before diving head first into the tutorials, you must implement a way to let the framework know whenever any of your custom content entries is added, updated, or deleted. The next tutorial covers that. From that point onward, each tutorial shows you how to leverage a particular asset framework feature in your UI. It's time to start your asset framework training!

Configuration

86.2 Adding, Updating, and Deleting Assets for Custom Entities

To use Liferay's asset framework with an entity, you must inform the asset framework about each entity instance you create, modify, and delete. In this sense, it's similar to informing Liferay's permissions framework about a new resource. All you have to do is invoke a method of the asset framework that associates an `AssetEntry` with the entity so Liferay can keep track of the entity as an asset. When it's time to update the entity, you update the asset at the same time. To see how to asset-enable entities in a working example portlet, visit the tutorial Assets: Integrating with Liferay's Framework.

To leverage assets, you must also implement indexers for your portlet's entities. Liferay's asset framework uses indexers to manage assets. For instructions on creating an indexer in a working example portlet, see the tutorial Enabling Search and Indexing.

This tutorial shows you how to enable assets for your custom entities and implement indexes for them. It's time to get started!

Preparing Your Project for the Asset Framework

In your project's `service.xml` file, add an asset entry entity reference for your custom entity. Add the following `reference` tag before your custom entity's closing `</entity>` tag.

```
<reference package-path="com.liferay.portlet.asset" entity="AssetEntry" />
```

Then run Service Builder.

Now you're ready to implement adding and updating assets!

Adding and Updating Assets

Your `-LocalServiceImpl` Java class inherits from its parent base class an `AssetEntryLocalService` instance; it's assigned to the variable `assetEntryLocalService`. To add your custom entity as a Liferay asset, you must invoke the `assetEntryLocalService`'s `updateEntry` method.

Here's what the `updateEntry` method's signature looks like:

```
AssetEntry updateEntry(
    long userId, long groupId, Date createDate, Date modifiedDate,
    String className, long classPK, String classUuid, long classTypeId,
    long[] categoryIds, String[] tagNames, boolean listable,
    boolean visible, Date startDate, Date endDate, Date publishDate,
    Date expirationDate, String mimeType, String title,
    String description, String summary, String url, String layoutUuid,
    int height, int width, Double priority)
throws PortalException
```

Here are descriptions of each of the `updateEntry` method's parameters:

- `userId`: identifies the user updating the content.
- `groupId`: identifies the scope of the created content. If your content doesn't support scopes (extremely rare), pass `0` as the value.

- `createDate`: the date the entity was created.
- `modifiedDate`: the date of this change to the entity.
- `className`: identifies the entity's class. The recommended convention is to use the name of the Java class that represents your content type. For example, you can pass in the value returned from `[YourClassName].class.getName()`.
- `classPK`: identifies the specific entity instance, distinguishing it from other instances of the same type. It's usually the primary key of the table where the entity is stored.
- `classUuid`: serves as a secondary identifier that's guaranteed to be universally unique. It correlates entity instances across scopes. It's especially useful if your content is exported and imported across separate portals.
- `classTypeId`: identifies the particular variation of this class, if it has any variations. Otherwise, use `0`.
- `categoryIds`: represent the categories selected for the entity. The asset framework stores them for you.
- `tagNames`: represent the tags selected for the entity. The asset framework stores them for you.
- `listable`: specifies whether the entity can be shown in dynamic lists of content (such as asset publisher configured dynamically).
- `visible`: specifies whether the entity is approved.
- `startDate`: the entity's publish date. You can use it to specify when an Asset Publisher should show the entity's content.
- `endDate`: the date the entity is taken down. You can use it to specify when an Asset Publisher should stop showing the entity's content.
- `publishDate`: the date the entity will start to be shown.
- `expirationDate`: the date the entity will no longer be shown.
- `mimetype`: the Multi-Purpose Internet Mail Extensions type, such as ContentTypes.TEXT_HTML, used for the content.
- `title`: the entity's name.
- `description`: a `String`-based textual description of the entity.
- `summary`: a shortened or truncated sample of the entity's content.
- `url`: a URL to optionally associate with the entity.
- `layoutUuid`: the universally unique ID of the layout of the entry's default display page.
- `height`: this can be set to `0`.
- `width`: this can be set to `0`.
- `priority`: specifies how the entity is ranked among peer entity instances. Low numbers take priority over higher numbers.

The following code from Liferay's Wiki application's WikiPageLocalServiceImpl Java class demonstrates invoking the `updateEntry` method on the wiki page entity called `WikiPage`. In your `add-` method, you could invoke `updateEntry` after adding your entity's resources. Likewise, in your `update-` method, you could invoke `updateEntry` after calling the `super.update-` method. The code below is called in the `WikiPageLocalServiceImpl` class's `updateStatus(...)` method.

```
AssetEntry assetEntry = assetEntryLocalService.updateEntry(
    userId, page.getGroupId(), page.getCreateDate(),
    page.getModifiedDate(), WikiPage.class.getName(),
    page.getResourcePrimKey(), page.getUuid(), 0,
    assetCategoryIds, assetTagNames, true, true, null, null,
    page.getCreateDate(), null, ContentTypes.TEXT_HTML,
    page.getTitle(), null, null, null, null, 0, 0, null);

Indexer<JournalArticle> indexer = IndexerRegistryUtil.nullSafeGetIndexer(
    WikiPage.class);

indexer.reindex(page);
```

Immediately after invoking the `updateEntry` method, you must update the respective asset and index the entity instance. The above code calls the indexer to index (or re-index, if updating) the entity. It's that easy to update assets and indexes.

Tip: The current user's ID and the scope group ID are commonly made available in service context parameters. If the service context you use contains them, then you can access them in calls like these:
long userId = serviceContext.getUserId(); long groupId = serviceContext.getScopeGroupId();

Next, you'll learn what's needed to properly delete an entity that's associated with an asset.

Deleting Assets

When deleting your entities, you should delete the associated assets and indexes at the same time. This cleans up stored asset and index information, which keeps the Asset Publisher from showing information for the entities you've deleted.

In your `-LocalServiceImpl` Java class, open your `delete-` method. After the code that deletes the entity's resource, you must delete the entity instance's asset entry and index.

Here's some code which deletes an asset entry and an index associated with a portlet's entity.

```
assetEntryLocalService.deleteEntry(
    ENTITY.class.getName(), ENTITY.getInsultId());

Indexer indexer = IndexerRegistryUtil.nullSafeGetIndexer(ENTITY.class);
indexer.delete(ENTITY);
```

In your `-LocalServiceImpl` class, you can write similar code. Replace the *ENTITY* class name and variable with your entity's name.

Important: In order for Liferay's Asset Publisher application to show your entity, the entity must have an Asset Renderer. To learn how to implement an Asset Renderer for your custom entity, refer to the Rendering an Asset tutorial. Note also that an Asset Renderer is how you show a user the components of your entity in the Asset Publisher. On deploying your portlet with asset, indexer, and asset rendering implementations in place, an Asset Publisher can show your custom entities!

Great! Now you know how to add, update, and delete assets in your apps!

86.3 Implementing Asset Categorization and Tagging

In this tutorial, you'll allow content authors the ability to specify tags and categories for their entities in the UI. Liferay provides a set of JSP tags for showing category and tag inputs in your UI. Before beginning, your entities should be asset-enabled and you should have asset renderers enabled for them.

Now it's time to get started!

You can use the following tags in the JSPs you provide for adding/editing custom entities. Here's what the tags look like in the edit_entry.jsp for the Blogs portlet:

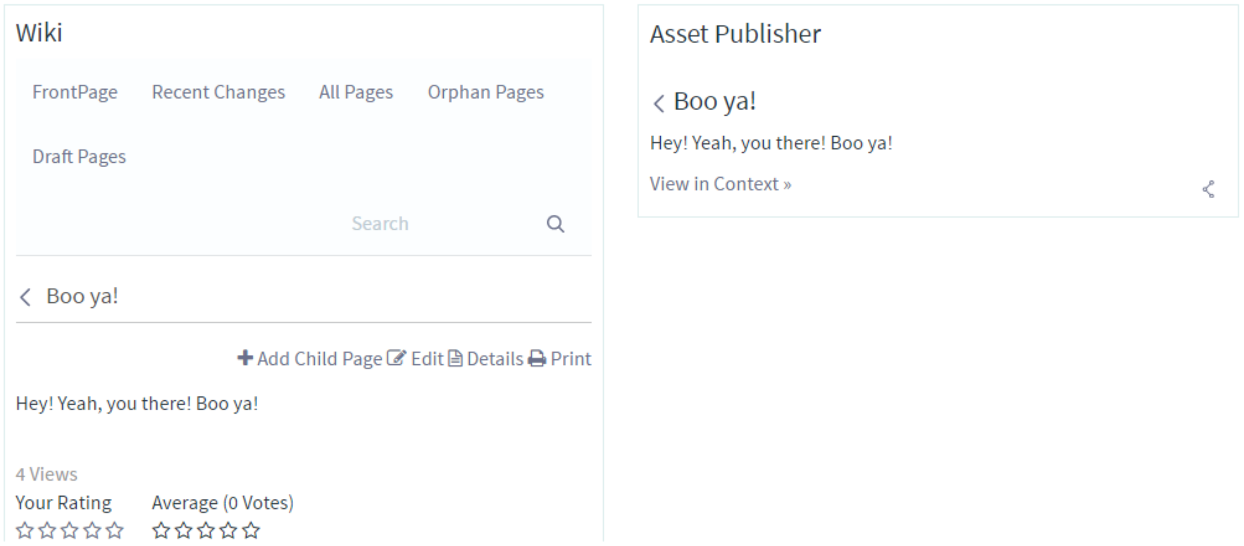

Figure 86.1: It can be useful to show custom entities, like this wiki page entity, in a JSP or in an Asset Publisher.

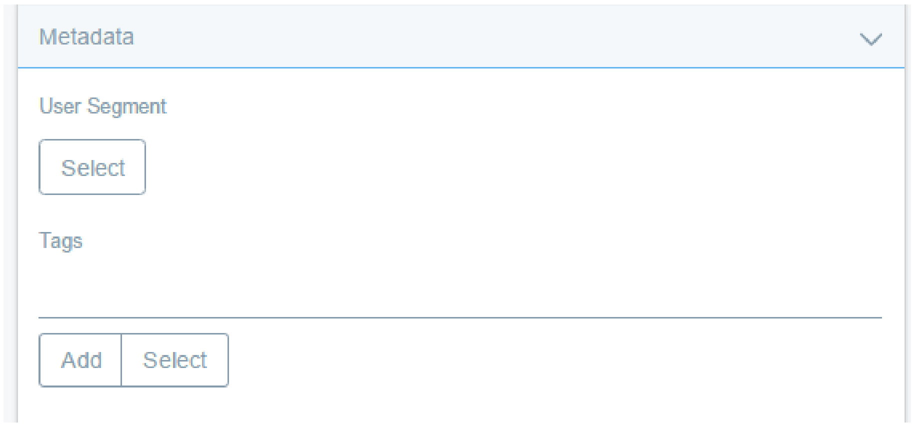

Figure 86.2: Adding category and tag input options lets authors aggregate and label custom entities.

```
<liferay-ui:asset-categories-error />
<liferay-ui:asset-tags-error />
...
<aui:fieldset-group markupView="lexicon">
    ...
    <aui:fieldset collapsed="<%= true %>" collapsible="<%= true %>" label="categorization">
        <aui:input name="categories" type="assetCategories" />

        <aui:input name="tags" type="assetTags" />
    </aui:fieldset>
    ...
</aui:fieldset-group>
```

These category and tag aui:input tags generate form controls that let users browse/select a categories for the entity, browse/select tags, and/or create new tags to associate with the entity.

The liferay-ui:asset-categories-error and liferay-ui:asset-tags-error tags show messages for errors occurring during the asset category or tag input process. The aui:fieldset tag uses a container that lets users hide or show the category and tag input options.

For styling purposes, the `aui:fieldset-group` tag is given the `lexicon` markdup view.

Once the tags and categories have been entered, you'll want to show them along with the content of the asset. Here's how to display the tags and categories:

```
<p><liferay-ui:message key="categories" />:</p>

<div class="entry-categories">
    <liferay-ui:asset-categories-summary
        className="<%= BlogsEntry.class.getName() %>"
        classPK="<%= entry.getEntryId() %>"
        portletURL="<%= renderResponse.createRenderURL() %>"
    />
</div>

...

<div class="entry-tags">
    <p><liferay-ui:message key="tags" />:</p>

    <liferay-ui:asset-tags-summary
        className="<%= BlogsEntry.class.getName() %>"
        classPK="<%= entry.getEntryId() %>"
        portletURL="<%= renderResponse.createRenderURL() %>"
    />
</div>
```

You'll notice the `portletURL` parameter is used for both tags and categories, which supports navigation amongst the two. Each tag that uses this parameter becomes a link containing the `portletURL` *and* `tag` or `categoryId` parameter value. To implement this, you need to implement the look-up functionality in your portlet code. Do this by reading the values of those two parameters and using `AssetEntryService` to query the database for entries based on the specified tag or category.

Deploy your changes and add/edit a custom entity in your UI. Your form shows the categorization and tag input options in a panel that the user can hide/show.

Great! Now you know how to make category and tag input options available to your app's content authors.

Adding, Updating, and Deleting Assets for Custom Entities

What is Service Builder?

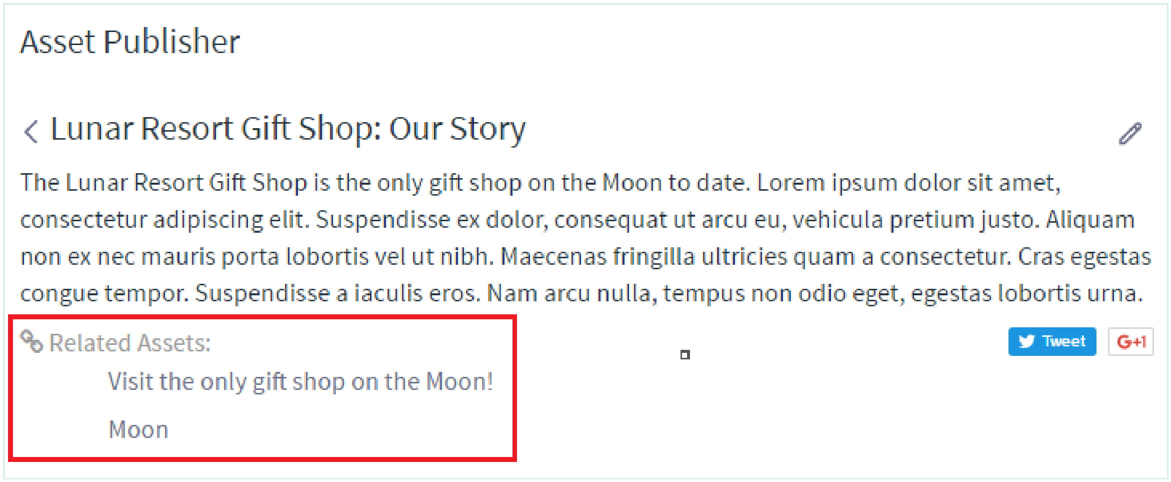
86.4 Relating Assets

The ability to relate assets is one of the most powerful features of Liferay's asset framework. By relating assets, you can connect individual pieces of content across your site or portal. This helps your users discover related content, particularly when there's an abundance of other available content. For example, assets related to a web content article appear alongside that entry in the Asset Publisher application.

This tutorial shows you how to provide a way for authors to relate content. This tutorial assumes that you've asset enabled your appliation. If you've already done this, go ahead and begin relating your assets!

Relating Assets in the Service Layer

First, you must make some modifications to your portlet's service layer. You must implement persisting your entity's asset relationships. In your portlet's `service.xml`, put the following line of code below any finder method elements and then run Service Builder:



Asset Publisher

Lunar Resort Gift Shop: Our Story

The Lunar Resort Gift Shop is the only gift shop on the Moon to date. Lorem ipsum dolor sit amet, consectetur adipiscing elit. Suspendisse ex dolor, consequat ut arcu eu, vehicula pretium justo. Aliquam non ex nec mauris porta lobortis vel ut nibh. Maecenas fringilla ultricies quam a consectetur. Cras egestas congue tempor. Suspendisse a iaculis eros. Nam arcu nulla, tempus non odio eget, egestas lobortis urna.

Related Assets:
Visit the only gift shop on the Moon!
Moon

Figure 86.3: You and your users can find it helpful to relate assets to entities, such as this blogs entry.

```
<reference package-path="com.liferay.portlet.asset" entity="AssetLink" />
```

Next, you need to modify the add-, delete-, and update- methods in your -LocalServiceImpl to persist the asset relationships. You'll use your -LocalServiceImpl's assetLinkLocalService instance variable to execute persistence actions.

For example, consider the Wiki application. When you update wiki assets and statuses, both methods utilize the updateLinks via your instance variable assetLinkLocalService. Here's the updateLinks invocation in the Wiki application's WikiPageLocalServiceImpl.updateStatus(...) method:

```
assetLinkLocalService.updateLinks(
    userId, assetEntry.getEntryId(), assetLinkEntryIds,
    AssetLinkConstants.TYPE_RELATED);
```

To call the updateLinks method, you need to pass in the current user's ID, the asset entry's ID, the ID's of the asset link entries, and the link type. You should invoke this method after creating the asset entry. You can assign to an AssetEntry variable (e.g., one called assetEntry) the value returned from invoking assetEntryLocalService.updateEntry. That way you can get the asset entry's ID for updating its asset links. Lastly, in order to specify the link type parameter, make sure to import com.liferay.portlet.asset.model.AssetLinkConstants.

In your -LocalServiceImpl class' delete- method, you must delete the asset's relationships before deleting the asset. For example, you could delete your existing asset link relationships by using the following code:

```
AssetEntry assetEntry = assetEntryLocalService.fetchEntry(
    ENTITY.class.getName(), ENTITYId);

assetLinkLocalService.deleteLinks(assetEntry.getEntryId());
```

Make sure to replace the *ENTITY* place holders for your custom -delete method.

Super! Now your portlet's service layer can handle related assets. Even so, there's still nothing in your portlet's UI that lets your users relate assets. You'll take care of that in the next step.

Relating Assets in the UI

You typically implement the UI for linking assets in the JSP that you provide users the ability to create and edit your entity, This way only content creators can relate other assets to the entity. Related assets are implemented in the JSP by using the Liferay UI tag `liferay-ui:input-asset-links` inside of a collapsible panel. This code is placed inside the `aui:fieldset` tags of the JSP. The panel and `liferay-ui:input-asset-links` tag are shown below for the Blogs application:

```
<aui:fieldset collapsed="<%= true %>" collapsible="<%= true %>" label="related-assets">
    <liferay-ui:input-asset-links
        className="<%= BlogsEntry.class.getName() %>"
        classPK="<%= entryId %>"
    />
```

Your content authors are able to relate assets once you add this code and redeploy your portlet.

The following screenshot shows the Related Assets menu for an appliation. Note that it is contained in a collapsible panel titled Related Assets.

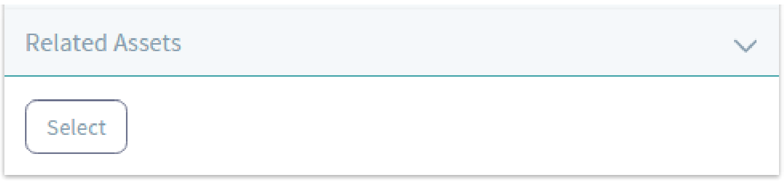


Figure 86.4: Your portlet's entity is now available in the Related Assets *Select* menu.

Even though you've provided a way for authors to assign related assets, the Related Assets menu shows your entity's fully qualified class name, instead of a more concise name. To replace the long fully qualified class name shown in the menu with a simplified name for your entity, add a language key that uses the fully qualified class name as the key's name and the new simplified name as the key's value. Put the language key in file `docroot/WEB-INF/src/content/Language.properties` in your portlet. You can refer to the Overriding Language Keys tutorial for more documentation on using language properties.

Upon redeploying your portlet, the value you assigned to the fully qualified class name in your `Language.properties` file shows in the Related Assets menu:

Awesome! Now content creators and editors can relate the assets of your application. The next thing you need to do is reveal any such related assets to the rest of your application's users. After all, you don't want to give everyone edit access just so they can view related assets!

Showing Related Assets

You can show related assets in your application's view of that entity or, if you've implemented asset rendering for your custom entity, you can show related assets in the full content view of your entity for users to view in an Asset Publisher portlet.

This section shows you how to access an entity's asset entry in your entity's view JSP and how to display links to its related assets. When you finish, users can click on the entity instances in your portlet to view any related assets.

In your entity's view JSP you can use `ParamUtil` to get the ID of the entity from the render request. Then you can create an entity object using your `-LocalServiceUtil` class. You can use an entity instance object to get the `AssetEntry` object associated with it.

```
<%
long insultId = ParamUtil.getLong(renderRequest, "insultId");
```

```
Insult ins = InsultLocalServiceUtil.getInsult(insultId);
AssetEntry assetEntry = AssetEntryLocalServiceUtil.getEntry(Insult.class.getName(), ins.getInsultId());
%>
```

To show the entity's related assets, you can use the `liferay-ui:asset-links` tag. For this tag, you should retrieve the entity's class name and the variable holding your instance object, so you can return its ID. The example code below uses the example entity class `Insult` and an instance object variable called `ins`:

```
<liferay-ui:asset-links
    assetEntryId="<%=(assetEntry != null) ? assetEntry.getEntryId() : 0%>"
    className="<%=Insult.class.getName()%>"
    classPK="<%=ins.getInsultId()%>" />
```

Go ahead and use a the `liferay-ui:asset-links` tag in your JSP. Great! Now you have the JSP that lets your users view related assets.

If you've already connected your portlet's view to the view JSP for your entity, you've completed the tutorial. You can otherwise follow the remainder of this tutorial to learn how to implement that connection.

Creating a URL to Your New JSP

Now that you've implemented showing off this asset feature, you must connect your application's main view JSP to your entity's view JSP. If your main view JSP uses a search container to list your entity instances, you can insert a `portlet:renderURL` tag just after the `liferay-ui:search-container-row` tag. For example, your `view.jsp` could look like this:

```
<liferay-ui:search-container-row
    className="com.sample.portlet.insults.model.Insult"
    keyProperty="insultId"
    modelVar="insult" escapedModel="<%= true %>"
>

<portlet:renderURL windowState="maximized" var="rowURL">
    <portlet:param name="mvcPath" value="/html/insult/view_insult.jsp" />
    <portlet:param name="insultId" value="<%= String.valueOf(insult.getInsultId()) %>" />
</portlet:renderURL>
```

Next, add to the first search container column an `href` attribute with the value of the URL you just created in the `portlet:renderURL` tag. For example, the value of `href` that corresponds with the render URL created above is `"<%=rowURL %>"`. Your `search-container-column-text` tag can look similar to this tag:

```
<liferay-ui:search-container-column-text
    name="Insult"
    value="<%= insult.getInsultString() %>"
    href="<%=rowURL %>"
/>
```

Now, redeploy your portlet and refresh the page so that your portlet's view JSP reloads. Each entity listed is a link. Click on one to view your entity's JSP that you made in the previous step of this tutorial.

Related assets, if you've created any yet, should be visible near the bottom of the page.

Excellent! Now you know how to implement related assets in your apps. Another thing you might want to do is investigate permissioning in the UI. For more information on this, see the tutorial Checking Permissions in the UI.

Defining Content Relationships

86.5 Implementing Asset Priority

The Asset Publisher lets you order assets by priority. For this to work, however, users must be able to set the asset's priority when creating or editing the asset. For example, when creating or editing web content, users can assign a priority in the Metadata section's Priority field.

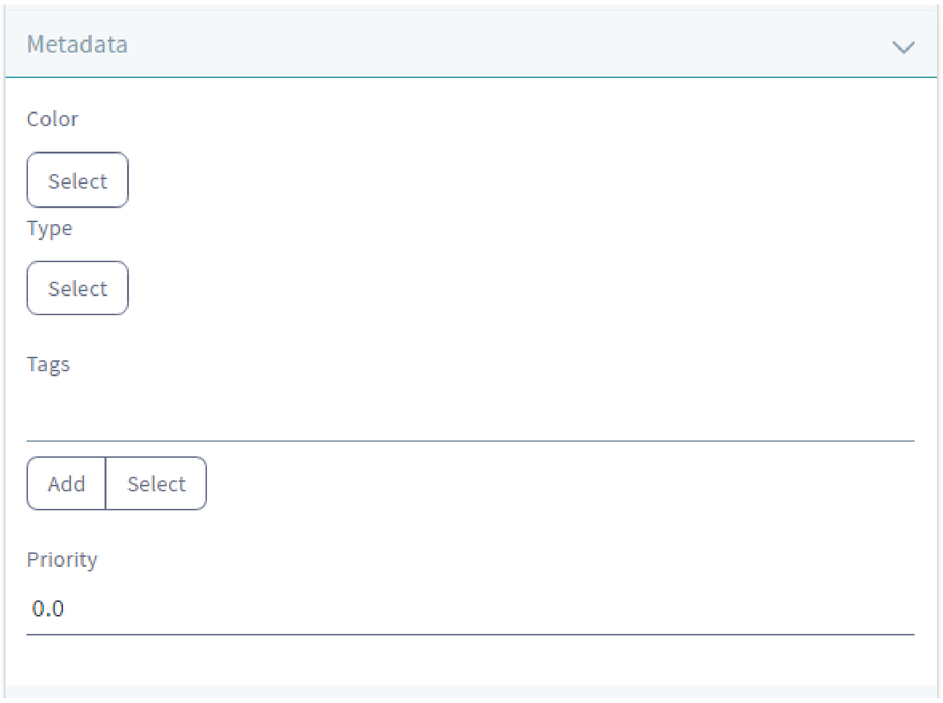

Figure 86.5: The Priority field lets users set an asset's priority.

This field isn't enabled by default for your custom assets. You must manually add support for it. Fortunately, this is very straightforward. This tutorial shows you how. Onwards!

Add the Priority Field to Your JSP

In the JSP for adding and editing your asset, add the following input field that lets users set the asset's priority. This example also validates the input to make sure the value the user sets is a number higher than zero:

```
<aui:input label="priority" name="assetPriority" type="text" value="<%= priority %>">
    <aui:validator name="number" />

    <aui:validator name="min">[0]</aui:validator>
</aui:input>
```

That's it for the view layer! Now when users create or edit your custom asset, they can enter its priority. Next, you'll learn how to use that value in your service layer.

Using the Priority Value in Your Service Layer

To make the priority value functional, you must retrieve it from the view and add it to the asset in your database. The priority value is automatically available in your service layer via the `ServiceContext` variable `serviceContext`. Retrieve it with `serviceContext.getAssetPriority()`, and then pass it as the last argument to the `assetEntryLocalService.updateEntry` call in your `-LocalServiceImpl`. You can see an example of this in the `BlogsEntryLocalServiceImpl` class of Liferay DXP's Blogs app. The `updateAsset` method takes a `priority` argument, which it passes as the last argument to its `assetEntryLocalService.updateEntry` call:

```
@Override
public void updateAsset(
        long userId, BlogsEntry entry, long[] assetCategoryIds,
        String[] assetTagNames, long[] assetLinkEntryIds, Double priority)
    throws PortalException {

    ...

    AssetEntry assetEntry = assetEntryLocalService.updateEntry(
        userId, entry.getGroupId(), entry.getCreateDate(),
        entry.getModifiedDate(), BlogsEntry.class.getName(),
        entry.getEntryId(), entry.getUuid(), 0, assetCategoryIds,
        assetTagNames, true, visible, null, null, null, null,
        ContentTypes.TEXT_HTML, entry.getTitle(), entry.getDescription(),
        summary, null, null, 0, 0, priority);

    ...
}
```

The `BlogsEntryLocalServiceImpl` class calls this `updateAsset` method when adding or updating a blog entry. Note that `serviceContext.getAssetPriority()` retrieves the priority:

```
updateAsset(
        userId, entry, serviceContext.getAssetCategoryIds(),
        serviceContext.getAssetTagNames(),
        serviceContext.getAssetLinkEntryIds(),
        serviceContext.getAssetPriority());
```

Sweet! Now you know how to enable priorities for your app's assets.

86.6 Rendering an Asset

There are several options you have for rendering an asset in Liferay DXP. Before setting up the rendering process for your asset, make sure it's added to the asset framework by following the Adding, Updating, and Deleting Assets tutorial. Once you have your asset added to the framework, Liferay DXP can render the asset by default using the Asset Publisher application. The default rendering process Liferay DXP provides, however, only displays the asset's title and description text. Any further rendering of your asset requires additional coding. For instance, you might want these additional things:

- An edit feature for modifying an asset.
- Viewing an asset in its original context (e.g., a blog in the Blogs application; a post in the Message Boards application).
- Embedding images, videos, and audio.
- Restricting access to users who do not have permissions to interact with the asset.
- Allowing users to comment on the asset.

Liferay lets you dictate your asset's rendering capabilities by providing the *Asset Renderer* framework. Implementing an asset renderer for an existing asset is easy because Liferay offers interfaces and factories to help get your custom asset rendering implemented fast. There are two things you must do to get your asset renderer functioning properly for your asset:

- Create an asset renderer for your custom asset.
- Create an asset renderer factory to create an instance of the asset renderer for each asset entity.

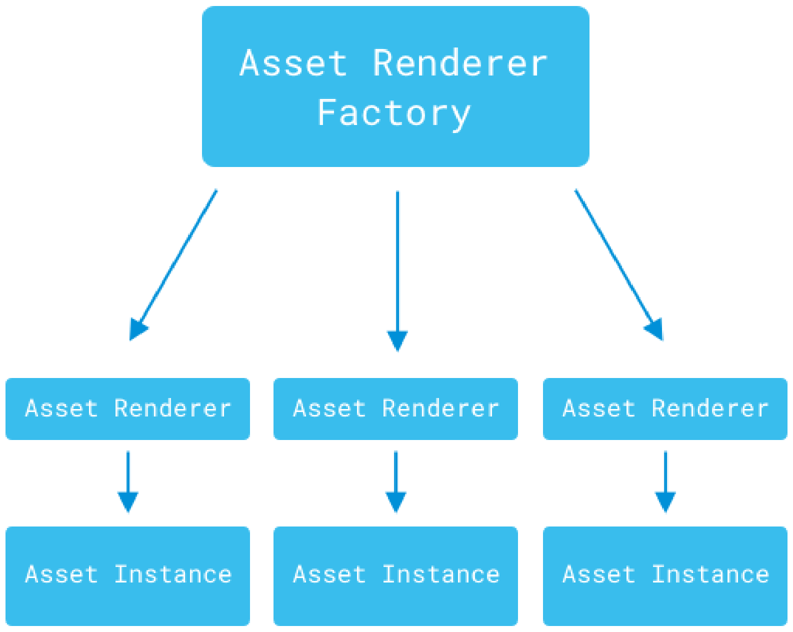

Figure 86.6: The asset renderer factory creates an asset renderer for each asset instance.

You'll learn how to create an asset renderer and an asset renderer factory by studying a Liferay asset that already uses both by default: Blogs. The Blogs application offers many different ways to access and render a blogs asset. You'll learn how a blogs asset provides an edit feature, comment section, original context viewing (i.e., viewing an asset from the Blogs application), workflow, etc. You'll also learn how it uses JSP templates to display various blog views. The Blogs application is an extensive example of how an asset renderer can be customized to fit your needs.

If you want to create an asset and make it do more than display its title and description, read on to learn more!

Prerequisites for Asset Enabling and Application

To asset-enable your application, you need two things:

1. The application must store asset data. Applications that store a data model meet this requirement.

2. The application must contain at least one non-instanceable portlet. `Edit` links for the asset cannot be generated without a non-instanceable portlet.

Some applications may consist of only one non-instanceable portlet, while others may consist of a both instanceable and non-instanceable portlets. If your application does not currently include a non-instanceable portlet, adding a configuration interface through a panel app will both enhance the usability of the application, and meet the requirement for adding a non-instanceable component to the application. See our tutorial on Adding Custom Panel Apps to learn how to add one.

Now that you have all that taken care of, you can move on to creating an Asset Renderer.

Creating an Asset Renderer

An asset renderer lets you provide your own HTML for your asset. The `AssetRenderer` interface requires that you choose a templating technology (JSP, FreeMarker, Soy, etc.) to display an asset's HTML. For this tutorial, you'll use JSP templates to render an asset's HTML. You'll learn how to associate your JSP templates with an asset renderer, along with configuring several other options.

To learn how an asset renderer is created, you'll create the pre-existing BlogsEntryAssetRenderer class, which configures the asset renderer framework for the Blogs application.

1. Create a new package in your existing project for your asset-related classes. For instance, the `BlogsEntryAssetRenderer` class resides in the `com.liferay.blogs.web` module's `com.liferay.blogs.web.asset` package.

2. Create your `-AssetEntry` class for your application in the new `-.asset` package and have it implement the AssetEntry interface. Consider the `BlogsEntryAssetRenderer` class as an example:

```
public class BlogsEntryAssetRenderer
    extends BaseJSPAssetRenderer<BlogsEntry> implements TrashRenderer {
```

   The `BlogsEntryAssetRenderer` class extends the BaseJSPAssetRenderer, which is an extension class intended for those who plan on using JSP templates to generate their asset's HTML. The `BaseJSPAssetRenderer` class implements the `AssetRenderer` interface. You'll notice the asset renderer is also implementing the TrashRenderer interface. This is a common practice for many Liferay DXP applications, which enables its assets to use Liferay DXP's Recycle Bin.

3. Define the asset renderer class's constructor, which typically sets the asset object to use in the asset renderer class.

```
public BlogsEntryAssetRenderer(
    BlogsEntry entry, ResourceBundleLoader resourceBundleLoader) {

    _entry = entry;
    _resourceBundleLoader = resourceBundleLoader;
}
```

The `BlogsEntryAssetRenderer` also sets the resource bundle loader, which loads the language keys for a module. You can learn more about the resource bundle loader in the Overriding Language Keys tutorial.

Also, make sure to define the `_entry` and `_resourceBundleLoader` fields in the class:

```
private final BlogsEntry _entry;
private final ResourceBundleLoader _resourceBundleLoader;
```

4. Now that your class declaration and constructor are defined for the blogs asset renderer, you must begin connecting your asset renderer to your asset. The following getter methods accomplish this:

```
@Override
public BlogsEntry getAssetObject() {
    return _entry;
}

@Override
public String getClassName() {
    return BlogsEntry.class.getName();
}

@Override
public long getClassPK() {
    return _entry.getEntryId();
}

@Override
public long getGroupId() {
    return _entry.getGroupId();
}

@Override
public String getType() {
    return BlogsEntryAssetRendererFactory.TYPE;
}

@Override
public String getUuid() {
    return _entry.getUuid();
}
```

These methods are pretty self-explanatory, but there are a couple things to point out. The `getAssetObject()` method sets the `BlogsEntry` that was set in the constructor as your asset to track. Likewise, the `getType()` method references the blogs asset renderer factory for the type of asset your asset renderer renders. Of course, the asset renderer type is `blog`, which you'll set in the factory later.

5. Your asset renderer must link to the portlet that owns the entity. In the case of a blogs asset, its portlet ID should be linked to the Blogs application.

```
@Override
public String getPortletId() {
    AssetRendererFactory<BlogsEntry> assetRendererFactory =
        getAssetRendererFactory();

    return assetRendererFactory.getPortletId();
}
```

The `getPortletId()` method instantiates an asset renderer factory for a `BlogsEntry` and retrieves the portlet ID for the portlet used to display blogs entries.

6. If you're interested in enabling workflow for your asset, add the following method similar to what was done for the Blogs application:

   ```
   @Override
   public int getStatus() {
       return _entry.getStatus();
   }
   ```

   This method retrieves the workflow status for the asset.

7. Another popular feature many developers want for their asset is to comment on it. This is enabled for the Blogs application with the following method:

   ```
   @Override
   public String getDiscussionPath() {
       if (PropsValues.BLOGS_ENTRY_COMMENTS_ENABLED) {
           return "edit_entry_discussion";
       }
       else {
           return null;
       }
   }
   ```

   A comments section is an available option if it returns a non-null value. A JSP template defining a comments section is not required. For the comments section to display for your asset, you must enable it in the Asset Publisher's *Options* (⋮) → *Configuration* → *Setup* → *Display Settings* section.

8. At a minimum, you should create a title and summary for your asset. Here's how the `BlogsEntryAssetRenderer` does it:

   ```
   @Override
   public String getSummary(
       PortletRequest portletRequest, PortletResponse portletResponse) {

       int abstractLength = AssetUtil.ASSET_ENTRY_ABSTRACT_LENGTH;

       if (portletRequest ≠ null) {
           abstractLength = GetterUtil.getInteger(
               portletRequest.getAttribute(
                   WebKeys.ASSET_ENTRY_ABSTRACT_LENGTH),
               AssetUtil.ASSET_ENTRY_ABSTRACT_LENGTH);
       }

       String summary = _entry.getDescription();

       if (Validator.isNull(summary)) {
           summary = HtmlUtil.stripHtml(
               StringUtil.shorten(_entry.getContent(), abstractLength));
       }

       return summary;
   }

   @Override
   public String getTitle(Locale locale) {
       ResourceBundle resourceBundle =
           _resourceBundleLoader.loadResourceBundle(
               LanguageUtil.getLanguageId(locale));

       return BlogsEntryUtil.getDisplayTitle(resourceBundle, _entry);
   }
   ```

These two methods return information about your asset in a generic way, so the asset publisher can display it. Anything appropriate for your asset can be the title or the summary.

The `getSummary(...)` method for Blogs returns the abstract description for a blog asset. If the abstract description does not exist, the content of the blog is used as an abstract. You'll learn more about abstracts and other content specifications later.

The `getTitle(...)` method for Blogs uses the resource bundle loader you configured in the constructor to load your module's resource bundle and return the display title for your asset.

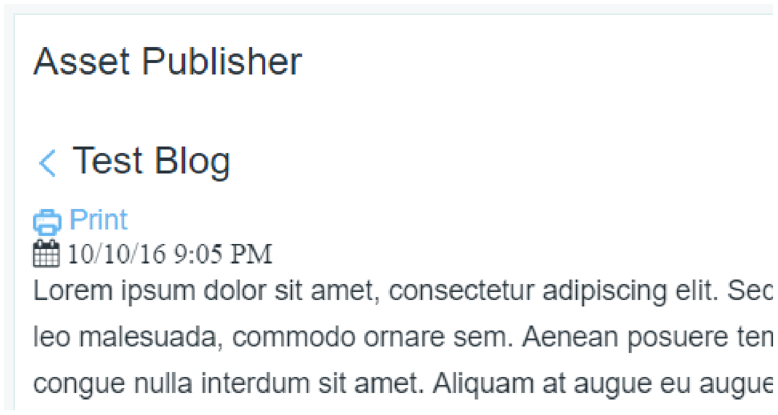
9. If you want to provide a unique URL for your asset, you can specify a URL title. A URL title is the URL used to access your asset directly (e.g., localhost:8080/-/this-is-my-blog-asset). You can do this by providing the following method:

```
@Override
public String getUrlTitle() {
    return _entry.getUrlTitle();
}
```

10. Insert the `isPrintable()` method, which enables the Asset Publisher's printing capability for your asset.

```
@Override
public boolean isPrintable() {
    return true;
}
```

This displays a Print icon when your asset is displayed in the Asset Publisher. For the icon to appear, you must enable it in the Asset Publisher's *Options* (⋮) → *Configuration* → *Setup* → *Display Settings* section.



Asset Publisher

Test Blog

Print
10/10/16 9:05 PM
Lorem ipsum dolor sit amet, consectetur adipiscing elit. Sec
leo malesuada, commodo ornare sem. Aenean posuere ten
congue nulla interdum sit amet. Aliquam at augue eu augue

Figure 86.7: Enable printing in the Asset Publisher to display the Print icon for your asset.

11. If your asset is protected by permissions, you should set permissions for the asset. You can do this via the asset renderer as well. See the logic below for an example used in the `BlogsEntryAssetRenderer` class:

```
@Override
public long getUserId() {
    return _entry.getUserId();
}
```

```
    @Override
    public String getUserName() {
        return _entry.getUserName();
    }

    public boolean hasDeletePermission(PermissionChecker permissionChecker) {
        return BlogsEntryPermission.contains(
            permissionChecker, _entry, ActionKeys.DELETE);
    }

    @Override
    public boolean hasEditPermission(PermissionChecker permissionChecker) {
        return BlogsEntryPermission.contains(
            permissionChecker, _entry, ActionKeys.UPDATE);
    }

    @Override
    public boolean hasViewPermission(PermissionChecker permissionChecker) {
        return BlogsEntryPermission.contains(
            permissionChecker, _entry, ActionKeys.VIEW);
    }
```

Before you can check if a user has permission to view your asset, you must distinguish the user. The `getUserId()` and `getUserName()` retrieves the entry's user ID and username, respectively. Then there are three boolean permission methods, which check if the user can view, edit, or delete your blogs entry. These permissions are for specific entity instances. Global permissions for blog entries are implemented in the factory, which you'll do later.

Awesome! You've learned how to set up the blogs asset renderer to

- connect to an asset
- connect to the asset's portlet
- use workflow management
- use a comments section
- retrieve the asset's title and summary
- generate the asset's unique URL
- display a print icon
- set up permissioning for the asset

You may recall that a major cog in asset renderer development generating HTML using a templating technology. The `BlogsEntryAssetRenderer` is configured to use JSP templates to generate HTML for the Asset Publisher. You'll learn more about how to do this next.

Configuring JSP Templates for an Asset Renderer

An asset can be displayed in several different ways in the Asset Publisher, by default. There are three templates to implement provided by the `AssetRenderer` interface:

- `abstract`
- `full_content`
- `preview`

Besides these supported templates, you can also create JSPs for buttons you'd like to provide for direct access and manipulation of the asset. For example,

- Edit
- View
- View in Context

The BlogsEntryAssetRenderer customizes the AssetRenderer's provided JSP templates and adds a few other features using JSPs. You'll inspect how the blogs asset renderer is put together to satisfy JSP template development requirements.

1. Add the getJspPath(...) method to your asset renderer. This method should return the path to your JSP, which is rendered inside the Asset Publisher. This is how the BlogsEntryAssetRenderer uses this method:

   ```
   @Override
   public String getJspPath(HttpServletRequest request, String template) {
       if (template.equals(TEMPLATE_ABSTRACT) ||
           template.equals(TEMPLATE_FULL_CONTENT)) {

           return "/blogs/asset/" + template + ".jsp";
       }
       else {
           return null;
       }
   }
   ```

   Blogs assets provide abstract.jsp and full_content.jsp templates. This means that a blogs asset can render a blog's abstract description or the blog's full content in the Asset Publisher. Those templates are located in the com.liferay.blogs.web module's src/main/resources/META-INF/resources/blogs/asset folder. You could create a similar folder for your JSP templates used for this method. The other template provided by the AssetRenderer interface, preview.jsp, is not customized by the blogs asset renderer, so its default template is implemented.

   You must create a link to display the full content of the asset. You'll do this later.

2. Now that you've added the path to your JSP, you must include that JSP. Since the BlogsEntryAssetRenderer class extends the BaseJSPAssetRenderer, it already has an include(...) method to render a specific JSP. You must override this method to set an attribute in the request to use in the blog's views:

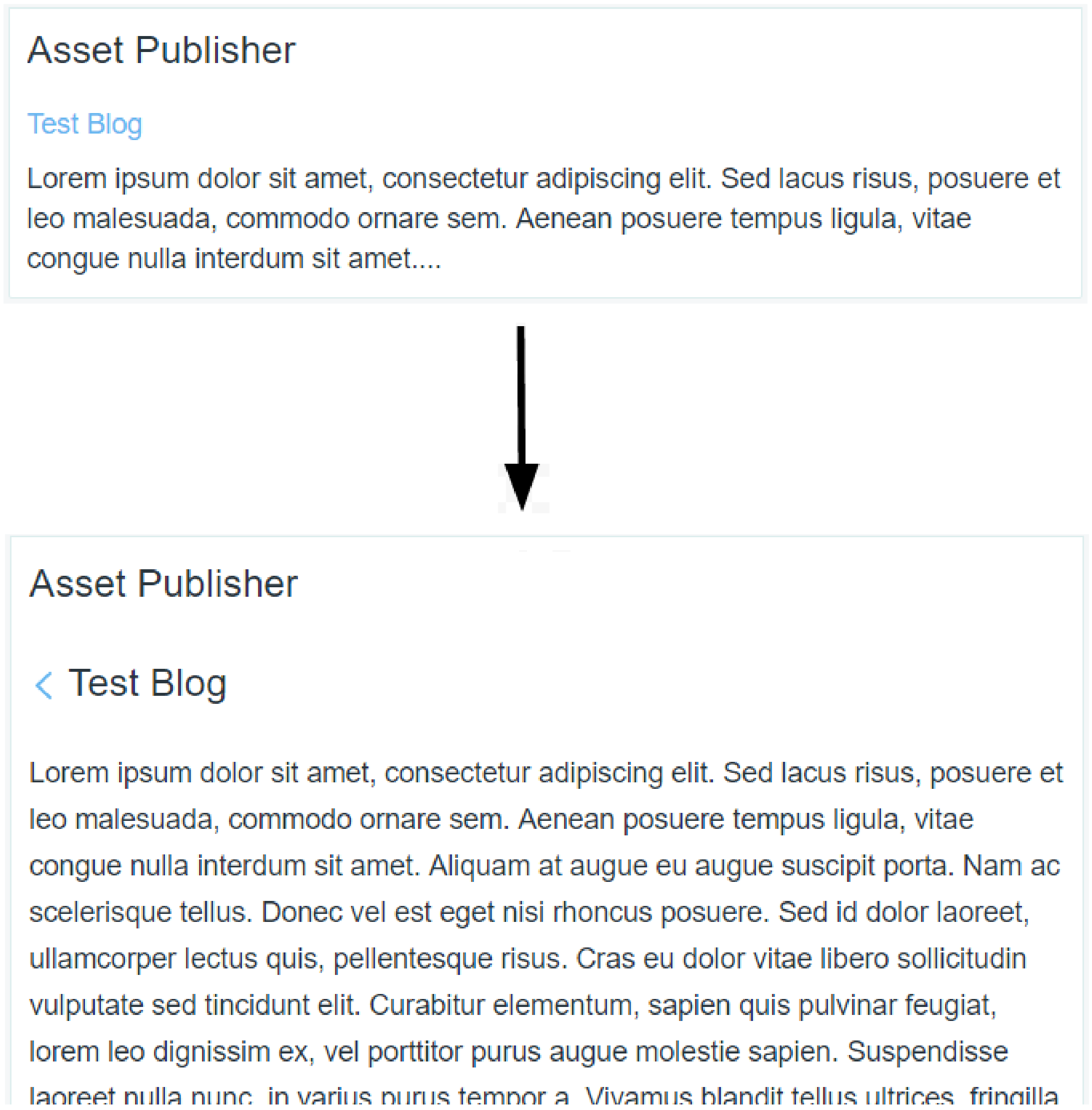
   ```
   @Override
   public boolean include(
           HttpServletRequest request, HttpServletResponse response,
           String template)
       throws Exception {

       request.setAttribute(WebKeys.BLOGS_ENTRY, _entry);

       return super.include(request, response, template);
   }
   ```

   The attribute includes the blogs entry object. Adding the blog object this way is not mandatory; you could obtain the blog entry directly from the view. Using the include(...) method, however, follows the best practice for MVC portlets.

Terrific! You've learned how to apply JSPs supported by the Asset Publisher for your asset. That's not all you can do with JSP templates, however! The asset renderer framework provides several other methods that let you render convenient buttons for your asset.



Asset Publisher

Test Blog

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Sed lacus risus, posuere et leo malesuada, commodo ornare sem. Aenean posuere tempus ligula, vitae congue nulla interdum sit amet....

Asset Publisher

Test Blog

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Sed lacus risus, posuere et leo malesuada, commodo ornare sem. Aenean posuere tempus ligula, vitae congue nulla interdum sit amet. Aliquam at augue eu augue suscipit porta. Nam ac scelerisque tellus. Donec vel est eget nisi rhoncus posuere. Sed id dolor laoreet, ullamcorper lectus quis, pellentesque risus. Cras eu dolor vitae libero sollicitudin vulputate sed tincidunt elit. Curabitur elementum, sapien quis pulvinar feugiat, lorem leo dignissim ex, vel porttitor purus augue molestie sapien. Suspendisse laoreet nulla nunc, in varius purus tempor a. Vivamus blandit tellus ultrices, fringilla

Figure 86.8: The abstract and full content views are rendererd differently for blogs.

1. Blogs assets provide an Edit button ( ) that lets you edit the asset. This is provided by adding the following method to the `BlogsEntryAssetRenderer` class:

```
@Override
public PortletURL getURLEdit(
        LiferayPortletRequest liferayPortletRequest,
        LiferayPortletResponse liferayPortletResponse)
    throws Exception {

    Group group = GroupLocalServiceUtil.fetchGroup(_entry.getGroupId());

    PortletURL portletURL = PortalUtil.getControlPanelPortletURL(
        liferayPortletRequest, group, BlogsPortletKeys.BLOGS, 0, 0,
        PortletRequest.RENDER_PHASE);

    portletURL.setParameter("mvcRenderCommandName", "/blogs/edit_entry");
    portletURL.setParameter("entryId", String.valueOf(_entry.getEntryId()));
    return portletURL;
}
```

The Asset Publisher loads the blogs asset using the Blogs application. Then the `edit_entry.jsp` template generates the HTML for an editing UI. Once the necessary edits are made to the asset, it can be saved from the Asset Publisher. Pretty cool, right?

2. You can specify how to view your asset by providing methods similar to the methods outlined below in the `BlogsEntryAssetRenderer` class:

```
@Override
public String getURLView(
        LiferayPortletResponse liferayPortletResponse,
        WindowState windowState)
    throws Exception {

    AssetRendererFactory<BlogsEntry> assetRendererFactory =
        getAssetRendererFactory();

    PortletURL portletURL = assetRendererFactory.getURLView(
        liferayPortletResponse, windowState);

    portletURL.setParameter("mvcRenderCommandName", "/blogs/view_entry");
    portletURL.setParameter("entryId", String.valueOf(_entry.getEntryId()));
    portletURL.setWindowState(windowState);

    return portletURL.toString();
}

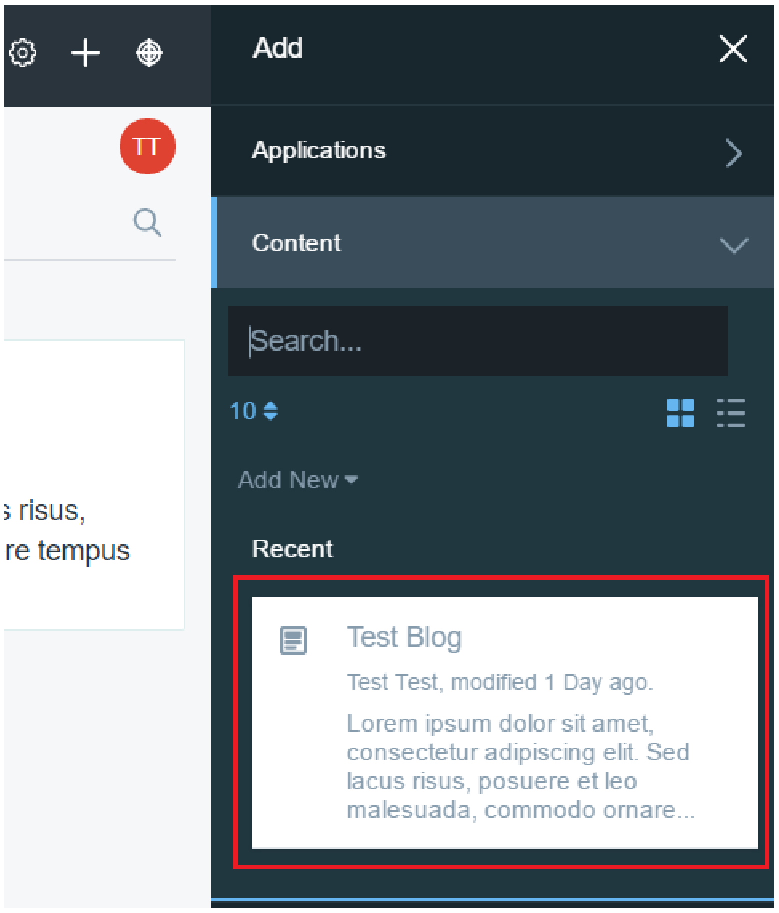
@Override
public String getURLViewInContext(
    LiferayPortletRequest liferayPortletRequest,
    LiferayPortletResponse liferayPortletResponse,
    String noSuchEntryRedirect) {

    return getURLViewInContext(
        liferayPortletRequest, noSuchEntryRedirect, "/blogs/find_entry",
        "entryId", _entry.getEntryId());
}
```

The `getURLView(...)` method generates a URL that displays the full content of the asset in the Asset Publisher. This is assigned to the clickable asset name. The `getURLViewInContext(...)` method provides a similar URL assigned to the asset name, but the URL redirects to the original context of the asset (e.g., viewing a blogs asset in the Blogs application). Deciding which view to render in Liferay DXP is configurable by navigating to the Asset Publisher's *Options* (⋮) → *Configuration* → *Setup* → *Display Settings* section and choosing between *Show Full Content* and *View in Context* for the Asset Link Behavior drop-down menu.

The Blogs application provides `abstract` and `full_content` JSP templates that override the ones provided by the `AssetRenderer` interface. The third template, `preview`, could also be customized. You can view the default `preview.jsp` template rendered in the *Add* (➕) → *Content* menu.

You've learned all about implementing the `AssetRenderer`'s provided templates and customizing them to fit your needs. Next, you'll put your asset renderer into action by creating a factory.



Test Blog

Test Test, modified 1 Day ago.

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Sed lacus risus, posuere et leo malesuada, commodo ornare...

Figure 86.9: The `preview` template displays a preview of the asset in the Content section of the Add menu.

Creating a Factory for the Asset Renderer

You've successfully created an asset renderer, but you must create a factory class to generate asset renderers for each asset instance. For example, the blogs asset renderer factory instantiates `BlogsEntryAssetRenderer` for each blogs asset displayed in an Asset Publisher.

You'll continue the blogs asset renderer example by creating the blogs asset renderer factory.

1. Create an `-AssetRenderFactory` class in the same folder as its asset renderer class. For blogs, the `BlogsEntryAssetRendererFactory` class resides in the `com.liferay.blogs.web` module's `com.liferay.blogs.web.asset` package. The factory class should extend the `BaseAssetRendererFactory` class and the asset type should be specified as its parameter. You can see how this was done in the `BlogsEntryAssetRendererFactory` class below

```
public class BlogsEntryAssetRendererFactory
    extends BaseAssetRendererFactory<BlogsEntry> {
```

2. Create an `@Component` annotation section above the class declaration. This annotation is responsible for registering the factory instance for the asset.

```
@Component(
    immediate = true,
    property = {"javax.portlet.name=" + BlogsPortletKeys.BLOGS},
    service = AssetRendererFactory.class
)
public class BlogsEntryAssetRendererFactory
    extends BaseAssetRendererFactory<BlogsEntry> {
```

There are a few annotation elements you should set:

- The `immediate` element directs the factory to start in Liferay DXP when its module starts.
- The `property` element sets the portlet that is associated with the asset. The Blogs portlet is specified, since this is the Blogs asset renderer factory.
- The `service` element should point to the `AssetRendererFactory.class` interface.

```
**Note:** In previous versions of Liferay DXP, you had to register the asset
renderer factory in a portlet's `liferay-portlet.xml` file. The registration
process is now completed automatically by OSGi using the `@Component`
annotation.
```

---

3. Create a constructor for the factory class that presets private attributes of the factory.

```
public BlogsEntryAssetRendererFactory() {
    setClassName(BlogsEntry.class.getName());
    setCategorizable(true);
    setLinkable(true);
    setPortletId(BlogsPortletKeys.BLOGS);
    setSearchable(true);
    setSelectable(true);
}
```

   - *linkable*: other assets can select blogs assets as their related assets.
   - *categorizable*: blogs can be used to delimit the scope of a vocabulary from the Categories Administration.
   - *searchable*: blogs can be found when searching for assets.
   - *selectable*: blogs can be selected when choosing assets to display in the Asset Publisher.

   Setting the class name and portlet ID links the asset renderer factory to the entity.

4. Create the asset renderer for your asset. This is done by calling its constructor.

```
@Override
public AssetRenderer<BlogsEntry> getAssetRenderer(long classPK, int type)
    throws PortalException {

    BlogsEntry entry = _blogsEntryLocalService.getEntry(classPK);

    BlogsEntryAssetRenderer blogsEntryAssetRenderer =
        new BlogsEntryAssetRenderer(entry, _resourceBundleLoader);

    blogsEntryAssetRenderer.setAssetRendererType(type);
    blogsEntryAssetRenderer.setServletContext(_servletContext);

    return blogsEntryAssetRenderer;
}
```

For blogs, the asset is retrieved by calling the Blogs application's local service. Then the asset renderer is instantiated using the blogs asset and resource bundle loader. Next, the type and servlet context is set for the asset renderer. Finally, the configured asset renderer is returned.

There are a few variables in the `getAssetRenderer(...)` method you must create. You'll set those variables and learn what they're doing next.

a. You must get the entry by calling the Blogs application's local service. You can instantiate this service by creating a private field and setting it using a setter method:

   @Reference(unbind = "-") protected void setBlogsEntryLocalService(BlogsEntryLocalService blogsEntryLocalService) {

   ```
    _blogsEntryLocalService = blogsEntryLocalService;
   ```

   }

   private BlogsEntryLocalService _blogsEntryLocalService;

The setter method is annotated with the `@Reference` tag. Visit the Invoking Liferay Services Locally section of the *Finding and Invoking Liferay Services* tutorial for more information.

b. You must specify the resource bundle loader since it was specified in the `BlogsEntryAssetRenderer`'s constructor:

   @Reference(target = "(bundle.symbolic.name=com.liferay.blogs.web)", unbind = "-") public void setResourceBundleLoader(ResourceBundleLoader resourceBundleLoader) {

   ```
    _resourceBundleLoader = resourceBundleLoader;
   ```

   }

   private ResourceBundleLoader _resourceBundleLoader;

Make sure the `osgi.web.symbolicname` in the `target` property of the `@Reference` annotation is set to the same value as the `Bundle-SymbolicName` defined in the `bnd.bnd` file of the module the factory resides in.

c. The asset renderer `type` integer is set for the asset renderer, but why an integer? Liferay DXP needs to differentiate when it should display the latest *approved* version of the asset, or the latest version, even if it's unapproved (e.g., unapproved versions would be displayed for reviewers of the asset in a workflow). For these situations, the asset renderer factory should receive either

   - `0` for the latest version of the asset
   - `1` for the latest approved version of the asset

d. Since the Blogs application provides its own JSPs, it must pass a reference of the servlet context to the asset renderer. This is always required when using custom JSPs in an asset renderer:

   @Reference(target = "(osgi.web.symbolicname=com.liferay.blogs.web)", unbind = "-") public void setServletContext(ServletContext servletContext) { _servletContext = servletContext; }

   private ServletContext _servletContext;

5. Set the type of asset that the asset factory associates with and provide a getter method to retrieve that type. Also, provide another getter to retrieve the blogs entry class name, which is required:

   ```
   public static final String TYPE = "blog";

   @Override
   public String getType() {
       return TYPE;
   }

   @Override
   public String getClassName() {
       return BlogsEntry.class.getName();
   }
   ```

6. Set the Lexicon icon for the asset:

   ```
   @Override
   public String getIconCssClass() {
       return "blogs";
   }
   ```

   You can find a list of all available Lexicon icons at https://liferay.github.io/clay/content/icons-lexicon/.

7. Add methods that generate URLs to add and view the asset.

   ```
   @Override
   public PortletURL getURLAdd(
       LiferayPortletRequest liferayPortletRequest,
       LiferayPortletResponse liferayPortletResponse, long classTypeId) {

       PortletURL portletURL = PortalUtil.getControlPanelPortletURL(
           liferayPortletRequest, getGroup(liferayPortletRequest),
           BlogsPortletKeys.BLOGS, 0, 0, PortletRequest.RENDER_PHASE);

       portletURL.setParameter("mvcRenderCommandName", "/blogs/edit_entry");

       return portletURL;
   }

   @Override
   public PortletURL getURLView(
       LiferayPortletResponse liferayPortletResponse,
       WindowState windowState) {

       LiferayPortletURL liferayPortletURL =
           liferayPortletResponse.createLiferayPortletURL(
               BlogsPortletKeys.BLOGS, PortletRequest.RENDER_PHASE);

       try {
           liferayPortletURL.setWindowState(windowState);
       }
       catch (WindowStateException wse) {
       }

       return liferayPortletURL;
   }
   ```

   If you're paying close attention, you may have noticed the `getURLView(...)` method was also implemented in the `BlogsEntryAssetRenderer` class. The asset renderer's `getURLView(...)` method creates a URL for the specific asset instance, whereas the factory uses the method to create a generic URL that only points to the application managing the assets (e.g., Blogs application).

8. Set the global permissions for all blogs assets:

```
@Override
public boolean hasAddPermission(
        PermissionChecker permissionChecker, long groupId, long classTypeId)
    throws Exception {

    return BlogsPermission.contains(
        permissionChecker, groupId, ActionKeys.ADD_ENTRY);
}

@Override
public boolean hasPermission(
        PermissionChecker permissionChecker, long classPK, String actionId)
    throws Exception {

    return BlogsEntryPermission.contains(
        permissionChecker, classPK, actionId);
}
```

Great! You've finished creating the Blogs application's asset renderer factory! Now you have the knowledge to implement an asset renderer and produce an asset renderer for each asset instance using a factory!

Chapter 87

Liferay's Workflow Framework

Enabling your application's entities to support workflow is so easy, you could do it in your sleep (but don't try). Workflow enabled entities require a few things:

- A workflow handler class to interact with Liferay's workflow back end and the entity's service layer.
- Some extra fields in their database table that help keep track of their status.

  In most Liferay applications, Service Builder will be used to create those fields.
- Updates to the service layer.

  The service layer needs code to populate the new fields when entities are added to the database.

  The service layer needs to send the entity through Liferay's workflow, and it needs to handle the workflow status of the entity when it's returned by the workflow.

  The service layer needs getters that return entities of the desired workflow status (usually *approved*).
- The View layer should account for the workflow status of displayed entities.

The code for most Liferay applications spans multiple modules, so where should you implement the workflow handler? It should go in the module with your service implementations. It's nice to keep your back end code separate from your view layer and controller (in the MVC pattern).

87.1 Creating a Workflow Handler

First create a Component class. It should extend `BaseWorkflowHandler<T>`, an abstract class that provides a default implementation of the `WorkflowHandler<T>` service. Pass the interface for your model as the type parameter for the class.

```
FooEntity WorkflowHandler extends BaseWorkflowHandler<FooEntity>
```

Since you're publishing a service to be consumed in the OSGi runtime, your workflow handler class needs to be registered. If you're using Declarative Services, make it a Component class, using the `@Component` annotation.

```
@Component(
    property = {"model.class.name=com.my.app.package.model.FooEntity"},
    service = WorkflowHandler.class
)
```

It needs one property, to set `model.class.name` to the fully qualified class name of the class you passed as the type parameter. It also needs to declare the type of service being implemented (`WorkflowHandler.class`).

What methods do you need to override in your workflow handler? Just three:

```
@Override
public String getClassName() {

@Override
public String getType(Locale locale) {

@Override
public FooEntity updateStatus(int status, Map<String, Serializable> workflowContext) {
```

The first two are pretty boilerplate. Most of the heavy lifting is being done in the `updateStatus` method. It returns a call to a local service method of the same name, so the status returned from the workflow back end can be persisted to the entity table in the database.

The `updateStatus` method should take a user ID, the primary key for the class (for example, `fooEntityId`), the workflow status, the service context, and the workflow context. The status and the workflow context can be obtained from the workflow back end. You'll need to define the rest of the parameters, which can be obtained from the workflow context.

```
@Override
public FooEntity updateStatus(
        int status, Map<String, Serializable> workflowContext)
    throws PortalException {

    long userId = GetterUtil.getLong(
        (String)workflowContext.get(WorkflowConstants.CONTEXT_USER_ID));
    long classPK = GetterUtil.getLong(
        (String)workflowContext.get(
            WorkflowConstants.CONTEXT_ENTRY_CLASS_PK));

    ServiceContext serviceContext = (ServiceContext)workflowContext.get(
        "serviceContext");

    return _fooEntityLocalService.updateStatus(
        userId, classPK, status, serviceContext, workflowContext);
}
```

Now your entity can be handled by Liferay's workflow framework. Next, update the service methods to account for workflow status, and add a new method to update the status of an entity in the database.

87.2 Updating the Service Layer

Make sure your entity database table has `status`, `statusByUserId`, `statusByUserName`, and `statusDate` fields. If you're using service builder, add this to your `service.xml` if you haven't already:

```
<column name="status" type="int" />
<column name="statusByUserId" type="long" />
<column name="statusByUserName" type="String" />
<column name="statusDate" type="Date" />
```

Wherever you're setting the other database fields in your persistence code, set the workflow status as a draft and set the other fields.

```
fooEntity.setStatus(WorkflowConstants.STATUS_DRAFT);
fooEntity.setStatusByUserId(userId);
fooEntity.setStatusByUserName(user.getFullName());
fooEntity.setStatusDate(serviceContext.getModifiedDate(null));
```

With Service Builder driven Liferay applications, this will be in the local service implementation class (`-LocalServiceImpl`).

Whenever an entity is added to the database you need to detect whether workflow is installed and active. If not, you need to automatically mark the entity as approved so it appears in the UI. If it is, you want to leave it in draft status and send it to the workflow back end where it can be properly handled. Thankfully, this whole process is easily done with a single call to `WorkflowHandlerRegistryUtil.startWorkflowInstance`. There are several methods of this name which take a different parameter set, so inspect the `WorkflowHandlerRegistryUtil` class and decide which is right for your case.

```
WorkflowHandlerRegistryUtil.startWorkflowInstance(fooEntity.getCompanyId(),
        fooEntity.getGroupId(), fooEntity.getUserId(), FooEntity.class.getName(),
        fooEntity.getPrimaryKey(), fooEntity, serviceContext);
```

Once you've set the database fields for workflow status and started the workflow instance, implement the `updateStatus` method that you need to call in the workflow handler. The workflow handler gets the entity's status from the workflow back end and passes it to your service layer, which persists the updated entity to the database.

```
fooEntity.setStatus(status);
fooEntity.setStatusByUserId(user.getUserId());
fooEntity.setStatusByUserName(user.getFullName());
fooEntity.setStatusDate(serviceContext.getModifiedDate(now));

fooEntityPersistence.update(fooEntity);
```

After setting the workflow fields for the entity, think about the specifics of your situation and whether any additional logic should be added to this method. For instance, if your entities are Liferay Assets already, you'll want to change the visibility of the asset depending on its workflow status. You don't want the Asset Publisher displaying entities that haven't yet been approved in the workflow process.

```
if (status == WorkflowConstants.STATUS_APPROVED) {

    assetEntryLocalService.updateEntry(
        FooEntity.class.getName(), fooEntityId, fooEntity.getDisplayDate(),
        null, true, true);
}

else {

    assetEntryLocalService.updateVisible(
        fooEntity.class.getName(), entryId, false);
}
```

If approved, the asset is updated, with the publication date, a `listable` boolean, and a `visible` boolean being updated to reflect the current state of the asset. If the workflow status is anything other than approved, its visibility is set to `false`.

For an example of a fully implemented `updateStatus` method, see the `com.liferay.portlet.blogs.service.impl.BlogsEntry` class in `portal-impl`.

Before leaving the service layer, add a call to `deleteWorkflowInstanceLinks` in the `deleteEntity` method. Here's what it looks like:

```
workflowInstanceLinkLocalService.deleteWorkflowInstanceLinks(
    fooEntity.getCompanyId(), fooEntity.getGroupId(),
    FooEntity.class.getName(), fooEntity.getFooEntityId());
```

When you send an entity to the workflow framework via the `startWorkflowInstance` call, it creates an entry in the `workflowinstancelink` database table. This `delete` call ensures there are no orphaned entries in the `workflowinstancelinks` table.

Note, to get the `WorkflowInstanceLocalService` injected into your `*LocalServiceBaseImpl` so you can call its methods in the `LocalServiceImpl`, add this to your entity declaration in `service.xml`:

```
    <reference entity="WorkflowInstanceLink" package-path="com.liferay.portal" />
```

Save your work and run Service Builder. Once you've accounted for workflow status in your service layer, there's only one thing left to do: update the user interface.

87.3 Workflow Status and the View Layer

If you have an application with database entities, you're likely displaying them. If you're sending entities through a workflow process, you only want to display approved entities to your end users.

This often involves the following steps:

- Create a *finder* for your entities that accounts for the `status` field in your database table.
- Expose the finder in a *getter* method of your service layer.
- Update the view layer to use the new getter for displaying entities (e.g., in a Search Container).

If you're using Service Builder, define your finder in your application's `service.xml` and let Service Builder generate it for you.

```
<finder name="G_S" return-type="Collection">
    <finder-column name="groupId"></finder-column>
    <finder-column name="status"></finder-column>
</finder>
```

Then make sure you have a getter in your service layer that uses the new finder.

```
public List<FooEntity> getFooEntities(long groupId, int status)
       throws SystemException {
    return fooEntityPersistence.findByG_S(groupId,
         WorkflowConstants.STATUS_APPROVED);
}
```

Now all you need to do is update your JSP to use the appropriate getter.

```
<liferay-ui:search-container-results
    results="<%=FooEntityLocalServiceUtil.getFooEntities(scopeGroupId,
             fooEntityId(), Workflowconstants.STATUS_APPROVED, searchContainer.getStart(),
             searchContainer.getEnd())%>"
    ...
```

In an *administrative* type application (in other words, one that's displayed in the Site Menu's *Content* section) you might want to display all the entities, with their current workflow status (for example, include workflow status as a column in the search container). To do so, use the `<aui:worklfow-status>` tag.

```
    <aui:workflow-status markupView="lexicon" showIcon="<%= false %>" showLabel="<%= false %>" status="<%= fooEntity.getStatus() %>" />
```

You only needed one new class, one new method in the service layer, and some updates to your view, and workflow is fully implemented and ready to use in your Liferay application.

	Title	Author	Create Date	Display Date	Views	Status	
■	Turbo Encabulator Giveaway!	Test Test	1 Minute Ago	2 Minutes Ago	0	Approved	⋮

Figure 87.1: You can display the workflow status of your entities. This is useful in administrative applications.

Chapter 88

Export/Import and Staging

Liferay DXP's Export/Import and Staging features give users the power to plan page publication and manage content. The Export/Import feature lets users export content from the Portal and import external content into the Portal. Providing the export feature in your application allows users the flexibility of exporting content they've created in your application to other places, such as another portal instance, or to save the content for a later use. Import does the opposite: it brings the data from a LAR file into your portal.

For instance, suppose you're managing an online education course using Liferay DXP. Because of the nature of an online course, the site's data (grades, assignments, etc.) is purged every semester to make way for new incoming students. In a scenario like this, there is a need frequently to store a complete record of all data given during a course. The institution offering the course must usually keep records of the course's data for a minimum number of years. To abide by these requirements, having a gradebook application with an export/import feature would allow you to clear the application's data for a new semester, but save the previous class's work. You could export the students' grades as a LAR file and save it outside the course's site. If the grades ever needed to be accessed again, you could import the LAR and view the student records.

The Export/Import feature adds another dimension to your application by letting you produce reusable content and import content from other places. To learn more about using the Export/Import feature, visit the Exporting/Importing App Data section of the User Guide.

Staging lets you change your site behind the scenes without affecting the live site, and then you can publish all the changes in one fell swoop. Keep in mind that Staging leverages the Export/Import framework, which is an essential part of the publishing process. If you include staging support in your application, your users can stage its content until it's ready.

For example, if you have an application that provides information intended only during a specific holiday, supporting the Staging environment lets users save your application's assets specific for that holiday. They'll reside in the Staging environment until they're ready for publishing. To learn more about Staging, visit the Staging Content for Publication section.

Besides configuring these features for your application, Liferay also provides an API that allows developers to write custom code, extending Liferay's default functionality.

In this section of tutorials, you'll learn how to implement Staging and the Export/Import framework. The main areas of Staging code to focus on are outlined below:

1. `StagedModel` Interface: The `StagedModel` is the cornerstone of Staging. All content that must be handled in Staging should implement this interface; it provides the behavior contract for the entities Staging uses during the Staging process.

2. `StagedModelDataHandler`: These data handlers are responsible for handling one specific entity class. For example, the `BookmarksEntryStagedModelDataHandler` handles the `BookmarksEntry` during Staging: exporting data, serializing content, finding existing entries, etc.

3. `PortletDataHandler`: These data handlers are responsible for handling aspects of the portlet's configuration and publication during Staging.

4. `ExportActionableDynamicQuery`: This framework is useful when developing Staging support. Its purpose is to query data from the database and process it during publication. It's automatically generated if your entity contains the right fields so there's no need to worry about configuring it.

5. `ExportImportContentProcessor` and `ExportImportPortletPreferencesProcessor`: Advanced frameworks only needed in special cases. The `ExportImportContentProcessor` lets you process your content during a publication process. The `ExportImportPortletPreferencesProcessor` lets you process your portlet preferences (application's configuration) during a publication process.

88.1 Decision to Implement Staging

Liferay DXP's Staging feature is an advanced publication tool that lets you create or modify your site before releasing it to the public. Most of Liferay DXP's included applications (e.g., Web Content and Bookmarks) support Staging. Implementing Staging in your own application can be beneficial, but how do you know if it's the right move?

Not every application needs to support Staging and Export/Import. The most important question to consider during the decision process is

What part of your application are you primarily focused on using Staging for?

When Staging is enabled in Liferay DXP, all pages and applications are staged automatically. Liferay DXP's architecture separates the application and its configuration from the actual content, meaning that content can exist without any application to display it and vice versa. Although Staging and the Export/Import framework supports all applications and their configurations by default, not all applications' content is supported by Staging.

Implementing Staging for your application means you're defining the logic for how the Staging framework should process, serialize, and de-serialize your app's content, and how to insert it into a database.

Therefore, if you want to track your application's content, you should implement Staging in your application. Here are a few other scenarios where you should implement Staging in your application:

- You're using remote staging. When publishing to a remote live site, your content must be transferred to a different Liferay DXP installation. Therefore, Staging must be able to recognize the content to facilitate the transfer.
- You want a space where you can freely edit and test your content before publishing it to a live audience.
- Your content is being referenced from another content type that supports Staging.
- You want to process your portlet's preferences during publication (i.e., you might want to publish some content with it or complete extra steps).
- You want to process the content during publication (e.g., writing validation for your content during the import process).

If none of these options are beneficial for you, implementing Staging in your application is unnecessary.

When content supports Staging and Staging is enabled, it is created in a Staging group and is only published to a live site when that site is published. When content is **not** supported by Staging, it is never added to a Staging group and is not reviewable during the Staging publication process; it's added and removed from the live site only.

From a technical standpoint, publishing an entity or content follows the process below:

1. The entity's possible references are discovered and processed.
2. The entity's fields are processed.
3. The entity is serialized into a LAR file.
4. The LAR is transferred to the live site (local or remote live).
5. After de-serialization, the entity's fields are processed.
6. The entity is added to the database.

Awesome! You should now have a good idea about whether you should implement Staging for your application.

88.2 Understanding Staged Models

To track an entity of an application with the Staging framework, you must implement the StagedModel interface in the app's model classes. It provides the behavior contract for entities during the Staging process. For example, the Bookmarks application manages BookmarksEntrys and BookmarksFolders, and both implement the `StagedModel` interface. Once you've configured your staged models, you can create staged model data handlers, which supply information about a staged model (entity) and its referenced content to the Export/Import and Staging frameworks. See the Understanding Data Handlers tutorial for more information.

There are two ways to create staged models for your application's entities:

- Using Service Builder to generate the required Staging implementations (tutorial).
- Implementing the required Staging interfaces manually (tutorial).

You can follow step-by-step procedures for creating staged models for your entities by visiting their respective tutorials.

Using Service Builder to generate your staged models is the easiest way to create staged models for your app. You define the necessary columns in your `service.xml` file and set the `uuid` attribute to `true`. Then you run Service Builder, which generates the required code for your new staged models.

Implementing the necessary staged model logic *manually* should be done if you **don't** want to extend your model with special attributes only required to generate Staging logic (i.e., not needed by your business logic). In this case, you should adapt your business logic to meet the Staging framework's needs. You'll learn more about this later.

You'll explore the provided staged model interfaces next.

Staged Model Interfaces

The `StagedModel` interface must be implemented by your app's model classes, but this is typically done through inheritance by implementing one of the interfaces that extend the base interface:

- StagedAuditedModel
- StagedGroupedModel

You must implement these when you want to use certain features of the Staging framework like automatic group mapping or entity level *Last Publish Date* handling. So how do you choose which is right for you?

The `StagedAuditedModel` interface provides all the audit fields to the model that implements it. You can check the AuditedModel interface for the specific audit fields provided. The `StagedAuditedModel` interface is intended for models that function independent from the group concept (sometimes referred to as company models). If your model is a group model, you should not implement the `StagedAuditedModel` interface.

The `StagedGroupedModel` interface must be implemented for group models. For example, if your application requires the `groupId` column, your model is a group model. If your model satisfies both the `StagedGroupModel` and `StagedAuditedModel` requirements, it should implement the `StagedGroupedModel`. Your model should only implement the `StagedAuditedModel` if it doesn't fulfill the grouped model needs, but does fulfill the audited model needs. If your model does not fulfill either the `StagedAuditedModel` or `StagedGroupedModel` requirements, you should implement the base `StagedModel` interface.

As an example for extending your model class, you can visit the BookmarksEntryModel class, which extends the `StagedGroupedModel` interface; this is done because bookmark entries are group models.

```
public interface BookmarksEntryModel extends BaseModel<BookmarksEntry>,
    ShardedModel, StagedGroupedModel, TrashedModel, WorkflowedModel {
```

Now that you have a better understanding about staged model interfaces, you'll dive into the attributes used in Staging and why they're important.

Important Attributes in Staging

If you'd like to generate your staged models using Service Builder, you must define the proper attributes in your project's `service.xml` file. If you'd like more detail on how this is done, see the Generating Staged Models using Service Builder tutorial. You'll learn some general information about this process next.

One of the most important attributes used by the Staging framework is the UUID (Universally Unique Identifier). This attribute must be set to `true` in your `service.xml` file for Service Builder to recognize your model as an eligible staged model. The UUID is used to differentiate entities between environments. Because the UUID always remains the same, it's unique across multiple systems. Why is this so important?

Suppose you're using remote staging and you create a new entity on your local staging site and publish it to your remote live site. What happens when you go back to modify the entity on your local site and want to publish those changes? Without a UUID, the Staging framework has no way to know the local and remote entities are the same. To publish entities properly, the Staging framework needs entities uniquely identified across systems to recognize the original entity on the remote site and update it. The UUID provides that.

In addition to the UUID, there are several columns that must be defined in your `service.xml` file for Service Builder to define your model as a staged model:

- `companyId`
- `createDate`
- `modifiedDate`

If you want a staged grouped model, also include the `groupId` and `lastPublishDate` columns. If you want a staged audited model, include the `userId` and `userName` columns.

Next, you'll learn how to build staged models from scratch.

Adapting Your Business Logic to Build Staged Models

What if you don't want to extend your model with special attributes that may not be needed in your business logic? In this case, you should adapt your business logic to meet the Staging framework's needs. Liferay provides the ModelAdapterBuilder framework, which lets you adapt your model classes to staged models.

As an example, assume you have an app that is fully developed and you want to configure it to work with Staging. Your app, however, does not require a UUID for any of its entities, and therefore, does not provide them. Instead of configuring your app to handle UUIDs just for the sake of generating staged models, you can leverage the Model Adapter Builder to build your staged models.

Another example for building staged models from scratch is for applications that use REST services to access their attributes instead of the database. Since this kind of app is developed to pull its attributes from a remote system, it would be more convenient to build your staged models yourself instead of relying on Service Builder, which is database driven.

To adapt your model classes to staged models, follow the steps outlined below:

1. Create a `Staged[Entity]` interface, which extends the model specific interface (e.g., `[Entity]`) and the appropriate staged model interface (e.g., `StagedModel`). This class serves as the Staged Model Adapter.
2. Create a `Staged[Entity]Impl` class that implements the `Staged[Entity]` interface and provides necessary logic for your entity model to be recognized as a staged model.
3. Create a `Staged[Entity]ModelAdapterBuilder` class that implements `ModelAdapterBuilder<[Entity], Staged[Entity]>`. This class adapts the original model to the newly created Staged Model Adapter.
4. Adapt your existing model and call one of the provided APIs to export or import the entity automatically.

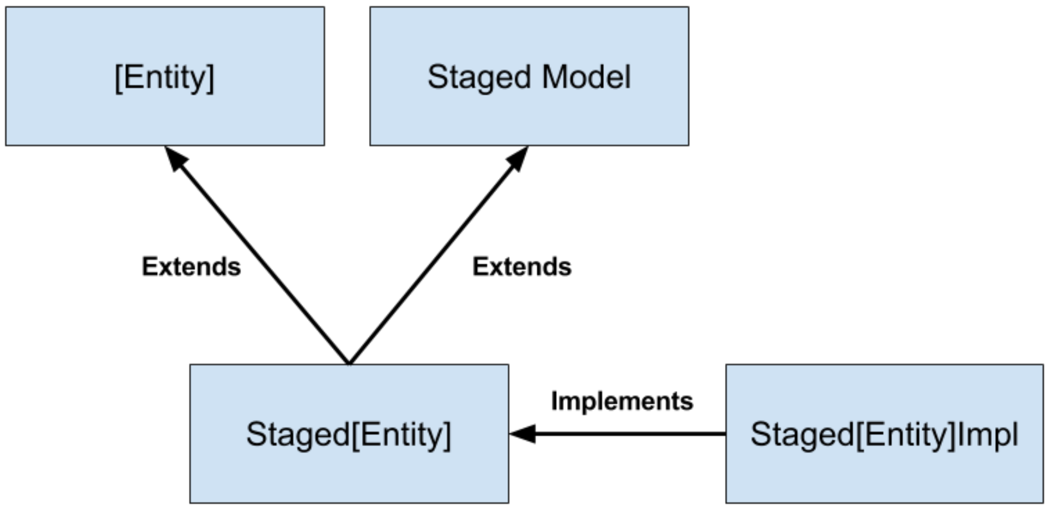


Figure 88.1: The Staged Model Adapter class extends your entity and staged model interfaces.

To step through the process for leveraging the Model Adapter Builder for an existing app, visit the Creating Staged Models Manually tutorial.

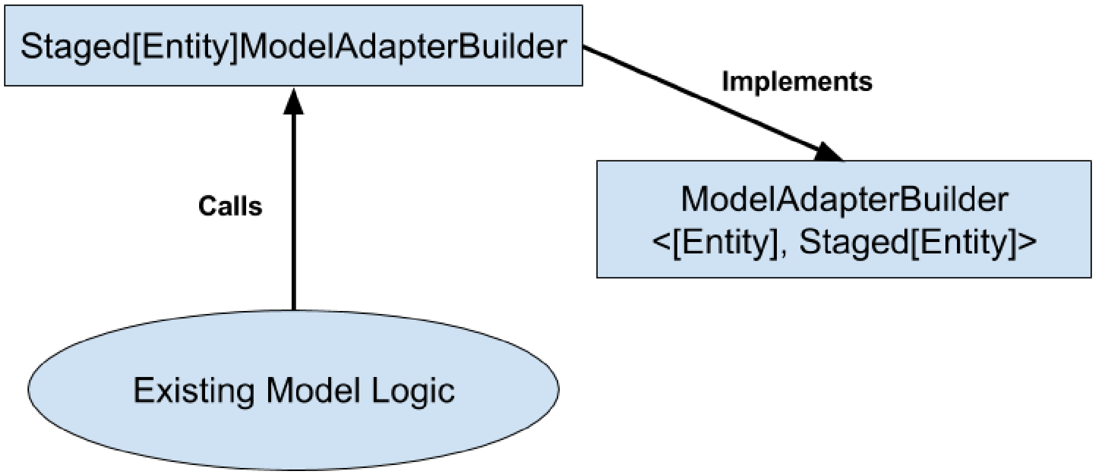

Figure 88.2: The Model Adapter Builder gets an instance of the model and outputs a staged model.

88.3 Generating Staged Models Using Service Builder

This document has been updated and ported to Liferay Learn and is no longer maintained here.

A Staged model is an essential building block to implementing the Staging and Export/Import frameworks in your application. Instead of having to create staged models for your app manually, you can leverage Service Builder to generate the necessary staged model logic for you. Before diving into this tutorial, make sure you've read the Understanding Staged Models tutorial for information on how staged models work. Also, if your app doesn't use Liferay's Service Builder, you must configure it in your project. If you need help doing this, follow the Defining an Object-Relational Map with Service Builder tutorial.

This tutorial assumes you have a Service Builder project with `*api` and `*service` modules. If you want to follow along with this tutorial, download the staged-model-example Service Builder project. This is a bare-bones project that you can test to observe the Staging-related changes generated by running Service Builder. This tutorial assumes your project is built with Gradle. The example project's `service.xml` file contains the following configuration:

```
<service-builder package-path="com.liferay.docs">
    <namespace>FOO</namespace>
    <entity local-service="true" name="Foo" remote-service="true" uuid="true">

        <!-- PK fields -->

        <column name="fooId" primary="true" type="long" />

        <!-- Group instance -->

        <column name="groupId" type="long" />

        <!-- Audit fields -->
        <column name="companyId" type="long" />
        <column name="createDate" type="Date" />
        <column name="modifiedDate" type="Date" />

        ...
        ...

    </entity>
</service-builder>
```

For simplicity, you'll track the Service Builder-generated changes applied to an entity model file to observe how staged models are assigned to your entity. Keep in mind the specific staged attributes necessary for each staged model. Depending on the attributes defined in your `service.xml` file, Service Builder assigns your entity model to a specific staged model type.

1. Navigate to your project's *`service` module at the command line. Run Service Builder (e.g., `gradlew buildService`) to generate your project's models based on the current `service.xml` configuration.

2. Open your project's `[Entity]Model.java` interface and observe the inherited interfaces.

   ```
   public interface FooModel extends BaseModel<Foo>, ShardedModel, StagedModel {
   ```

   Your model was generated as a staged model! This is because the UUID is set to true and the `companyId`, `createDate`, and `modifiedDate` columns are defined. There is much more logic generated for your app behind the scenes, but this shows that Service Builder deemed your entity eligible for the Staging and Export/Import frameworks.

3. Add the `userId` and `userName` columns to your `service.xml` file:

   ```
       <column name="userId" type="long" />
       <column name="userName" type="String" />
   ```

4. Rerun Service Builder and observe your `[Entity]Model.java` interface again:

   ```
   public interface FooModel extends BaseModel<Foo>, GroupedModel, ShardedModel,
       StagedAuditedModel {
   ```

   Your model is now a staged audited model!

5. Add the `lastPublishDate` column to your `service.xml` file:

   ```
   <column name="lastPublishDate" type="Date" />
   ```

6. Rerun Service Builder and observe your `[Entity]Model.java` interface again:

   ```
   public interface FooModel extends BaseModel<Foo>, ShardedModel,
       StagedGroupedModel {
   ```

   Your model is now a staged grouped model! The `groupId` column is also required to extend the `StagedGroupedModel` interface, but it was already defined in the original `service.xml` file.

Fantastic! You've witnessed firsthand how easy it is to generate staged models using Service Builder.

88.4 Creating Staged Models Manually

There are times when using Service Builder to generate your staged models is not practical. In these cases, you should create your staged models manually. Make sure to read the Adapting Your Business Logic to Build Staged Models section to determine if creating staged models manually is beneficial for your use case.

In this tutorial, you'll explore how the Asset Link framework (a Liferay DXP framework used for relating assets) manually creates staged models. This framework is separate from Staging and is referenced solely as an example for how to leverage the ModelAdapterBuilder framework, which lets you adapt your model classes to staged models.

Asset links do not provide UUIDs by default; however, they still need to be tracked in the Staging and Export/Import frameworks. Therefore, they require staged models. Since they don't provide a UUID, Service Builder cannot generate staged models for asset links. The Asset Link framework has to create staged models differently using the Model Adapter Builder. The naming convention for this interface typically follows the `Staged[Entity]` syntax. The Asset Link framework uses a generic entity called `AssetLink`.

Follow the steps below to leverage the Model Adapter Builder in your app.

1. Create a new interface that extends one of the staged model interfaces and your model specific interface. For example,

   ```
   public interface StagedAssetLink extends AssetLink, StagedModel {

   }
   ```

   This interface should define methods required for your model to qualify as a staged model. For asset links, methods for retrieving entry UUIDs (among others) are defined:

   ```
   public String getEntry1Uuid();

   public String getEntry2Uuid();
   ```

   These will be implemented by a new implementation class later.

2. Create an implementation class that implements your new `Staged[Entity]`. For example, the Asset Link framework does this:

   ```
   public class StagedAssetLinkImpl implements StagedAssetLink {

   }
   ```

   This class provides necessary logic for your entity model to be recognized as a staged model. Below is a subset of logic in the example `StagedAssetLinkImpl` class used to populate UUIDs for asset link entries:

   ```
   public StagedAssetLinkImpl(AssetLink assetLink) {
        _assetLink = assetLink;

       ...

        populateUuid();
   }

   @Override
   public String getEntry1Uuid() {
       if (Validator.isNotNull(_entry1Uuid)) {
           return _entry1Uuid;
   ```

```
    }

    populateEntry1Attributes();

    return _entry1Uuid;
}

@Override
public String getEntry2Uuid() {
    if (Validator.isNotNull(_entry2Uuid)) {
        return _entry2Uuid;
    }

    populateEntry2Attributes();

    return _entry2Uuid;
}

protected void populateEntry1Attributes() {

    ...

    AssetEntry entry1 = AssetEntryLocalServiceUtil.fetchAssetEntry(
        _assetLink.getEntryId1());

    ...

    _entry1Uuid = entry1.getClassUuid();
}

protected void populateEntry2Attributes() {

    ...

    AssetEntry entry2 = AssetEntryLocalServiceUtil.fetchAssetEntry(
        _assetLink.getEntryId2());

    ...

    _entry2Uuid = entry2.getClassUuid();
}

protected void populateUuid() {

    ...

    String entry1Uuid = getEntry1Uuid();
    String entry2Uuid = getEntry2Uuid();

    ...

    _uuid = entry1Uuid + StringPool.POUND + entry2Uuid;
        }
}

private AssetLink _assetLink;
private String _entry1Uuid;
private String _entry2Uuid;
private String _uuid;
```

This logic retrieves asset link entries and populates UUIDs for them usable by the Staging and Export/Import frameworks. With the newly generated UUIDs, asset link model classes can be converted to staged models.

3. Create a Model Adapter Builder class and implement the ModelAdapterBuilder interface. You should define the entity type and your Staged Model Adapter class when implementing the interface:

```
public class StagedAssetLinkModelAdapterBuilder
    implements ModelAdapterBuilder<AssetLink, StagedAssetLink> {

    @Override
    public StagedAssetLink build(AssetLink assetLink) {
        return new StagedAssetLinkImpl(assetLink);
    }

}
```

For the `StagedAssetLinkModelAdapterBuilder`, the entity type is `AssetLink` and the Staged Model Adapter is `StagedAssetLink`. Your app should follow a similar design. The Model Adapter Builder outputs a new instance of the `Staged[Entity]Impl` object.

4. Now you need to adapt your existing business logic to call the provided APIs. You can call the ModelAdapterUtil class to create an instance of your Staged Model Adapter. See how the Asset Link framework does this below:

```
StagedAssetLink stagedAssetLink = ModelAdapterUtil.adapt(
    assetLink, AssetLink.class, StagedAssetLink.class);
```

Once you've created Staged Model Data Handlers, you can begin exporting/importing your now Staging-compatible entities:

```
StagedModelDataHandlerUtil.exportStagedModel(
    portletDataContext, stagedAssetLink);
```

Visit the Understanding Data Handlers tutorial if you're unfamiliar with how data handlers work.

Awesome! You've successfully adapted your business logic to build staged models!

88.5 Understanding Data Handlers

A common requirement for many data driven applications is to import and export data. This *could* be accomplished by accessing your database directly and running SQL queries to export/import data; however, this has several drawbacks:

- Working with different database vendors might require customized SQL scripts.
- Access to the database may be tightly controlled, restricting the ability to export/import on demand.
- You'd have to come up with your own means of storing and parsing the data.

Liferay provides a more convenient and reliable way to export/import your data without accessing the database.

Liferay Archive (LAR) File

An easier way to export/import your application's data is to use a Liferay ARchive (LAR) file. Liferay provides the LAR feature to address the need to export/import data in a database agnostic manner. So what exactly is a LAR file?

A LAR file is a compressed file (ZIP archive) Liferay DXP uses to export/import data. LAR files can be created for single portlets, pages, or sets of pages. Portlets that are LAR-capable provide an interface to let you control how their data are imported/exported. There are several Liferay DXP use cases that require the use of LAR files:

- Backing up and restoring portlet-specific data without requiring a full database backup.
- Cloning sites.
- Specifying a template to be used for users' public or private pages.
- Using Local Live or Remote Live staging.

Liferay provides the data handler framework so developers don't have to create/modify a LAR file manually. **It is strongly recommended never to modify a LAR file.** You should always use Liferay's provided data handler APIs to construct it.

Knowing how a LAR file is constructed, however, is beneficial to understand the overall purpose of your application's data handlers. Next, you'll explore a LAR file's anatomy.

LAR File Anatomy

What is a LAR file? You know the general concept for *why* it's used, but you may want to know what lives inside to make your export/import processes work. With a fundamental understanding for how a LAR file is constructed, you can better understand what your data handlers generate behind the scenes.

Below is the structure of a simple LAR file. It illustrates the exportation of a single Bookmarks entry and the portlet's configuration:

- `Bookmarks_Admin-201701091904.portlet.lar`
  - `group`
    - `20143`
      - `com.liferay.bookmarks.model.BookmarksEntry`
      - `35005.xml`

      - `portlet`
      - `com_liferay_bookmarks_web_portlet_BookmarksAdminPortlet`
      - `20137`
      - `portlet.xml`

      - `20143`
      - `portlet-data.xml`
  - `manifest.xml`

You can tell from the LAR's generated name what information is contained in the LAR: the Bookmarks Admin app's data. The `manifest.xml` file sits at the root of the LAR file. It provides essential information about the export process. The `manifest.xml` for the sample Bookmarks LAR is pretty bare since it's not exporting much content, but this file can become large when exporting pages of content. There are four main parts (tags) to a `manifest.xml` file.

- `header`: contains information about the LAR file, current process, and site you're exporting (if necessary). For example, it can include locales, build information, export date, company ID, group ID, layouts, themes, etc.

- `missing-references`: lists entities that must be validated during import. For example, suppose you're exporting a web content article that references an image (e.g., an embedded image residing in the document library). If the image was not selected for export, the image must already exist in the site where the article is imported. Therefore, the image would be flagged as a missing reference in the LAR file. If the missing reference does not exist in the site when the LAR is imported, the import process fails. If your import fails, the Import UI shows you the missing references that weren't validated.
- `portlets`: defines the portlets (i.e., portlet data) exported in the LAR. Each portlet definition has basic information on the exported portlet and points to the generated `portlet.xml` for more specialized portlet information.
- `manifest-summary`: contains information on what has been exported. The Staging and Export frameworks export or publish some entities even though they weren't marked for it, because the process respects data integrity. This section holds information for all the entities that have been processed. The entities defining a non-zero `addition-count` attribute are displayed in the Export/Import UI.

The `manifest.xml` file also defines layout information if you've exported pages in your LAR. For example, your manifest could have `LayoutSet`, `Layout`, and `LayoutFriendlyURL` tags specifying staged models and their various references in an exported page.

Now that you've learned about the LAR's `manifest.xml` and how it's used to store high-level data about your export process, you can dive deeper into the LAR file's `group` folder. The `group` folder has two main parts:

- Entities
- Portlets

If you look at the anatomy of the sample Bookmarks LAR, you'll notice that `group/[groupId]` folder holds a folder named after the entity you're exporting (e.g., `com.liferay.bookmarks.model.BookmarksEntry`) and a `portlet` folder holding a folder named after the portlet from which you're exporting (e.g., `com_liferay_bookmarks_web_portlet_BookmarksAdminPortlet`). For each entity/portlet you export, there are subsequent folders holding data about them. Entities and portlets can also be stored in a `company` folder. Although the majority of entities belong to a group, some exist outside of a group scope (e.g., users).

If you open the `/group/20143/com.liferay.bookmarks.model.BookmarksEntry/35005.xml` file, you'll find serialized data about the entity, which is similar to what is stored in the database.

The `portlet` folder holds all the portlets you exported. Each portlet has its own folder that holds various XML files with data describing the exported content. There are three main XML files that can be generated for a single portlet:

- `portlet.xml`: provides essential information about the portlet, similar to a manifest file. For example, this can include the portlet ID, high-level entity information stored in the portlet (e.g., web content articles in a web content portlet), permissioning, etc.
- `portlet-data.xml`: describes specific entity data stored in the portlet. For example, for the web content portlet, articles stored in the portlet are defined in `staged-model` tags and are linked to their serialized entity XML files.
- `portlet-preferences.xml`: defines the settings of the portlet. For example, this can include portlet preferences like the portlet owner, default user, article IDs, etc.

Note that when you import a LAR, it only includes the portlet data. You have to deploy the portlet to be able to use it.

You now know how exported entities, portlets, and pages are defined in a LAR file. For a summarized outline of what you've learned about LAR file construction, see the diagram below.

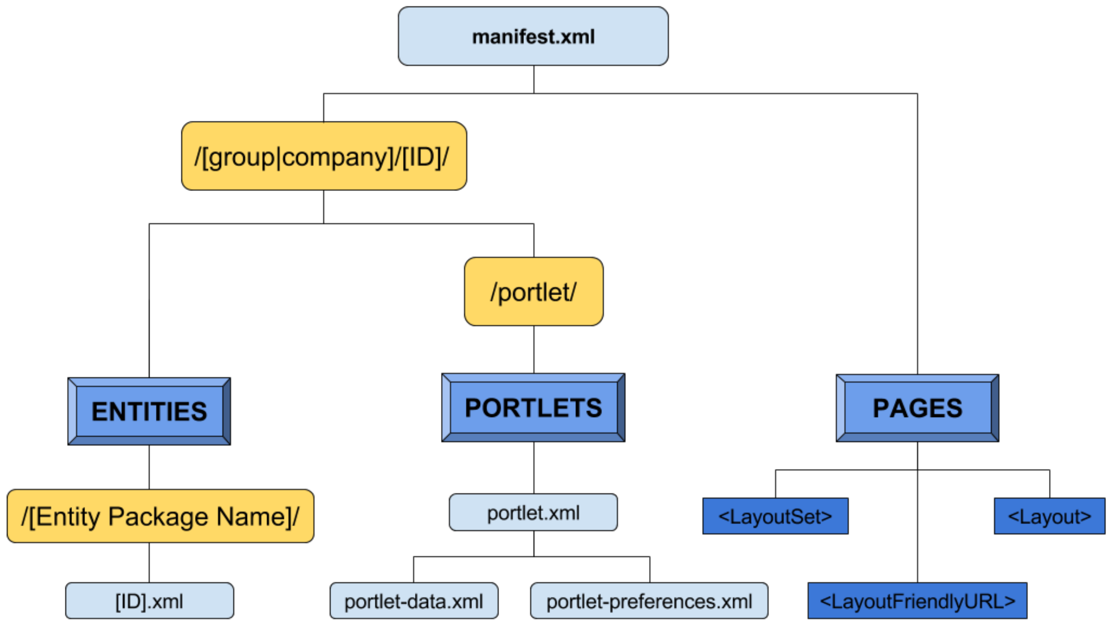

Figure 88.3: Entities, Portlets, and Pages are defined in a LAR in different places.

Excellent! You now have a fundamental understanding for how a LAR file is generated and how it's structured.

Next, you'll learn about data handler fundamentals and the prerequisites required to implement them.

Data Handler Fundamentals

To leverage the Export/Import framework's ability to export/import a LAR file, you can implement Data Handlers in your application. There are two types of data handlers: *Portlet Data Handlers* and *Staged Model Data Handlers*.

A Portlet Data Handler imports/exports portlet specific data to a LAR file. These classes only have the role of querying and coordinating between staged model data handlers. For example, the Bookmarks application's portlet data handler tracks system events dealing with Bookmarks entities. It also configures the Export/Import UI options for the Bookmarks application.

To track each entity of an application for staging, you should create staged models by implementing the StagedModel interface. Staged models are the parent interface of an entity in the Staging framework. For example, the Bookmarks application manages BookmarksEntrys and BookmarksFolders, and both implement the `StagedModel` interface.

A Staged Model Data Handler supplies information about a staged model (entity) to the Export/Import framework, defining a display name for the UI, deleting an entity, etc. It's also responsible for exporting referenced content. For example, if a Bookmarks entry resides in a Bookmarks folder, the `BookmarksEntry` staged model data handler invokes the export of the `BookmarksFolder`.

You're not required to implement a staged model data handler for every entity in your application, but they're necessary for any entity you want to export/import or have the staging framework track.

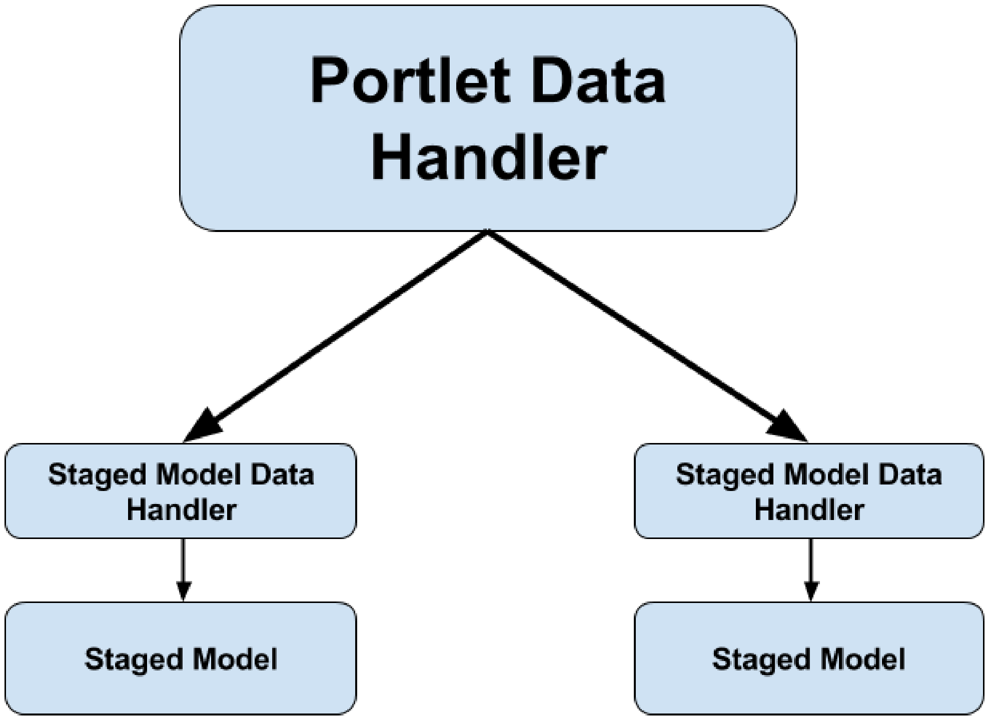

Figure 88.4: The Data Handler framework uses portlet data handlers and staged model data handlers to track and export/import portlet and staged model information, respectively.

Before implementing data handlers, make sure your application is ready for the Export/Import and Staging frameworks by running Service Builder in your application. Using Service Builder to create staged models is not required, but is recommended since it generates many requirements for you. To ensure Service Builder recognizes your entity as a staged model, you must set the `uuid` attribute to `true` in your `service.xml` file and have the following columns declared:

- `companyId`
- `groupId`
- `userId`
- `userName`
- `createDate`
- `modifiedDate`

You can learn how to create a `service.xml` file for your application by visiting the Defining an Object-Relational Map with Service Builder tutorial.

To learn how to develop data handlers for your app, visit the Developing Data Handlers tutorial.

88.6 Developing Data Handlers

To leverage the Export/Import framework's ability to export/import a LAR file, you can implement Data Handlers in your application. There are two types of data handlers you can implement: *Portlet Data Handlers* and *Staged Model Data Handlers*. For more information on the fundamentals behind Liferay's data handlers and how a LAR file is constructed, see the Understanding Data Handlers tutorial. You also must ensure your application is properly configured to use data handlers; this is also covered in the linked tutorial.

To learn how to implement data handlers for your custom application, you'll examine how the Bookmarks application does it. First you'll start with its portlet data handler implementation.

Portlet Data Handlers

The following steps create the `BookmarksPortletDataHandler` class used for the Bookmarks application.

1. Create a new package in your existing Service Builder project for your data handler classes. For instance, the Bookmarks application's data handler classes reside in the `com.liferay.bookmarks.service` module's `com.liferay.bookmarks.internal.exportimport.data.handler` package.

2. Create your `-PortletDataHandler` class for your application in the new `-exportimport.data.handler` package and have it implement the PortletDataHandler interface by extending the BasePortletDataHandler class. See the `BookmarksPortletDataHandler` class as an example:

   ```
   public class BookmarksPortletDataHandler extends BasePortletDataHandler {
   ```

3. Create an `@Component` annotation section above the class declaration. This annotation registers this class as a portlet data handler in the OSGi service registry.

   ```
   @Component(
       immediate = true,
       property = {
           "javax.portlet.name=" + BookmarksPortletKeys.BOOKMARKS,
           "javax.portlet.name=" + BookmarksPortletKeys.BOOKMARKS_ADMIN
       },
       service = PortletDataHandler.class
   )
   ```

   There are a few annotation attributes you should set:

   - The `immediate` element directs the container to activate the component immediately once its provided module has started.
   - The `property` element sets various properties for the component service. You must associate the portlets you wish to handle with this service so they function properly in the export/import environment. For example, since the Bookmarks data handler is used for two portlets, they're both configured using the `javax.portlet.name` property.
   - The `service` element should point to the `PortletDataHandler.class` interface.

```
**Note:** In previous versions of Liferay DXP, you had to register the portlet
data handler in a portlet's `liferay-portlet.xml` file. The registration
process is now completed automatically by OSGi using the `@Component`
annotation.
```

---

4. Set what the portlet data handler controls and the portlet's Export/Import UI by adding an `activate` method:

```
@Activate
protected void activate() {
    setDataPortletPreferences("rootFolderId");
    setDeletionSystemEventStagedModelTypes(
        new StagedModelType(BookmarksEntry.class),
        new StagedModelType(BookmarksFolder.class));
    setExportControls(
        new PortletDataHandlerBoolean(
            NAMESPACE, "entries", true, false, null,
            BookmarksEntry.class.getName()));
    setImportControls(getExportControls());
}
```

This method is called during initialization of the component by using the @Activate annotation. This method is invoked after dependencies are set and before services are registered.

The four set methods called in the BookmarksPortletDataHandler's activate method are described below:

- setDataPortletPreferences: sets portlet preferences the Bookmarks application should handle.
- setDeletionSystemEventStagedModelTypes: sets the staged model deletions that the portlet data handler should track. For the Bookmarks application, Bookmark entries and folders are tracked.
- setExportControls: adds fine grained controls over export behavior that are rendered in the Export UI. For the Bookmarks application, a checkbox is added to select Bookmarks content (entries) to export.
- setImportControls: adds fine grained controls over import behavior that are rendered in the Import UI. For the Bookmarks application, a checkbox is added to select Bookmarks content (entries) to import.

For more information on these methods, visit the PortletDataHandler API.

5. For the Bookmarks portlet data handler to reference its entry and folder staged models successfully, you must set them in your class:

```
@Reference(unbind = "-")
protected void setBookmarksEntryLocalService(
    BookmarksEntryLocalService bookmarksEntryLocalService) {

    _bookmarksEntryLocalService = bookmarksEntryLocalService;
}

@Reference(unbind = "-")
protected void setBookmarksFolderLocalService(
    BookmarksFolderLocalService bookmarksFolderLocalService) {

    _bookmarksFolderLocalService = bookmarksFolderLocalService;
}

private BookmarksEntryLocalService _bookmarksEntryLocalService;
private BookmarksFolderLocalService _bookmarksFolderLocalService;
```

The set methods must be annotated with the @Reference annotation. Visit the Invoking Liferay Services Locally section of the *Finding and Invoking Liferay Services* tutorial for more information on using the 'Liferay DXPproduct@.

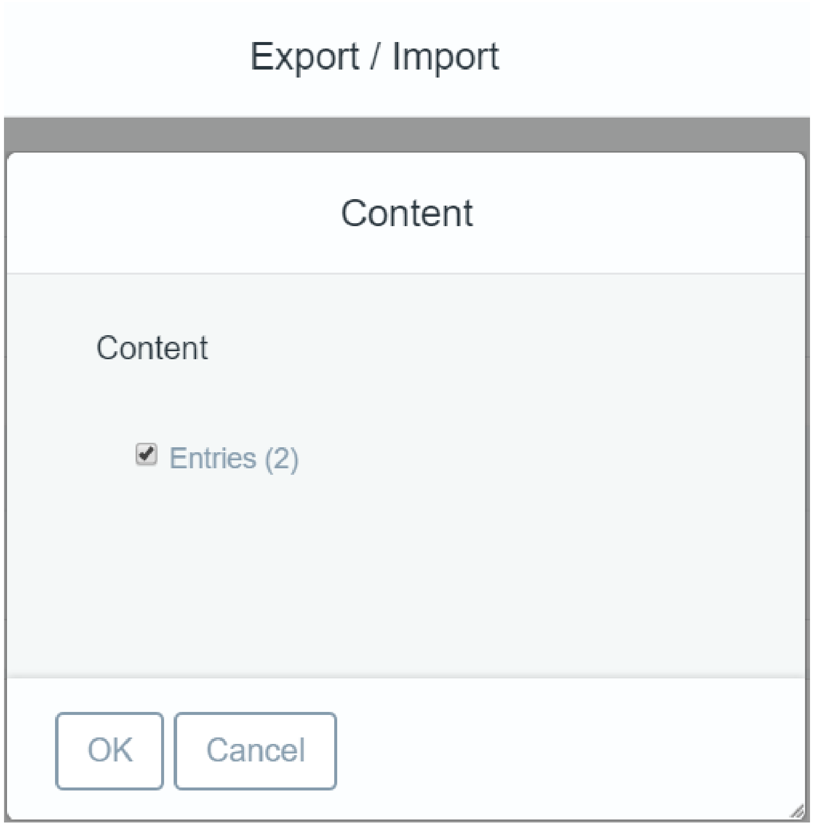

Figure 88.5: You can select the content types you'd like to export/import in the UI.

Important: Liferay DXP's official Bookmarks app does not use local services in its portlet data handler; instead, it uses the `StagedModelRepository` framework. This is not recommended for custom applications, however; it's only intended for internal Liferay applications at this time. Because of this, the code in this tutorial has been modified to highlight the recommended way for custom apps.

6. You must create a namespace for your entities so the Export/Import framework can identify your application's entities from other entities in Liferay DXP. The Bookmarks application's namespace declaration looks like this:

```
public static final String NAMESPACE = "bookmarks";
```

   You'll see how this namespace is used later.

7. Your portlet data handler should retrieve the data related to its staged model entities so it can properly export/import it. Add this functionality by inserting the following methods:

```
@Override
protected String doExportData(
        final PortletDataContext portletDataContext, String portletId,
        PortletPreferences portletPreferences)
    throws Exception {

    Element rootElement = addExportDataRootElement(portletDataContext);

    if (!portletDataContext.getBooleanParameter(NAMESPACE, "entries")) {
        return getExportDataRootElementString(rootElement);
    }

    portletDataContext.addPortletPermissions(
        BookmarksResourcePermissionChecker.RESOURCE_NAME);

    rootElement.addAttribute(
        "group-id", String.valueOf(portletDataContext.getScopeGroupId()));

    ExportActionableDynamicQuery folderActionableDynamicQuery =
        _bookmarksFolderLocalService.
            getExportActionableDynamicQuery(portletDataContext);

    folderActionableDynamicQuery.performActions();

    ActionableDynamicQuery entryActionableDynamicQuery =
        _bookmarksEntryLocalService.
            getExportActionableDynamicQuery(portletDataContext);

    entryActionableDynamicQuery.performActions();

    return getExportDataRootElementString(rootElement);
}

@Override
protected PortletPreferences doImportData(
        PortletDataContext portletDataContext, String portletId,
        PortletPreferences portletPreferences, String data)
    throws Exception {

    if (!portletDataContext.getBooleanParameter(NAMESPACE, "entries")) {
        return null;
    }

    portletDataContext.importPortletPermissions(
        BookmarksResourcePermissionChecker.RESOURCE_NAME);

    Element foldersElement = portletDataContext.getImportDataGroupElement(
        BookmarksFolder.class);

    List<Element> folderElements = foldersElement.elements();

    for (Element folderElement : folderElements) {
        StagedModelDataHandlerUtil.importStagedModel(
            portletDataContext, folderElement);
    }

    Element entriesElement = portletDataContext.getImportDataGroupElement(
        BookmarksEntry.class);

    List<Element> entryElements = entriesElement.elements();

    for (Element entryElement : entryElements) {
        StagedModelDataHandlerUtil.importStagedModel(
            portletDataContext, entryElement);
    }

    return null;
}
```

The doExportData method first checks if anything should be exported. The `portletDataContext.getBooleanParameter(...` method checks if the user selected Bookmarks entries for export. Later, the `ExportImportActionableDynamicQuery` framework runs a query against bookmarks folders and entries to find ones which should be exported to the LAR file.

The `-ActionableDynamicQuery` classes are automatically generated by Service Builder and are available in your application's local service. It queries the database searching for certain Staging-specific parameters (e.g., `createDate` and `modifiedDate`), and based on those parameters, finds a list of exportable records from the staged model data handler.

The `doImportData` queries for Bookmark entry and folder data in the imported LAR file that should be added to the database. This is done by extracting XML elements from the LAR file by using utility methods from the StagedModelDataHandlerUtil class. The extracted elements tell Liferay DXP what data to import from the LAR file.

8. Add a method that deletes the portlet's data. The Staging framework has an option called *Delete Portlet Data Before Importing* that lets the user delete portlet data before importing any new data. The `doDeleteData(...)` method is called to execute this deletion operation.

```
@Override
protected PortletPreferences doDeleteData(
        PortletDataContext portletDataContext, String portletId,
        PortletPreferences portletPreferences)
    throws Exception {

    if (portletDataContext.addPrimaryKey(
            BookmarksPortletDataHandler.class, "deleteData")) {

        return portletPreferences;
    }

    _bookmarksEntryLocalService.deleteEntries(
        portletDataContext.getScopeGroupId(),
        BookmarksFolderConstants.DEFAULT_PARENT_FOLDER_ID);

    _bookmarksFolderLocalService.deleteFolders(
        portletDataContext.getScopeGroupId());

    return portletPreferences;
}
```

   This method can also return a modified version of the portlet preferences if it contains references to data that no longer exists.

9. Add a method that counts the number of affected entities based on the current export or staging process:

```
@Override
protected void doPrepareManifestSummary(
        PortletDataContext portletDataContext,
        PortletPreferences portletPreferences)
    throws Exception {

    ActionableDynamicQuery entryExportActionableDynamicQuery =
        _bookmarksEntryLocalService.
            getExportActionableDynamicQuery(portletDataContext);

    entryExportActionableDynamicQuery.performCount();

    ActionableDynamicQuery folderExportActionableDynamicQuery =
        _bookmarksFolderLocalService.
            getExportActionableDynamicQuery(portletDataContext);

    folderExportActionableDynamicQuery.performCount();
}
```

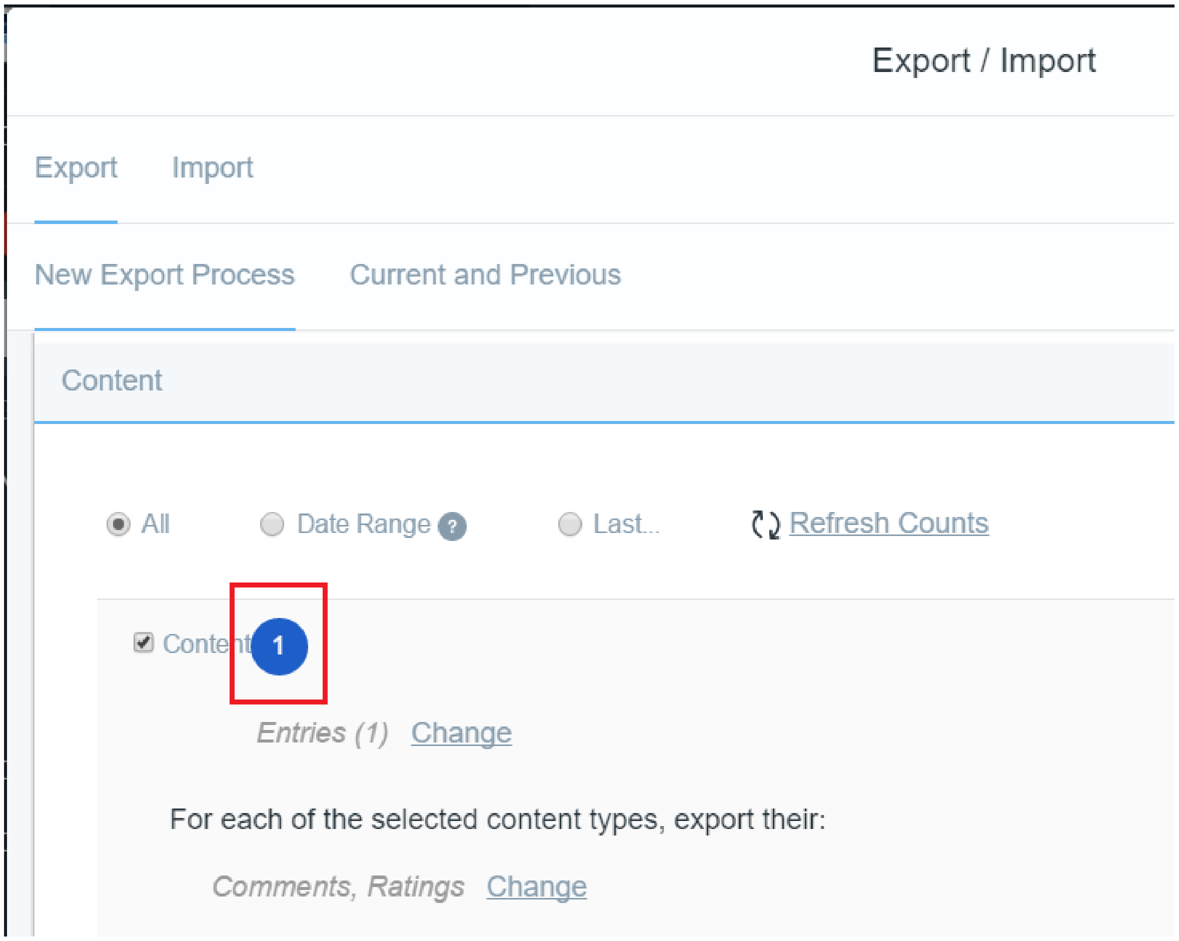

Figure 88.6: The number of modified Bookmarks entities are displayed in the Export UI.

This number is displayed in the Export and Staging UI. Note that since the Staging framework traverses the entity graph during export, the built-in components provide an approximate value in some cases.

10. Set the XML schema version for the XML files included in your exported LAR file:

```
public static final String SCHEMA_VERSION = "1.0.0";

@Override
public String getSchemaVersion() {
    return SCHEMA_VERSION;
}
```

Awesome! You've set up your portlet data handler and your application can now support the Export/Import framework and display a UI for it. The next step for supporting data handlers in your app is to implement staged model data handlers for your staged models. You'll do this next.

Staged Model Data Handlers

Now that your application has a portlet data handler and staged models, you'll create the staged model data handlers. The Bookmarks application has two staged models: entries and folders. Creating data handlers for these two entities is similar, so you'll examine how this is done for Bookmark entries.

1. Create a `-StagedModelDataHandler` class in the same folder as its portlet data handler class. For Bookmarks, the `BookmarksEntryStagedDataHandler` class resides in the `com.liferay.bookmarks.service` module's `com.liferay.bookmarks.internal.exportimport.data.handler` package. The staged model data handler class should extend the BaseStagedModelDataHandler class and the entity type should be specified as its parameter. You can see how this was done for the `BookmarksEntryStagedModelDataHandler` class below:

   ```
   public class BookmarksEntryStagedModelDataHandler
       extends BaseStagedModelDataHandler<BookmarksEntry> {
   ```

2. Create an `@Component` annotation section above the class declaration. This annotation is responsible for registering the class as a staged model data handler similar to the portlet data handler.

   ```
   @Component(immediate = true, service = StagedModelDataHandler.class)
   ```

   The `immediate` element directs the container to activate the component immediately once its provided module has started. The `service` element should point to the `StagedModelDataHandler.class` interface.

```
**Note:** In previous versions of Liferay DXP, you had to register the staged
model data handler in a portlet's `liferay-portlet.xml` file. The
registration process is now completed automatically by OSGi using the
`@Component` annotation.
```

---

3. Create a getter and setter method for the local service of the staged model for which you want to provide a data handler:

   ```
   @Override
   protected BookmarksEntryLocalService getBookmarksEntryLocalService() {
       return _bookmarksEntryLocalService;
   }

   @Reference(unbind = "-")
   protected void setBookmarksEntryLocalService(
       BookmarksEntryLocalService bookmarksEntryLocalService) {

       _bookmarksEntryLocalService = bookmarksEntryLocalService;
   }

   private BookmarksEntryLocalService _bookmarksEntryLocalService;
   ```

   These methods are used to link this data handler with the staged model for bookmark entries.

   Important: Liferay DXP's official Bookmarks app does not use local services in its staged model data handlers; instead, it uses the `StagedModelRepository` framework. This is not recommended for custom applications, however; it's only intended for internal Liferay applications at this time. Because of this, the code in this tutorial has been modified to highlight the recommended way for custom apps.

4. You must provide the class names of the models the data handler tracks. You can do this by overriding the StagedModelDataHandler's `getClassnames()` method:

```
public static final String[] CLASS_NAMES = {BookmarksEntry.class.getName()};

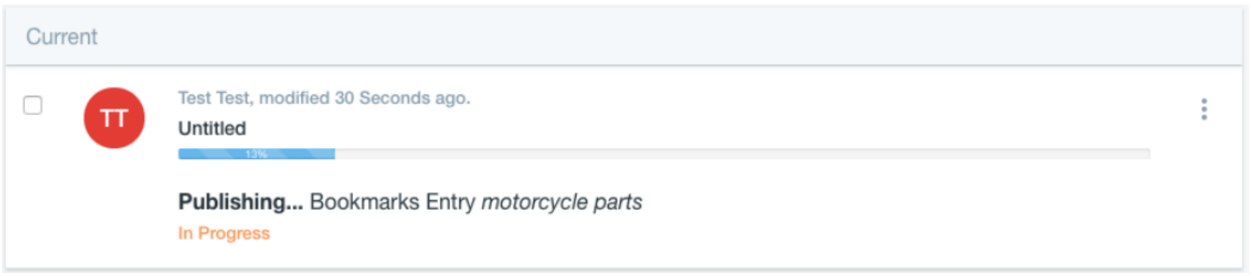
@Override
public String[] getClassNames() {
    return CLASS_NAMES;
}
```

As a best practice, you should have one staged model data handler per staged model. It's possible to use multiple class types, but this is not recommended.

5. Add a method that retrieves the staged model's display name:

```
@Override
public String getDisplayName(BookmarksEntry entry) {
    return entry.getName();
}
```

The display name is presented with the progress bar during the export/import process.



Test Test, modified 30 Seconds ago.

Publishing... Bookmarks Entry *motorcycle parts*

In Progress

Figure 88.7: Your staged model data handler provides the display name in the Export/Import UI.

6. A staged model data handler should ensure everything required for its operation is also exported. For example, in the Bookmarks application, an entry requires its folder to keep the folder structure intact. Therefore, the folder should be exported first followed by the entry.

   Add methods that import and export your staged model and its references.

```
@Override
protected void doExportStagedModel(
        PortletDataContext portletDataContext, BookmarksEntry entry)
    throws Exception {

    if (entry.getFolderId() ≠
            BookmarksFolderConstants.DEFAULT_PARENT_FOLDER_ID) {

        StagedModelDataHandlerUtil.exportReferenceStagedModel(
            portletDataContext, entry, entry.getFolder(),
            PortletDataContext.REFERENCE_TYPE_PARENT);
    }

    Element entryElement = portletDataContext.getExportDataElement(entry);

    portletDataContext.addClassedModel(
        entryElement, ExportImportPathUtil.getModelPath(entry), entry);
}

@Override
protected void doImportStagedModel(
        PortletDataContext portletDataContext, BookmarksEntry entry)
    throws Exception {

    Map<Long, Long> folderIds =
        (Map<Long, Long>)portletDataContext.getNewPrimaryKeysMap(
            BookmarksFolder.class);

    long folderId = MapUtil.getLong(
        folderIds, entry.getFolderId(), entry.getFolderId());

    ServiceContext serviceContext =
        portletDataContext.createServiceContext(entry);

    BookmarksEntry importedEntry = null;

    if (portletDataContext.isDataStrategyMirror()) {

        BookmarksEntry existingEntry =
            _bookmarksEntryLocalService. fetchBookmarksEntryByUuidAndGroupId(
                entry.getUuid(), portletDataContext.getScopeGroupId());

        if (existingEntry == null) {

            serviceContext.setUuid(entry.getUuid());
            importedEntry = _bookmarksEntryLocalService.addEntry(
              userId, portletDataContext.getScopeGroupId(), folderId, entry.getName(), entry.getUrl(), entry.getDescription(), serviceContext);
        }
        else {
            importedEntry = _bookmarksEntryLocalService.updateEntry(
                userId, existingEntry.getEntryId(), portletDataContext.getScopeGroupId(), folderId, entry.getName(), entry.getUrl(), entry.getDescri
        }
    }
    else {
        importedEntry = _bookmarksEntryLocalService.addEntry(userId, portletDataContext.getScopeGroupId(), folderId,entry.getName(), entry.getUrl(),
    }

    portletDataContext.importClassedModel(entry, importedEntry);
}
```

The doExportStagedModel method retrieves the Bookmark entry's data element from the PortletDataContext and then adds the class model characterized by that data element to the PortletDataContext. The PortletDataContext is used to populate the LAR file with your application's data during the export process. Note that once an entity has been exported, subsequent calls to the export method won't actually repeat the export process multiple times, ensuring optimal performance.

An important feature of the import process is that all exported reference elements in the Bookmarks example are automatically imported when needed. The doImportStagedModel method does not need to import the reference elements manually; it must only find the new assigned ID for the folder before importing the entry.

The PortletDataContext keeps this information and a slew of other data up-to-date during the import process. The old ID and new ID mapping can be reached by using the portletDataContext.getNewPrimaryKeysMap() method as shown in the example. The method proceeds with checking the import mode (e.g., *Copy As New* or *Mirror*) and depending on the process configuration and existing environment, the entry is either added or updated.

7. When importing a LAR that specifies a missing reference, the import process expects the reference to be available and must validate that it's there. You must add a method that maps the missing reference ID from the export to the existing ID during import.

   For example, suppose you export a FileEntry as a missing reference with an ID of 1. When importing that information, the LAR only provides the ID but not the entry itself. Therefore, during the import process, the Data Handler framework searches for the entry to replace, but the entry to replace has a different ID of 2. You must provide a method that maps these two IDs so the import process can recognize the missing reference.

```
@Override
protected void doImportMissingReference(
        PortletDataContext portletDataContext, String uuid, long groupId,
        long entryId)
    throws Exception {

    BookmarksEntry existingEntry = fetchMissingReference(uuid, groupId);

    if (existingEntry == null) {
        return;
    }

    Map<Long, Long> entryIds =
        (Map<Long, Long>)portletDataContext.getNewPrimaryKeysMap(
            BookmarksEntry.class);

    entryIds.put(entryId, existingEntry.getEntryId());
}
```

This method maps the existing staged model to the old ID in the reference element. When a reference is exported as missing, the Data Handler framework calls this method during the import process and updates the new primary key map in the portlet data context.

Fantastic! You've created a data handler for your staged model. The Export/Import framework can now track your entity's behavior and data.

With the ability to track entity data, your application is available during the Export/Import and Staging processes.

88.7 Initiating New Processes with ExportImportConfiguration Objects

Liferay DXP's Staging and Export/Import features are the building blocks for creating, managing, and publishing a site. These features can be accessed in your Portal's *Publishing Tools* menu. You can also, however, start these processes programatically. This lets you provide new interfaces or mimic the functionality of these features in your own application.

Providing the ability to stage your application's assets makes using your application much more site administrator-friendly. Your new assets no longer have to be saved somewhere off-site until they're ready to be published. You can publish them to a staging environment, test their usability, and save them to a page. Once the time is right for publishing, you can publish your application's assets to the live site with one mouse click. The export/import feature offers similar conveniences: if you want to export your application's assets to use in another place or you need to clear its data but save a copy you can implement the export feature. Implementing the import feature lets you bring your assets/data back into your application.

To initiate a export/import or staging process, you must pass in an `ExportImportConfiguration` object. This object encapsulates many parameters and settings that are required while the export/import is running. Having one single object with all your necessary data makes executing these frameworks quick and easy.

When you want to implement, for example, export, you must call services offered by the `ExportImportService` interface. All the methods in this interface require an `ExportImportConfiguration` object. Liferay DXP provides a way to generate these configuration objects, so you can easily pass them in your service methods.

It's also important to know that `ExportImportConfiguration` is a Portal entity, similar to `User` or `Group`. This means that the `ExportImportConfiguration` framework offers local and remote services, models, persistence classes, and more.

In this tutorial, you'll learn about the `ExportImportConfiguration` framework and how you can take advantage of provided services and factories to create these controller obects. Once they're created, you can easily impment whatever import/export functionality you need.

Your first step is to create an `ExportImportConfiguration` object and use it to initiate your custom export/import or staging process.

1. Use the Export Import Configuration factory classes to build your `ExportImportConfiguration` object. Below is a common way to do it:

   ```
   Map<String, Serializable> exportLayoutSettingsMap =
       ExportImportConfigurationSettingsMapFactory.
           buildExportLayoutSettingsMap(...);

   ExportImportConfiguration exportImportConfiguration =
       exportImportConfigurationLocalService.
           addDraftExportImportConfiguration(
               user.getUserId(),
               ExportImportConfigurationConstants.TYPE_EXPORT_LAYOUT,
               exportLayoutSettingsMap);
   ```

   This example uses the ExportImportConfigurationSettingsMapFactory to create a layout export settings map. Then this map is used as a parameter to create an `ExportImportConfiguration` by calling an *add* method in the entity's local service interface. The ExportImportConfigurationLocalService provides several useful methods to create and modify your custom `ExportImportConfiguration`.

   The `ExportImportConfigurationSettingsMapFactory` provides many `build` methods to create settings maps for various scenarios, like importing, exporting, and publishing layouts and portlets. For examples of this particular scenario, you can reference UserGroupLocalServiceImpl.exportLayouts(...) and GroupLocalServiceImpl.addDefaultGuestPublicLayoutsByLAR(...).

   There are two other important factories provided by this framework that are useful during the creation of `ExportImportConfiguration` objects:

   - ExportImportConfigurationFactory: This factory is used to build `ExportImportConfiguration` objects used for default local/remote publishing.
   - ExportImportConfigurationParameterMapFactory: This factory is used to build parameter maps, which are required during export/import and publishing.

2. Call the appropriate service to initiate the export/import or staging process. There are two important service interfaces that you can use in the cases of exporting, importing, and staging: ExportImportLocalService and StagingLocalService. In the previous step's example code snippet, you created an `ExportImportConfiguration` object intended for exporting layouts. Here's how to initiate that process:

   ```
   files[0] = exportImportLocalService.exportLayoutsAsFile(
       exportImportConfiguration);
   ```

   By calling this interface's method, you're exporting layouts from Portal into a `java.io.File` array. Notice that your `ExportImportConfiguration` object is the only needed parameter in the method. Your configuration object holds all the required parameters and settings necessary to export your layouts from Portal. Although this example code resides in Liferay DXP, you could easily use this framework from your own plugin or module.

```
**Note:** If you're not calling the export/import or staging service methods
from an OSGi module, you should not use the interface. The Liferay
OSGi container automatically handles interface referencing, which is why
using the interface is permitted for modules. If you're calling
export/import or staging service methods outside of a module, you should use
their service Util classes (e.g., `ExportImportLocalServiceUtil`).
```

It's that easy! To start your own export/import or staging process, you must create an `ExportImportConfiguration` object using a combination of the three provided `ExportImportConfiguration` factories. Once you have your configuration object, provide it as a parameter in one of the many service methods available to you by the Export/Import or Staging interfaces to begin your desired process.

88.8 Using the Export/Import Lifecycle Listener Framework

The `ExportImportLifecycleListener` framework allows developers to write code that listens for certain staging or export/import events during the publication process. The staging and export/import processes have many behind-the-scenes events that you cannot listen to by default. Some of these, like export successes and import failures, may be events on which you'd want to take some action. You also have the ability to listen for processes comprised of many events and implement custom code when these processes are initiated. Here is a short list of events you can listen for:

- Staging has started
- A portlet export has failed
- An entity export has succeeded

The concept of listening for export/import and staging events sounds cool, but you may be curious as to why listening for certain events is useful. Listening for events can help you know more about your application's state. Suppose you'd like a detailed log of when certain events occur during an import process. You could configure a listener to listen for certain import events you're interested in and print information about those events to your console when they occur.

Liferay DXP uses this framework by default in several cases. For instance, Liferay clears the cache when a web content import process finishes. To accomplish this, the lifecycle listener framework listens for an event that specifies that a web content import process has completed. Once that event occurs, there is an event listener that automatically clears the cache. You could implement this sort of functionality yourself for any Portal event. You can listen for a specific event and then complete an action based on when that event occurs. For a list of events you can listen for during Export/Import and Staging processes, see ExportImportLifecycleConstants.

Some definitions are in order:

Events are particular actions that occur during processing.

Processes are longer running groups of events.

In this tutorial, you'll learn how to use the `ExportImportLifecycleListener` framework to listen for processes/events during the staging and export/import lifecycles.

Listening to Lifecycle Events

To begin creating your lifecycle listener, you must create a module. Follow the steps below:

1. Create an OSGi module.

2. Create a unique package name in the module's `src` directory and create a new Java class in that package. To follow naming conventions, begin the class name with the entity or action name you're processing, followed by *ExportImportLifecycleListener* (e.g., `LoggerExportImportLifecycleListener`).

3. You must extend one of the two Base classes provided with the Export/Import Lifecycle Listener framework: BaseExportImportLifecycleListener or BaseProcessExportImportLifecycleListener. To choose, you'll need to consider what parts of a lifecycle you want to listen for.

   Extend the `BaseExportImportLifecycleListener` class if you want to listen for specific *events* during a lifecycle. For example, you may want to write custom code if a layout export fails.

   Extend the `BaseProcessExportImportLifecycleListener` class if you want to listen for *processes* during a lifecycle. For example, you may want to write custom code if a site publication fails. Keep in mind that a process usually consists of many individual events. Methods provided by this base class are only run once when the desired process action occurs.

4. Directly above the class's declaration, insert the following annotation:

   ```
   @Component(immediate = true,
              service = ExportImportLifecycleListener.class)
   ```

   This annotation declares the implementation class of the component and specifies that the portal should start the module immediately.

5. Specify the methods you want to implement in your class.

Once you've successfully created your export/import lifecycle listener module, generate the module's JAR file and copy it to your Portal's `osgi/modules` directory. Once your module is installed and activated in your Portal's service registry, your lifecycle listener is ready for use in your Portal instance.

If you're still thirsting for more information on this framework, you're in luck! Here's an example, using the LoggerExportImportLifecycleListener. This listener extends the `BaseExportImportLifecycleListener`, so you should immediately know that it deals with lifecycle events.

The first method `isParallel()` determines whether your listener should run in parallel with the import/export process, or if the calling method should stop, execute the listener, and return to where the event was fired after the listener has finished. The next method is the `onExportImportLifecycleEvent(...)` method, which consumes the lifecycle event and passes it through the base class's method (as long as Debug mode is not enabled).

Each remaining method is called to print logging information for the user. For example, when a layout export starts, succeeds, or fails, logging information directly related to that event is printed. In summary, the `LoggerExportImportLifecycleListener` uses the lifecycle listener framework to print messages to the log when an export/import event occurs. Other good examples of event lifecycle listeners are CacheExportImportLifecycleListener and JournalCacheExportImportLifecycleListener.

For an example of a lifecycle listener extending the `BaseProcessExportImportLifecycleListener` class, inspect the ExportImportProcessCallbackLifecycleListener class. Instead of listening for lifecycle events, this class only listens for process actions.

Terrific! You learned about the Export/Import Lifecycle Listener framework, and you've learned how to create your own listener for events/processes that occur during export/import of your portal's content.

Chapter 89

Configuration

Many applications provide users a way of setting preferences for their use. In Liferay DXP, this could be as simple as setting a location for a weather display or as complex as settings for a mail or a time sheet application.

The Portlet standard defines an API for portlet preferences that can be used for this sort of thing, but it's limited and for that reason isn't used much. Instead, many developers have tended to create their own methods for configuring their applications.

But that isn't necessary anymore: now there's a configuration API that's easy to use and full-featured. It's used throughout Liferay DXP's applications, and because we like it, we think you'll like it too.

The following tutorials show you how to use it.

89.1 Making Your Applications Configurable

This tutorial explains how to make your applications configurable. It starts with basic configuration and then covers some advanced use cases.

Note that the methods described here are not mandatory. You can make your applications configurable using any other mechanism that you're already familiar with. We have found, however, that the method described below provides the greatest benefit with the least amount of effort.

Note: To quickly see a working application configuration, deploy the `configuration-action` Blade sample and navigate to System Settings (*Control Panel → Configuration → System Settings*). In the Other category, click the *Message display configuration* entry.

Add the *Blade Message Portlet* to a page to test your configuration choices.

Fundamentals

While you don't need to know much to make your applications configurable, understanding a few key concepts helps you achieve a higher degree of configurability with little effort.

- Typed Configuration: The method described here uses *typed* configuration. This means that the application configuration isn't just a list of key-value pairs. The values can have types, like `Integer`, a list of `Strings`, a URL, etc. It's even possible to use your own custom types, although that's beyond the scope of this tutorial. Typed configurations are easier to use than untyped configurations, and they prevent many programmatic errors. Related to this, the configuration options should be programmatically explicit, so that developers can use autocomplete in modern IDEs to find out all of the configuration options of a given application or one of its components.

- Modularity: In Liferay DXP, applications are *modular* and built as a collection of lightweight components. A *component* is just a class that has the `@Component` annotation, often along with a set of properties to provide metadata. The configuration mechanisms described here leverage the concept of components.

- Configuration Scope: If your application must support different configurations at different scopes, the APIs described below handle most of the burden for you. It's still important, however, for you to understand the term *configuration scope*. Here are the most common configuration scopes that Liferay applications can have:

    1. **System:** configuration that is unique for the complete installation of the application.

    2. **Virtual Instance:** configuration that can vary per virtual instance.

    3. **Site:** configuration that can vary per Liferay site.

    4. **Portlet Instance:** applicable for applications that are placed on a page (i.e., portlets). Each placement (instance) of the application on the page can have a different configuration.

Enough with the conceptual stuff. You're ready to get started with some code. If you already had a portlet or service that was configurable using the traditional mechanisms of Liferay Portal 6.2 and before, refer to the Transitioning from Portlet Preferences to the Configuration API tutorial.

Making Your Application Configurable

There's a minimal amount of code you need to write to make your application configurable the Liferay DXP way. First, you'll learn how to create a configuration at the system scope.

First create a Java interface to represent the configuration and its default values. Using a Java interface allows for an advanced type system for each configuration option. Here is an example of such an interface:

```
@Meta.OCD(id = "com.liferay.docs.exampleconfig.ExampleConfiguration")
public interface ExampleConfiguration {

    @Meta.AD(
        deflt = "blue",
        required = false
    )
    public String favoriteColor();

    @Meta.AD(
       deflt = "red|green|blue",
       required = false
    )
    public String[] validColors();

    @Meta.AD(required = false)
    public int itemsPerPage();

}
```

As you can see, you are using two Java annotations to provide some metadata about the configuration. Here is what they do:

1. **Meta.OCD** Registers this class as a configuration with a specific id. **The ID must be the fully qualified configuration class name.**
2. **Meta.AD** Specifies the default value of a configuration field as well as whether it's required or not. Note that if you set a field as required and don't specify a default value, the system administrator must specify a value in order for your application to work properly. Use the `deflt` property to specify a default value.

The fully-qualified class name of the `Meta` class referred to above is `aQute.bnd.annotation.metatype.Meta`. For more information about this class and the `Meta.OCD` and `Meta.AD` annotations, please refer to this bnd documentation: http://bnd.bndtools.org/chapters/210-metatype.html. In order to use the `Meta.OCD` and `Meta.AD` annotations in your modules, you must specify a dependency on the bnd library. We recommend using bnd version 3. Here's an example of how to include this dependency in a Gradle project:

```
dependencies {
    compile group: "biz.aQute.bnd", name: "biz.aQute.bndlib", version: "3.1.0"
}
```

Note: The annotations `@Meta.OCD` and `@Meta.AD` are part of the bnd library but have also been included as part of the OSGi standard version R6 with the names `@ObjectClassDefinition` and `@AttributeDefinition`. However, Liferay still uses the bnd annotations since the standard annotations are not available at runtime, which is necessary for some of the Liferay specific features described below. For the basic usage (the one described in this section) the standard annotations can be used safely.

Add the following line to your project's `bnd.bnd` file:

```
-metatype: *
```

This line lets bnd use your configuration interface to generate an XML configuration file. With this information, Liferay already knows a lot about your application's configuration options. In fact, it knows enough to generate a user interface automatically. Cool, isn't it?

Even if you agree that this is pretty cool, you might be wondering how to read the configuration from your application's code. It's actually quite easy. Here's a simple example:

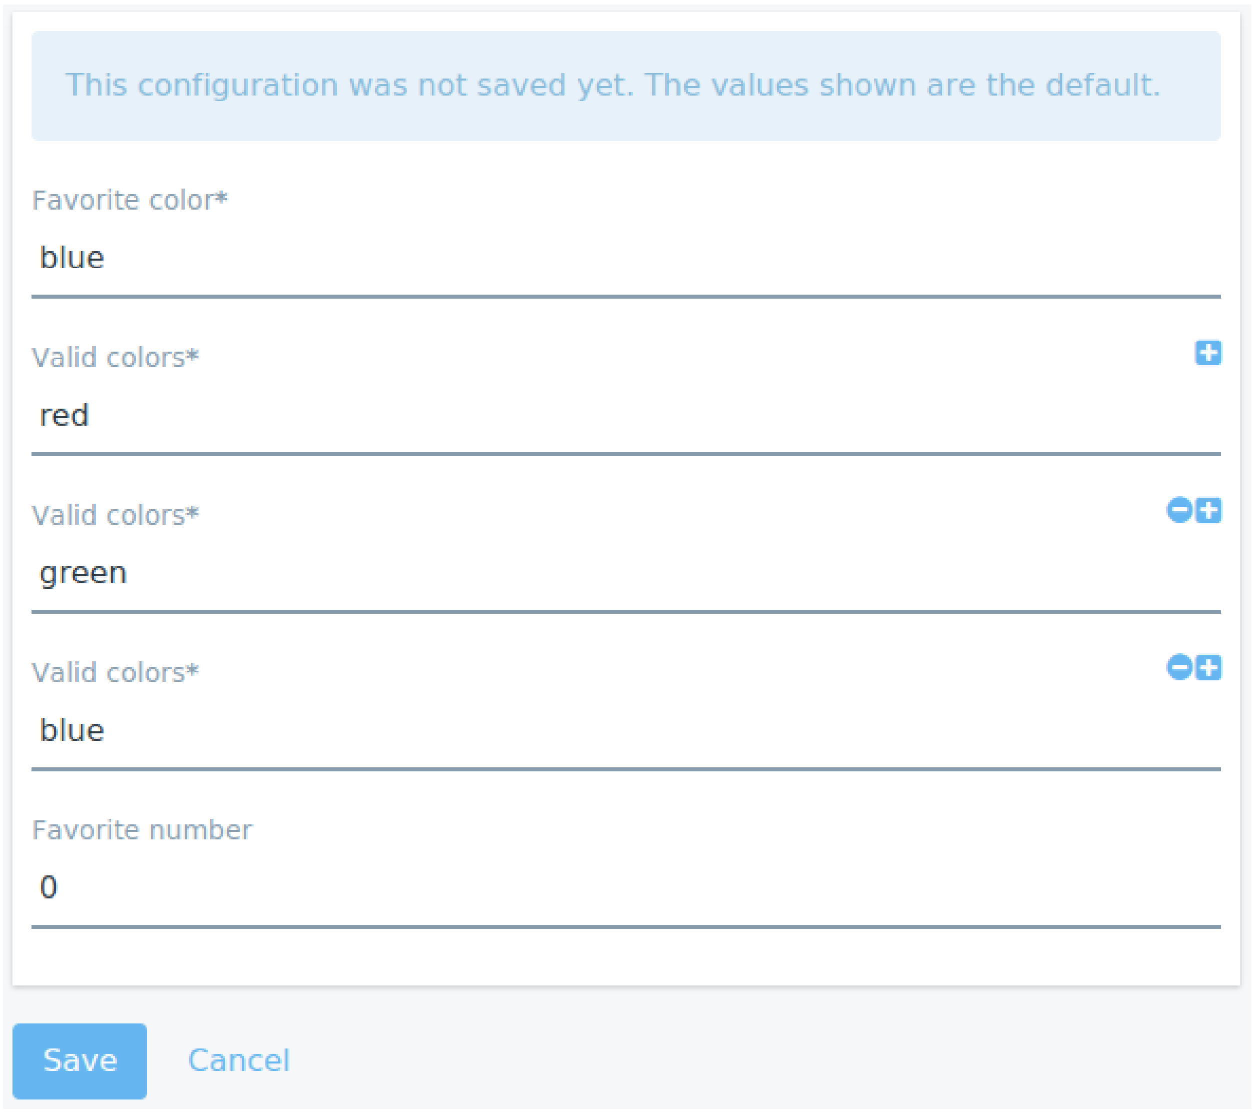
```
@Component(configurationPid = "com.liferay.docs.exampleconfig.ExampleConfiguration")
public class MyAppManager {

    public String getFavoriteColor(Map colors) {
       return colors.get(_configuration.favoriteColor());
    }

    @Activate
    @Modified
    protected void activate(Map<String, Object> properties) {
        _configuration = ConfigurableUtil.createConfigurable(
        ExampleConfiguration.class, properties);
    }

    private volatile ExampleConfiguration _configuration;

}
```



This configuration was not saved yet. The values shown are the default.

Favorite color*

blue

Valid colors*

red

Valid colors*

green

Valid colors*

blue

Favorite number

0

Figure 89.1: Navigate to the Control Panel and then click on *Configuration* → *System Settings*. Then click on *Other*, find the *Example configuration* link, and click on it.

Here are the most relevant aspects of this example:

1. This class is a component, specified with the `@Component` annotation.
2. This component uses the configuration with the ID `com.liferay.docs.exampleconfig.ExampleConfiguration`. As a result, this method is invoked when the application starts (due to the `@Activate` annotation) and whenever the configuration is modified (due to the `@Modified` annotation).
3. The `activate()` method uses the method `ConfigurableUtil.createConfigurable()` to convert a map of properties with the configuration to our typed class, which is easier to handle.
4. The configuration is stored in a `volatile` field. Don't forget to make it `volatile` or you'll run into weird problems.

Note: The bnd library also provides a class called `aQute.bnd.annotation.metatype.Configurable` with a `createConfigurable()` method. You can use that instead of Liferay's `com.liferay.portal.configuration.metatype.bnd.util.Co` without any problems. Liferay's developers created the `ConfigurableUtil` class to improve the performance of bnd's implementation, and it's used in internal code. Feel free to use whichever method you prefer.

That's it. With very few lines of code, you have a configurable application that dynamically changes its configuration, has an auto-generated UI, and uses a simple API to access the configuration.

Accessing Your Configuration in a JSP Portlet Application

In Liferay DXP it's very common to read a configuration from a portlet class. If the portlet is a JSP portlet, the configuration object can be added to the request object so that configurations can be read from the JSPs that comprise the application's view layer. In this section, you'll see an example of reading a configuration from a portlet class, adding it to the request, and reading from the view layer. The import statements are included in the code snippets so that you can see the fully qualified class names of all the classes that are used.

Note: There's shortcut method for obtaining a portlet instance configuration. The method described in this section takes a straightforward approach that does not use this shortcut. See the Accessing the Portlet Instance Configuration Through the PortletDisplay section below to learn about the shorter method.

```
package com.liferay.docs.exampleconfig;

import java.io.IOException;
import java.util.Map;

import javax.portlet.Portlet;
import javax.portlet.PortletException;
import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;

import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Modified;

import com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet;

import com.liferay.portal.configuration.metatype.bnd.util.ConfigurableUtil;

@Component(
    configurationPid = "com.liferay.docs.exampleconfig.ExampleConfiguration",
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.instanceable=true",
        "javax.portlet.security-role-ref=power-user,user",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.resource-bundle=content.Language"
    },
    service = Portlet.class
)
public class ExampleConfigPortlet extends MVCPortlet {

    @Override
    public void doView(RenderRequest renderRequest,
        RenderResponse renderResponse) throws IOException, PortletException {

        renderRequest.setAttribute(
            ExampleConfiguration.class.getName(), _configuration);

        super.doView(renderRequest, renderResponse);
    }

    public String getFavoriteColor(Map colors) {
        return (String) colors.get(_configuration.favoriteColor());
    }

    @Activate
    @Modified
    protected void activate(Map<String, Object> properties) {
        _configuration = ConfigurableUtil.createConfigurable(
        ExampleConfiguration.class, properties);
    }

    private volatile ExampleConfiguration _configuration;

}
```

The main difference between this example and the first one is that this class is a portlet class and it sets the configuration object as a request attribute in its `doView()` method. To read configuration values from a JSP, first add these imports to your `init.jsp` file:

```
<%@ page import="com.liferay.docs.exampleconfig.ExampleConfiguration" %>
<%@ page import="com.liferay.portal.kernel.util.GetterUtil" %>
```

In a JSP portlet application, your full `init.jsp` file should at least have contents like this:

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
<%@ taglib uri="http://java.sun.com/portlet_2_0" prefix="portlet" %>

<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>
<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>
<%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

<%@ page import="com.liferay.docs.exampleconfig.ExampleConfiguration" %>
<%@ page import="com.liferay.portal.kernel.util.GetterUtil" %>

<portlet:defineObjects />
<liferay-theme:defineObjects />
```

It's a Liferay convention that all JSP imports in your application should go in an `init.jsp` file. All of your application's other JSPs import `init.jsp`. This convention ensures that you only have to manage JSP dependencies in a single file.

Next, obtain the configuration object from request object and read the desired configuration value from it. Here's an example `view.jsp` file that does this:

```
<%@ include file="/init.jsp" %>

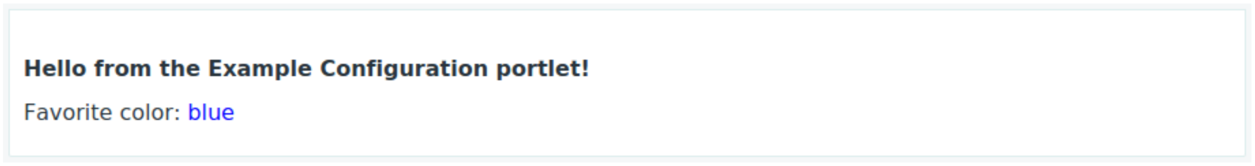
<p>
    <b>Hello from the Example Configuration portlet!</b>
</p>

<%
ExampleConfiguration configuration = (ExampleConfiguration) GetterUtil.getObject(
    renderRequest.getAttribute(ExampleConfiguration.class.getName()));

String favoriteColor = configuration.favoriteColor();
%>

<p>Favorite color: <span style="color: <%= favoriteColor %>;"><%= favoriteColor %></span></p
```

The example code here would make the application display a message like this:



Hello from the Example Configuration portlet!

Favorite color: blue

Figure 89.2: Here, the Example Configuration portlet's `view.jsp` is rendered. This JSP reads the value of the `favoriteColor` configuration and displays it.

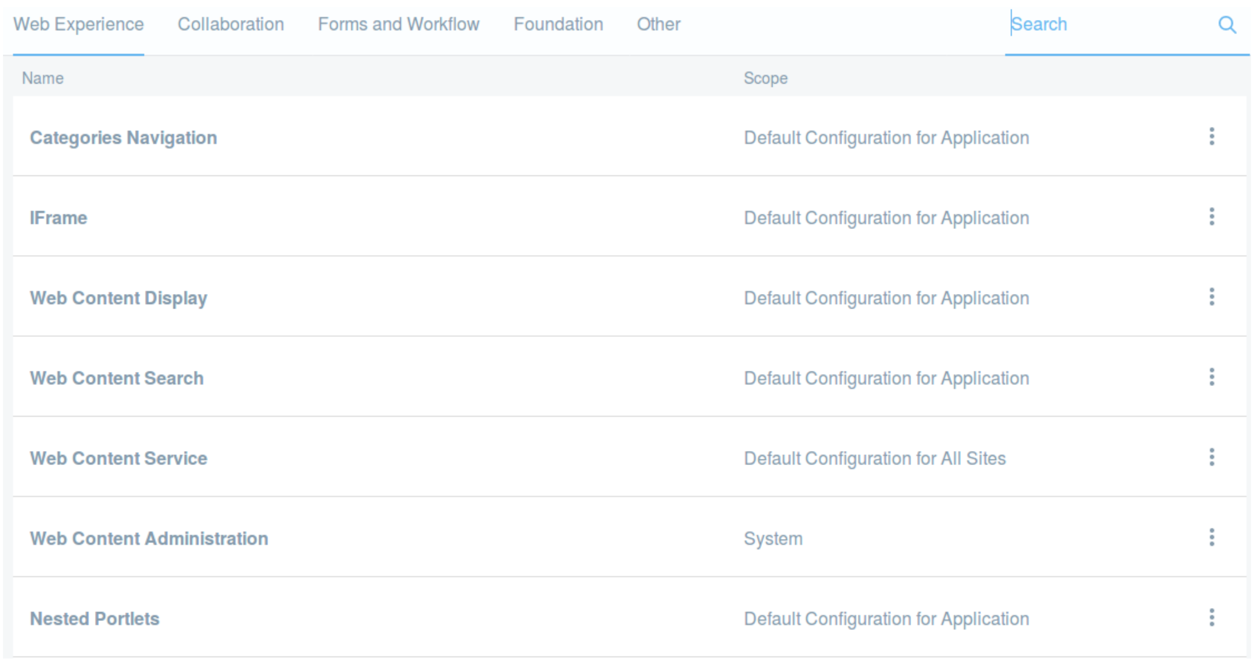
```
Favorite color: blue
```

The word 'blue' should be written in blue text. Note that 'blue' is displayed by default since you specified it as the default in your `ExampleConfiguration` interface. If you go to *System* → *System Settings* → *Other* and click on the *Example configuration* link, you can find the `Favorite color` setting and change its value. Your application's JSP will reflect this update when you refresh the page.

Categorizing the Configuration

Because it's easy to make any application or service configurable, there are already lots of configuration options in Liferay DXP by default. If you've deployed custom applications and services to your portal, there will be even more. To make it easier for portal administrators to find the right configuration options, Liferay provides a mechanism for developers to specify a category in which the configuration will be shown in the auto-generated System Settings UI in the Control Panel.

Here's how the System Settings UI looks:



Name	Scope
Categories Navigation	Default Configuration for Application
IFrame	Default Configuration for Application
Web Content Display	Default Configuration for Application
Web Content Search	Default Configuration for Application
Web Content Service	Default Configuration for All Sites
Web Content Administration	System
Nested Portlets	Default Configuration for Application

Figure 89.3: Navigate to the Control Panel, click on *Configuration* and then *System Settings*. You'll find five categories of configurations, including Other. Click on any configuration to access a form through which the configuration values can be updated.

By default, the following configuration categories are defined:

1. Web Experience
2. Collaboration
3. Forms and Workflow
4. Foundation
5. Other

You can use any other category and it will be injected in alphabetical order after Platform. Other will always be shown last. In order to specify a category, you must use the `@ExtendedObjectClassDefinition` annotation as in the following example:

```
@ExtendedObjectClassDefinition(category = "platform")
@Meta.OCD(
    factory = true,
    id = "com.liferay.portal.ldap.configuration.SystemLDAPConfiguration",
    localization = "content/Language"
)
```

The fully qualified class name of the `@ExtendedObjectClassDefinition` class is `com.liferay.portal.configuration.metatype.`

Note: Currently, the infrastructure used by System Settings relies on the `configurationPid` being the same as the class name of the interface. If they don't match, it will not be able to provide any information provided through `ExtendedObjectClassConfiguration`.

The `@ExtendedObjectClassDefinition` annotation is distributed through the `com.liferay.portal.configuration.metatype` module, which you can configure as a dependency.

Supporting Different Configurations per Virtual Instance, Site, or Portlet Instance

When an application is deployed to Liferay, it's common to need different configurations depending on the scope. That means having different configurations for a given application per virtual instance (a.k.a. Company), site (a.k.a. Group), or portlet instance. Liferay DXP provides an easy way to achieve this with little effort through a new framework called the Configuration API that is based on the standard OSGi Configuration Admin API shown in the previous section.

Using the Configuration Provider

When using the Configuration Provider, instead of receiving the configuration directly, the class that wants to access it will need to receive a `ConfigurationProvider` from which to obtain the configuration. Additionally, you need to "register" your class.

Note: `ConfigurationProvider` is part of Liferay's kernel API so you don't need to add a new dependency to use it. However, its implementation is distributed as a module called `portal-configuration-module-configuration`, so you will need to make sure it is installed in order to use it.

Before using the `ConfigurationProvider`, register the configuration class by writing a class that implements `ConfigurationBeanDeclaration`. This class only has one method that returns the class of the interface you created in the previous section. By doing this, the system is able to keep track of any configuration changes as they happen. This makes requests for the configuration very fast.

Declare the configuration interface by creating a `ConfigurationBeanDeclaration` class:

```
@Component
public class RSSPortletInstanceConfigurationBeanDeclaration
    implements ConfigurationBeanDeclaration {

    @Override
    public Class getConfigurationBeanClass() {
        return RSSPortletInstanceConfiguration.class;
    }

}
```

Once you have created your `ConfigurationBeanDeclaration`, you can use a `ConfigurationProvider`. Here's how you can obtain a reference to it:

- For components:

  ```
  @Reference
  protected void setConfigurationProvider(ConfigurationProvider configurationProvider) {
      _configurationProvider = configurationProvider;
  }
  ```

- For Service Builder services:

  ```
  @ServiceReference(type = ConfigurationProvider.class)
  protected ConfigurationProvider configurationProvider;
  ```

- For Spring beans: It is possible to use the same mechanism as for Service Builder services (`@ServiceReference`). Check the documentation on how to integrate Spring beans with OSGi services for more details.

Later, the configuration can be obtained using one of the following methods of the provider:

- `getCompanyConfiguration()`: Used when you want to support different configurations per virtual instance. In this case, the configuration is usually entered by an admin through Control Panel → Configuration → Instance Settings. Since this UI is not automatically generated (yet) you will need to extend the UI with your own form.

- `getGroupConfiguration()`: Used when you want to support different configurations per site (or, if desired, per page scope). Usually this configuration is specified by an admin through the Configuration menu option in an app accessing through the site administration menu. That UI is developed as a portlet configuration view.

- `getPortletInstanceConfiguration()`: Used to obtain the configuration for an specific portlet instance. Most often you should not be using this directly and use the convenience method in `PortletDisplay` instead as shown below.

- `getSystemConfiguration`: Used to obtain the configuration for the system scope. These settings are specified by an admin via the System Settings application or with an OSGi configuration file.

Here are a couple real world examples from Liferay's source code:

```
JournalGroupServiceConfiguration configuration =
    configurationProvider.getGroupConfiguration(
        JournalGroupServiceConfiguration.class, groupId);

MentionsGroupServiceConfiguration configuration =
  _configurationProvider.getCompanyConfiguration(
     MentionsGroupServiceConfiguration.class, entry.getCompanyId());
```

Next, you'll learn how to access a portlet's configuration from outside of an OSGi component.

Accessing the Portlet Instance Configuration Through the PortletDisplay

Often it's necessary to access a portlet's settings from its JSPs or from Java classes that are not OSGi components. To make it easier to read the settings in these cases, a new method has been added to `PortletDisplay` (available as a request object). Here is an example of how to use it:

```
RSSPortletInstanceConfiguration rssPortletInstanceConfiguration =
    portletDisplay.getPortletInstanceConfiguration(
        RSSPortletInstanceConfiguration.class);
```

As you can see, it knows how to find the values and returns a typed bean containing them just by passing the configuration class.

Specifying the Scope of the Configuration

The `ExtendedObjectClassDefinition` annotation allows you to specify the scope of the configuration. This should match how the configuration object is retrieved through the provider (your choice). The valid options are:

- `Scope.GROUP`: for site scope
- `Scope.COMPANY`: For virtual instance scope
- `Scope.SYSTEM`: for system scope

Here is an example:

```
@ExtendedObjectClassDefinition(
    category = "productivity", scope = ExtendedObjectClassDefinition.Scope.GROUP
)
@Meta.OCD(
    id = "com.liferay.dynamic.data.lists.form.web.configuration.DDLFormWebConfiguration",
    localization = "content/Language", name = "%ddl.form.web.configuration.name"
)
public interface DDLFormWebConfiguration {
...
}
```

In Liferay DXP version 7.0, the scope property isn't used for anything other than making it appear in System Settings so that an administrator can change its value. In future releases, may have more purposes.

Summary

In this tutorial, you've learned how to make your applications configurable. Creating a simple configuration interface allows Liferay to auto-generate a configuration UI that's accessible via System Settings in the Control Panel. You've also learned how to categorize your configurations within System Settings, how read configuration settings in your application at runtime, how to support different configurations at different scopes, and how to reuse the same configuration class for different scenarios.

89.2 Implementing Configuration Actions

When developing an application, it's important to think about the different configuration options that your application should support. It's also important to think about how users should be able to access your application's configuration interface. Liferay DXP supports a flexible mechanism for configuring applications. You can read about it in the Making Your Applications Configurable tutorial. In this tutorial,

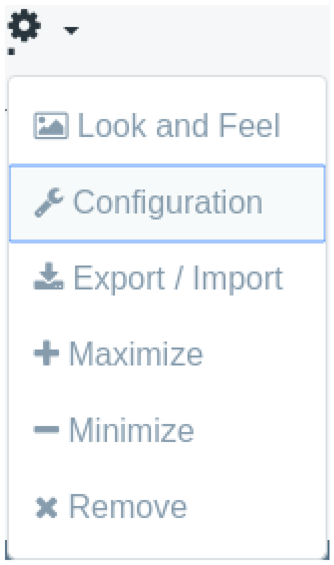


Figure 89.4: When a user clicks the gear icon and selects *Configuration*, the application's configuration action is invoked.

you'll learn to implement a configuration action. The configuration action is invoked when a user clicks on the gear icon and selects *Configuration*.

Liferay applications support a default configuration action. If you click on the gear icon of an application that has not been customized and then select *Configuration*, you'll find two standard tabs: Permissions and Sharing. These tabs provide standard options for configuring who can access your application and how you can make your application more widely available. If you follow the instructions in this tutorial, you'll learn how to create a Setup tab that allows custom configuration fields to be manipulated. To implement a configuration action, follow these steps:

1. Create an interface to represent your configuration
2. Implement your application class and add a reference to your configuration in your application class
3. Implement your configuration action class and add a reference to your configuration in your configuration action class
4. Implement the user interface for configuring your application

---

Note: To quickly see a working configuration action, deploy the `configuration-action` Blade sample and add the *Blade Message Portlet* to a page. Click the *Options* button (⋮) and select *Configuration*. Change the configuration options and save them to see them in action.

Let's get started.

Creating a Configuration Interface

As explained in the Making Your Applications Configurable tutorial, if you want to make your application configurable, you should create a Java interface to represent the configuration. Decorate your interface with the `@Meta.OCD` annotation and specify a unique ID using the annotation's `id` attribute. A common pattern is to use the fully qualified class name of the interface for the ID since fully qualified class names are unique. Create public methods to represent configuration fields and decorate the methods with the `@Meta.AD` annotation. The return type of the method specifies the type of the field. To specify a field's default value, use the annotation's `deflt` attribute. To specify that a field is optional, set `required=false`. For more information about the `Meta.OCD` and `Meta.AD` annotations, please see the bnd documentation. Here's a simple example:

```
package com.liferay.docs.exampleconfig.configuration;

import aQute.bnd.annotation.metatype.Meta;

@Meta.OCD(id = "com.liferay.docs.exampleconfig.configuration.ExampleConfiguration")
public interface ExampleConfiguration {

    @Meta.AD(required = false)
    public String favoriteColor();

}
```

Add the following line to your project's `bnd.bnd` file:

```
-metatype: *
```

This line lets bnd use your configuration interface to generate an XML configuration file. This lets Liferay DXP auto-generate a UI for your configuration in the System Settings area of the Control Panel. However, it's sometimes preferable for users to be able to access your configuration directly from the portlet without having to go to the Control Panel. In this tutorial, you'll learn how to facilitate this.

This sample configuration contains a single string field called `favoriteColor`.

Referencing Your Configuration From Your Application Class

As was also explained in the Making Your Applications Configurable tutorial, if you want a reference to the configuration in your application class, you need to declare the configuration as a `volatile` member variable, decorate your application class with the `@Component` annotation, specify the appropriate `configurationPid` in the `@Component` annotation, add an appropriately annotated `activate` method that instantiates the configuration variable, and add a public getter method for each configuration field. Here's a simple example that makes the sample configuration discussed earlier available to a portlet class:

```
package com.liferay.docs.exampleconfig.portlet;

import java.io.IOException;
import java.util.Map;

import javax.portlet.Portlet;
import javax.portlet.PortletException;
import javax.portlet.RenderRequest;
import javax.portlet.RenderResponse;

import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Modified;

import com.liferay.docs.exampleconfig.configuration.ExampleConfiguration;
import com.liferay.portal.configuration.metatype.bnd.util.ConfigurableUtil;
import com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet;

@Component(
    configurationPid =
    "com.liferay.docs.exampleconfig.configuration.ExampleConfiguration",
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.instanceable=true",
        "javax.portlet.security-role-ref=power-user,user",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.resource-bundle=content.Language"
    },
    service = Portlet.class
)
public class ExampleConfigPortlet extends MVCPortlet {

        @Override
        public void doView(RenderRequest renderRequest,
                RenderResponse renderResponse) throws IOException, PortletException {

                renderRequest.setAttribute(
                        ExampleConfiguration.class.getName(),
                        _exampleConfiguration);

                super.doView(renderRequest, renderResponse);
        }

        public String getFavoriteColor(Map labels) {
                return (String) labels.get(_exampleConfiguration.favoriteColor());
        }

        @Activate
        @Modified
        protected void activate(Map<Object, Object> properties) {
                _exampleConfiguration = ConfigurableUtil.createConfigurable(
                        ExampleConfiguration.class, properties);
        }

        private volatile ExampleConfiguration _exampleConfiguration;

}
```

In this example, overriding the `doView` method is not strictly necessary. However, it's useful since adding the configuration to the request object before calling `super.doView` makes the configuration able to be read from the request by the application's JSPs.

Implementing a Configuration Action

To implement a configuration action, you should create a class that extends Liferay DXP's `DefaultConfigurationAction` class. Then you need to add a reference to your configuration the same way that you added such a reference to your application class. Declare the configuration as a `volatile` member variable, decorate your configuration action class with the `@Component` annotation, specify the appropriate `configurationPid` in the `@Component` annotation, add an appropriately annotated `activate` method that instantiates the configuration variable, and add a public getter method for each configuration field.

Next, you should specify `configurationPolicy = ConfigurationPolicy.OPTIONAL` in your class's `@Component` annotation. An optional configuration policy means that the component is created regardless of whether or not the configuration was set. You also need to specify the portlet to which your configuration action class applies. To do so, make the following specification in your class's `@Component` annotation:

```
property = {
    "javax.portlet.name=com_liferay_docs_exampleconfig_portlet_ExampleConfigPortlet"
},
```

Your component should be registered as a configuration action class so you should specify `service = ConfigurationAction.class` in your class's `@Component` annotation.

Next, you should override the `processAction` method so that it reads a URL parameter from the action request, sets the value as a portlet preference, and invokes the `processAction` method of the `SettingsConfigurationAction` ancestor class. Finally, you should override the `include` method so that it sets the configuration as an attribute of the HTTP servlet request and then invokes the include method of the BaseJSPSettingsConfigurationAction class. Here's an example:

```
package com.liferay.docs.exampleconfig.action;

import java.util.Map;

import javax.portlet.ActionRequest;
import javax.portlet.ActionResponse;
import javax.portlet.PortletConfig;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Activate;
import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.ConfigurationPolicy;
import org.osgi.service.component.annotations.Modified;

import com.liferay.docs.exampleconfig.configuration.ExampleConfiguration;
import com.liferay.portal.configuration.metatype.bnd.util.ConfigurableUtil;
import com.liferay.portal.kernel.portlet.ConfigurationAction;
import com.liferay.portal.kernel.portlet.DefaultConfigurationAction;
import com.liferay.portal.kernel.util.ParamUtil;

@Component(
    configurationPid = "com.liferay.docs.exampleconfig.configuration.ExampleConfiguration",
    configurationPolicy = ConfigurationPolicy.OPTIONAL,
    immediate = true,
    property = {
        "javax.portlet.name=com_liferay_docs_exampleconfig_portlet_ExampleConfigPortlet"
    },
    service = ConfigurationAction.class
)
public class ExampleConfigurationAction extends DefaultConfigurationAction {

    @Override
    public void processAction(
            PortletConfig portletConfig, ActionRequest actionRequest,
            ActionResponse actionResponse)
        throws Exception {

        String favoriteColor = ParamUtil.getString(actionRequest, "favoriteColor");
        setPreference(actionRequest, "favoriteColor", favoriteColor);

        super.processAction(portletConfig, actionRequest, actionResponse);
    }

    @Override
    public void include(
        PortletConfig portletConfig, HttpServletRequest httpServletRequest,
        HttpServletResponse httpServletResponse) throws Exception {

        httpServletRequest.setAttribute(
            ExampleConfiguration.class.getName(),
            _exampleConfiguration);

        super.include(portletConfig, httpServletRequest, httpServletResponse);
    }

    @Activate
    @Modified
    protected void activate(Map<Object, Object> properties) {
        _exampleConfiguration = ConfigurableUtil.createConfigurable(
            ExampleConfiguration.class, properties);
    }

    private volatile ExampleConfiguration _exampleConfiguration;
}
```

Now that your configuration action class has been created, you're ready to create a user interface for selecting configuration options and submitting the selections.

Implementing the User Interface For Configuring Your Application

When creating a JSP-based user interface, it's convenient to create an `init.jsp` page for your application. The `init.jsp` page should contain all of the imports, tag library declarations, and other page components are required by your other JSPs. Each of your other pages should import `init.jsp` so that you don't need to duplicate code. Liferay DXP follows this convention.

Here's an example `init.jsp` file:

```
<%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>
<%@ taglib uri="http://java.sun.com/portlet_2_0" prefix="portlet" %>

<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>
<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>
<%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

<%@ page import="com.liferay.docs.exampleconfig.configuration.ExampleConfiguration" %>
<%@ page import="com.liferay.portal.kernel.util.StringPool" %>
<%@ page import="com.liferay.portal.kernel.util.Validator" %>

<portlet:defineObjects />

<liferay-theme:defineObjects />

<%
    ExampleConfiguration exampleConfiguration =
        (ExampleConfiguration)
        renderRequest.getAttribute(ExampleConfiguration.class.getName());

    String favoriteColor = StringPool.BLANK;

    if (Validator.isNotNull(exampleConfiguration)) {
        favoriteColor =
            portletPreferences.getValue(
                "favoriteColor", exampleConfiguration.favoriteColor());
    }
%>
```

This JSP not only declares some tag libraries and imports some classes. It uses the `<portlet:defineObjects />` and `<liferay-theme:defineObjects />` tags to make certain variables available on the page. The scriptlet at the end of the file uses one of these variables, `renderRequest`, to get the configuration which was stored in the `renderRequest` by your portlet's `doView` method. Finally, the value of a specific field (`favoriteColor`) is read from the configuration.

The default view of your application is provided by your application's `view.jsp`. Your `view.jsp` should import your `init.jsp` so that the same tag libraries, imports, and variables are available on the page. Here's an example `view.jsp` file:

```
<%@ include file="/init.jsp" %>

<p>
    <liferay-ui:message key="com_liferay_docs_exampleconfig_portlet_ExampleConfigPortlet.caption"/>
</p>

<%
```

```
    boolean noConfig = Validator.isNull(favoriteColor);
%>

<c:choose>
    <c:when test="<%= noConfig %>">
        <p>
            Please select use the portlet configuration to select a favorite color.
        </p>
    </c:when>

    <c:otherwise>
        <p style="color: <%= favoriteColor %>">
            Favorite color: <%= favoriteColor %>!
        </p>
    </c:otherwise>
</c:choose>
```

This JSP simply checks whether or not the `favoriteColor` variable is empty. If it's empty, a message is displayed that tells the user that they need to select a favorite color in the portlet's configuration. If the `favoriteColor` variable is not empty, the name of the selected color is displayed in the selected color. Note: The value of the `com_liferay_docs_exampleconfig_portlet_ExampleConfigPortlet.caption` language key must be specified in your application's `Language.properties` file. The default location for this file is in the `content` package.

The configuration user interface of your application is provided by your application's `configuration.jsp` file. This interface is displayed on the Setup tab when a user clicks on your application's gear icon and then selects *Configuration*. As previously discussed, your `configuration.jsp` should import your `init.jsp` file. Here's an example `configuration.jsp` file:

```
<%@ include file="/init.jsp" %>

<%@ page import="com.liferay.portal.kernel.util.Constants" %>

<liferay-portlet:actionURL portletConfiguration="<%= true %>"
    var="configurationActionURL" />

<liferay-portlet:renderURL portletConfiguration="<%= true %>"
    var="configurationRenderURL" />

<aui:form action="<%= configurationActionURL %>" method="post" name="fm">

    <aui:input name="<%= Constants.CMD %>" type="hidden"
        value="<%= Constants.UPDATE %>" />

    <aui:input name="redirect" type="hidden"
        value="<%= configurationRenderURL %>" />

    <aui:fieldset>

        <aui:select name="favoriteColor" label="Favorite Color"
            value="<%= favoriteColor %>">
            <aui:option value="indigo">Indigo</aui:option>
            <aui:option value="blue">Blue</aui:option>
            <aui:option value="green">Green</aui:option>
            <aui:option value="yellow">Yellow</aui:option>
            <aui:option value="orange">Orange</aui:option>
            <aui:option value="red">Red</aui:option>
        </aui:select>

    </aui:fieldset>
    <aui:button-row>
        <aui:button type="submit"></aui:button>
    </aui:button-row>
</aui:form>
```

This JSP uses the `<liferay-portlet:actionURL />` and `<liferay-portlet:renderURL />` tags to construct two URLs in the variables `configurationActionURL` and `configurationRenderURL`. The JSP presents a simple form that allows the user to select a favorite color. When the user submits the form, the `configurationActionURL` is invoked and the application's `processAction` method is invoked with the `favoriteColor` included as a request parameter:

```
<aui:form action="<%= configurationActionURL %>" method="post" name="fm">
```

If the request fails, the user is redirected to the configuration page:

```
<aui:input name="redirect" type="hidden"
    value="<%= configurationRenderURL %>" />
```

It's a best practice to supply a URL parameter named `cmd` (`Constants.CMD` equals `cmd`) whose value indicates the purpose of the request. In this example, the value of the `cmd` parameter is `update` (`Constants.CMD` equals `update`):

```
<aui:input name="<%= Constants.CMD %>" type="hidden"
    value="<%= Constants.UPDATE %>" />
```

Many core applications read the value of the `cmd` parameter and perform some processing depending on its value.

If you're developing an application using the example code from this tutorial, deploy the application to Liferay DXP, add it to a page, and click on the *Options* button (⋮), then select *Configuration*. Select a favorite color and click *Save*. To confirm that your selection was saved as a portlet configuration setting, look for the application to display a message like this:

```
Favorite color: blue!
```

Excellent! Now you know how to create application configurations and how to create a mechanism to allow users to edit the configuration.

89.3 Transitioning from Portlet Preferences to the Configuration API

This tutorial describes how to take an existing portlet developed for Liferay Portal 6.2 or prior, which uses portlet preferences to allow administrators to configure the portlet, and convert it to use the new Configuration API.

For more information on the Configuration API and the recommended ways to develop configurable applications for 7.0, please see the Making your applications configurable tutorial.

Before you start, it's important to understand the benefits of making this change. That will allow you to decide whether to go ahead with the change or not, since previous configuration mechanisms of Liferay Portal 6.2 and prior still work in 7.0.

The main benefits are:

- Ability to modify the default portlet preferences through the new System Settings UI. Previously the default configuration of a portlet could only be set by modifying the portlet.xml file, which was not easy to extend.

- In the future Liferay will support modifying the default values for any portlet using this API for each company or site. If you use the new API you won't need to make any change to benefit from this.

- You can now use the PortletPreferences API to allow users to have their own personal preferences for the portlet, which was the original intention of this API.
- Have full programmatic control of the scope of the configuration (Portlet Instance or Group), instead of leaving it to the liferay-portlet.xml file.
- It becomes easier to read the configuration of the portlet from any class or JSP just by knowing its name. The configuration is also presented as a typed object which reduces the possibility of error reading a property name or type.

One final thing to note is that using the new Configuration API preserves all existing configurations of the portlet, since it uses the same persistence storage (the PortletPreferences table). That means that you can deploy a new version of the portlet to a running system and the existing portlets that may have been added to its pages and configured will not need to be reconfigured.

If your existing (Liferay Portal 6.2 or prior) application uses portlet preferences and you have decided to convert it to use the new Configuration API, follow these steps to update your application:

1. Identify the existing preferences of the portlet configuration.

   For example, you could check the `configuration.jsp` (where you will find DOM elements with the name `preferences--XXX--`, where `XXX` is the name of the preference).

2. Determine the scope of the portlet configuration. The traditional way of specifying it is through `liferay-portlet.xml`. Look at the elements `preferences-company-wide`, `preferences-unique-per-layout` and `preferences-owned-by-group` to determine the right scope. The following table maps out the scopes:

liferay-portlet.xml	Scope
preferences-company-wide=true	Company
preferences-owned-by-group=true AND preferences-unique-per-layout=false	Group
preferences-owned-by-group=true AND preferences-unique-per-layout=true	Portlet Instance

```
Related to this, we make the following recommendations for the scope of the
configuration of a portlet:

* For any portlet that can be added to a page it should be Portlet Instance.

* For any portlet that is accessible through the product menu and is used to
administer the site it should be Group.
```

3. Create a Java interface that will represent the configuration, with one method per existing preference.

   By Liferay's convention, the suggested names for these interfaces are `[Portlet Name]PortletInstanceConfiguration` for the portlet scoped ones or `[Portlet Name]GroupServiceConfiguration` for the group scoped ones. However you can choose different conventions.

   This interface will use two annotations (`@Meta.OCD` and `@ExtendedObjectClassDefinition`) to declare that it represents a configuration and to specify the desired scope. The `id` specified in the `@Meta.OCD` annotation must be the fully qualified class name of the interface.

   For example,

```
@ExtendedObjectClassDefinition(
    category = "[category]",
    scope = ExtendedObjectClassDefinition.Scope.GROUP
)
@Meta.OCD(
    id = "[package].[PortletName]GroupServiceConfiguration",
)
public interface [PortletName]GroupServiceConfiguration {
    @Meta.AD(deflt = "", required = false)
    public String displayStyle();

    @Meta.AD(deflt = "0", required = false)
    public long displayStyleGroupId(long defaultDisplayStyleGroupId);
}
```

4. In the code above replace [category] with a category name of your choice. Out of the box Liferay uses: wem, forms, collaboration and foundation. If your portlet fits in any of those go ahead and use them. If you pick any other name it will be added, but you will need to provide a translation as well.

5. If you want to specify the name of the configuration as it will appear in System Settings (and optionally translate it to several languages) add the attributes name and localization (to specify the location of a resource bundle file) to the @Meta.OCD annotation:

```
@Meta.OCD(
    localization = "content/Language",
    name = "[PortletName].group.service.configuration.name"
    id = "[package].[PortletName]GroupServiceConfiguration",
)
```

6. Create one class that implements the Configuration Bean Declaration interface to let the Configuration framework know about the Configuration class.

```
@Component
public class [PortletName]GroupServiceConfigurationBeanDeclaration
        implements ConfigurationBeanDeclaration {

    @Override
    public class getConfigurationBeanClass() {
        return [[PortletName]GroupServiceConfiguration.class;
    }

}
```

7. Change the configuration JSP to retrieve the configuration using the Configuration API. If the scope is "Portlet Instance" the configuration can be retrieved from `portletDisplay`:

```
[PortletName]PortletInstanceConfiguration portletInstanceConfiguration =
    portletDisplay.getPortletInstanceConfiguration(
        [PortletName]PortletInstanceConfiguration.class);
```

Once the configuration object is obtained, the individual preferences can now be changed from this:

```
String displayStyle = portletPreferences.getValue("displayStyle", defaultValue);
```

... to this ...

```
String displayStyle = v.displayStyle();
```

8. Finally it is usually necessary to read the configuration from Java classes or other JSPs. In cases where the `portletDisplay` is not available, or when the scope is "Group" or "Company", the `PortletProvider` class offers methods to obtain the configuration. The best way to access the `PortletProvider` depends on who is making the invocation:

   Within an OSGi Component a reference to the `ConfigurationProvider` can be obtained and used as follows:

```
@Component(service = Foo)
    public class Foo {

        protected void methodWhichNeedsConfiguration() {
            _configurationProvider.getGroupConfiguration(
                [PortletName]GroupServiceConfiguration.class, groupId);
        }

        @Reference
        private ConfigurationProvider _configurationProvider;
    }
```

   Within a service created with Service Builder the code is very similar:

```
    public class FooServiceImpl {

        protected void methodWhichNeedsConfiguration() {
            _configurationProvider.getGroupConfiguration(
                [PortletName]GroupServiceConfiguration.class, groupId);
        }

        @Reference
        private ConfigurationProvider _configurationProvider;
    }
```

   For all other cases it is preferred to get the configuration injected or passed as a parameter. As a last resort it is possible to use `ConfigurationProviderUtil` to obtain the configuration, although this method might have issues in highly dynamic environments:

```
[PortletName]GroupServiceConfiguration groupConfiguration
        ConfigurationProviderUtil.getGroupConfiguration(
            [PortletName]GroupServiceConfiguration.class, groupId);
```

Chapter 90

Social

Liferay DXP's social framework lets users provide feedback on content, share that content with others across social networks, and subscribe to notifications on content, so they can stay up to date on the latest and greatest that you have to share.

The tutorials that follow show you how to take advantage of Liferay DXP's social framework to enable these features in your own app.

90.1 Applying Social Bookmarks

When you enable social bookmarks, icons for sharing on Twitter, Facebook, and Google Plus appear below your app's content. Liferay DXP's taglibs provide the markup you need to add this feature to your app.

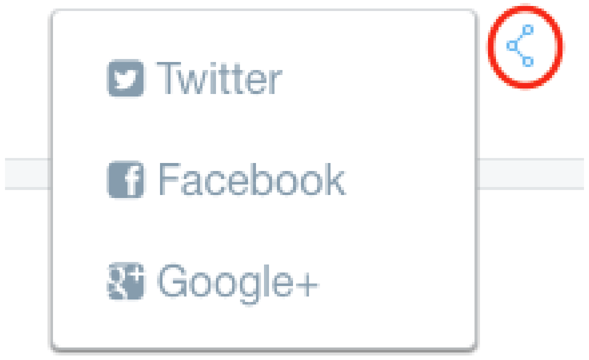

Figure 90.1: Social bookmarks are enabled in the built-in Blogs portlet

Follow these steps to add social bookmarks to your app:

1. Make sure your entity is asset enabled.

2. Choose a view in which to show the social bookmarks. For example, you can display them in one of your portlet's views, or if you've implemented asset rendering you can display them in the full content view in the Asset Publisher portlet.

3. In your JSP, include the `liferay-ui` taglib declaration:

```
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>
```

4. Use `ParamUtil` to get the entity's ID from the render request. Then use your `-LocalServiceUtil` class to create an entity object:

```
<%
long entryId = ParamUtil.getLong(renderRequest, "entryId");
entry = EntryLocalServiceUtil.getEntry(entryId);
%>
```

5. Use the `liferay-ui:social-bookmarks` tag to add the social bookmarks component. The `target` attribute refers to the HTML target. Pass the content's URL in the `url` attribute, using `PortalUtil` to retrieve the URL. The URL and `title` you provide is sent to the social network and becomes part of the link you create there:

```
<liferay-ui:social-bookmarks
    contentId="<%= String.valueOf(assetEntry.getEntryId()) %>"
    displayStyle="menu"
    target="_blank"
    title="<%= String.valueOf(entry.getName()) %>"
    url="<%= PortalUtil.getCanonicalURL((PortalUtil.getCurrentURL(request)),
        themeDisplay, layout) %>"
/>
```

   Pay special attention to the `displayStyle` attribute. This attribute sets the social bookmarks' appearance. Setting `displayStyle` to `menu`, as in this example, hides the share buttons in a clutter-free menu (see above screenshot).

   Setting `displayStyle` to `simple` displays the share buttons in a simple row without share stats.

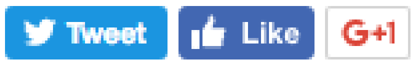

Figure 90.2: Here are the share buttons with `displayStyle` set to `simple`.

   Setting `displayStyle` to `vertical` displays the share buttons in a column, with share stats above each (share stats show the number of times the asset has been shared on the corresponding social network).

   Setting `displayStyle` to `horizontal` displays the share buttons in a row with share stats to the right of each.

The social bookmarks UI component now shows in your entity's view.

Note: You can install the Social Bookmarks app from the Marketplace (available for CE and DXP) to let your users share your app's content across more social networks. For more information, see the article Integrating with Facebook, Twitter, and More.

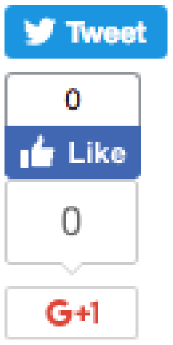

Figure 90.3: Here are the share buttons with displayStyle set to vertical.

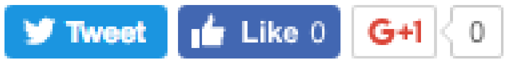

Figure 90.4: Here are the share buttons with displayStyle set to horizontal.

Great! Now you know how to let users share content in your asset enabled apps.

Using the Liferay UI Taglib

90.2 Adding Comments to your App

Users adding comments to your content makes your site come alive. Instead of you statically giving users information, now the flow goes both ways. Liferay DXP's asset framework makes it easy to add a comment system to your app.

This tutorial shows you how to add the comment feature for your application's content.

Follow these steps:

1. Make sure your entity is asset enabled.

2. Choose a read-only view of the entity for the comments. You can display the comments component in your portlet's view, or if you've implemented asset rendering, you can display it in the full content view in the Asset Publisher portlet.

3. Include the Liferay-UI taglib and Portlet taglib declarations in your JSP:

```
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>
<%@ taglib prefix="portlet" uri="http://java.sun.com/portlet_2_0" %>
```

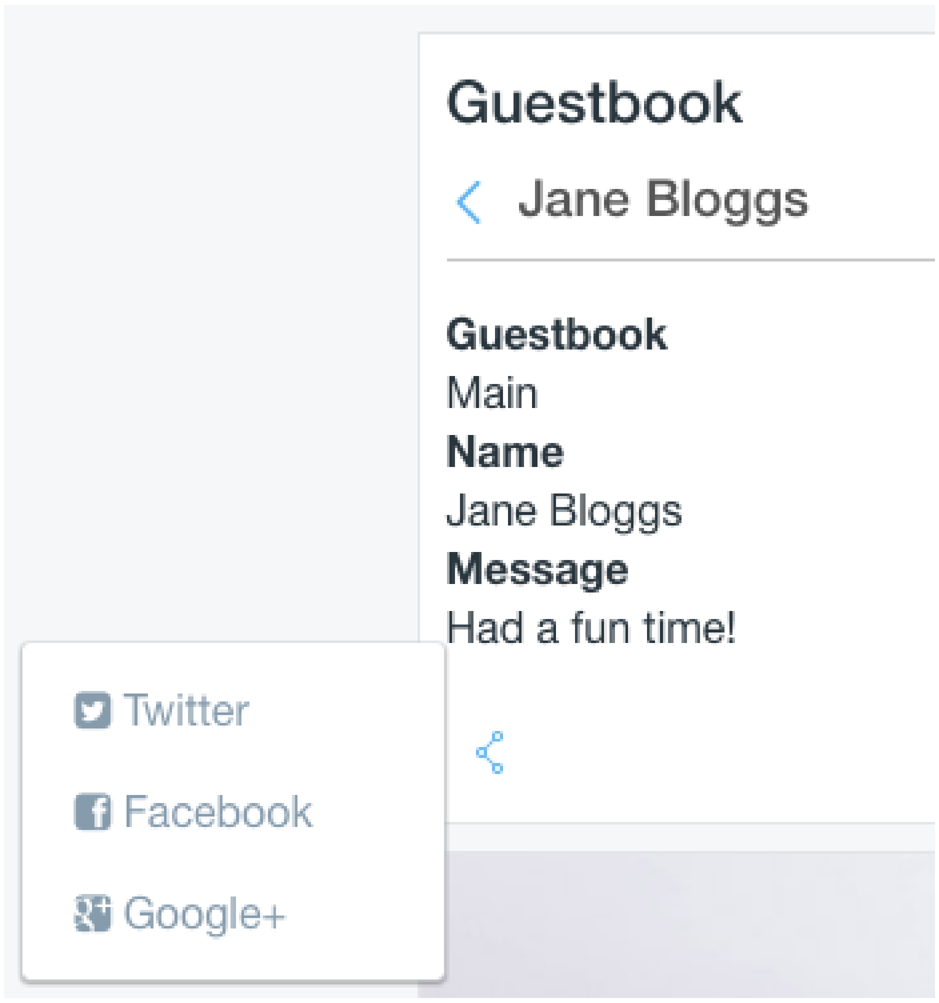

Figure 90.5: The new JSP lets users share app content to social networks.

4. Use `ParamUtil` to get the entity's ID from the render request. Then create an entity object using the `-LocalServiceUtil` class. Below is an example configuration:

```
<%
long entryId = ParamUtil.getLong(renderRequest, "entryId");
entry = EntryLocalServiceUtil.getEntry(entryId);
%>
```

5. Create a collapsible panel for the comments using the `liferay-ui:panel-container` and `liferay-ui:panel` tags. This makes the discussion area hide-able. Below is an example configuration:

```
<liferay-ui:panel-container extended="<%=false%>"
  id="guestbookCollaborationPanelContainer" persistState="<%=true%>">
  <liferay-ui:panel collapsible="<%=true%>" extended="<%=true%>"
    id="guestbookCollaborationPanel" persistState="<%=true%>"
    title="Collaboration">
```

6. Next, create a URL for the discussion using the `portlet:actionURL` tag:

```
<portlet:actionURL name="invokeTaglibDiscussion" var="discussionURL" />
```

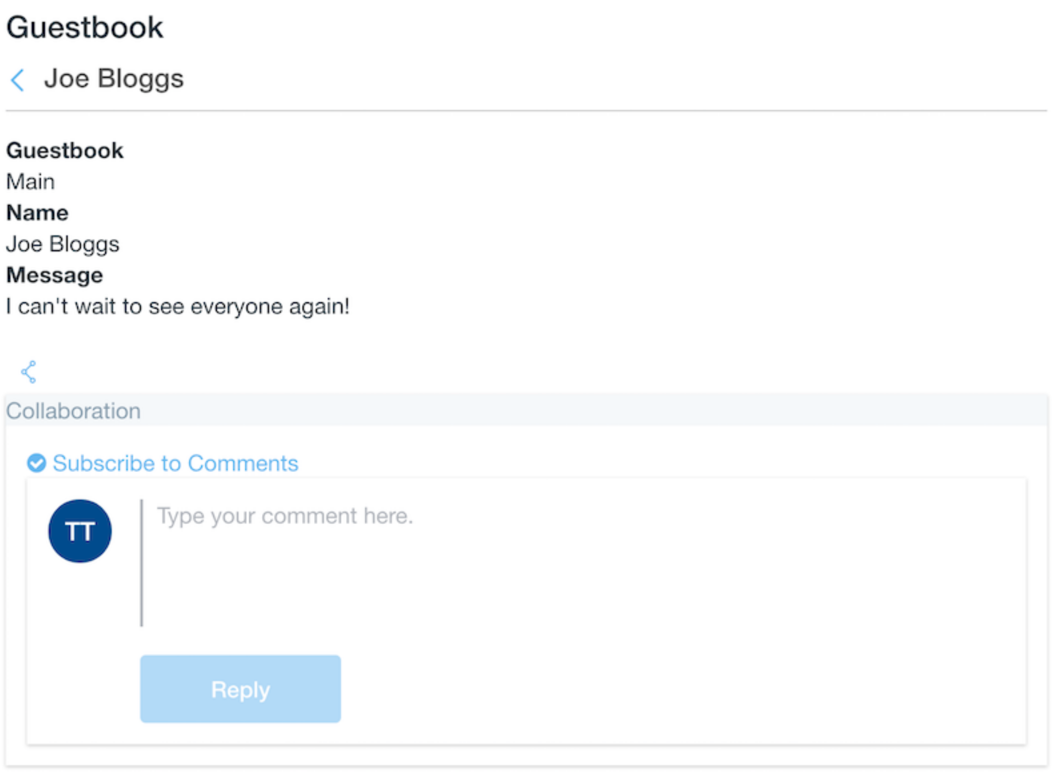

Figure 90.6: Your JSP lets users comment on content in your portlet.

7. Finally, add the discussion with the `liferay-ui:discussion` tag. Pass the current URL using the `redirect` attribute, so the user can return to the JSP after making a comment. You can use `PortalUtil.getCurrentURL((renderRequest))` to get the current URL from the request object. Below is an example configuration:

```
    <liferay-ui:discussion className="<%=Entry.class.getName()%>"
      classPK="<%=entry.getEntryId()%>"
      formAction="<%=discussionURL%>" formName="fm2"
      ratingsEnabled="<%=true%>" redirect="<%=currentURL%>"
      userId="<%=entry.getUserId()%>" />

  </liferay-ui:panel>
</liferay-ui:panel-container>
```

If you haven't already connected your portlet's view to the JSP for your entity, you can refer here to see how to connect a portlet's main view JSP to an entity's view JSP.

Great! Now you know how to let users comment on content in your asset enabled portlets.

90.3 Rating Assets

Liferay DXP's asset framework supports a system for rating content in apps. This feature appears in many core apps, such as the Blogs portlet. Ratings give your users a voice, and you can benefit from their feedback. Thanks to Liferay DXP's taglibs, you can enable ratings for your app in only a few lines of code.

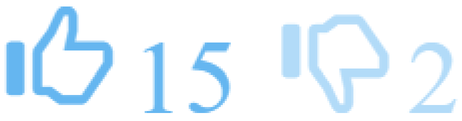

Figure 90.7: Ratings let users quickly provide feedback on content.

Follow these steps:

1. Make sure your entity is asset enabled.
2. Choose a read-only view of the entity for the ratings. You can display them in one of your portlet's views, or if you've implemented asset rendering you can display them in the full content view in the Asset Publisher portlet.
3. In the JSP, include the `liferay-ui`taglib declaration:

```
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>
```

4. Use `ParamUtil` to get the entity's ID from the render request. Then use the `-LocalServiceUtil` class to create an entity object:

```
<%
long entryId = ParamUtil.getLong(renderRequest, "entryId");
entry = EntryLocalServiceUtil.getEntry(entryId);
%>
```

5. Use the `liferay-ui:ratings` tag to add the ratings component:

```
<liferay-ui:ratings className="<%=Entry.class.getName()%>"
    classPK="<%=entry.getEntryId()%>" type="stars" />
```

The type attribute specifies the type of rating system to display:

- *like*: a likes rating system
- *stars*: a five star rating system
- *thumbs*: a thumbs-up or thumbs-down rating system, as shown in the figure above

Although the ratings type is specified here, you can make the type configurable for administrators by Implementing Ratings Type Selection and Value Type Transformation in your app.

Great! Now you know how to let users rate content in your asset-enabled portlets.

90.4 Implementing Ratings Type Selection and Value Transformation

Liferay DXP has three different mechanisms for rating content: Stars, Thumbs Up/Down, and Likes. Prior to 7.0, there was no way for administrators to select a ratings type as it was hard-coded. Now, portal and site admins can select the ratings type for portlet entities through the Control Panel and Site Administration. Portal admins can select default values for the ratings type while site admins can override values for their sites. All Liferay portlets take advantage of this feature, and so can custom portlets.

A custom portlet that uses ratings must define its ratings type through an OSGi component that implements the `PortletRatingsDefinition` interface. This class declares the usage of ratings (specifying the portlet and the entity) and the default ratings type (that can be overridden by portal and site admins). Developers can include their portlet entities in this section by defining the ratings type for the entities using OSGi modules.

The ratings values are stored in the database as normalized values to be able to easily switch among different ratings types. When the administrators change the ratings type for an entity, Liferay does a best match of the previous ratings values to values for the new ratings type. For example, when changing from Thumbs Up/Down to Likes, Portal considers all the Thumbs Up values as if they are Likes and omits all Thumbs Down values. Also, when changing from Stars to Thumbs Up/Down Portal considers ratings with 3, 4, or 5 Stars as Thumbs Up and ratings with 1 or 2 Stars as Thumbs Down.

However, there are some cases where this may not be enough or where you want to apply different or complex criteria to determine the new ratings values. Liferay provides a mechanism to allow developers to transform the ratings values as needed when admins change the ratings type. Keep in mind, this is not an interpretation of the data, this is modification of the stored ratings values. Third party developers can define their own transformations by creating an OSGi component that implements the `RatingsDataTransformer` interface. The highest OSGi ranking implementation is used.

Liferay by default doesn't provide any `RatingsDataTransformer` implementation; the ratings values always remain the same while Liferay interprets existing values for the selected ratings type.

Specifying an Entity's Ratings Type

Ratings type definitions needs to implement the `PortletRatingsDefinition` interface. The implementation of method `getDefaultRatingsType` returns the entity's default ratings type. Note, it can be overridden by portal and site admins. The implementation of method `getPortletId` returns the portlet ID of the main portlet that uses the entity.

Implementations of `PortletRatingsDefinition` need to be registered in OSGi to be used by the portal. You do this in the implementation by specifying the OSGi annotation `@Component` with an attribute `model.class.name` set to the name or names of the classes to use the ratings definition.

Here is an example of a `PortletRatingsDefition` implementation for the Blogs portlet that defines the `blogsEntry` ratings data:

```
@Component(
    property = {
        "model.class.name=com.liferay.portlet.blogs.model.BlogsEntry"
    }
)
public class BlogsPortletRatingsDefinition implements PortletRatingsDefinition {
    @Override
    public RatingsType getDefaultRatingsType() {
        return RatingsType.THUMBS;
    }

    @Override
    public String getPortletId() {
        return PortletKeys.BLOGS;
    }

}
```

Next, let's examine how to transform values between ratings types.

Transforming Ratings Values Between Ratings Types

If the site admin or portal admin changes the ratings type and there are existing ratings values in the database, Liferay doesn't modify any of them. It interprets the values using the selected ratings type according to the following mechanism:

1. When changing from Stars to …

    - **Like:** 1 or 2 Stars aren't considered. 3, 4, or 5 Stars is considered a Like.
    - **Thumbs Up/Down:** 1 or 2 Stars are considered a Thumbs Down. 3, 4, or 5 Stars is considered a Thumbs Up.

2. When changing from Thumbs Up/Down to …

    - **Like:** A Like is considered a Thumbs Up.
    - **Stars:** A Thumbs Down is considered 1 Star. A Thumbs Up is considered 5 Stars.

3. When changing from Like to …

    - **Stars:** A Like is considered 5 Stars.
    - **Thumbs Up/Down:** A Like is considered a Thumbs Up.

There may be cases where this interpretation is insufficient for you or where a different criteria or algorithm needs to be applied. For these cases, Liferay provides a mechanism to allow transforming the existing ratings values. Keep in mind that this modifies the values stored in the database. Since these changes may not be reversible, you must be careful. Developers will need to create an OSGi component that implements the `RatingsDataTransformer` interface.

The implementation of method `transformRatingsData` performs the data transformation. In order to obtain a fine-grained behaviour, the framework provides the methods `fromRatingsType` and `toRatingsType`. The developer can implement them to transform data as needed, and perform different transformations for different circumstances.

This is an example of a `RatingsDataTransformer` that resets the score from the ratings type when passing from `LIKE` to `STARS`. In this particular case, changes are not reversible.

```
@Component
public class DummieRatingsDataTransformer implements RatingsDataTransformer {
    @Override
    public ActionableDynamicQuery.PerformActionMethod transformRatingsData(
            final RatingsType fromRatingsType, final RatingsType toRatingsType)
        throws PortalException {
```

```
        return new ActionableDynamicQuery.PerformActionMethod() {

            @Override
            public void performAction(Object object)
                throws PortalException {

                if (fromRatingsType.getValue().equals(RatingsType.LIKE) &&
                    toRatingsType.getValue().equals(RatingsType.STARS)) {

                    RatingsEntry ratingsEntry = (RatingsEntry) object;

                    ratingsEntry.setScore(0);

                    RatingsEntryLocalServiceUtil.updateRatingsEntry(
                        ratingsEntry);
                }
            }
        };
    }

}
```

Once you've implemented ratings type selection and value type transformation for your app's entities, you can configure the default ratings type values through the Control Panel by going to *Configuration* → *Instance Settings* and selecting the *Social* tab. To override the default values for a site, go to Site Administration → *Configuration* → *Site Settings* and select the *Social* tab.

In this tutorial, you have learned how to set a ratings type for an entity and how to implement a ratings data transformer. Liferay salutes you with a Thumbs Up!

Adding Comments to Your App

90.5 Flagging Inappropriate Asset Content

In a perfect world, people would post nice, kind, and decent content. They would reply to comments with constructive feedback and never lash out at one another. Unfortunately, sometimes people have a bad day and decide to take their frustration out on Joe Bloggs in the form of an inappropriate post. No worries though, Liferay DXP's asset framework supports a system for flagging content in apps. Letting users flag inappropriate content takes much of the work off site administrators.

This tutorial shows you how to enable flagging of content in a portlet.

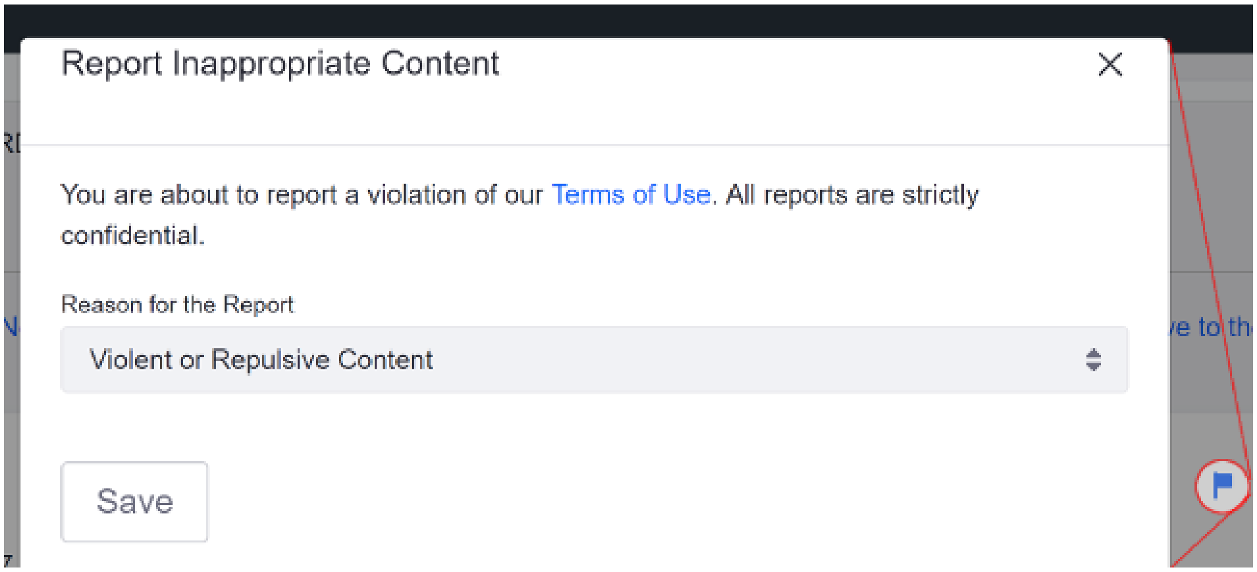
Follow these steps:

1. Make sure your entity is asset enabled.

2. Choose a read-only view of the entity for the flags. You can display them in one of your portlet's views, or if you've implemented asset rendering, you can display them in the full content view in the Asset Publisher portlet.

3. In the JSP, include the `liferay-flags` taglib declaration:

   ```
   <%@ taglib prefix="liferay-flags" uri="http://liferay.com/tld/flags" %>
   ```



Report Inappropriate Content
You are about to report a violation of our Terms of Use. All reports are strictly confidential.
Reason for the Report
Violent or Repulsive Content
Save

Figure 90.8: Flags for letting users mark objectionable content are enabled in the Message Boards portlet.

4. Use the -LocalServiceUtil class to get the entity:

```
<%
long entryId = ParamUtil.getLong(renderRequest, "entryId");
entry = EntryLocalServiceUtil.getEntry(entryId);
%>
```

5. Use the liferay-flags:flags tag to add the flags component:

```
<liferay-flags:flags
    className="<%= Entry.class.getName() %>"
    classPK="<%= entry.getEntryId() %>"
    contentTitle="<%= title %>"
    message="flag-this-content"
    reportedUserId="<%= reportedUserId %>"
/>
```

   The reportedUserId attribute specifies the user who flagged the asset.

Great! Now you know how to let users flag content in your asset-enabled portlets.

Chapter 91

Item Selector

People's tasks often involve making choices: which shirt to wear, what to eat for breakfast, or what profile picture to use. The power of choice is a terrific privilege, but the means by which a person makes his/her selection can make an experience good or bad. Here are some factors that influence the experience:

- Item organization
- Consistency
- UI intuitiveness

Liferay DXP's Item Selector provides all these things. It is a UI component that enables users to select entities in a consistent easy-to-use manner. Many Liferay portlets, such as Documents and Media, Web Content, Blogs and more, use Item Selectors for selecting things such as images, videos, audio files, documents, and pages.

The Item Selector API provides a framework for developers to use and extend Item Selectors. They can add Item Selectors to their apps, customize Liferay DXP's Item Selectors, and create Item Selectors to select any kind of entity.

Selection views are the framework's key components. In an Item Selector, selection views show entities of particular types from different sources.

For example, an Item Selector configured to show images might show selection views from the following sources:

- Documents and Media
- Third-party image provider
- Drag-and-drop interface

Here are some different Item Selector use cases:

1. Enabling your application to select Liferay DXP entities such as sites, pages, or documents from Documents and Media.
2. Customizing a selection experience by adding a new selection view for an entity (e.g., a view of images from an external image repository).
3. Creating new selectable entities for other applications to use in their Item Selectors.

This group of tutorials demonstrates how to satisfy these use cases.

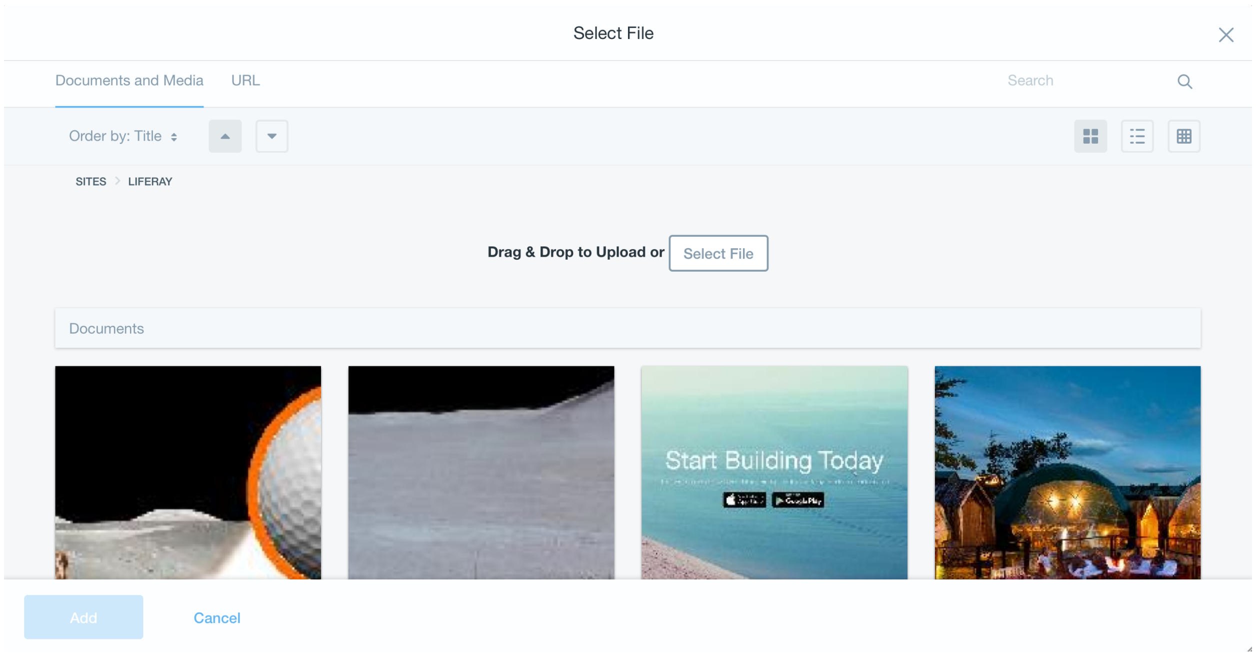

Figure 91.1: Item Selectors let users browse and select different kinds of entities.

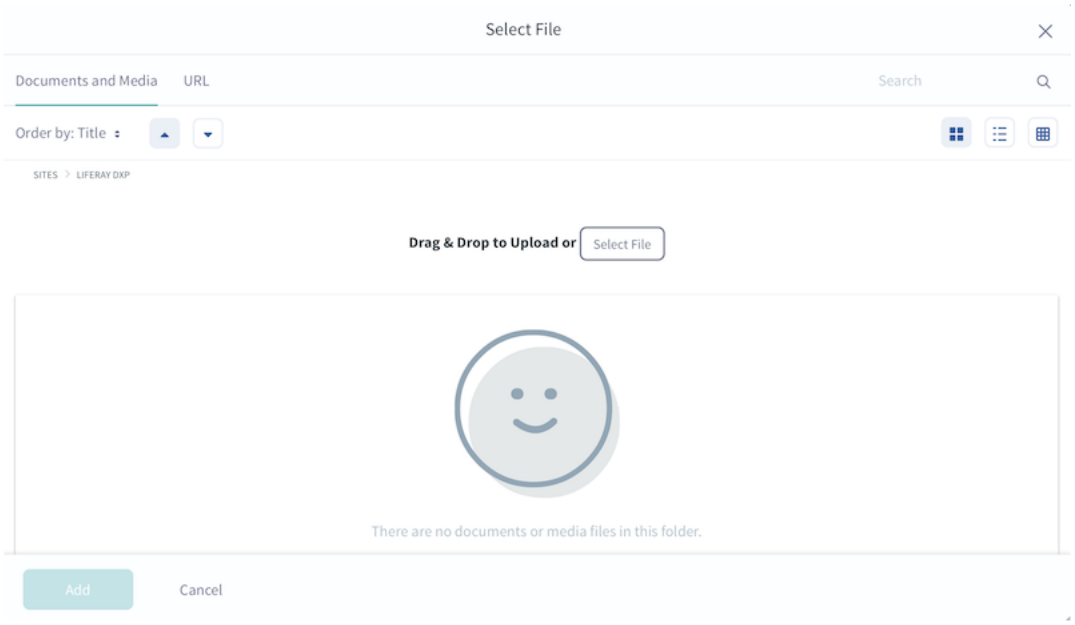
91.1 Selecting Entities Using the Item Selector

The Item Selector allows users to select entities, such as images, videos, documents, and sites.



There are no documents or media files in this folder.

Figure 91.2: The Item Selector makes selecting entities a breeze.

Here's what's required to use an Item Selector:

1. **Determine Item Criteria**

2. **Get an Item Selector for the Criteria**

3. **Use an Item Selector Dialog**

Determining Item Selector Criteria

The first step is determining entity types to select from the Item Selector and the data you expect from them. What kind of entity do you want to select? Do you want to select a user, an image, a video, or something else?

Once you know the entities you want, you need *criterion* classes to represent them in the Item Selector. Criterion classes must implement the `ItemSelectorCriterion` interface. The Item Selector Criterion and Return Types reference lists criterion classes Liferay's apps and app suites provide.

If there's no criterion class for your entity, you can create your own `ItemSelectorCriterion` class (tutorial coming soon).

Then determine the type of information (return type) you expect from the entities when users select them. Do you expect a URL? A Universally Unique Identifier (UUID)? A primary key? Each return type must be represented by an implementation of the `ItemSelectorReturnType` class. The Item Selector Criterion and Return Types reference also lists return type classes Liferay's apps and app suites provide.

If there's no return type class that meets your needs, you can implement your own `ItemSelectorReturnType` class (tutorial coming soon).

Note: Each criterion must have at least one `ItemSelectorReturnType` (return type) associated with it.

For example, if you want to allow users to select an image and want the image's URL returned, you could use the `ImageItemSelectorCriterion` criterion class and the `URLItemSelectorReturnType` return type.

The criterion and return types are collectively referred to as the Item Selector's *criteria*. The Item Selector uses it to decide which selection views (tabs of items) to show.

Once you've defined your criteria, you can get an Item Selector to use with it.

Getting an Item Selector for the Criteria

In order to use an Item Selector with your criteria, you must get an Item Selector URL based on the criteria. The URL is needed to open the Item Selector dialog in your UI. In Java, you build the criteria and pass it in a call to get the Item Selector's URL.

First, get an Item Selector OSGi Service Component using Declarative Services.

```
import com.liferay.item.selector.ItemSelector;
import org.osgi.service.component.annotations.Reference;

@Reference
private ItemSelector _itemSelector
```

The component annotations are available in the `org.osgi.service.component.annotations` module.

To get a URL to the Item Selector, you must call its `getItemSelectorURL` method using the following parameters:

- `RequestBackedPortletURLFactory`: Factory that creates portlet URLs.
- `ItemSelectedEventName`: Unique arbitrary JavaScript event name that is triggered by the Item Selector when the element is selected.
- `ItemSelectorCriterion`: Criterion (or an array of criterion objects) that specifies the type of elements to make available in the Item Selector.

The following code demonstrates getting a URL to an Item Selector configured with criteria for images:

```
RequestBackedPortletURLFactory requestBackedPortletURLFactory =
    RequestBackedPortletURLFactoryUtil.create(request);

List<ItemSelectorReturnType> desiredItemSelectorReturnTypes =
    new ArrayList<>();
desiredItemSelectorReturnTypes.add(new URLItemSelectorReturnType());

ImageItemSelectorCriterion imageItemSelectorCriterion =
    new ImageItemSelectorCriterion();

imageItemSelectorCriterion.setDesiredItemSelectorReturnTypes(
    desiredItemSelectorReturnTypes);

PortletURL itemSelectorURL = _itemSelector.getItemSelectorURL(
    requestBackedPortletURLFactory, "sampleTestSelectItem",
    imageItemSelectorCriterion);
```

First it gets a factory to create the URL by invoking the `RequestBackedPortletURLFactoryUtil.create` method, passing it the current request object. The request can be an `HttpServletRequest` or `PortletRequest`.

Then it creates a list of return types expected for the image entity and a criterion for images. The return types list consists of a URL return type `URLItemSelectorReturnType`. The list is passed to the criterion's `setDesiredItemSelectorReturnTypes` method.

Lastly the method `getItemSelectorURL` is called to return a URL based on the criteria. The method requires a URL factory, an arbitrary event name, and a series of criterion (one, in this case).

Note: You can invoke the URL object's `toString` method to get its value.

An Item Selector can be configured to use any number of criterion. The criterion can use any number of return types.

The Item Selector's criterion order determines the selection view order. For example, if you pass the item selector criteria in this order: `ImageItemSelectorCriterion`, `VideoItemSelectorCriterion`, the Item Selector displays the image selection views first and then the ones for videos. If you reverse the order, it shows the video selection views first and the image selection views second.

Return type order is also significant. A view uses the first return type it supports from each criterion's return type list.

Now that you've got a URL to the Item Selector you've configured, you can start using the Item Selector in your UI.

Using the Item Selector Dialog

To open the Item Selector in your UI, you must use the `LiferayItemSelectorDialog` JavaScript component from AlloyUI's `liferay-item-selector-dialog` module. The component listens for the item selected event that you specified for the Item Selector URL. The event returns the selected element's information according to its return type.

Here are the steps for using the Item Selector dialog in a JSP:

1. Declare the AUI tag library.

   ```
   <%@ taglib prefix="aui" uri="http://liferay.com/tld/aui" %>
   ```

2. Add the `<aui:script>` tag and configure it to use the `liferay-item-selector-dialog` module:

```
<aui:script use="liferay-item-selector-dialog">

</aui:script>
```

3. Attach an event handler to the UI element you want to use to open the Item Selector dialog.

   For example, the configuration below creates a *Choose* button with the ID `chooseImage` with a click event and function attached.

```
<aui:button name="chooseImage" value="Choose" />

<aui:script use="liferay-item-selector-dialog">

    $('#<portlet:namespace />chooseImage').on(
    'click',
      function(event) {
        <!-- function logic goes here -->
      }
    );

</aui:script>
```

4. Inside the function, you must create a new instance of the `LiferayItemSelectorDialog` AlloyUI Component and configure it to use the Item Selector. Here's what you need to do in the function:

   - Set the function's `eventName` attribute to the item selected event name you specified in your Java code (the code that gets the Item Selector URL).
   - For the `on` attribute, implement a function that operates on the selected item change. The example code below demonstrates this.
   - Set the function's `title` attribute. This becomes the dialog's title.
   - Set the function's `url` attribute to the Item Selector URL you obtained earlier.
   - Call the dialog's `open` method.

The example code below and steps that follow show how to configure an Item Selector dialog to work with selected items.

```
<aui:button name="chooseImage" value="Choose" />

<%
String itemSelectorURL = GetterUtil.getString(request.getAttribute("itemSelectorURL"));
%>

<aui:script use="liferay-item-selector-dialog">

    $('#<portlet:namespace />chooseImage').on(
        'click',
        function(event) {
            var itemSelectorDialog = new A.LiferayItemSelectorDialog(
                {
                    eventName: 'ItemSelectedEventName',
                    on: {
                            selectedItemChange: function(event) {
                                var selectedItem = event.newVal;

                                if (selectedItem) {
                                    var itemValue = JSON.parse(
                                    selectedItem.value
                                    );
                                    itemSrc = itemValue.url;
                                    <!-- use item as needed -->
                                }
                            }
                    },
                    title: '<liferay-ui:message key="select-image" />',
                    url: '<%= itemSelectorURL.toString() %>'
                }
            );
            itemSelectorDialog.open();
        }
    );
</aui:script>
```

Here's what the code does:

1. This line creates a new instance of the Liferay Item Selector dialog:

   ```
   var itemSelectorDialog = new A.LiferayItemSelectorDialog(...)
   ```

2. The constructor sets the `eventName` attribute. This makes the dialog listen for the item selected event. The event name is the same as the one specified for the Item Selector URL generated earlier in the Java code.
3. When the user selects a new item, the `selectedItemChange` function fires, setting its variables for the newly selected item. The information available to parse depends on the return type(s) that were set.
4. As the comment indicates, the developer adds logic for using the selected element here.
5. The `LiferayItemSelectorDialog`'s `title` attribute sets the dialog's title.
6. The Item Selector URL retrieved previously in the Java code becomes the `url` attribute's value.
7. The `open` method opens the Item Selector dialog.

When the user clicks the *Choose* button, a new dialog opens, rendering the Item Selector with the views that support the criterion and return type(s) that were set.

Adding an Item Selector to your app is as easy as what's been demonstrated! It involves specifying criteria for the selectable items, applying them to an Item Selector, and configuring an Item Selector dialog to operate on the selected item. Using Item Selector API, you can give app users the power of choice!

Front-End Taglibs

91.2 Creating Custom Item Selector Entities

Does your app require users to select an item that the Item Selector isn't configured for? No problem. You can create a new entity.

This tutorial explains how to create a new entity for the Item Selector.

Creating Item Selector Criterion

First, you must create a new criterion for your entity. Follow these steps to create an Item Selector criterion:

1. Create a class that extends the `BaseItemSelectorCriterion` class.

   The example below creates a class called `TaskItemSelectorCriterion`:

   ```
   public class TasksItemSelectorCriterion extends
   BaseItemSelectorCriterion {

   }
   ```

   This class specifies what kind of entity the user is selecting and what information the Item Selector should return. The methods inherited from the `BaseItemSelectorCriterion` class provide the logic for obtaining this information:

   ```
   public abstract class BaseItemSelectorCriterion
           implements ItemSelectorCriterion {

           @Override
           public List<ItemSelectorReturnType> getDesiredItemSelectorReturnTypes() {
                   return _desiredItemSelectorReturnTypes;
           }

           @Override
           public void setDesiredItemSelectorReturnTypes(
                   List<ItemSelectorReturnType> desiredItemSelectorReturnTypes) {

                   _desiredItemSelectorReturnTypes = desiredItemSelectorReturnTypes;
           }

           private List<ItemSelectorReturnType> _desiredItemSelectorReturnTypes;

   }
   ```

   Note that you can use this class to pass information to the view if needed. For example, the `JournalItemSelectorCriterion` class passes information about the primary key so the view can use it:

   ```
   public class JournalItemSelectorCriterion extends
   BaseItemSelectorCriterion {

           public JournalItemSelectorCriterion() {
           }

           public JournalItemSelectorCriterion(long resourcePrimKey) {
                   _resourcePrimKey = resourcePrimKey;
           }

           public long getResourcePrimKey() {
                   return _resourcePrimKey;
           }

           public void setResourcePrimKey(long resourcePrimKey) {
                   _resourcePrimKey = resourcePrimKey;
           }

           private long _resourcePrimKey;

   }
   ```

```
**Note:** Criterion fields should be serializable and should expose a
public empty constructor (as shown above).
```

---

2. Create an OSGi component class that implements the `BaseItemSelectorCriterionHandler` class. Each criterion requires a criterion handler, which is responsible for obtaining the proper selection view.

   The example below creates a criterion handler for the `TaskItemSelectorCriterion` class:

   ```
   @Component(service = ItemSelectorCriterionHandler.class)
   public class TaskItemSelectorCriterionHandler extends
   BaseItemSelectorCriterionHandler<TaskItemSelectorCriterion> {

       public Class <TaskItemSelectorCriterion>
       getItemSelectorCriterionClass() {
           return TasksItemSelectorCriterionHandler.class;
       }

       @Activate
       @Override
       protected void activate(BundleContext bundleContext) {
               super.activate(bundleContext);
       }

   }
   ```

   The `@Activate` and `@Override` tokens are required to activate this OSGi component.

Depending on the needs of your app, you may not need to create a return type. If your entity returns information that is already defined by an existing return type, you can use that return type instead.

You can view the default available criteria in the Item Selector Criterion and Return Types reference.

If, however, your entity returns information that is not covered by an existing return type, you'll need to create a new return type next.

Creating Item Selector Return Types

To create a return type, you must create a class that implements the `ItemSelectorReturnType` class.

The example below creates a new return type called `TaskItemSelectorReturnType`:

```
/**
* This return type should return the task ID and the user who
* created the task as a string.
*
* @author Joe Bloggs
*/
public class TaskItemSelectorReturnType implements ItemSelectorReturnType{

}
```

The `*ItemSelectorReturnType` class is used as an identifier by the Item Selector and does not return any information itself. You should determine the information you expect returned (an ID, a URL, a more complex object, etc.), and create a return type to handle that information. The return type class is an API that connects the return type to the Item Selector views. **Whenever the return type is used, the view must ensure that the proper information is returned.** It's recommended that you specify the information that the return type returns, as well as the format, as Javadoc (as shown in the `TaskItemSelectorReturnType` example above).

So far, you've created an API that you can use to create a selection view for your new entity. The entity's criterion and return type classes are used by your application to create the Item Selector URL. You can follow the Selecting Entities using the Item Selector tutorial to learn how to obtain the Item Selector URL.

The selection view is responsible for returning the proper entity information specified by the return type. Currently there isn't a selection view to select your entity. Follow the Creating Custom Item Selector Views tutorial to learn how to create your new view.

Now you know how to create an entity for the Item Selector!

Selecting Entities using the Item Selector

Creating Custom Item Selector Views

91.3 Creating Custom Item Selector Views

Have you found you need to create a new selection view for your app? No problem. Item Selector views are determined by the type of entity the user is selecting. The Item Selector can render multiple views for the same entity type. For example, when a user requires an image from the Item Selector, the selection views shown below are rendered:

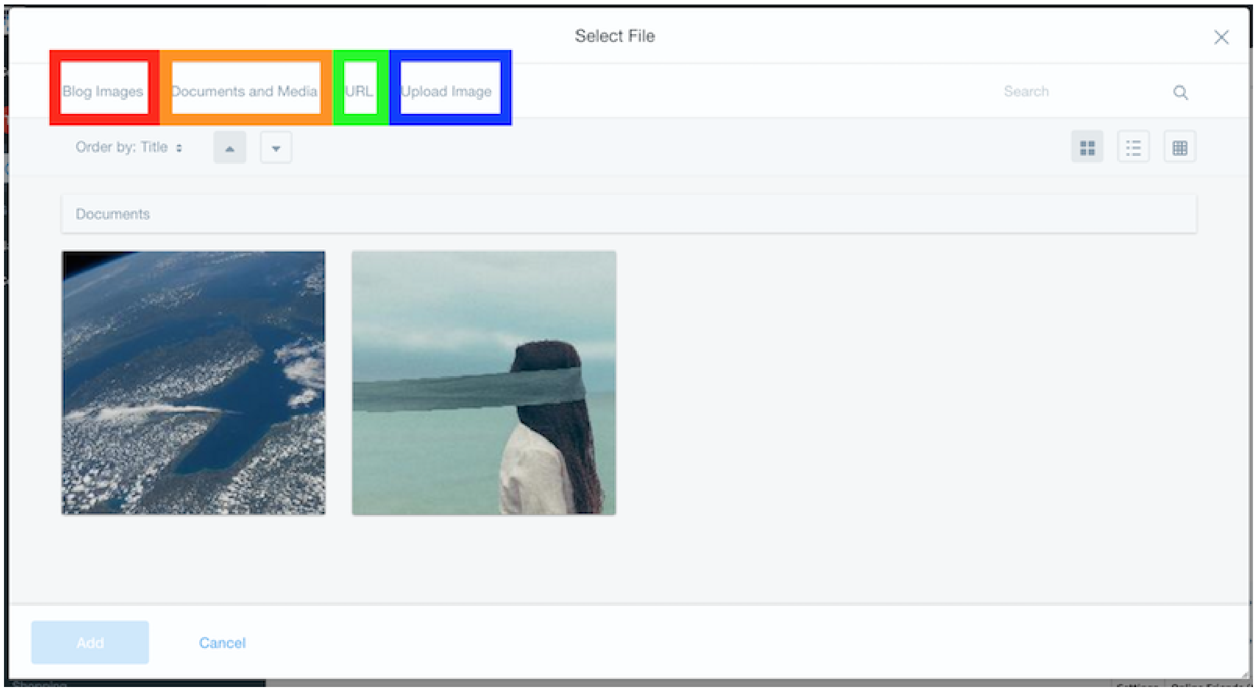

Figure 91.3: An entity type can have multiple selection views.

Each tab: *Blog Images*, *Documents and Media*, *URL*, and *Upload Image*, is a selection view for the Item Selector, each one represented by an `*ItemSelectorCriterion` class. The tabs in figure 1 are represented by the following `*ItemSelectorCriterion`:

- `BlogsItemSelectorCriterion` class: Blog Images View
- `ImageItemSelectorCriterion` class: Documents and Media View

- URLItemSelectorCriterion class: URL View
- UploadItemSelectorCriterion class: Upload Image View

The default selection views may provide everything you need for your application. If, however, your application requires a custom selection view, for instance to link to an external image provider, you can follow the steps outlined in this tutorial.

This tutorial covers how to create new selection views for the Item Selector.

Get started by configuring the module for your view next.

Configuring the Module

Follow these steps to prepare your module:

1. Add these dependencies to your module's build.gradle:

```
dependencies {
        compileOnly group: "com.liferay", name: "com.liferay.item.selector.api", version: "2.0.0"
        compileOnly group: "com.liferay", name: "com.liferay.item.selector.criteria.api", version: "2.0.0"
        compileOnly group: "com.liferay.portal", name: "com.liferay.portal.impl", version: "2.0.0"
        compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
        compileOnly group: "com.liferay.portal", name: "com.liferay.util.taglib", version: "2.0.0"
        compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
        compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
        compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

2. Add your module's information to the bnd.bnd file. For example, the configuration below adds the information for a module called My Custom View.

```
Bundle-Name: My Custom View
Bundle-SymbolicName: com.liferay.docs.my.custom.view
Bundle-Version: 1.0.0
```

3. Add a Web-ContextPath to your bnd.bnd to point to the resources for your module. For example:

```
Include-Resource:\
        META-INF/resources=src/main/resources/META-INF/resources
Web-ContextPath: /my-custom-view
```

   If you don't have a Web-ContextPath your module won't know where your resources are. The Include-Resource header points to the relative path for the module's resources.

Now that your module is configured, you can create the view next.

Implementing the View

To create a new view you must first know what kind of entities you want to select in the new view: images, videos, users, etc. The kind of entities you choose determines the specific ItemSelectorCriterion you need to use. For example if you were selecting images, you must use the ImageItemSelectorCriterion.

Next, you need to know the type of information the entity can return when it's selected. For example, if the entity returns its URL, you would use URLItemSelectorReturnType for the return type.

For a full list of the available criterion and returns types that Liferay's apps and app suite's provide see the Item Selector Criterion and Return Types reference.

Once you've determined the kinds of entities you wish to select, follow these steps to create your selection view:

1. Create an Item Selector View Component class:

   ```
   @Component(
       property = {"item.selector.view.order:Integer=200"},
       service = ItemSelectorView.class
   )
   ```

   Note that the OSGi component is registered with the property `item.selector.view.order`. The Item Selector view order (the order of the rendered tab views) is prioritized according to these settings:

   - The criteria order specified in the `getItemSelectorURL` method of the application.
   - The `item.selector.view.order` property's value for multiple views with the same criteria. The lower the value is, the more priority it has, and the sooner it will appear in the order.

2. Implement the `ItemSelectorView` interface using the *criterion* the view requires. For example, the configuration below uses the `ImageItemSelectorCriterion` class to implement the view:

   ```
   public class SampleItemSelectorView
       implements ItemSelectorView<ImageItemSelectorCriterion> {

       @Override
       public Class<ImageItemSelectorCriterion> getItemSelectorCriterionClass()
       {
           return ImageItemSelectorCriterion.class;
       }

       @Override
       public ServletContext getServletContext() {
           return _servletContext;
       }

       @Override
       public List<ItemSelectorReturnType> getSupportedItemSelectorReturnTypes() {
           return _supportedItemSelectorReturnTypes;
       }

   }
   ```

   The implementation above also sets up some methods you'll use in the steps that follow. The `getSupportedItemSelectorReturnTypes` method returns a list of *ItemSelectorReturnTypes*. You'll populate this list in a later step to specify the return types the selection view supports.

```
**Note:** If you want your new selection view to be available only when
selecting the entity for something specific such as a blog entry, replace
the `*ItemSelectorCriterion` in your `*ItemSelectorView` class with the
`*ItemSelectorCriterion` class you wish to use, such as the
[`BlogsItemSelectorCriterion` class](@app-ref@/collaboration/latest/javadocs/com/liferay/blogs/item/selector/criterion/BlogsItemSelectorCriterion.html).
```

---

3. Configure the title, search options, and visibility settings for the selection view:

   An example configuration is shown below for a selection view called `Sample Selector`:

```
@Override
public String getTitle(Locale locale) {
    return "Sample Selector";
}

@Override
public boolean isShowSearch() {
    return false;
}

@Override
public boolean isVisible(ThemeDisplay themeDisplay) {
    return true;
}
```

The following methods are demonstrated above:

- `getTitle` method: returns the localized title of the tab to display in the Item Selector dialog.
- `isShowSearch()` method: returns whether the Item Selector view should show the search field.

```
**Note:** To implement search, return `true` for this method. The
`renderHTML` method, covered in the next section, indicates whether a user
performed a search based on the value of the `search` parameter. Then the
keywords the user searched can be obtained as follows:

    String keywords = ParamUtil.getString(request, "keywords");
```

```
- [`isVisible()` method](@app-ref@/collaboration/latest/javadocs/com/liferay/item/selector/ItemSelectorView.html#isVisible-com.liferay.portal.kernel.theme.T
):
returns whether the Item Selector view is visible. In most cases, you'll
want to set this to `true`. You can use this method to add conditional logic
to disable the view.
```

4. Next, set the render settings for your view, using the `renderHTML` method. The example below points to a JSP file to render the view:

```
@Override
public void renderHTML(
    ServletRequest request, ServletResponse response,
    ImageItemSelectorCriterion itemSelectorCriterion,
    PortletURL portletURL, String itemSelectedEventName,
    boolean search
)
throws IOException, ServletException {

    request.setAttribute(_ITEM_SELECTED_EVENT_NAME,
    itemSelectedEventName);

    ServletContext servletContext = getServletContext();

    RequestDispatcher requestDispatcher =
    servletContext.getRequestDispatcher("/sample.jsp");

    requestDispatcher.include(request, response);
}
```

The renderHTML methods passes the *ItemSelectorCriterion required to display the selection view. Next, the portletURL, used to invoke the Item Selector, is passed. Then the itemSelectedEventName is passed. This is the event name that the caller listens for. When an element is selected, the view fires a JavaScript event with this name. Finally, a search boolean is passed, specifying when the view should render search results. When the user performs a search, this boolean should be set to true.

Note that the itemSelectedEventName is passed as a request attribute, so it can be used in the view markup.

The view markup is specified this way:

```
RequestDispatcher requestDispatcher =
        servletContext.getRequestDispatcher("/sample.jsp");
```

Although the example uses JSPs, you can use another language such as FreeMarker to render the markup.

5. Use the @Reference annotation to reference your module's class for the setServletContext method.

   Below is an example configuration:

```
@Reference(
    target =
    "(osgi.web.symbolicname=com.liferay.item.selector.sample.web)",
    unbind = "-"
)
```

   public void setServletContext(ServletContext servletContext) { _servletContext = servletContext; }

   The target parameter is used to specify the available services for the servlet context. In this case, it specifies the com.liferay.selector.sample.web class as the default value, using the osgi.web.symbolicname property. Finally, the unbind = _ parameter specifies that there is no unbind method for this module. A method is defined to set the servlet context as well.

6. Finally, populate the _supportedItemSelectorReturnTypes list specified in step 2 with the return types that this view supports.

   The example below adds the URLItemSelectorReturnType class and FileEntryItemSelectorReturnType class to the list of supported return types, but you could use more return types if the view could return them. More return types means that the view is more reusable:

```
private static final List<ItemSelectorReturnType>
    _supportedItemSelectorReturnTypes =
    Collections.unmodifiableList(
        ListUtil.fromArray(
            new ItemSelectorReturnType[] {
                new FileEntryItemSelectorReturnType(),
                new URLItemSelectorReturnType()
            }));

 private ServletContext _servletContext;
```

   The servlet context variable is declared at the bottom of the file.

As a complete example, below is the full code for the FlickrItemSelectorView class:

```
public class FlickrItemSelectorView
        implements ItemSelectorView<FlickrItemSelectorCriterion> {

        @Override
        public Class<FlickrItemSelectorCriterion> getItemSelectorCriterionClass() {
                return FlickrItemSelectorCriterion.class;
        }

        @Override
        public List<ItemSelectorReturnType> getSupportedItemSelectorReturnTypes() {
                return _supportedItemSelectorReturnTypes;
        }

        @Override
        public String getTitle(Locale locale) {
                return FlickrItemSelectorView.class.getName();
        }

        @Override
        public boolean isShowSearch() {
                return false;
        }

        @Override
        public boolean isVisible(ThemeDisplay themeDisplay) {
                return true;
        }

        @Override
        public void renderHTML(
                        ServletRequest request, ServletResponse response,
                        FlickrItemSelectorCriterion flickrItemSelectorCriterion,
                        PortletURL portletURL, String itemSelectedEventName,
                        boolean search)
                throws IOException {

                PrintWriter printWriter = response.getWriter();

                printWriter.print(
                        "<html>" + FlickrItemSelectorView.class.getName() +
                        "</html>");
        }

        private static final List<ItemSelectorReturnType>
                _supportedItemSelectorReturnTypes =
                Collections.unmodifiableList(
                        ListUtil.fromArray(
                                new ItemSelectorReturnType[] {
                                        new TestURLItemSelectorReturnType()
                                }));

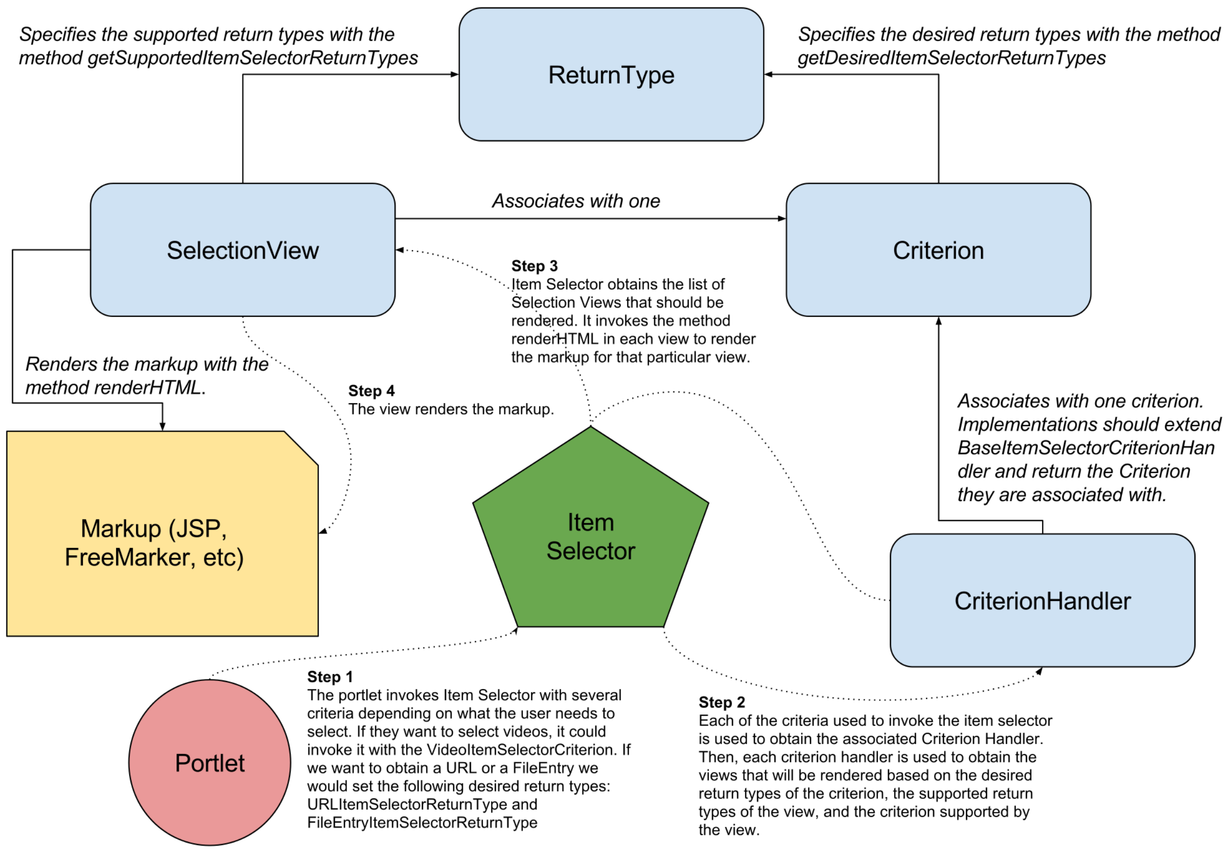
}
```

The diagram below illustrates how the Item Selector's API works (right-click to view larger image):
Once you've implemented your Item Selector view, you must create the view markup.

Writing your View Markup

You've implemented your view, specifying the criteria and return types, along with important configuration information, such as how to render the view. All that's left is to write the markup for your selection view.

Naturally, the markup for your selection view will vary greatly depending on the requirements of your app. You can use taglibs, AUI components, or even pure HTML and JavaScript if you prefer, to write your view. Regardless of the approach you choose to create your view, the view must do two key things:



Specifies the supported return types with the method getSupportedItemSelectorReturnTypes
ReturnType
Specifies the desired return types with the method getDesiredItemSelectorReturnTypes
SelectionView
Associates with one
Criterion
Step 3
Item Selector obtains the list of Selection Views that should be rendered. It invokes the method renderHTML in each view to render the markup for that particular view.
Renders the markup with the method renderHTML.
Step 4
The view renders the markup.
Associates with one criterion. Implementations should extend BaseItemSelectorCriterionHandler and return the Criterion they are associated with.
Markup (JSP, FreeMarker, etc)
Item Selector
CriterionHandler
Step 1
The portlet invokes Item Selector with several criteria depending on what the user needs to select. If they want to select videos, it could invoke it with the VideoItemSelectorCriterion. If we want to obtain a URL or a FileEntry we would set the following desired return types: URLItemSelectorReturnType and FileEntryItemSelectorReturnType
Portlet
Step 2
Each of the criteria used to invoke the item selector is used to obtain the associated Criterion Handler. Then, each criterion handler is used to obtain the views that will be rendered based on the desired return types of the criterion, the supported return types of the view, and the criterion supported by the view.

Figure 91.4: Item Selector views are determined by the desired return types of the criterion, the supported return types of the view, and the criterion supported by the view.

- Render the entities for the user to select
- Contain JavaScript logic that passes the information specified by the Item Selector return type via a JavaScript event when an entity is selected.

If you're following the example in the last section, the JavaScript event name has been passed as a request attribute in the `renderHTML` method of the `*ItemSelectorView` class, so it can be used in the view markup as follows:

```
Liferay.fire(
        `<%= {ITEM_SELECTED_EVENT_NAME} %>',

        {
            data:{
                the-data-your-client-needs-according-to-the-return-type
            }
        }
);
```

Below is the complete `Layouts.jsp` view markup for the `com.liferay.layout.item.selector.web` module: Some Java imports are defined first:

```
<%
LayoutItemSelectorViewDisplayContext layoutItemSelectorViewDisplayContext =
(LayoutItemSelectorViewDisplayContext)request.getAttribute(
BaseLayoutsItemSelectorView.LAYOUT_ITEM_SELECTOR_VIEW_DISPLAY_CONTEXT);

LayoutItemSelectorCriterion layoutItemSelectorCriterion =
layoutItemSelectorViewDisplayContext.getLayoutItemSelectorCriterion();

Portlet portlet = PortletLocalServiceUtil.getPortletById(
company.getCompanyId(), portletDisplay.getId());
%>
```

Note that the `LayoutItemSelectorViewDisplayContext` is an optional class that contains additional information about the criteria and view, but it isn't required.

The snippet below imports a CSS file for styling and places it in the <head> of the page:

```
<liferay-util:html-top>
        <link href="<%= PortalUtil.getStaticResourceURL(
        request, application.getContextPath() + "/css/main.css",
        portlet.getTimestamp())
        %>" rel="stylesheet" type="text/css" />
</liferay-util:html-top>
```

You can learn more about using the `liferay-util` taglibs in the Using the Liferay Util Taglib tutorial.

This snippet creates the UI to display the layout entities. It uses the `liferay-layout:layouts-tree` taglib along with the Lexicon design language to create cards:

```
<div class="container-fluid-1280 layouts-selector">
        <div class="card-horizontal main-content-card">
                <div class="card-row card-row-padded">
                        <liferay-layout:layouts-tree
                                checkContentDisplayPage="<%= layoutItemSelectorCriterion.isCheckDisplayPage() %>"
                                draggableTree="<%= false %>"
                                expandFirstNode="<%= true %>"
                                groupId="<%= scopeGroupId %>"
                                portletURL="<%= layoutItemSelectorViewDisplayContext.getEditLayoutURL() %>"
                                privateLayout="<%= layoutItemSelectorViewDisplayContext.isPrivateLayout() %>"
                                rootNodeName="<%= layoutItemSelectorViewDisplayContext.getRootNodeName() %>"
                                saveState="<%= false %>"
                                selectedLayoutIds="<%= layoutItemSelectorViewDisplayContext.getSelectedLayoutIds() %>"
                                selPlid="<%= layoutItemSelectorViewDisplayContext.getSelPlid() %>"
                                treeId="treeContainer"
                        />
                </div>
        </div>
</div>
```

The configuration above renders the UI shown in the figure below:

This portion of the `aui:script` returns the path for the page:

```
<aui:script use="aui-base">
        var LString = A.Lang.String;

        var getChosenPagePath = function(node) {
                var buffer = [];

                if (A.instanceOf(node, A.TreeNode)) {
                        var labelText = LString.escapeHTML(node.get('labelEl').text());

                        buffer.push(labelText);

                        node.eachParent(
                                function(treeNode) {
```

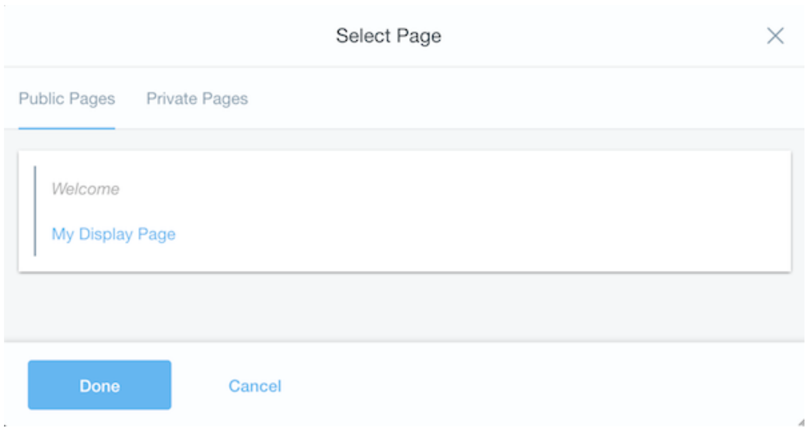


Figure 91.5: The Layouts Item Selector view uses Lexicon and Liferay Layout taglibs to create the UI.

```
                                var labelEl = treeNode.get('labelEl');

                                if (labelEl) {
                                        labelText = LString.escapeHTML(labelEl.text());

                                        buffer.unshift(labelText);
                                }
                        }
                );
        }

        return buffer.join(' > ');
};
```

The snippet below passes the return type data when the layout(entity) is selected. In particular, take note of the `url` and `uuid` variables, which retrieve the URL or UUID for the layout:

```
var setSelectedPage = function(event) {
        var disabled = true;

        var messageText = '<%= UnicodeLanguageUtil.get(request, "there-is-no-selected-page") %>';

        var lastSelectedNode = event.newVal;

        var labelEl = lastSelectedNode.get('labelEl');

        var link = labelEl.one('a');

        var url = link.attr('data-url');
        var uuid = link.attr('data-uuid');

        var data = {};

        if (link && url) {
                disabled = false;

                data.layoutpath = getChosenPagePath(lastSelectedNode);
```

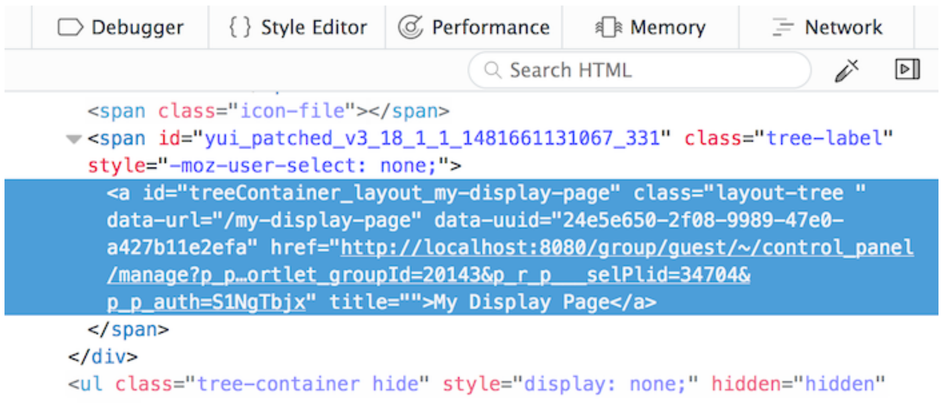
This checks if the return type information is a URL or a UUID; then it sets the value for the JSON object's data attribute accordingly:

```
                <c:choose>
                        <c:when test="<%= Objects.equals(layoutItemSelectorViewDisplayContext.getItemSelectorReturnTypeName(), URLItemSelectorReturn
                                data.value = url;
```

```
                    </c:when>
                    <c:when test="<%= Objects.equals(layoutItemSelectorViewDisplayContext.getItemSelectorReturnTypeName(), UUIDItemSelectorRetur
                            data.value = uuid;
                    </c:when>
                </c:choose>
            }

            <c:if test="<%= Validator.isNotNull(layoutItemSelectorViewDisplayContext.getCkEditorFuncNum()) %>">
                data.ckeditorfuncnum: <%= layoutItemSelectorViewDisplayContext.getCkEditorFuncNum() %>;
            </c:if>
```

The data-url and data-uuid attributes are in the HTML markup for the Layouts Item Selector. The HTML markup for an instance of the Layouts Item Selector is shown below:



```
<span class="icon-file"></span>
<span id="yui_patched_v3_18_1_1_1481661131067_331" class="tree-label"
style="-moz-user-select: none;">
  <a id="treeContainer_layout_my-display-page" class="layout-tree "
  data-url="/my-display-page" data-uuid="24e5e650-2f08-9989-47e0-
  a427b11e2efa" href="http://localhost:8080/group/guest/~/control_panel
  /manage?p_p…ortlet_groupId=20143&p_r_p___selPlid=34704&
  p_p_auth=S1NgTbjx" title="">My Display Page</a>
</span>
</div>
<ul class="tree-container hide" style="display: none;" hidden="hidden"
```

Figure 91.6: The URL and UUID can be seen in the data-url and data-uuid attributes of the Layout Item Selector's HTML markup.

The last line adds the CKEditorFuncNum for the editor to the JSON object's data attribute.

The JavaScript trigger event, specified in the Item Selector return type, is fired, passing the data JSON object with the required return type information:

```
            Liferay.Util.getOpener().Liferay.fire(
                '<%= layoutItemSelectorViewDisplayContext.getItemSelectedEventName() %>',
                {
                    data: data
                }
            );
        };
```

Finally, the layout is set to the selected page:

```
        var container = A.one('#<portlet:namespace />treeContainerOutput');

        if (container) {
            container.swallowEvent('click', true);

            var tree = container.getData('tree-view');

            tree.after('lastSelectedChange', setSelectedPage);
        }
</aui:script>
```

Your new selection view is automatically rendered by the Item Selector in every portlet that uses the criterion and return types you defined, without modifying anything in those portlets.

Now you know how to create custom views for the Item Selector!

CHAPTER 92

ADAPTIVE MEDIA

The Adaptive Media app on Liferay Marketplace lets administrators tailor the quality of images in Liferay DXP to the device viewing those images. For information on using this app, see the Adaptive Media user guide.

But what if you want to leverage Adaptive Media in your own app? Then you're in the right place! The tutorials in this section explain how to use adapted images in your app. You'll also learn how to change Adaptive Media's image processing.

Onwards!

92.1 Displaying Adapted Images in Your App

To display adapted images in your apps, Adaptive Media offers a convenient taglib in the module `com.liferay.adaptive.media.image.taglib`. This taglib only has one mandatory attribute: `fileVersion`. This attribute indicates the file version of the adapted image that you want to display. You can also add as many attributes as needed, such as `class`, `style`, `data-sample`, and so on. Any attributes you add are then added to the adapted images in the markup the taglib renders.

This tutorial uses the Adaptive Media Samples app to show you how to use this taglib. When added to a page, this app displays all the adapted images from the current site's Documents and Media app, provided that Adaptive Media image resolutions and Documents and Media images exist.

Follow these steps to use the taglib:

1. Include the module taglib dependency in your project. If you're using Gradle, for example, you must add the following line in your project's `build.gradle` file:

   ```
   provided group: "com.liferay", name: "com.liferay.adaptive.media.image.taglib", version: "1.0.0"
   ```

   For example, the Adaptive Media Samples app's `build.gradle` file contains this taglib.

2. Declare the taglib in your JSP:

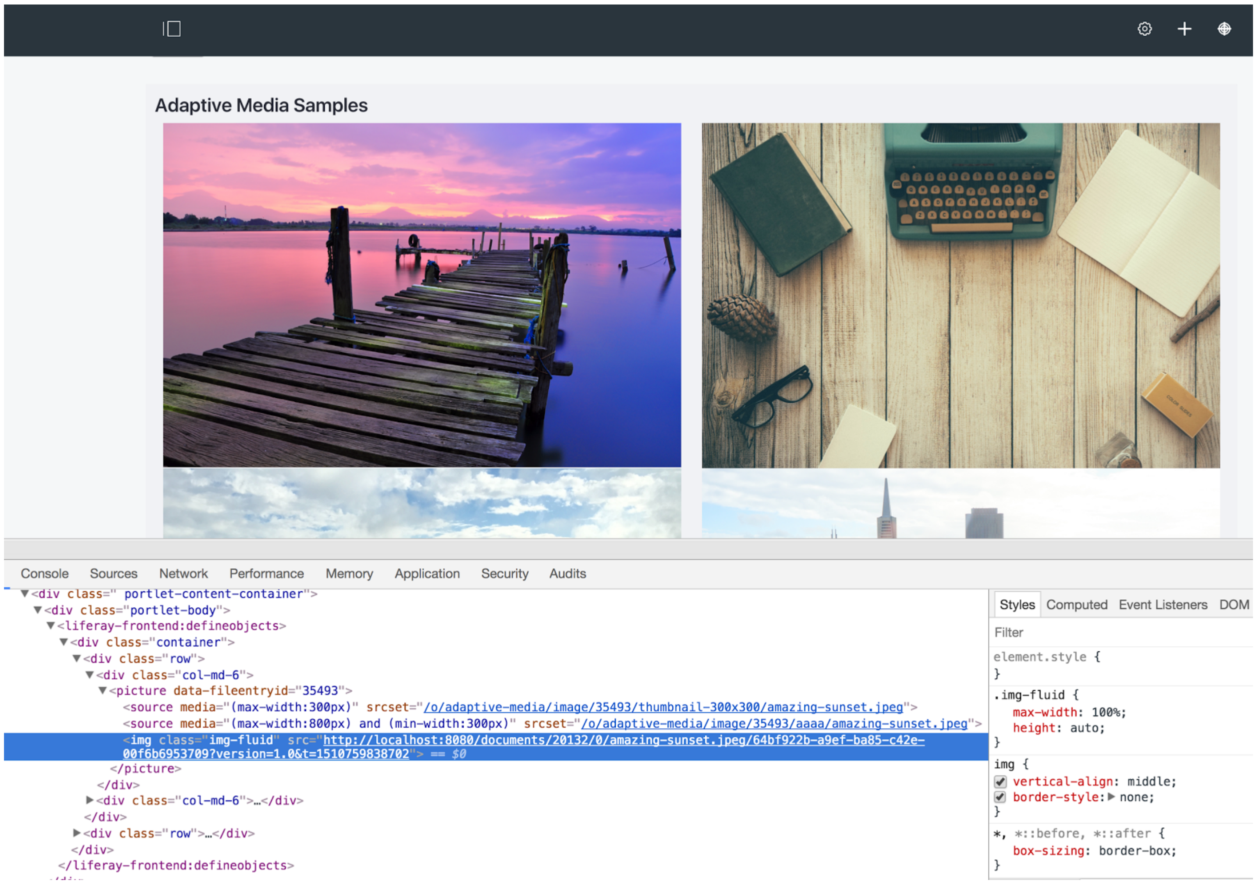
   ```
   <%@ taglib uri="http://liferay.com/tld/adaptive-media-image" prefix="liferay-adaptive-media" %>
   ```

   For example, the Adaptive Media Samples app's `init.jsp` declares all the taglibs the app needs.

3. Use the taglib wherever you want the adapted image to appear in your app's JSP files:

```
<liferay-adaptive-media:img class="img-fluid" fileVersion="<%= fileEntry.getFileVersion() %>" />
```

For example, the Adaptive Media Samples app's `view.jsp` uses the taglib to display the adapted images in a grid with the `col-md-6` column container class. Looking at the markup the app generates, you can see that it uses the `<picture>` tag as described in the article Creating Content with Adapted Images.



```
▼<div class=" portlet-content-container">
  ▼<div class="portlet-body">
    ▼<liferay-frontend:defineobjects>
      ▼<div class="container">
        ▼<div class="row">
          ▼<div class="col-md-6">
            ▼<picture data-fileentryid="35493">
                <source media="(max-width:300px)" srcset="/o/adaptive-media/image/35493/thumbnail-300x300/amazing-sunset.jpeg">
                <source media="(max-width:800px) and (min-width:300px)" srcset="/o/adaptive-media/image/35493/aaaa/amazing-sunset.jpeg">
                <img class="img-fluid" src="http://localhost:8080/documents/20132/0/amazing-sunset.jpeg/64bf922b-a9ef-ba85-c42e-
                00f6b6953709?version=1.0&t=1510759838702"> == $0
              </picture>
            </div>
          ▶<div class="col-md-6">…</div>
          </div>
        ▶<div class="row">…</div>
        </div>
      </liferay-frontend:defineobjects>
```

```
element.style {
}
.img-fluid {
   max-width: 100%;
   height: auto;
}
img {
✓ vertical-align: middle;
✓ border-style:▶ none;
}
*, *::before, *::after {
   box-sizing: border-box;
}
```

Figure 92.1: The Adaptive Media Samples app shows all the site's adapted images.

Well done! Now you know how to display adapted images in your app.

Finding Adapted Images

Changing Adaptive Media's Image Processing

Adapting Your Media Across Multiple Devices

92.2 Finding Adapted Images

In most cases, you can rely on the Adaptive Media taglib to display adapted images in your app. This taglib uses the file version you give it to query Adaptive Media's finder API and display the adapted image appropriate for the device making the request. If you need more control, however, you can write your own query with the API instead of using the taglib. For example, if you have an app that needs a specific image in a specific dimension, it's best to query Adaptive Media's finder API directly. You can then display the image however you like (e.g., with an HTML `<img>` tag).

Adaptive Media's finder API lets you write queries that get adapted images based on certain search criteria and filters. For example, you can get adapted images that match a file version or resolution, or are ordered by an attribute like image width. You can even get adapted images that match approximate attribute values (*fuzzy* attributes).

This tutorial shows you how to call Adaptive Media's API to get adapted images in your app. First, you'll learn how to construct such API calls.

Calling Adaptive Media's API

The entry point to Adaptive Media's API is the `AMImageFinder` interface. To use it, you must first inject the OSGi component in your class, which must also be an OSGi component, as follows:

```
@Reference
private AMImageFinder _amImageFinder;
```

This makes an `AMImageFinder` instance available. It has one method, `getAdaptiveMediaStream`, that returns a stream of `AdaptiveMedia` objects. This method takes a `Function` that creates an `AMQuery` (the query for adapted images) via `AMImageQueryBuilder`, which can search adapted images based on different attributes (e.g., width, height, order, etc.). The `AMImageQueryBuilder` methods you call depend on the exact query you want to construct.

For example, here's a general `getAdaptiveMediaStream` call:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.methodToCall(arg).done());
```

The argument to `getAdaptiveMediaStream` is a lambda expression that returns an `AMQuery` constructed via `AMImageQueryBuilder`. Note that `methodToCall(arg)` is a placeholder for the `AMImageQueryBuilder` method you want to call and its argument. The exact call depends on the criteria you want to use to select adapted images. The `done()` call that follows this, however, isn't a placeholder–it creates and returns the `AMQuery` regardless of which `AMImageQueryBuilder` methods you call.

For more information on creating `AMQuery` instances, see the Javadoc for `AMImageQueryBuilder`.

Next, you'll see specific examples of constructing calls that get adapted images.

Getting Adapted Images for a Specific File Version

To get adapted images for a specific file version, you must call the `AMImageQueryBuilder` method `forFileVersion` with a `FileVersion` object as an argument:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(fileVersion).done());
```

To get the adapted images for the latest approved file version, use the `forFileEntry` method with a `FileEntry` object:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileEntry(fileEntry).done());
```

Note that these calls only return the adapted images for enabled image resolutions. Adapted images for disabled resolutions aren't included in the stream. To retrieve all adapted images regardless of any image resolution's status, you must also call the withConfigurationStatus method with the constant AMImageQueryBuilder.ConfigurationStatus.ANY:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(fileVersion)
            .withConfigurationStatus(AMImageQueryBuilder.ConfigurationStatus.ANY).done());
```

To get adapted images for a specific file version when the image resolution is disabled, make the same call but instead use the constant AMImageQueryBuilder.ConfigurationStatus.DISABLED:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(fileVersion)
            .withConfigurationStatus(AMImageQueryBuilder.ConfigurationStatus.DISABLED).done());
```

Next, you'll learn how to get adapted images for a specific image resolution.

Getting the Adapted Images for a Specific Image Resolution

By providing an image resolution's UUID to AMImageFinder, you can get that resolution's adapted images. This UUID is defined when adding the resolution in the Adaptive Media app. To get a resolution's adapted images, you must pass that resolution's UUID to the forConfiguration method.

For example, this code gets the adapted images that match a file version, and belong to an image resolution with the UUID hd-resolution. It returns the adapted images regardless of whether the resolution is enabled or disabled:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinder.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(fileVersion)
            .forConfiguration("hd-resolution").done());
```

Next, you'll learn how to return adapted images in a specific order.

Getting Adapted Images in a Specific Order

It's also possible to define the order in which getAdaptiveMediaStream returns adapted images. To do this, call the orderBy method with your sort criteria just before calling the done() method. The orderBy method takes two arguments: the first specifies the image attribute to sort by (e.g., width/height), while the second specifies the sort order (e.g., ascending/descending).

For example, this code gets all the adapted images regardless of whether the image resolution is enabled, and puts them in ascending order by the image width:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinderImpl.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(_fileVersion)
            .withConfigurationStatus(AMImageQueryBuilder.ConfigurationStatus.ANY)
            .orderBy(AMImageAttribute.AM_IMAGE_ATTRIBUTE_WIDTH, AMImageQueryBuilder.SortOrder.ASC)
            .done());
```

The orderBy arguments AMImageAttribute.AM_IMAGE_ATTRIBUTE_WIDTH and AMImageQueryBuilder.SortOrder.ASC specify the image width and ascending sort, respectively. You can alternatively use AMImageAttribute.AM_IMAGE_ATTRIBUTE_HEIG to sort by image height, and AMImageQueryBuilder.SortOrder.DESC to perform a descending sort.

Next, you'll learn how to specify approximate attribute values when getting adapted images.

Getting Adapted Images with Fuzzy Attributes

Adaptive Media also lets you get adapted images that match *fuzzy attributes* (approximate attribute values). For example, fuzzy attributes let you ask for adapted images whose height is around 200px, or whose size is around 100kb. The API returns a stream with elements ordered by how close they are to the specified attribute. For example, imagine that there are four image resolutions that have adapted images with the heights 150px, 350px, 600px, and 900px. Searching for adapted images whose height is approximately 400px returns this order in the stream: 350px, 600px, 150px, 900px.

So how close, exactly, is *close*? It depends on the attribute. In the case of width, height, and length, a numeric comparison orders the images. In the case of content type, file name, or UUID, the comparison is more tricky because these attributes are strings and thus delegated to the Java `String.compareTo` method.

To specify a fuzzy attribute, call the `with` method with your search criteria just before calling the `done()` method. The `with` method takes two arguments: the image attribute, and that attribute's approximate value. For example, this code gets adapted images whose height (`AMImageAttribute.AM_IMAGE_ATTRIBUTE_HEIGHT`) is approximately 400px:

```
Stream<AdaptiveMedia<AMImageProcessor>> adaptiveMediaStream =
    _amImageFinderImpl.getAdaptiveMediaStream(
        amImageQueryBuilder -> amImageQueryBuilder.forFileVersion(_fileVersion)
            .with(AMImageAttribute.AM_IMAGE_ATTRIBUTE_HEIGHT, 400).done());
```

To search for image width instead, use `AMImageAttribute.AM_IMAGE_ATTRIBUTE_WIDTH` as the first argument to the `width` method.

Using the Adaptive Media Stream

Once you have the `AdaptiveMedia` stream, you can get the information you need from it. For example, this code prints the URI for each adapted image:

```
adaptiveMediaStream.forEach(
    adaptiveMedia -> {
        System.out.println(adaptiveMedia.getURI());
    }
);
```

You can also get other values and attributes from the `AdaptiveMedia` stream. Here are a few examples:

```
// Get the InputStream
adaptiveMedia.getInputStream()

// Get the content length
adaptiveMedia.getValueOptional(AMAttribute.getContentLengthAMAttribute())

// Get the image height
adaptiveMedia.getValueOptional(AMImageAttribute.AM_IMAGE_ATTRIBUTE_HEIGHT)
```

Awesome! Now you know how to find and use adapted images.

Changing Adaptive Media's Image Processing

Adapting Your Media Across Multiple Devices

92.3 Changing Adaptive Media's Image Scaling

As described in the Adaptive Media user guide, Adaptive Media scales images to match the image resolutions defined by the Liferay DXP administrator. The default scaling is usually suitable, but you can also customize it to your needs. Before doing so, however, you should understand how this scaling works.

Understanding Image Scaling in Adaptive Media

Adaptive Media contains an extension point that lets you replace the way it scales images. The `AMImageScaler` interface defines Adaptive Media's image scaling logic. Out of the box, Adaptive Media provides two implementations of this interface:

- `AMDefaultImageScaler`: The default image scaler. It's always enabled and uses `java.awt` for its image processing and scaling.
- `AMGIFImageScaler`: A scaler that works only with GIF images. It depends on the installation of the external tool gifsicle in the Liferay DXP instance. This scaler must be enabled in *Control Panel → System Settings*.

You must register image scalers in Liferay DXP's OSGi container using the `AMImageScaler` interface. Each scaler must also set the `mime.type` property to the MIME type it handles. For example, if you set a scaler's MIME type to `image/jpeg`, then that scaler can only handle `image/jpeg` images. If you specify the special MIME type `*`, the scaler can process any image. Note that the `AMDefaultImageScaler` is registered using `mime.type=*`, while the `AMGIFImageScaler` is registered using `mime.type=image/gif`. Both scalers, like all scalers, implement `AMImageScaler`.

You can add as many image scalers as you need, even for the same MIME type. Even so, Adaptive Media uses only one scaler per image, using this process to determine the best one:

1. Select only the image scalers registered with the same MIME type as the image.
2. Select the enabled scalers from those selected in the first step (the `AMImageScaler` method `isEnabled()` returns `true` for enabled scalers).
3. Of the scalers selected in the second step, select the scaler with the highest `service.ranking`.

If these steps return no results, they're repeated, but the first step uses the special MIME type `*`. Also note that if an image scaler is registered for specific MIME types and has a higher `service.ranking`, it's more likely to be chosen than if it's registered for the special MIME type `*` or has a lower `service.ranking`.

Creating an Image Scaler

Now that you know how Adaptive Media scales images, you'll learn how to customize this scaling. As an example, you'll see a sample image scaler that customizes the scaling of PNG images.

Follow these steps to create a custom image scaler:

1. Create your scaler class to implement `AMImageScaler`. You must also annotate your scaler class with `@Component`, setting `mime.type` properties for each of the scaler's MIME types, and registering an `AMImageScaler` service. If there's more than one scaler for the same MIME type, you must also set the `@Component` annotation's `service.ranking` property. For your scaler to take precedence over other scalers of the same MIME type, its service ranking property must be higher than that of the other scalers. If `service.ranking` isn't set, it defaults to `0`.

```
**Note:** The `service.ranking` property isn't set for the image scalers
included with Adaptive Media (`AMDefaultImageScaler` and
`AMGIFImageScaler`). Their service ranking therefore defaults to `0`. To
replace either scaler, you must set your scaler to the same MIME type and
give it a service ranking higher than `0`.
```

```
For example, this sample image scaler scales PNG and x-PNG images, and has a
service ranking of `100`:

    @Component(
        immediate = true,
        property = {"mime.type=image/png", "mime.type=image/x-png", "service.ranking:Integer=100"},
        service = {AMImageScaler.class}
    )
    public class SampleAMPNGImageScaler implements AMImageScaler {...

This requires these imports:

    import com.liferay.adaptive.media.image.scaler.AMImageScaler;
    import org.osgi.service.component.annotations.Component;
```

2. Implement the `isEnabled()` method to return true when you want to enable the scaler. In many cases, you always want the scaler enabled, so you can simply return true in this method. This is the case with the example `SampleAMPNGImageScaler`:

   ```
   @Override
   public boolean isEnabled() {
       return true;
   }
   ```

   This method gets more interesting when the scaler depends on other tools or features. For example, the `isEnabled()` method in `AMGIFImageScaler` determines whether gifsicle is enabled. This scaler must only be enabled when the tool it depends on, gifsicle, is also enabled:

   ```
   @Override
   public boolean isEnabled() {
       return _amImageConfiguration.gifsicleEnabled();
   }
   ```

3. Implement the `scaleImage` method. This method contains the scaler's business logic, and must return an `AMImageScaledImage` instance. For example, the example `scaleImage` implementation in `SampleAMPNGImageScaler` uses `AMImageConfigurationEntry` to get the maximum height and width values for the scaled image, and `FileVersion` to get the image to scale. The scaling is done with the help of a private inner class, assuming that the methods `_scalePNG`, `_getScalePNGHeight`, `_getScalePNGWidth`, and `_getScalePNGSize` implement the actual scaling:

   ```
   @Override
   public AMImageScaledImage scaleImage(FileVersion fileVersion,
       AMImageConfigurationEntry amImageConfigurationEntry) {

       Map<String, String> properties = amImageConfigurationEntry.getProperties();

       int maxHeight = GetterUtil.getInteger(properties.get("max-height"));
       int maxWidth = GetterUtil.getInteger(properties.get("max-width"));
   ```

```
        try {
            InputStream inputStream =
                _scalePNG(fileVersion.getContentStream(false), maxHeight, maxWidth);

            int height = _getScalePNGHeight();
            int width = _getScalePNGWidth();
            long size = _getScalePNGSize();

            return new AMImageScaledImageImpl(inputStream, height, width, size);
        }
        catch (PortalException pe) {
            throw new AMRuntimeException.IOException(pe);
        }
    }

    private class AMImageScaledImageImpl implements AMImageScaledImage {

        @Override
        public int getHeight() {
            return _height;
        }

        @Override
        public InputStream getInputStream() {
            return _inputStream;
        }

        @Override
        public long getSize() {
            return _size;
        }

        @Override
        public int getWidth() {
            return _width;
        }

        private AMImageScaledImageImpl(InputStream inputStream, int height,
            int width, long size) {

            _inputStream = inputStream;
            _height = height;
            _width = width;
            _size = size;
        }

        private final int _height;
        private final InputStream _inputStream;
        private final long _size;
        private final int _width;

    }
```

This requires these imports:

```
import com.liferay.adaptive.media.exception.AMRuntimeException;
import com.liferay.adaptive.media.image.configuration.AMImageConfigurationEntry;
import com.liferay.adaptive.media.image.scaler.AMImageScaledImage;
import com.liferay.portal.kernel.exception.PortalException;
import com.liferay.portal.kernel.repository.model.FileVersion;
import com.liferay.portal.kernel.util.GetterUtil;
import java.io.InputStream;
import java.util.Map;
```

Great! Now you know how to write your own image scalers.

Chapter 93

Liferay Forms

Many modern websites rely on forms for their functionality. Liferay's Forms application is maturing rapidly, offering rich out-of-the-box functionality. Many use cases, from the simplest to the most complex, can be met using the Forms application as it is. However, why not make the application behave exactly as you'd like it to? Just because something is good, doesn't mean it's perfect for your specific use case. Liferay's Forms solution can be adapted to your specific needs. You can even develop forms using its API.

In this section, learn to extend the Forms application's functionality and leverage its APIs.

- Build your own field types for Liferay's Forms application.
  - Create field types that look just like the built-in field types (both their source code and their UI appearance).
  - Add custom configuration options to your form field types.
- Use annotations to leverage the Dynamic Data Mapping (DDM) API and build reusable forms quickly.
  - Create forms using annotations.
  - Create fields and reusable fieldsets using annotations.
  - Configure form rules using annotations.

Chapter 94

Form Field Types

The Forms application contains many highly configurable field types out-of-the-box. Most use cases will be met with one of the existing field types.

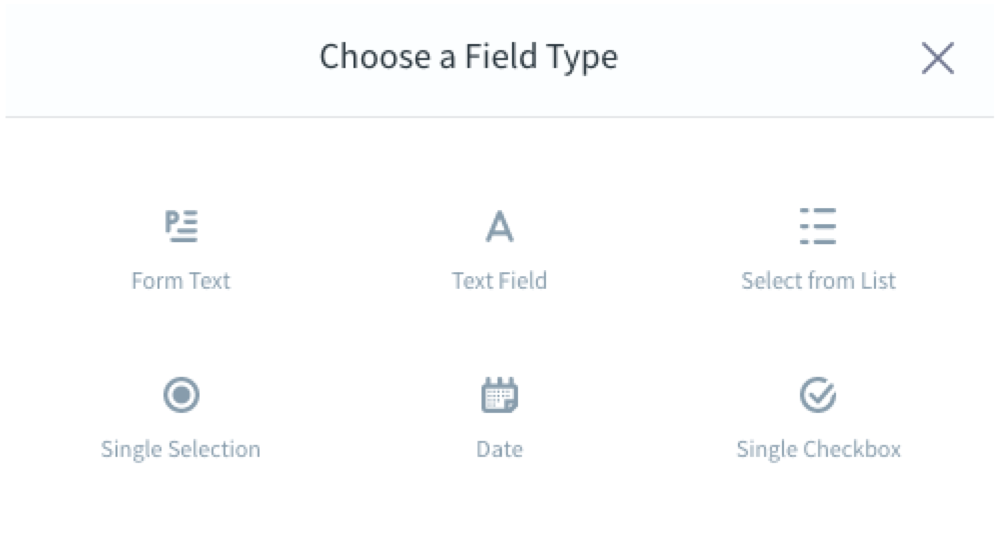

Figure 94.1: The Forms application has useful out-of-the-box field types, but you can add your own if you need to.

If you're reading this, however, your use case probably wasn't met with the default field types. For example, perhaps you need a color picker field. You could create a select field that lists the color options, but some users don't know that *gamboge* is the color of spicy mustard (maybe a little darker), and anyway, seeing colors is much more interesting than listing them. Another example is a dedicated *time* field. You can use a text field and add a tip to tell users something like *enter the time in the format hour*`:minute`, but some users will still enter something indecipherable, like *8:88*. Instead, add a *time* field to Liferay DXP's Forms application. You can think of other uses where it's best to break free of the mold of existing field types and create your own that serve your needs best. Keep reading to find out how.

In these tutorials, learn to

- create a module that adds a *Time* form field type with a timepicker
- add custom configuration options to your field types

Example project: The source code for the example *time* project developed in these tutorials can be downloaded for your convenience. Click here to begin downloading the source code zip file.

Before getting started, learn what Liferay DXP's field types consist of.

94.1 Anatomy of a Field Type Module

The `dynamic-data-mapping-type-*` modules in Liferay DXP's source code (inside the *Forms and Workflow* application suite) are good templates to follow when developing your own field types. For example, look at the directory structure of the `dynamic-data-mapping-type-paragraph` module (version 2.0.7) in the Forms and Workflow application suite:

```
bnd.bnd
build.gradle
src
└── main
    ├── java
    │   └── com
    │       └── liferay
    │           └── dynamic
    │               └── data
    │                   └── mapping
    │                       └── type
    │                           └── paragraph
    │                               └── internal
    │                                   ├── ParagraphDDMFormFieldRenderer.java
    │                                   ├── ParagraphDDMFormFieldType.java
    │                                   └── ParagraphDDMFormFieldTypeSettings.java
    └── resources
        ├── content
        │   ├── Language.properties
        │   └── Language_xx_XX.properties
        │   └── ...
        └── META-INF
            └── resources
                ├── config.js
                ├── paragraph_field.js
                ├── paragraph.soy
                └── paragraph.soy.js
```

Custom field type modules are nearly identical in structure to those included in Liferay DXP, as presented above. You won't need a `*TypeSettings` class in your initial module (see the tutorial on adding settings to your form field types to learn more about `*TypeSettings`), and the `*.soy.js` is generated from the `*.soy` file at compile time. These are the Java classes and resources you'll need to create:

- `*DDMFormFieldRenderer.java`: Controls the rendering of the template. Sets the language, declares the namespace, and loads the template resources on activation of the Component. Extending the abstract class that implements the `DDMFormFieldRenderer` makes your work here easier.
- `*DDMFormFieldType.java`: Define the form field type in the backend. If you extend the abstract class that implements the interface, you automatically include the default form configuration options for your form field type. In that case, override the interface's `getName` method and you're done. To see the default configuration options your form field type will inherit, look at the `DefaultDDMFormFieldTypeSettings` class in the `dynamic-data-mapping-form-field-type` module.
- `config.js`: Autogenerated if you use Blade CLI, `config.js` defines the dependencies of all declared JavaScript components.

- `[name-of-field-type]_field.js`: The JavaScript file that models your field.
- `[name-of-field-type].soy`: The template that defines the appearance of the field.
- `Language_xx.properties`: Define any terms that need to be translated into different languages.

In addition to the Java classes, Soy templates, and JavaScript files, Liferay DXP applications contain a `bnd.bnd` file to manage the module's metadata, and a `build.gradle` file to manage its dependencies and build properties. This example follows those patterns.

94.2 Creating Form Field Types

Liferay's Forms application does not contain a dedicated time field out-of-the-box. For ease of use and to ensure proper data is collected, you can develop a time field and learn how Liferay DXP's field types work at the same time.

There are several steps involved in creating a form field type:

1. Specify the OSGi metadata
2. Configure your build script and dependencies
3. Create a `DDMFormFieldType` component
4. Implement a `DDMFormFieldType`
5. Render the field type

Note: To avoid manually creating your own project, use BladeCLI. If you have Blade CLI on your machine, there's a template for creating form fields you can leverage using the following command syntax:

```
blade create -t form-field [ADDITIONAL OPTIONS] [PROJECT NAME]
```

See the BladeCLI documentation for more information, such as the answer to yuor question, What are those additional options?"

Using Blade CLI, you get a project skeleton with much of the boilerplate filled in, and you can focus on coding without delay.

Start by setting up the project's metadata.

Specifying OSGi Metadata

First specify the necessary OSGi metadata in a `bnd.bnd` file (see here for more information). Here's what it would look like for a module in a folder called `dynamic-data-mapping-type-time`:

```
Bundle-Name: Liferay Dynamic Data Mapping Type Time
Bundle-SymbolicName: com.liferay.dynamic.data.mapping.type.time
Bundle-Version: 1.0.0
Liferay-JS-Config: /META-INF/resources/config.js
Web-ContextPath: /dynamic-data-mapping-type-time
```

First name the bundle with a reader-friendly `Bundle-Name` and a unique `Bundle-SymbolicName` (it's common to use the root package of your module's Java classes), then set the version. Point to the JavaScript configuration file (`config.js`) that defines JavaScript modules added by your module (you'll get to that later), and set the Web Context Path so your module's resources are made available upon module activation.

Next add your dependencies to a `build.gradle` file.

Specifying Dependencies

If you're using Gradle to manage your dependencies (as Liferay DXP modules do), add this to your `build.gradle` file:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins", version: "3.0.23"
    }

    repositories {
        mavenLocal()

        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.plugin"

dependencies {
    compile group: "com.liferay", name: "com.liferay.dynamic.data.mapping.api", version: "3.2.0"
    compile group: "com.liferay", name: "com.liferay.dynamic.data.mapping.form.field.type", version: "2.0.5"
    compile group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "org.osgi", name: "org.osgi.compendium", version: "5.0.0"
}

repositories {
    mavenLocal()

    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}

classes {
    dependsOn buildSoy
}

transpileJS {
    soySrcIncludes = ""
    srcIncludes = "**/*.es.js"
}

wrapSoyAlloyTemplate {
    enabled = true
    moduleName = "liferay-ddm-form-field-time-template"
    namespace = "ddm"
}
```

Along with the regular Java `dependencies`, there's some JavaScript dependency configuration you need to include here. It's all boilerplate and can be copied directly into your module's `build.gradle` if you follow the conventions presented here.

Next craft the OSGi Component that marks your class as an implementation of `DDMFormFieldType`.

Creating a DDMFormFieldType Component

If you're creating a *Time* field type, define the Component at the top of your `*DDMFormFieldType` class like this:

```
@Component(
  immediate = true,
  property = {
    "ddm.form.field.type.display.order:Integer=8",
    "ddm.form.field.type.icon=star-o",
    "ddm.form.field.type.js.class.name=Liferay.DDM.Field.Time",
    "ddm.form.field.type.js.module=liferay-ddm-form-field-time",
    "ddm.form.field.type.label=time-field-type-label",
    "ddm.form.field.type.name=time"
  },
  service = DDMFormFieldType.class
)
```

Define the field type's properties (`property=...`) and declare that you're implementing the `DDMFormFieldType` service (`service=...`).

`DDMFormFieldType` Components can have several properties:

`ddm.form.field.type.display.order` Integer that defines the field type's position in the *Choose a Field Type* dialog of the form builder.

`ddm.form.field.type.icon` The icon to be used for the field type. Choosing one of the Lexicon icons makes your form field blends in with the existing form field types.

`ddm.form.field.type.js.class.name` The field type's JavaScript class name–the JavaScript file is used to define the field type's behavior.

`ddm.form.field.type.js.module` The name of the JavaScript module–provided to the Form engine so the module can be loaded when needed.

`ddm.form.field.type.label` The field type's label. Its localized value appears in the *Choose a Field Type* dialog.

`ddm.form.field.type.name` The field type's name must be unique. Each Component in a field type module references the field type name, and it's used by OSGi service trackers to filter the field's capabilities (for example, rendering and validation).

Next code the *`DDMFormFieldType` class.

Implementing DDMFormFieldType

Implementing the field type in Java is made easier because of `BaseDDMFormFieldType`, an abstract class you can leverage in your code.

After extending `BaseDDMFormFieldType`, override the `getName` method by specifying the name of your new field type:

```
public class TimeDDMFormFieldType extends BaseDDMFormFieldType {
    @Override
    public String getName() {
        return "time";
    }
}
```

That's all there is to defining the field type. Next determine how your field type is rendered.

Rendering Field Types

Before you get to the frontend coding necessary to render your field type, there's another Component to define and a Java class to code.

The Component only has one property, `ddm.form.field.type.name`, and then you declare that you're adding a `DDMFormFieldRenderer` implementation to the OSGi framework:

```
@Component(
    immediate = true,
    property = "ddm.form.field.type.name=time",
    service = DDMFormFieldRenderer.class
)
```

There's another abstract class to leverage, this time `BaseDDMFormFieldRenderer`. It gives you a default implementation of the `render` method, the only required method for implementing the API. The form engine calls the render method for every form field type present in a form, and returns the plain HMTL of the rendered field type. The abstract implementation also includes some utility methods. Here's what the time field's `DDMFormFieldRenderer` looks like:

```
public class TimeDDMFormFieldRenderer extends BaseDDMFormFieldRenderer {

    @Override
    public String getTemplateLanguage() {
        return TemplateConstants.LANG_TYPE_SOY;
    }

    @Override
    public String getTemplateNamespace() {
        return "ddm.time";
    }

    @Override
    public TemplateResource getTemplateResource() {
        return _templateResource;
    }

    @Activate
    protected void activate(Map<String, Object> properties) {
        _templateResource = getTemplateResource("/META-INF/resources/time.soy");
    }

    private TemplateResource _templateResource;

}
```

Here you're setting the templating language (Soy closure templates), the template namespace (`ddm.time`), and pointing to the location of the templates within your module (`/META-INF/resource/time.soy`).

Note: Closure templates are a templating system for building UI elements. Liferay DXP developers chose to build the Forms UI with closure templates because they enable a smooth, responsive repainting of the UI as a user enters data. With closure templates there's no need to reload the entire page from the server side when the UI is updated by the user: only the relevant portion of the page is updated from the server. This makes for a smooth user experience.

Now it's time to write the template you referenced in the renderer: `time.soy` in the case of the time field type.

Create

```
src/main/resources/META-INF/resources/time.soy
```

and populate it with these contents:

```
{namespace ddm}

/**
 * Prints the DDM form time field.
 *
 * @param label
 * @param name
 * @param readOnly
 * @param required
 * @param showLabel
 * @param tip
 * @param value
 */
{template .time autoescape="deprecated-contextual"}
    <div class="form-group liferay-ddm-form-field-time" data-fieldname="{$name}">
        {if $showLabel}
            <label class="control-label">
                {$label}

                {if $required}
                    <span class="icon-asterisk text-warning"></span>
                {/if}
            </label>

            {if $tip}
                <p class="liferay-ddm-form-field-tip">{$tip}</p>
            {/if}
        {/if}

        <input class="field form-control" id="{$name}" name="{$name}" {if $readOnly}readonly{/if} type="text" value="{$value}">
    </div>
{/template}
```

There are three important things to do in the template:

1. Define the template namespace. The template namespace allows you to define multiple templates for your field type by adding the namespace as a prefix.

   ```
   {namespace ddm}
   ```

2. Describe the template parameters. The template above uses some of the parameters as flags to display or hide some parts of the HTML (for example, the `$required` parameter). If you extend `BaseDDMFormFieldRenderer`, all the listed parameters are passed by default.

   ```
   /**
    * Prints the DDM form time field.
    *
    * @param label
    * @param name
    * @param readOnly
    * @param required
    * @param showLabel
    * @param tip
    * @param value
    */
   ```

3. Write the template logic (everything encapsulated by the `{template}...{/template}` block). In the above example the template does these things:

   - Checks whether to show the label of the field, and if so, adds it.
   - Checks if the field is required, and adds `icon-asterisk` if it is.
   - Checks if a tip is provided, and displays it.
   - Provides the markup for the time field in the <input> tag. In this case a text input field is defined.

Once you have your template defined, write the JavaScript file modeling your field. Call it `time_field.js` and give it these contents:

```
AUI.add('liferay-ddm-form-field-time', function(A) {
    var TimeField = A.Component.create({
        ATTRS : {
            type : {
                value : 'time'
            }
        },

        EXTENDS : Liferay.DDM.Renderer.Field,
        NAME : 'liferay-ddm-form-field-time',

        prototype : {}
    });

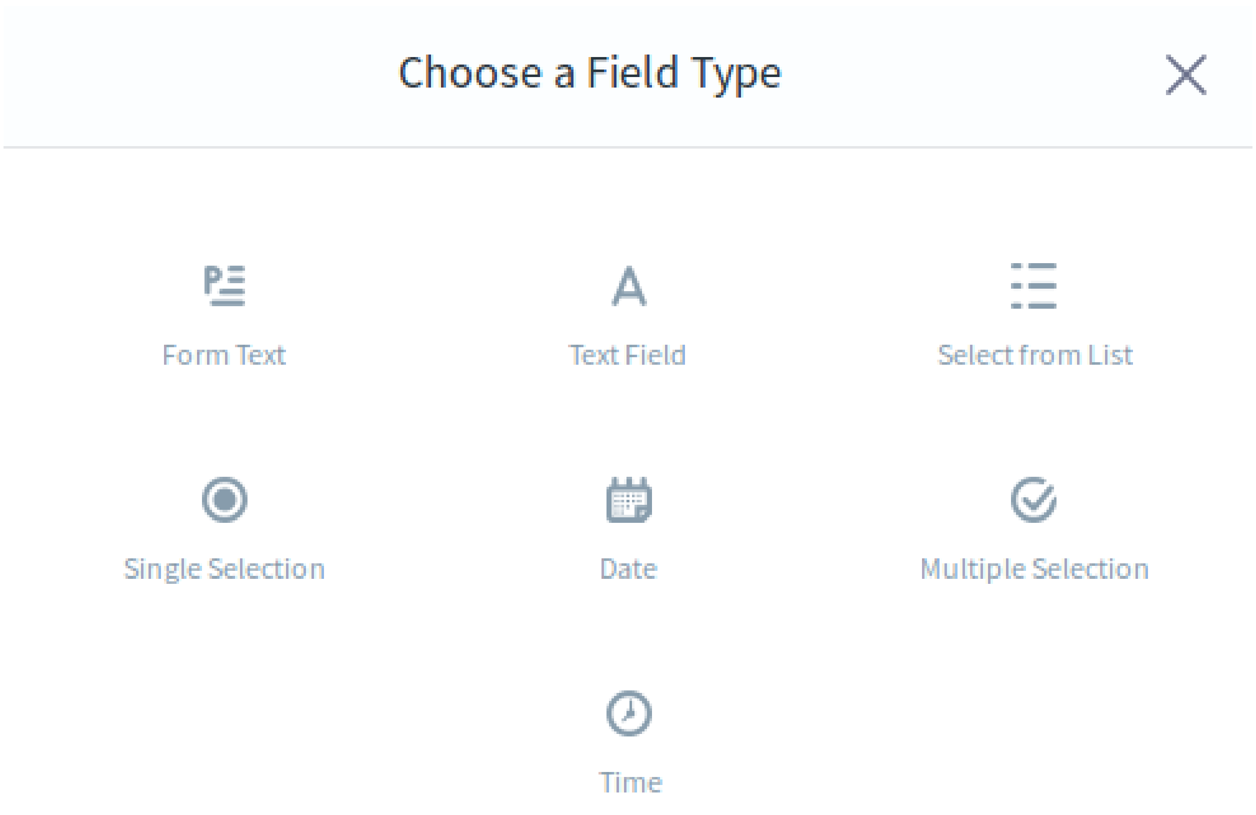
    Liferay.namespace('DDM.Field').Time = TimeField;
}, '', {
    requires : [ 'liferay-ddm-form-renderer-field' ]
});
```

The JavaScript above creates a component called `TimeField`. The component extends `Liferay.DDM.Renderer.Field`, which gives you automatic injection of the default field parameters.

All that's left to do is create the `config.js` file:

```
;
(function() {
    AUI().applyConfig({
        groups : {
            'field-time' : {
                base : MODULE_PATH + '/',
                combine : Liferay.AUI.getCombine(),
                modules : {
                    'liferay-ddm-form-field-time' : {
                        condition : {
                            trigger : 'liferay-ddm-form-renderer'
                        },
                        path : 'time_field.js',
                        requires : [ 'liferay-ddm-form-renderer-field' ]
                    },
                    'liferay-ddm-form-field-time-template' : {
                        condition : {
                            trigger : 'liferay-ddm-form-renderer'
                        },
                        path : 'time.soy.js',
                        requires : [ 'soyutils' ]
                    }
                },
                root : MODULE_PATH + '/'
            }
        }
    });
})();
```

This file is entirely boilerplate, and you'll never need anything different if you follow the conventions described above. In fact, if you use Blade CLI to generate a field type module, you won't need to modify anything in this file. So what is the `config.js` file for? It's a JavaScript file that defines the dependencies of the declared JavaScript components (`requires...`), and where the files are located (`path...`). The `config.js` is used by the Alloy loader when it satisfies dependencies for each JavaScript component. For more information about the Alloy loader see the tutorial on its usage.



[

If you build and deploy your new field type module, you'll see that you get exactly what you described in the `time.soy` file: a single text input field. Of course, that's not what you want! You need a time picker.

Adding Behavior to the Field

If you want to do more than simply provide a text input field, define the behavior in the `time_field.js` file. To add an AlloyUI timepicker, first specify that your component requires the `aui-timepicker` in the `requires...` block:

```
{
    requires: ['aui-timepicker','liferay-ddm-form-renderer-field']
}
```

Since you're now changing the default rendering of the field, overwrite the base `render` logic and instantiate the time picker. This occurs in the `prototype` block:

```
prototype: {
    render: function() {

        var instance = this;

        TimeField.superclass.render.apply(instance, arguments);

        instance._timePicker = new A.TimePicker(
            {
                trigger: instance.getInputSelector(),
                popover: {
                    zIndex: 1
            }
        }
    );
}
```

Invoke the original render method–it prints markup required by the Alloy time picker. Then instantiate the time picker, passing the field type input as a `trigger`. See the Alloy documentation for more information.

Now when the field is rendered, there's a real time picker.

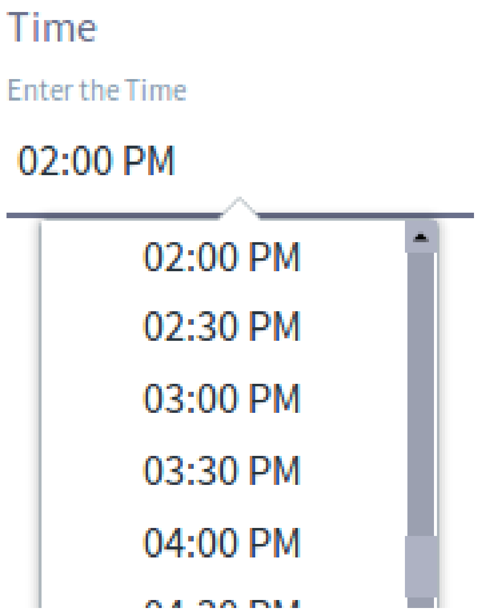


Figure 94.2: The Alloy UI Timepicker in action.

Now you know how to create a new field type and define its behavior. Currently, the field type only contains the default settings it inherits from its superclasses. If that's not sufficient, create additional settings for your field type. See the next tutorial (not yet written) to learn how.

94.3 Adding Settings to Form Field Types

Once you develop a Form Field Type, you might need to add settings to it. For example, your time field might need to be configured to accept different time formats. Here you'll learn how to add settings to form field types by adding a *mask* and a *placeholder* to the Time field type created in the previous tutorial.

Note: To learn more about using masks with the AUI Timepicker, go here. The mask just sets the format the timepicker uses to display the time choices. Use the strftime format to pick the mask you want.

To add settings to form field types, you'll use these steps:

- Write an interface that extends the default field type configuration, `DefaultDDMFormFieldTypesettings`.
- Update the `*FormFieldRenderer` so it makes the new configuration options available to the JavaScript component and/or the Soy template for rendering.
- Update the JavaScript component (defined in `time_field.js` in our example) to configure the new settings and their default values.

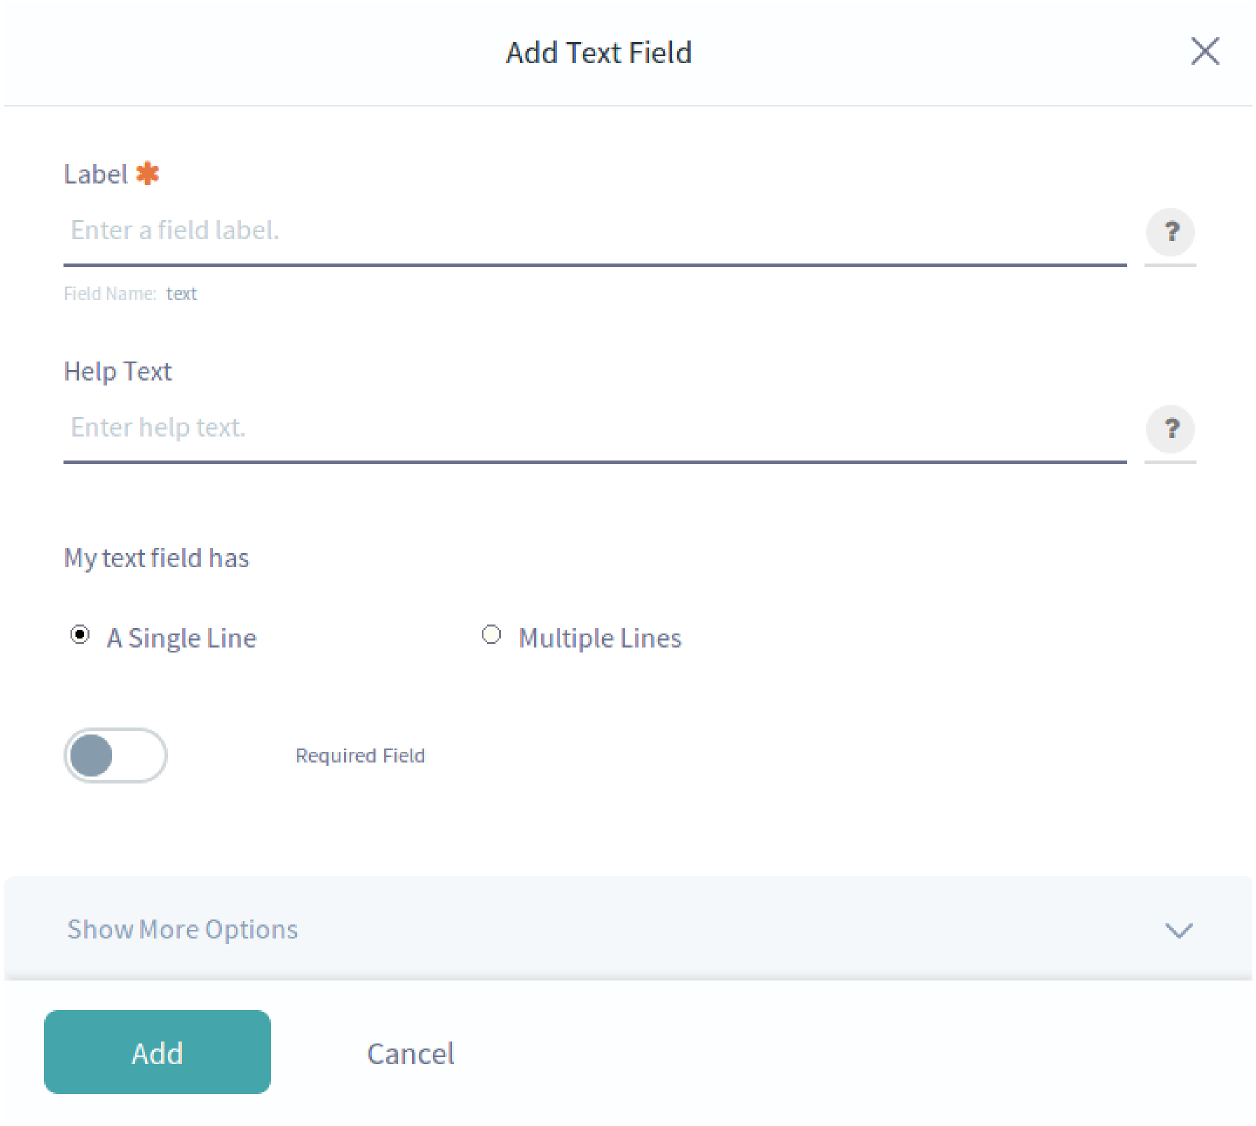
- Update the Soy template to include any settings that need to be rendered in a form (the placeholder, in our example).

Get started by crafting the interface that controls what settings your field has.

Extending the Default Type Settings

To add type settings, you need a `*TypeSettings` class that extends `DefaultDDMFormFieldTypeSettings`. Since this example works with a Time field type, call it `TimeDDMFormFieldTypeSettings`.

This class sets up the *Add [Field Type]* configuration form.



Add Text Field

Label *

Enter a field label.

Field Name: text

Help Text

Enter help text.

My text field has

[✓ A Single Line] Multiple Lines

Required Field

Figure 94.3: Like your custom field types, the text field type's settings are configured in a Java interface.

Here's what it looks like:

```
package com.liferay.docs.ddm.time;
```

```
import ...

@DDMForm
@DDMFormLayout(
    paginationMode = com.liferay.dynamic.data.mapping.model.DDMFormLayout.TABBED_MODE,
    value = {
        @DDMFormLayoutPage(
            title = "basic",
            value = {
                @DDMFormLayoutRow(
                    {
                        @DDMFormLayoutColumn(
                            size = 12,
                            value = {"label", "required", "tip", "mask", "placeholder"}
                        )
                    }
                )
            }
        ),
        @DDMFormLayoutPage(
            title = "properties",
            value = {
                @DDMFormLayoutRow(
                    {
                        @DDMFormLayoutColumn(
                            size = 12,
                            value = {
                                "predefinedValue", "visibilityExpression",
                                "fieldNamespace", "indexType", "localizable",
                                "readOnly", "dataType", "type", "name",
                                "showLabel", "repeatable"
                            }
                        )
                    }
                )
            }
        )
    }
)
public interface TimeDDMFormFieldTypeSettings
    extends DefaultDDMFormFieldTypeSettings {

    @DDMFormField(label = "%mask", predefinedValue="%I:%M %p")
    public String mask();

    @DDMFormField(label = "%placeholder")
    public String placeholder();

}
```

Would you look at that! Most of the work you need to do is in the class's annotations.

In this class you're setting up a dynamic form with all the settings your form field type needs. The form layout presented here gives your form the look and feel of a native form field type. See the note below for more information on the DDM annotations used in this form.

One thing to note is that all the default settings must be present in your settings form. Note the list of settings present for each tab (each `@DDMFormLayoutPage`) above. If you need to make one of the default settings unusable in the settings form for your field type, configure a *hide rule* for the field. Form field rules are configured using the `@DDMFormFieldRule` annotation. More information on configuring form rules will be written soon.

Your interface is extending the `DefaultDDMFormfieldTypeSettings` class. That's why the default settings are available to use in the class annotation, without setting them up in the class, as was necessary for the mask and placeholder.

DDM Annotations: The `@DDMForm` annotation on this class allows the form engine to convert the interface definition into a dynamic form. This makes it really intuitive to lay out your settings form.

For now, here are brief explanations for the annotations used in the above example:

`@DDMForm` Instantiates a new `DDMForm`. Creates a dynamic form from the annotation.

`@DDMFormLayout` Takes two variables: `paginationMode` and `value`. The pagination mode is a String that controls how the layout pages are displayed. The `pagionationMode` can be `TABBED_MODE`, `SINGLE_PAGE_MODE`, `SETTINGS_MODE`, or `WIZARD_MODE`. Under `value`, specify any `@DDMFormLayoutPages` that you want to use.

`@DDMFormLayoutPage` The sections of the type settings form. Takes two variables: `title` and `value`, where title is a String value that names the section of the form and value is one or more `@DDMFormLayoutRows`.

Note: The title of the layout pages are `basic` and `properties` for all of Liferay DXP's field types: in future versions of the Forms application, the localized value of the key you specify here will be the heading for the form section (the layout page is a section of the form). In the current version of Liferay DXP (at the time of this writing, DE DXP SP1 and CE 7.0 GA3), these are not displayed. To remain consistent with the Forms application's default fields, it's best to follow the standard approach and use `basic` and `properties`.

`@DDMFormLayoutRow` Use this to lay out the number of columns you want in the row. Most settings forms have just one row and one column.

`@DDMFormLayoutColumn` Use this to lay out the columns your settings form needs. Most settings forms have one row and one column. Each column accepts two argument, `size` and `value`.

`@DDMFormField` Use this annotation to add new fields to the settings form. In this example, the `mask` and `placeholder` settings are configured with this annotation.

Once your `*TypeSettings` class is finished, move on to update the `*Renderer` class for your form field type.

Updating the Renderer Class

To send the new configuration settings to the Soy template so they can be displayed to the end user, you need to modify the `*DDMFormFieldRenderer`.

Add this method to `TimeDDMFormFieldRenderer`:

```
@Override
protected void populateOptionalContext(
    Template template, DDMFormField ddmFormField,
    DDMFormFieldRenderingContext ddmFormFieldRenderingContext) {

    template.put(
        "placeholder", (String)ddmFormField.getProperty("placeholder"));

    template.put(
        "mask", (String)ddmFormField.getProperty("mask"));

    }
```

The `populateOptionalContext` method takes three parameters: The template object, the `DDMFormField`, and the `DDMFormFieldRenderingContext`. The `DDMFormField` represents the definition of the field type instance: you can use this object to access the configurations set for the field type (the mask and placeholder settings in our case). The `DDMFormFieldRenderingContext` object contains extra information about the form such as the user's locale, the HTTP request and response objects, the portlet namespace, and more (all of its included properties can be found here.

You're putting the new settings into the template object, which is just an extension of a Map that takes a String and an Object (in this case the Object is the property configured in the `@DDMFormField` in your `*TypeSettings` class, retrieved by the name of the field: `placeholder` and `mask`, respectively.

Now the JavaScript component and the Soy template can access the new settings. Next, update the JavaScript Component so it handles these properties and can use them, whether passing them to the template context (similar to the `*Renderer`, only this time for client-side rendering), or using them to configure the behavior of the JavaScript component itself.

Note: Remember that the Soy template can be used for server side or client side rendering. By defining the settings you're adding in both the Java Renderer and the JavaScript Renderer, you're allowing for the best possible user experience. For example, if a form builder is in the form builder, configuring a form field type, the configuration they enter can be directly passed to the template, and become visible in the UI, almost instantly. However, when the user clicks into a form field initially to begin editing, the rendering occurs from the server side.

Next configure the JavaScript component to include the new settings.

Adding Settings to the JavaScript Component

The JavaScript component needs to know about the new settings. First configure them as attributes of the component:

```
ATTRS: {
    mask: {
        value: '%I:%M %p'
    },
    placeholder: {
        value: ''
    },
    type: {
        value: 'time'
    }
},
```

The mask setting has a default value of `%I:%M %p`, and the placeholder is blank. Now that the new settings are declared as attributes of the component, make the JavaScript component pass the placeholder configuration to the Soy template on the client side. Just like in the Java renderer, pass the placeholder configuration to the template context. In this case, override the `getTemplateContext()` method to pass in the placeholder configuration. Add this to the `prototype` section of the JavaScript component definition:

```
getTemplateContext: function() {
    var instance = this;

return A.merge(
    TimeField.superclass.getTemplateContext.apply(instance, arguments),
        {
        placeholder: instance.get('placeholder')
        }
    );
},
```

Then in the component's render method, add the mask as an attribute of the AUI Timepicker using `mask: instance.get('mask')`.

```
        render: function() {
         var instance = this;

         TimeField.superclass.render.apply(instance, arguments);

         instance._timePicker = new A.TimePicker(
             {
                 trigger: instance.getInputSelector(),
                 mask: instance.get('mask'),
                 popover: {
                     zIndex: 1
                 }
             }
         );
    }
```

Now the field type JavaScript component is configured to include the settings. All you have left to do is to update the Soy template so the placeholder can be rendered in the form with the time field.

Updating the Soy Template

After all that, adding the placeholder setting to your Soy template's logic is simple.

The whole template is included below, but the only additions are in the commented section (adds the placeholder to the list of parameters–the ? indicates that the placeholder is not required), and then in the <input> tag, where you use the parameter value to configure the placeholder HTML property with the proper value.

```
{namespace ddm}

/**
 * Prints the DDM form time field.
 *
 * @param label
 * @param name
 * @param? placeholder
 * @param readOnly
 * @param required
 * @param showLabel
 * @param tip
 * @param value
 */
{template .time autoescape="deprecated-contextual"}
    <div class="form-group liferay-ddm-form-field-time" data-fieldname="{$name}">
        {if $showLabel}
            <label class="control-label">
                {$label}

                {if $required}
                    <span class="icon-asterisk text-warning"></span>
                {/if}
            </label>

            {if $tip}
                <p class="liferay-ddm-form-field-tip">{$tip}</p>
            {/if}
        {/if}

        <input class="field form-control" id="{$name}" name="{$name}" placeholder="{$placeholder}" {if $readOnly}readonly{/if} type="text" value="{$value}">
    </div>
{/template}
```

Why isn't the mask parameter added to the Soy template? The mask is not needed in the template because it's only used in the JavaScript for configuring the behavior of the timepicker. You don't need the dynamic rendering of the soy template to take the mask setting and configure it in the form. The maskv set by the form builder is captured in the rendering of the timepicker itself.

Now when you build the project and deploy your time field, you have a fully developed *time* form field type, complete with the proper JavaScript behavior and with additional settings.

Chapter 95

Search

Liferay stores its information in a database. If you need to search for data, why not search the database directly? Why add the complexity of a search engine? Database table merges are expensive! Documents in a search index often contain searchable fields from multiple tables in the database.

Searching with a search engine provides access to features such as relevance and scoring. Database searches do not support features like fuzzy searching or any type of relevancy. Moreover, when searching with a search engine, you can apply algorithms such as "More Like This" to obtain similar content. Search engines also support geolocation, faceting of search results, and multi-lingual searching.

95.1 Basic Search Concepts

Indexing: During indexing, a document is sent to the search engine. This document contains a collection of fields of various types (string, etc). The search engine processes each field within the document. For each field, the search engine determines whether it needs to simply store the field or if it needs to undertake special analysis (index time analysis). Index time analysis can be configured for each field (see Mapping Definitions).

For fields requiring analysis, the search engine first tokenizes the value to obtain individual words or tokens. Following tokenization, the search engine passes each token through a series of analyzers. Analyzers perform different functions. Some remove common words or stop words (e.g., "the", "and", "or") while others perform operations like lowercasing all characters.

Searching: Searching involves sending a search query and obtaining results (a.k.a. hits) from the search engine. The search query may be comprised of both queries and filters (more on this later). Each query or filter specifies a field to search within and the value to match against. Upon receiving the search query, the search engine iterates through each field within the nested queries and filters. During this process, the engine may perform special analysis prior to executing the query (search time analysis). Search time analysis can be configured for each field (see Mapping Definitions).

Mapping Definitions

Most search engines can be semi-intelligent in automatically deciphering how to process documents passed to them. However, there are many instances where it's desirable to explicitly configure how a field should be processed.

Mappings allow users to control how a search engine processes a given field. For instance, for all field names that end in “es_ES”, we want to process the field values as Spanish, removing any common Spanish words like “si”.

In Elasticsearch and Solr, the two supported search engines for Liferay Portal, we define mappings using `liferay-type-mappings.json` and `schema.xml`, respectively.

The Elasticsearch mapping JSON file can be seen here: https://github.com/liferay/liferay-portal/blob/7.0.6-ga7/modules/apps/foundation/portal-search/portal-search-elasticsearch/src/main/resources/META-INF/mappings/liferay-type-mappings.json

The Solr `schema.xml` can be seen here: https://github.com/liferay/liferay-portal/blob/7.0.6-ga7/modules/apps/portal-search-solr/portal-search-solr/src/main/resources/META-INF/resources/schema.xml

These are default mapping files that are shipped with the product. You can further customize these mappings to fit your needs. For example, you might want to use a special analyzer for a custom inventory number field.

Liferay Search Infrastructure

Search engines already provide native APIs. Why does Liferay provide search infrastructure to wrap search engines? Liferay’s search infrastructure ensures that documents are indexed with fields Liferay needs:

`entryClassName`, `entryClassPK`, `assetTagNames`, `assetCategories`, `companyId`, `groupId`, staging status, etc.

Liferay’s search infrastructure ensures that the proper set of filters are added to search queries to scope results. Liferay’s search infrastructure also provides capabilities like permission checking and creating hit summaries for display.

95.2 Liferay Search API

Liferay Portal’s Search API allows users to build a search query, execute it, and obtain search hits that match the query.

Queries and Filters

Elasticsearch and Solr do not make API level distinctions between queries and filters. However, Liferay’s API explicitly provides two sets of APIs, one for queries and one for filters.

A *filter* asks a yes or no question for every document. A *query* asks the same yes or no question AND how well (score) a document matches the specified criteria. For instance, a filter might ask is the status field equal to staging or live. A query might ask if the document’s content field field contains the words “Liferay”, “Content”, “Management”, and how relevant the content of the document is to the search terms.

With respect to performance, filters are much faster since the documents that match a filter can be easily cached. Queries not only match documents but also calculate scores. Liferay uses filters and queries together so that filters can reduce the number of matched documents before the query examines them for scoring.

Liferay’s Search API supports the following types of queries:

Full text queries:

- MatchQuery: Full text matching, scored by relevance.
- MultiMatchQuery: MatchQuery over several fields.
- StringQuery: Uses Lucene query syntax

Term queries:

- TermQuery: Exact matching on keyword fields and indexed terms

- TermRangeQuery: TermQuery with a range
- WildcardQuery: Wildcard (* and ?) matching on keyword fields and indexed terms
- FuzzyQuery: Scrambles characters in input before matching

Compound queries:

- BooleanQuery: Allows a combo of several query types. Individual queries are added as clauses with SHOULD | MUST | MUST_NOT.
- DisMaxQuery

Other queries:

- MoreLikeThisQuery
- MatchAllQuery: Matches all documents

Liferay's Search API supports the following types of filters:
Term filters:

- TermFilter
- TermsFilter
- PrefixFilter
- ExistsFilter
- MissingFilter
- RangeTermFilter

Compound filters:

- BooleanFilter

Geo filters: (Geolocation filters help filter documents based on the latitude and longitude fields)

- GeoDistanceFilter
- GeoDistanceRangeFilter
- GeoBoundingBoxFilter
- GeoPolygonFilter

Other filters:

- QueryFilter: Turns any query into a filter. E.g., can a BooleanQuery into a BooleanFilter
- MatchAllFilter: Matches all documents

Aggregations

Aggregations help summarize search results. Individual aggregations can be used to create more complex aggregations. Facets are a type of aggregation. In addition to facets, Liferay also provides group by and statistics aggregations.
Facets:

- Date Range Facet
- Modified Date Facet

- MultiValue Facet
- Range Facet
- Scope Facet
- Simple Facet

Statistics:
Stats provides general statistics for a desired field within the returned search results:

- count
- max
- mean
- min
- missing
- standard deviation
- sum
- sum of squares

GroupBy:
GroupBy is a powerful feature that allows you to group search results based on a particular field. For example, suppose you wish to group the search results based on the asset type (e.g., web content article, document, blog post, etc.). To do so, you would create a search query that contains a GroupBy aggregation with the field "entryClassName".
Other attributes you can specify:

- The maximum number of results in each group
- Special sorting for the grouped results

Indexers

There is an Indexer for each asset in the portal (e.g., DLFileEntryIndexer). This allows each asset to control what fields are indexed and what filters are applied to the search query.
Generally, when you create an asset that requires indexing, you would implement a new Indexer by extending `com.liferay.portal.kernel.search.BaseIndexer<T>`.
For more information, consult the Javadocs for `com.liferay.portal.kernel.search.Indexer<T>` and `com.liferay.portal.kernel.search.BaseIndexer<T>`: @platform-ref@/7.0-latest/javadocs

IndexerPostProcessor

The IndexerPostProcessor allows developers to customize

- Search queries before they are sent to the search engine
- Documents before they are sent to the search engine
- Summaries for results before they are returned to the end users

This is the preferred way to customize existing Indexers.
Follow these steps to add a new IndexerPostProcessor:

1. Implement the interface `com.liferay.portal.kernel.search.IndexerPostProcessor`.
2. Publish it to the OSGi registry with the property `indexer.class.name`

`postProcessContextQueryBooleanFilter` allows the developer to customize the filters created by the `Indexer.getFacetBooleanFilter`. These filters are generally applied to the fields:

- entryClassName
- relatedClassName
- relatedEntryClassNames
- permissions related fields (e.g., roleId, groupId, etc.).

`postProcessFullQuery` allows the developer to customize the overall search query which includes

- Filters for any default facets, including those for

    - asset category ids
    - asset tag names
    - entry class names
    - folderIds
    - groupIds
    - layoutUUIDs
    - userId

- The keyword search queries. By default, this includes searches for the fields

    - description
    - title
    - userName
    - keyword
    - searchable Expando fields
    - localized fields for assetCategoryTitles

HitsProcessor

`com.liferay.portal.kernel.search.HitsProcessor` allows developers to preprocess the results from the search engine before they are returned to the user. This allows for features like

- spell checking
- suggesting related queries
- indexing search queries that have returned high quality search results

HitsProcessors are stored in a HitsProcessorRegistry and sorted by their `sort.order`. Essentially, we have a chain of responsibility held by the HitsProcessorRegistry.

By default, the HitsProcessor order is:

1. `CollatedSpellCheckHitsProcessor`

    - Performs a spell check if the minimum score for search results is less than a given threshold
    - Number of results defined in portal.properties (index.search.collated.spell.check.result.scores.threshold)

2. `AlternateKeywordQueryHitsProcessor`

    - Automatically issue a query using the suggested keywords from the `CollatedSpellCheckHitsProcessor`.

3. `QueryIndexingHitsProcessor`

    - If query indexing is enabled (`index.search.query.indexing.enabled` in `portal.properties`), then index the search query if the number of hits has exceeded a configured quantity (`index.search.query.indexing.threshold` in `portal.properties`).

4. `QuerySuggestionHitsProcessor`

    - If number of results returned has not met a given threshold (`index.search.query.suggestion.scores.threshold` in `portal.properties`), then suggest other potential queries that previous searches have yielded more results (`index.search.query.suggest.max` in `portal.properties`).

Suggestions

Suggestions are a powerful feature where the search engine can suggest "similar" results for a given query. For instance, suppose you have a blog entry with the title "Liferay Portal Content Management" and you would like to find other content with similar titles.

`com.liferay.portal.kernel.search.IndexSearcher` provides methods to access suggestion capabilities. It implements `com.liferay.portal.kernel.search.suggest.QuerySuggester`.

The QuerySuggester provides facilities for

- Spell Checking
- Related search queries
- General Suggester requests

Spell Checking

For Elasticsearch, spell checking heavily relies on the suggester API: - Dictionary words are analyzed by their language specific analyzer and indexed. - `TermSuggester` is used to provide suggestions for words based on specific `StringDistance` algorithms.

Solr's implementation of `Suggester` is less flexible and sophisticated. Solr's spell checking algorithm is based strictly on NGrams and does not handle Asian languages very well.

Note that using the search engine's spell checking functionality doesn't guarantee returned results. Instead, spell checking seeks to ensure that the query is correct.

Similar Search Queries

Like spell checking, similar search queries has a more robust implementation in Elasticsearch. The Elasticsearch implementation uses phrase suggesters on indexed keyword search queries.

Solr's similar search queries implementation is again based on tokenized NGrams.

Other Suggesters

You can also send custom Suggester requests and get SuggesterResults back from the search engine by calling `QuerySuggester.suggest(SearchContext, Suggester)`.

95.3 Search Adapter API

Search adapters convert Liferay Portal's API to the underlying search engine's API. This pluggable architecture allows customers to more easily integrate with other search engines. Liferay ships with two adapters: an Elasticsearch adapter and a Solr adapter.

The search adapter API has 2 primary interfaces:

- `IndexSearcher`: invoked for all search operations
- `IndexWriter`: used when adding, updating, or deleting documents from the search engine.

95.4 Transactional Search

Search engines do not operate within a traditional JTA/JTS transaction. In place of "real" transactions, Liferay buffers indexing operations (delete, update) until either the surrounding transaction has been committed or we have exceeded the max buffer size. The buffered indexer requests are abandoned in the event of transaction rollback. This gives us some semblance of transactional control, except in scenarios where we have large batches of commits (e.g., exceeds `maxBufferSize`).

When `maxBufferSize` has been exceeded, the search infrastructure executes buffered indexer requests to free up space in the buffer.

Buffered `IndexerRequests` always execute in FIFO order. There is no collation of `IndexerRequests` in the buffer.

You can activate / deactivate and set the buffer size by configuring `com.liferay.portal.search.configuration.IndexerRegis`
By default, the buffering is activated and the max buffer size is 200.

For a list of buffered methods, see `com.liferay.portal.kernel.search.Indexer`. All methods annotated with `@Bufferable` are subject to potential buffering.

95.5 Customizing Liferay Search

There are several extension points available for users to customize. The most obvious is the ability to add a new search engine adapter.

Adding a new Search Engine Adapter

To add a new search engine adapter, developers must create the following components and publish them to Liferay's OSGi registry:

1. Implement a new IndexSearcher that should convert the Liferay Search objects to the underlying search engine's dialects:

    - QueryTranslator: Translates Liferay Queries to the native search engine's queries.
    - FilterTranslator: Translates Liferay filters into native search engine's filters.
    - GroupByTranslator: Translates the GroupBy aggregation to the search engine's group by top hits aggregation.
    - StatsTranslator: Translates Stats request to the appropriate search engine's statistics aggregation.
    - SuggesterTranslator: Translates suggestion requests to the appropriate search engine's suggester API.

2. Implement a new IndexWriter that should

    - Convert the Liferay Document to a format understood by the underlying search engine's Document Format.
    - Use the search engine's API to update, add, and delete documents.

3. Implement a new SearchEngineConfigurator that should extend `AbstractSearchEngineConfigurator` to perform proper wiring.

4. Implement a new SearchEngine that

    - Should extend from `BaseSearchEngine` to perform any search engine specific initialization.
    - Should be published to Liferay's OSGi registry along with the property `search.engine.id=[searchEngineId]`.

Customizing IndexerRequestBufferOverflowHandler

`IndexerRequestBufferOverflowHandler` controls how the search infrastructure handles situations where buffered indexer requests has exceeded the configured maximum buffer size.

To customize, implement an `IndexerRequestBufferOverflowHandler` and publish it to Liferay's OSGi registry.

Customizing HitsProcessors

`com.liferay.portal.kernel.hits.HitsProcessor` objects are held in a `com.liferay.portal.kernel.hits.HitsProcessorRegistry` To add a new HitsProcessor, simply implement the interface and publish to the OSGi registry with the property `sort.order`.

Chapter 96

Application Security

Nothing has received more attention on the web in recent years than security. Liferay has a robust security model for you to use in your applications, and it supports a wide variety of security features. In this section, you can learn about these features:

- Resources, Roles, and Permissions
- Custom SSO Providers
- Authentication Pipelines
- Service Access Policies
- Authentication Verifiers

96.1 Adding Permissions to Resources

Public bulletin boards are great. Anyone can inform others of just about anything. On the other hand, *anyone* can post just about *anything* on the bulletin board. Some of this content might not be relevant to the community. Other content might be inappropriate. Thus, you sometimes need a way to restrict who can post or access content.

Fortunately, no matter what your portlet does, access to it and to its content can be controlled with permissions. Read on to learn about Liferay's permissions system and how to add permissions to your application.

Liferay's Permission System

Liferay's permission system uses a flexible mechanism that defines the actions that a given user can perform within the context of Liferay or a specific application. Liferay developers break down the operations that can be performed in Liferay or in a certain application into distinct *actions*. The act of granting the ability to perform an action to a specific role is the act of granting a *permission*. In Liferay, permissions are not granted to directly to users. Instead, permissions are granted to roles. Roles, in turn, can be assigned to specific users, sites, organizations, or user groups.

Developers need to define the different types of operations that are required to suit the business logic of their applications. They don't need to worry about which users will receive which permissions. Once the actions have been determined and configured, portal administrators can grant permissions to perform those actions to users, sites, organizations, or user groups by assigning roles. Administrators can use the portal's administration tools to grant permissions to roles or they can use the permissions UIs of individual portlets.

In this tutorial, you'll learn how to use Liferay's permissions system to provide Liferay administrators the same level of control over permissions that they have over the out-of-the-box Liferay applications.

Before proceeding, make sure you understand these critical terms:

Action: An operation that can be performed by a Liferay user. For example, actions that be performed on the Bookmarks application include `ADD_TO_PAGE`, `CONFIGURATION`, and `VIEW`. Actions that can be performed with respect to Bookmarks entry entity include `ADD_ENTRY`, `DELETE`, `PERMISSIONS`, `UPDATE`, and `VIEW`.

Resource: A generic representation of any application or entity in the portal on which an action can be performed. Resources are used for permission checking. For example, resources within a Liferay instance could include the RSS application with instance ID `hF5f`, a globally scoped Wiki page, a Bookmarks entry of the site X, and a Message Boards post with the ID `5052`.

Permission: An action that can be performed on a resource. In Liferay's database, resources and actions are saved in pairs. (Each entry in the `ResourceAction` table contains both the name of a portlet or entity and the name of an action.) For example, the `VIEW` action with respect to *viewing the Bookmarks application* is associated with the `com_liferay_bookmarks_web_portlet_BookmarksPortlet` portlet ID. The `VIEW` actions with respect to *viewing a Bookmarks Folder* or *viewing a Bookmarks entry* are associated with the `com.liferay.bookmarks.model.BookmarksFolder` and `com.liferay.bookmarks.model.BookmarksEntry` entities, respectively.

There are two kinds of resources in Liferay: *portlet resources* and *model resources*. Portlet resources represent portlet applications. The names of portlet resources typically correspond to the IDs of the portlets themselves. For example, the fully qualified name of the Bookmarks portlet class is `com.liferay.bookmarks.web.portlet.BookmarksPortlet`. Its ID is defined in the `BookmarksPortletKeys` class like this:

```
public static final String BOOKMARKS =
    "com_liferay_bookmarks_web_portlet_BookmarksPortlet";
```

This `BOOKMARKS` string is used when declaring portlet resources in `default.xml` files, as discussed below.

There are two kinds of resources in Liferay: *portlet resources* and *model resources*. Portlet resources represent portlets. The names of portlet resources are the portlet IDs from the portlets' `portlet.xml` files (or in the case of core portlets, Liferay's `portlet-custom.xml`). Model resources refer to entities within Liferay. The names of model resources are the fully qualified class names of the entities they represent. In the XML displayed below, permission implementations are first defined for the *portlet* resource and then for the *model* resources.

Model resources represent entities within Liferay, such as bookmarks folders or bookmarks entries. The names of model resources are the fully qualified class names of the entities they represent. In the `default.xml` files displayed below, permission implementations are first defined for the *portlet* resource and then for the *model* resources.

Note: For each resource, there are four scopes to which the permissions can be applied: company, group, group-template, or individual. See the Javadoc of ResourcePermissionImpl for more information.

You can add permissions to your custom portlets using four easy steps (also known as *DRAC*):

1. Define all resources and their permissions.

2. Register all defined resources in the permissions system. This is also known as *adding resources*.

3. Associate the necessary permissions with resources.

4. Check permission before returning resources.

Define All Resources and Permissions

Here you'll learn the first step, in which you define your resources and their actions. The Bookmarks application is used here to demonstrate how to define portlet resources and model resources. Open the `default.xml` file in `bookmarks-web` module of the Bookmarks application: default.xml. There, you'll see the following mapping of resources to actions:

```
<?xml version="1.0"?>
<!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-
resource-action-mapping_7_0_0.dtd">

<resource-action-mapping>
    <portlet-resource>
        <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksAdminPortlet</portlet-name>
        <permissions>
            <supports>
                <action-key>ACCESS_IN_CONTROL_PANEL</action-key>
                <action-key>CONFIGURATION</action-key>
                <action-key>VIEW</action-key>
            </supports>
            <site-member-defaults>
                <action-key>VIEW</action-key>
            </site-member-defaults>
            <guest-defaults>
                <action-key>VIEW</action-key>
            </guest-defaults>
            <guest-unsupported>
                <action-key>ACCESS_IN_CONTROL_PANEL</action-key>
                <action-key>CONFIGURATION</action-key>
            </guest-unsupported>
        </permissions>
    </portlet-resource>
    <portlet-resource>
        <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksPortlet</portlet-name>
        <permissions>
            <supports>
                <action-key>ADD_TO_PAGE</action-key>
                <action-key>CONFIGURATION</action-key>
                <action-key>VIEW</action-key>
            </supports>
            <site-member-defaults>
                <action-key>VIEW</action-key>
            </site-member-defaults>
            <guest-defaults>
                <action-key>VIEW</action-key>
            </guest-defaults>
            <guest-unsupported>
                <action-key>CONFIGURATION</action-key>
            </guest-unsupported>
        </permissions>
    </portlet-resource>
</resource-action-mapping>
```

This `default.xml` defines portlet resources. The bookmarks service module also contains a default.xml file:

```
<?xml version="1.0"?>
<!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-
resource-action-mapping_7_0_0.dtd">

<resource-action-mapping>
    <model-resource>
        <model-name>com.liferay.bookmarks</model-name>
        <portlet-ref>
            <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksPortlet</portlet-name>
            <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksAdminPortlet</portlet-name>
        </portlet-ref>
        <root>true</root>
        <weight>1</weight>
        <permissions>
            <supports>

        </portlet-ref>
        <weight>3</weight>
        <permissions>
            <supports>
                <action-key>DELETE</action-key>
                <action-key>PERMISSIONS</action-key>
                <action-key>SUBSCRIBE</action-key>
                <action-key>UPDATE</action-key>
                <action-key>VIEW</action-key>
            </supports>
            <site-member-defaults>
                <action-key>SUBSCRIBE</action-key>
                <action-key>VIEW</action-key>
            </site-member-defaults>
            <guest-defaults>
                <action-key>VIEW</action-key>
            </guest-defaults>
            <guest-unsupported>
                <action-key>SUBSCRIBE</action-key>
                <action-key>UPDATE</action-key>
            </guest-unsupported>
        </permissions>
    </model-resource>
</resource-action-mapping>
```

This `default.xml` file defines model resources.

The `<portlet-resource>` tag is used to define actions that can be taken with respect to the portlet window. For the Bookmarks application, such actions include these:

- `ADD_TO_PAGE`: *Add* the application to a page
- `CONFIGURATION`: *Access* the application's Configuration window
- `VIEW`: *View* the application

All the supported actions are defined in the `<supports>` tag, a sub-tag of the `<permissions>` tag (which is itself a sub-tag of the `<portlet-resource>` tag:

```
<supports>
    <action-key>ADD_TO_PAGE</action-key>
    <action-key>CONFIGURATION</action-key>
    <action-key>VIEW</action-key>
</supports>
```

The default permissions for site members are defined in the `<site-member-defaults>` tag. In the case of the Bookmarks application, site members can view any Bookmarks application in the site:

```
<site-member-defaults>
    <action-key>VIEW</action-key>
</site-member-defaults>
```

Similarly, the default permissions for guests are defined in the `<guest-defaults>` tag. Guests can also view any Bookmarks application in the site:

```
<guest-defaults>
    <action-key>VIEW</action-key>
</guest-defaults>
```

The `<guest-unsupported>` tag specifies permissions forbidden to guests. By default, guests cannot access the Bookmarks application in the Control Panel nor can they access the Bookmarks's configuration window:

```
<guest-unsupported>
    <action-key>ACCESS_IN_CONTROL_PANEL</action-key>
    <action-key>CONFIGURATION</action-key>
</guest-unsupported>
```

With respect to model resources, guests are forbidden from adding bookmarks entries and bookmarks folders. Guests are also not permitted to edit permissions or subscribe. Remember, these are just default permissions that can be changed by administrators. See the following entry in the first `<model-resource>` tag:

```
<guest-unsupported>
    <action-key>ADD_ENTRY</action-key>
    <action-key>ADD_FOLDER</action-key>
    <action-key>PERMISSIONS</action-key>
    <action-key>SUBSCRIBE</action-key>
</guest-unsupported>
```

The `<model-resource>` tag is used to define actions that can be performed with respect to models, also known as entities. There are two kinds of actions in Liferay: *top-level actions* and *resource actions*. Top-level actions are not applied to a particular resource. For example, the action of adding a new entity is not applied to a particular resource, so it's considered a top-level action. The first `<model-resource>` tag defines adding bookmark entry and bookmark folder resources as top-level actions:

```
<supports>
    <action-key>ADD_ENTRY</action-key>
    <action-key>ADD_FOLDER</action-key>
</supports>
```

The second and third `<model-resource>` tags define resource actions that can be applied to the `BookmarksFolder` and `BookmarksEntry` entities, respectively. For example, the permissions for the following actions are defined with respect to the resource associated with the `BookmarksEntry` entity:

```
<supports>
    <action-key>DELETE</action-key>
    <action-key>PERMISSIONS</action-key>
    <action-key>SUBSCRIBE</action-key>
    <action-key>UPDATE</action-key>
    <action-key>VIEW</action-key>
</supports>
```

Similarly, the permissions for the following actions are defined with respect to the resource associated with the `BookmarksFolder` entity:

```
<supports>
    <action-key>ACCESS</action-key>
    <action-key>ADD_ENTRY</action-key>
    <action-key>ADD_SUBFOLDER</action-key>
    <action-key>DELETE</action-key>
    <action-key>PERMISSIONS</action-key>
    <action-key>SUBSCRIBE</action-key>
    <action-key>UPDATE</action-key>
    <action-key>VIEW</action-key>
</supports>
```

In each `<model-resource>` tag, notice that the model name must be defined. The `<model-name>` must be either the fully-qualified name of a package or of an entity class. For example, `com.liferay.bookmarks` is the name of a package and `com.liferay.bookmarks.model.BookmarksEntry` is the name of an entity class. Using a package is the recommended convention for permissions that refer to top-level actions:

```
<model-name>com.liferay.bookmarks</model-name>
```

The `ADD_ENTRY` and `ADD_FOLDER` permissions are defined this way since they're top-level actions. For resource actions, the entity class is specified:

```
<model-name>com.liferay.bookmarks.model.BookmarksEntry</model-name>
```

The <portlet-ref> element comes next and contains a <portlet-name> sub-tag.

```
<portlet-ref>
    <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksPortlet</portlet-name>
    <portlet-name>com_liferay_bookmarks_web_portlet_BookmarksAdminPortlet</portlet-name>
</portlet-ref>
```

The value of <portlet-name> references the name of the portlet to which the model resource belongs. It's possible for a model resource to belong to multiple portlets referenced with multiple <portlet-name> elements. This is the case here since both the Bookmarks application and the Bookmarks Admin application can be used to perform actions on bookmark entries.

The <supports>, <site-member-defaults>, <guest-defaults>, and <guest-unsupported> tags work the same way in the <model-resource> tag as they do in the <portlet-resource> tag. The <supports> tag lets you specify a list of supported actions that require permission to perform. The <site-member-defaults> tag and the <guest-defaults> tags define default permissions for site members and guests, respectively. And the <guest-unsupported> tag specifies permissions forbidden to guests.

After defining resource permissions for your portlet, you need to point Liferay to the default.xml file that contains your definitions. In Liferay's core, there are multiple permissions XML definition files for various core Liferay portlets in the portal/portal-impl/src/resource-actions directory. The default.xml file in that folder contains pointers to the definition files of the various applications. This excerpt from Liferay's default.xml references the resource permission definition files for all built-in Liferay portlets:

```
<?xml version="1.0"?>
<!DOCTYPE resource-action-mapping PUBLIC "-//Liferay//DTD Resource Action Mapping 7.0.0//EN" "http://www.liferay.com/dtd/liferay-
resource-action-mapping_7_0_0.dtd">

<resource-action-mapping>
    <resource file="resource-actions/portal.xml" />
    <resource file="resource-actions/announcements.xml" />
    <resource file="resource-actions/asset.xml" />
    <resource file="resource-actions/blogs.xml" />
    ...
</resource-action-mapping>
```

Your application's permissions XML file should be named default.xml and should be placed in a directory in your module's classpath. src/resource-actions is the standard location. Once your project's default.xml file has been created, you should create a properties file named portlet.properties that contains a reference to your permissions XML file. In your portlet.properties file, create a property named resource.actions.configs with the relative path to your portlet's resource-action mapping file (e.g. default.xml) as its value. Here's what this property specification might look like:

```
resource.actions.configs=resource-actions/default.xml
```

Your permissions XML file must contain a root resource-action-mapping element. Check out a copy of the Liferay source code from the Liferay Portal repository to see how resources and permissions are defined for core Liferay portlets. Start by looking at the definition files found in the portal-impl/src/resource-actions directory. For a simple example of defining permissions in the context of a portlet plugin, check out the Liferay Plugins repository and examine the portlet sample-permissions-portlet.

CHAPTER 97

AUTHENTICATION PIPELINES

The authentication process in Liferay DXP is a pipeline through which users can be validated by one or several systems. Liferay DXP's flexibility and extensibility makes it possible for you to make it authenticate users to anything you wish, rather than be limited by what it supports out of the box.

Here's how authentication works under most circumstances:

1. Users provide their credentials to the Login Portlet to begin an authenticated session in a browser.

2. Alternatively, credentials are provided to Liferay DXP's API endpoints, where they are sent in an HTTP BASIC Auth header.

3. Alternatively, credentials can be provided by another system. These are managed by `AutoLogin` components.

4. Credentials are checked by default against the database, but they can be delegated to other systems instead of or in addition to it. This is called an *Authentication Pipeline*. You can add `Authenticators` to the pipeline to support any system.

5. You can also customize Liferay DXP's Login Portlet to support whatever user interface any of these systems need. This gives you full flexibility over the entire authentication process.

You can also support an authentication mechanism and/or accept credentials from a system that Liferay DXP doesn't yet support. If you don't like the user interface for signing in, you can replace it with your own.

This set of tutorials guides you through these customizations. You'll discover three kinds of customizations:

- Auto Login: the easiest of the three, this lets you authenticate to Liferay DXP using credentials provided in the HTTP header from another system.

- Authentication Pipelines: if you need to check credentials against other systems instead of or in addition to Liferay DXP's database, you can create a pipeline.

- Custom Login Portlet: if you want to change the user's sign-in experience completely, you can implement your own Login portlet.

Read on to discover how to customize your users' sign-in experience.

97.1 Auto Login

While Liferay DXP supports a wide variety of authentication mechanisms, you may use a home-grown system or some other product to authenticate users. To do so, you can write an Auto Login component to support your authentication system.

Auto Login components can check if the request contains something (a cookie, an attribute) that can be associated with a user in any way. If the component can make that association, it can authenticate that user to Liferay DXP.

Creating an Auto Login Component

Create a Declarative Services component. The component should implement the `com.liferay.portal.kernel.security.auto.lo` interface. Here's an example template:

```
import com.liferay.portal.kernel.security.auto.login.AutoLogin;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;

@Component(immediate = true)
public class MyAutoLogin implements Autologin {

    public String[] handleException(
            HttpServletRequest request, HttpServletResponse response,
            Exception e)
        throws AutoLoginException {

        /* This method is no longer used in the interface and can be
      left empty */

    }

    public String[] login(
            HttpServletRequest request, HttpServletResponse response)
        throws AutoLoginException {

        /* Your Code Goes Here */

    }

}
```

As you can see, you have access to the `HttpServletRequest` and the `HttpServletResponse` objects. If your sign-on solution places anything here that identifies a user, such as a cookie, an attribute, or a parameter, you can retrieve it and take whatever action you need to retrieve the user information and authenticate that user to Liferay DXP.

For example, say that there's a request attribute that contains the encrypted value of a user key in Liferay DXP. This can only be there if the user has authenticated with a third party system that knew the value of the user key, encrypted it, and added it as a request attribute. You could write code that reads the value, decrypts it using the same pre-shared key, and uses the value to look up and authenticate the user.

The `login` method is where this all happens. This method must return a `String` array with three items in this order:

- The user ID
- The user password

- A boolean flag that's true if the password is encrypted and false if it's not (Boolean.TRUE.toString() or Boolean.FALSE.toString()).

Sending redirects is an optional AutoLogin feature. Since AutoLogins are part of the servlet filter chain, you have two options. Both are implemented by setting attributes in the request. Here are the attributes:

- AutoLogin.AUTO_LOGIN_REDIRECT: This key causes AutoLoginFilter to stop the filter chain's execution and redirect immediately to the location specified in the attribute's value.
- AutoLogin.AUTO_LOGIN_REDIRECT_AND_CONTINUE: This key causes AutoLoginFilter to set the redirect and continue executing the remaining filters in the chain.

Auto Login components are useful ways of providing an authentication mechanism to a system that Liferay DXP doesn't yet support. You can write them fairly quickly to provide the integration you need.

Password-Based Authentication Pipelines

Writing a Custom Login Portlet

97.2 Password-Based Authentication Pipelines

By default, once a user submits credentials to Liferay DXP, those credentials are checked against Liferay DXP's database, though you can also delegate authentication to an LDAP server. To use some other system in your environment instead of or in addition to checking credentials against Liferay DXP's database, you can write an Authenticator and insert it as a step in Liferay DXP's authentication pipeline.

Because the Authenticator is checked by the Login Portlet, you can't use this approach if the user must be redirected to the external system or needs a token to authenticate. In those cases, you should use an Auto Login or an Auth Verifier.

Authenticators let you do these things:

- Log into Liferay DXP with a username and password maintained in an external system
- Make secondary user authentication checks
- Perform additional processing when user authentication fails

Read on to learn how to create an Authenticator.

Anatomy of an Authenticator

Authenticators are implemented for various steps in the authentication pipeline. Here are the steps:

1. auth.pipeline.pre: Comes before default authentication to the Liferay DXP database. In this step, you can instruct Liferay DXP to skip credential validation against the Liferay DXP database. Implemented by Authenticator.
2. Default (optional) authentication to the Liferay DXP database.
3. auth.pipeline.post: Further (secondary, tertiary) authentication checks. Implemented by Authenticator.
4. auth.failure: Perform additional processing after authentication fails. Implemented by AuthFailure.

To create an Authenticator, create a module and add a component that implements the interface:

```
@Component(
    immediate = true, property = {"key=auth.pipeline.post"},
    service = Authenticator.class
)
public class MyCustomAuth implements Authenticator {

    public int authenticateByEmailAddress(
            long companyId, String emailAddress, String password,
            Map<String, String[]> headerMap, Map<String, String[]> parameterMap)
        throws AuthException {

return Authenticator.SUCCESS;
}

    public int authenticateByScreenName(
            long companyId, String screenName, String password,
            Map<String, String[]> headerMap, Map<String, String[]> parameterMap)
        throws AuthException {

return Authenticator.SUCCESS;
    }

    public int authenticateByUserId(
            long companyId, long userId, String password,
            Map<String, String[]> headerMap, Map<String, String[]> parameterMap)
        throws AuthException {

return Authenticator.SUCCESS;
    }
}
```

This example has been stripped down so you can see its structure. First, note the @Component annotation's contents:

- immediate = true: sets the component to start immediately
- key=auth.pipeline.post: sets the Authenticator to run in the auth.pipeline.post phase. To run the auth.pipeline.pre phase, substitute auth.pipeline.pre.
- service = Authenticator.class: implements the Authenticator service. All Authenticators must do this.

The three methods below the annotation run based on how you've configured authentication: by email address (the default), by screen name, or by user ID. All the methods throw an AuthException in case the Authenticator is unable to perform its task–perhaps if the system it's authenticating against is unavailable or if some dependency can't be found. The methods in this barebones example return success in all cases. If you deploy its module, it has no effect. Naturally, you'll want to provide more functionality. Next is an example that shows you how to do that.

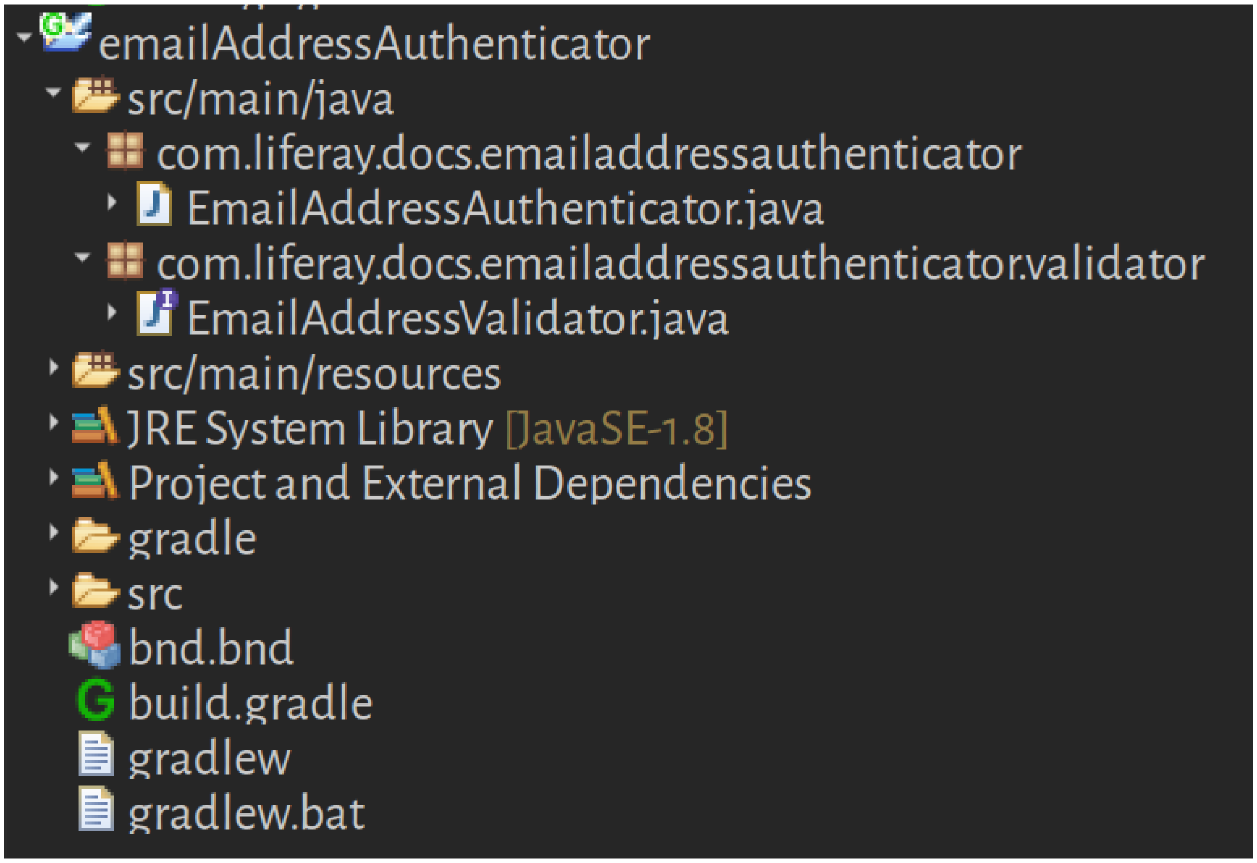
Creating an Authenticator

This example is an Authenticator that only allows users whose email addresses end with *@liferay.com* or *@example.com*. You can implement this using one module that does everything. If you think other modules might be able to use the functionality that validates the email addresses, you might create two modules: one to implement the Authenticator and one to validate email addresses. This example shows the two module approach.

To create an Authenticator, create a module for your implementation. The most appropriate Blade template for this is the service template. Once you have the module, creating the Activator is straightforward:

1. Add the @Component annotation to bind your Activator to the appropriate authentication pipeline phase.
2. Implement the Authenticator interface and provide the functionality you need.
3. Deploy your module. If you're using Blade CLI, do this via blade deploy.

For this example, you'll do this twice: once for the email address validator module and once for the Authenticator itself. The Authenticator project contains the interface for the validator, and the validator project contains the implementation. Here's what the Authenticator module structure looks like:



```
emailAddressAuthenticator
  src/main/java
    com.liferay.docs.emailaddressauthenticator
      EmailAddressAuthenticator.java
    com.liferay.docs.emailaddressauthenticator.validator
      EmailAddressValidator.java
  src/main/resources
  JRE System Library [JavaSE-1.8]
  Project and External Dependencies
  gradle
  src
  bnd.bnd
  build.gradle
  gradlew
  gradlew.bat
```

Figure 97.1: The Authenticator module contains the validator's interface and the authenticator.

Since the Authenticator is the most relevant, examine it first:

```
package com.liferay.docs.emailaddressauthenticator;

import java.util.Map;

import com.liferay.docs.emailaddressauthenticator.validator.EmailAddressValidator;
import com.liferay.portal.kernel.log.Log;
import com.liferay.portal.kernel.log.LogFactoryUtil;
import com.liferay.portal.kernel.security.auth.AuthException;
import com.liferay.portal.kernel.security.auth.Authenticator;
import com.liferay.portal.kernel.service.UserLocalService;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;
import org.osgi.service.component.annotations.ReferenceCardinality;
import org.osgi.service.component.annotations.ReferencePolicy;

@Component(
    immediate = true,
    property = {"key=auth.pipeline.post"},
    service = Authenticator.class
)
public class EmailAddressAuthenticator implements Authenticator {

    @Override
    public int authenticateByEmailAddress(long companyId, String emailAddress,
            String password, Map<String, String[]> headerMap,
            Map<String, String[]> parameterMap) throws AuthException {

        return validateDomain(emailAddress);
    }

    @Override
    public int authenticateByScreenName(long companyId, String screenName,
            String password, Map<String, String[]> headerMap,
            Map<String, String[]> parameterMap) throws AuthException {

        String emailAddress =
            _userLocalService.fetchUserByScreenName(companyId, screenName).getEmailAddress();

        return validateDomain(emailAddress);
    }

    @Override
    public int authenticateByUserId(long companyId, long userId,
            String password, Map<String, String[]> headerMap,
            Map<String, String[]> parameterMap) throws AuthException {

        String emailAddress =
            _userLocalService.fetchUserById(userId).getEmailAddress();

        return validateDomain(emailAddress);
    }

    private int validateDomain(String emailAddress) throws AuthException {

        if (_emailValidator == null) {

            String msg = "Email address validator is unavailable, cannot authenticate user";
            _log.error(msg);

            throw new AuthException(msg);
        }

        if (_emailValidator.isValidEmailAddress(emailAddress)) {
            return Authenticator.SUCCESS;
        }
        return Authenticator.FAILURE;
    }

    @Reference
    private volatile UserLocalService _userLocalService;

    @Reference(
        policy = ReferencePolicy.DYNAMIC,
        cardinality = ReferenceCardinality.OPTIONAL
    )
    private volatile EmailAddressValidator _emailValidator;

    private static final Log _log = LogFactoryUtil.getLog(EmailAddressAuthenticator.class);
}
```

This time, rather than stubs, the three authentication methods contain functionality. The authenticateByEmailAddress method directly checks the email address provided by the Login Portlet. The other two methods, authenticateByScreenName and authenticateByUserId call Liferay DXP's UserLocalService to look up the user's email address before checking it. This service is injected by the OSGi container because of the @Reference annotation. Note that the validator is also injected in this same manner, though it's configured not to fail if the implementation can't be found. This allows this module to start regardless of its dependency on the validator implementation. In this case, this is safe because the error is handled by throwing an AuthException and logging the error.

Why would you want to do it this way? To err gracefully. Because this is an auth.pipeline.post Authenticator, you presumably have other Authenticators checking credentials before this one. If this one isn't working, you want to inform administrators with an error message rather than catastrophically failing and preventing users from logging in.

The only other Java code in this module is the Interface for the validator:

```
package com.liferay.docs.emailaddressauthenticator.validator;

import aQute.bnd.annotation.ProviderType;

@ProviderType
public interface EmailAddressValidator {

    public boolean isValidEmailAddress(String emailAddress);
}
```

This defines a single method for checking the email address.

Next, you'll address the validator module.

This module contains only one class. It implements the Validator interface:

```
package com.liferay.docs.emailaddressvalidator.impl;

import java.util.Arrays;
import java.util.HashSet;
import java.util.Set;
import org.osgi.service.component.annotations.Component;
import com.liferay.docs.emailaddressauthenticator.validator.EmailAddressValidator;

@Component(
    immediate = true,
    property = {
    },
    service = EmailAddressValidator.class
)
public class EmailAddressValidatorImpl implements EmailAddressValidator {

    @Override
    public boolean isValidEmailAddress(String emailAddress) {

        if (_validEmailDomains.contains(
            emailAddress.substring(emailAddress.indexOf('@')))) {

            return true;
        }
        return false;
    }

    private Set<String> _validEmailDomains =
        new HashSet<String>(Arrays.asList(new String[] {"@liferay.com", "@example.com"}));
}
```

Figure 97.2: The validator project implements the Validator Interface and depends on the authenticator module.

This code checks to make sure that the email address is from the *@liferay.com* or *@example.com* domains. The only other interesting part of this module is the Gradle build script, because it defines a compile-only dependency between the two projects. This is divided into two files: a `settings.gradle` and a `build.gradle`.

The `settings.gradle` file defines the location of the project (the `Authenticator`) the validator depends on:

```
include ':emailAddressAuthenticator'
project(':emailAddressAuthenticator').projectDir = new File(settingsDir, '../com.liferay.docs.emailAddressAuthenticator')
```

Since this project contains the interface, it must be on the classpath at compile time, which is when `build.gradle` is running:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins", version: "3.0.23"
    }

    repositories {
        mavenLocal()

        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}
```

```
apply plugin: "com.liferay.plugin"

dependencies {
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "org.osgi", name: "org.osgi.compendium", version: "5.0.0"

    compileOnly project(":emailAddressAuthenticator")
}

repositories {
    mavenLocal()

    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Note the line in the dependencies section that refers to the `Authenticator` project defined in `settings.gradle`.

When these projects are deployed, the `Authenticator` you defined runs, enforcing logins for the two domains specified in the validator.

If you want to examine these projects further, you can download them in this ZIP file.

Writing a Custom Login Portlet

97.3 Writing a Custom Login Portlet

If you need to customize your users' authentication experience completely, you can write your own Login Portlet. The mechanics of this on the macro level are no different from writing any other portlet, so if you need to familiarize yourself with that, please see the portlets section of tutorials.

This tutorial shows only the relevant parts of a Liferay MVC Portlet that authenticates the user. You'll learn how to call Liferay DXP's authentication pipeline and then redirect the user to a location of your choice.

Authenticating to Liferay DXP

You can use the example project in this ZIP file as a starting point for your own.

It has only one view, which is used for logging in or showing the user who is already logged in:

```
<%@ include file="/init.jsp" %>

<p>
    <b><liferay-ui:message key="myloginportlet_MyLogin.caption"/></b>
</p>

<c:choose>
    <c:when test="<%= themeDisplay.isSignedIn() %>">

        <%
        String signedInAs = HtmlUtil.escape(user.getFullName());

        if (themeDisplay.isShowMyAccountIcon() && (themeDisplay.getURLMyAccount() != null)) {
            String myAccountURL = String.valueOf(themeDisplay.getURLMyAccount());

            signedInAs = "<a class=\"signed-in\" href=\"" + HtmlUtil.escape(myAccountURL) + "\">" + signedInAs + "</a>";
        }
        %>

        <liferay-ui:message arguments="<%= signedInAs %>" key="you-are-signed-in-as-x" translateArguments="<%= false %>" />
    </c:when>
    <c:otherwise>

        <%
        String redirect = ParamUtil.getString(request, "redirect");
        %>

        <portlet:actionURL name="/login/login" var="loginURL">
            <portlet:param name="mvcRenderCommandName" value="/login/login" />
        </portlet:actionURL>

        <aui:form action="<%= loginURL %>" autocomplete='on' cssClass="sign-in-form" method="post" name="loginForm">

            <aui:input name="saveLastPath" type="hidden" value="<%= false %>" />
            <aui:input name="redirect" type="hidden" value="<%= redirect %>" />

            <aui:input autoFocus="true" cssClass="clearable" label="email-address" name="login" showRequiredLabel="<%= false %>" type="text" value="">
                <aui:validator name="required" />
            </aui:input>

            <aui:input name="password" showRequiredLabel="<%= false %>" type="password">
                <aui:validator name="required" />
            </aui:input>

            <aui:button-row>
                <aui:button cssClass="btn-lg" type="submit" value="sign-in" />
            </aui:button-row>

        </aui:form>
    </c:otherwise>
</c:choose>
```

Note that in the form, authentication by email address (Liferay DXP's default setting) is hard-coded, as this is an example project. The current page is sent as a hidden field on the form so the portlet can redirect the user to it, but you can of course set this to any value you want.

The portlet handles all processing of this form using a single Action Command (imports left out for brevity):

```
@Component(
    property = {
        "javax.portlet.name=MyLoginPortlet",
        "mvc.command.name=/login/login"
    },
    service = MVCActionCommand.class
)
public class MyLoginMVCActionCommand extends BaseMVCActionCommand {

    @Override
    protected void doProcessAction(ActionRequest actionRequest,
            ActionResponse actionResponse) throws Exception {

        ThemeDisplay themeDisplay = (ThemeDisplay)actionRequest.getAttribute(
            WebKeys.THEME_DISPLAY);

        HttpServletRequest request = PortalUtil.getOriginalServletRequest(
            PortalUtil.getHttpServletRequest(actionRequest));

        HttpServletResponse response = PortalUtil.getHttpServletResponse(
            actionResponse);

        String login = ParamUtil.getString(actionRequest, "login");
        String password = actionRequest.getParameter("password");
        boolean rememberMe = ParamUtil.getBoolean(actionRequest, "rememberMe");
        String authType = CompanyConstants.AUTH_TYPE_EA;

        AuthenticatedSessionManagerUtil.login(
            request, response, login, password, rememberMe, authType);

        actionResponse.sendRedirect(themeDisplay.getPathMain());
    }

}
```

The only tricky/unusual code here is the need to grab the `HttpServletRequest` and the `HttpServletResponse`. This is necessary to call Liferay DXP's API for authentication. At the end of the Action Command, the portlet sends a redirect that sends the user to the same page. You can of course make this any page you want.

Implementing your own login portlet gives you complete control over the authentication process.

97.4 Service Access Policies

Service access policies are a layer of web service security on top of Liferay DXP's remote services. Together with the permissions layer, service access policies limit remote service access by remote client applications. This forms an additional security layer that protects user data from unauthorized access and modification.

To connect to a Liferay DXP instance, remote clients must authenticate with credentials in that instance. This grants the remote client the permissions assigned to those credentials in the Liferay DXP installation. Service access policies are a layer of security on top of this: they further limit the remote client's access to the remote services specified in the policy. Without such policies, authenticated remote clients are treated like users: they can call any remote API and read or modify data on behalf of the authenticated user. Since remote clients are often intended for a specific use case, granting them access to everything the user has permissions for poses a security risk.

For example, consider a mobile app (client) that displays a user's appointments from the Liferay Calendar app. This client app doesn't need access to the API that updates the user profile, even though the user has such permissions on the server. The client app doesn't even need access to the Calendar API methods that create, update, and delete appointments. It only needs access to the remote service methods for finding and retrieving appointments. A service access policy on the server can restrict the client's access to only these service methods. Otherwise, once authenticated it would have access to all the remote services the user has permission to access when logged in: services that create, update, and delete calendar appointments, as well as those that can update user data or other system entities the user can access. Since the client doesn't perform these operations, having access to them is a security risk if the mobile device is lost or stolen or the client app is compromised by an attacker.

How Service Access Policies Work

When a remote client issues a request to a web service, the request contains the user's credentials or an authorization token. An authentication module in Liferay DXP recognizes the client based on the credentials/token and grants the appropriate service access policy to the request. The service access policy authorization layer then processes all granted policies and lets the request access the remote service(s) permitted by the policy.

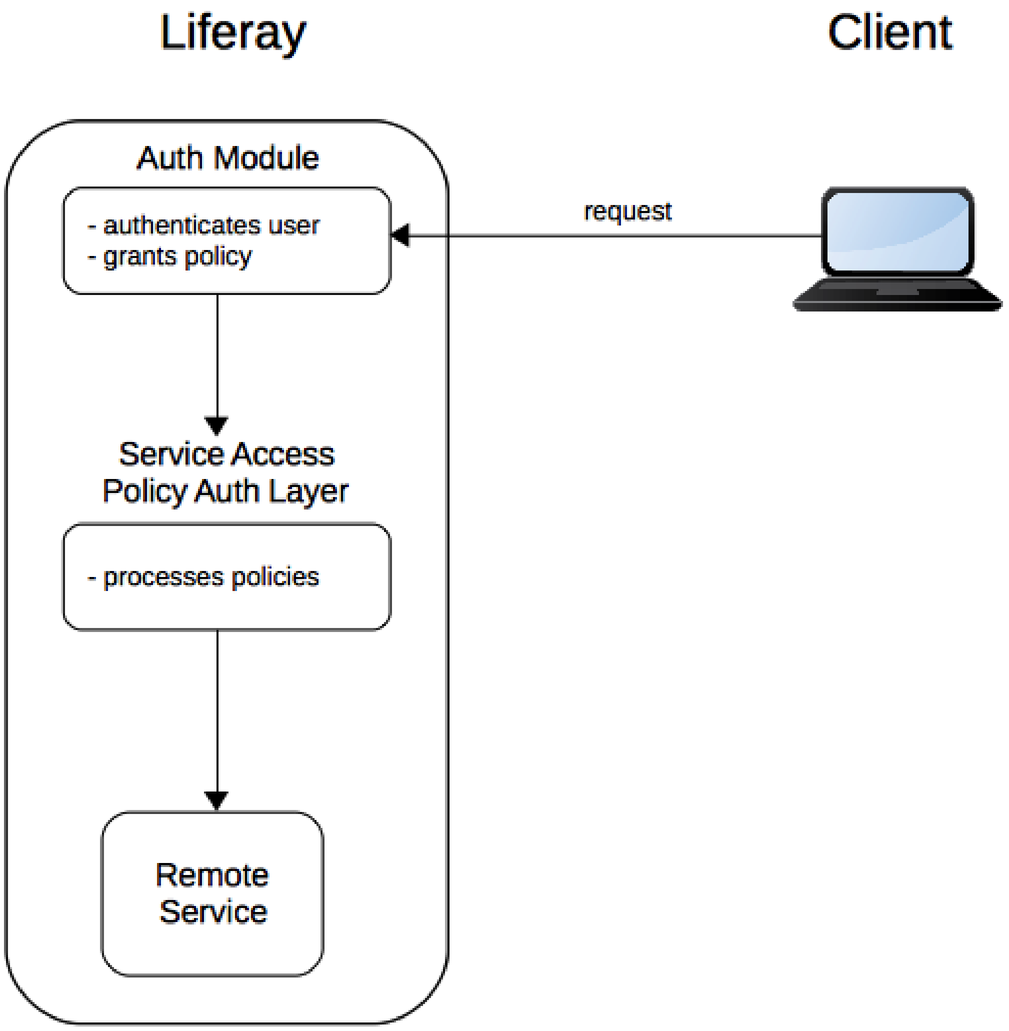

Figure 97.3: The authorization module maps the credentials or token to the proper Service Access Policy.

Service Access policies are created in the Control Panel by administrators. If you want to start creating policies yourself, see this article on service access policies that documents creating them in the UI.

There may be cases, however, when your server-side Liferay app needs to use the service access policies API. For example, your app may:

- use custom remote API authentication (tokens) and require certain services to be available for clients using the tokens.
- require its services be made available to guest users, with no authentication necessary.
- contain a remote service authorization layer that needs to drive access to remote services based on granted privileges.

API Overview

Liferay provides an Interface and a `ThreadLocal` if you don't want to roll your own policies. If you want to get low level, an API is provided that Liferay itself has used to implement Liferay Sync.

1. The Interface and `ThreadLocal` are available in the package `com.liferay.portal.kernel.security.service.access.policy` This package provides classes for basic access to policies. For example, you can use the singleton `ServiceAccessPolicyManagerUtil` to obtain Service Access Policies configured in the system. You can also use the `ServiceAccessPolicyThreadLocal` class to set and obtain Service Access Policies granted to the current request thread.

   At this level, you can get a list of the configured policies to let your app/client choose a policy for accessing services. Also, apps like OAuth can offer a list of available policies during the authorization step in the OAuth workflow and allow the user to choose the policy to assign to the remote application. You can also grant a policy to a current request thread. When a remote client accesses an API, something must tell the Liferay instance which policies are assigned to this call. This something is in most cases an `AuthVerifier` implementation. For example, in the case of the OAuth app, an `AuthVerifier` implementation assigns the policy chosen by the user in the authorization step.

2. The API ships with the product as OSGi modules:

- `com.liferay.portal.security.service.access.policy.api.jar`
- `com.liferay.portal.security.service.access.policy.service.jar`
- `com.liferay.portal.security.service.access.policy.web.jar`

  These OSGi modules are active in Liferay DXP by default, and you can use them to manage Service Access Policies programmatically. You can find their source code [here in GitHub](https://github.com/liferay/liferay-portal/tree/master/modules/apps/foundation/portal-security). Each module publishes a list of packages and services that can be consumed by other OSGi modules.

You can use both tools to develop a token verification module (a module that implements custom security token verification for use in authorizing remote clients) for your app to use. For example, this module may contain a JSON Web Token implementation for Liferay DXP's remote API. A custom token verification module must use the Service Access Policies API during the remote API/web service call to grant the associated policy during the request. The module:

- can use `com.liferay.portal.security.service.access.policy.api.jar` and `com.liferay.portal.security.service.acce` to create policies programmatically.

- should use the method ServiceAccessPolicyThreadLocal.addActiveServiceAccessPolicyName() to grant the associated policy during a web service request.

- can use ServiceAccessPolicyManagerUtil to display list of supported policies when authorizing the remote application, to associate the token with an existing policy.

Example

Liferay Sync's sync-security module is an example of such a module. It uses com.liferay.portal.security.service.access.pol to create the SYNC_DEFAULT and SYNC_TOKEN policies programmatically. For service calls to Sync's remote API, these policies grant access to Sync's com.liferay.sync.service.SyncDLObjectService#getSyncContext and com.liferay.sync.service.*, respectively. Here's the code in the sync-security module that defines and creates these policies:

```
@Component(immediate = true)
public class SyncSAPEntryActivator {

    // Define the policies
    public static final Object[][] SAP_ENTRY_OBJECT_ARRAYS = new Object[][] {
        {
            "SYNC_DEFAULT",
            "com.liferay.sync.service.SyncDLObjectService#getSyncContext", true
        },
        {"SYNC_TOKEN", "com.liferay.sync.service.*", false}
    };

    ...

    // Create the policies
    protected void addSAPEntry(long companyId) throws PortalException {
            for (Object[] sapEntryObjectArray : SAP_ENTRY_OBJECT_ARRAYS) {
                String name = String.valueOf(sapEntryObjectArray[0]);
                String allowedServiceSignatures = String.valueOf(
                    sapEntryObjectArray[1]);
                boolean defaultSAPEntry = GetterUtil.getBoolean(
                    sapEntryObjectArray[2]);

                SAPEntry sapEntry = _sapEntryLocalService.fetchSAPEntry(
                    companyId, name);

                if (sapEntry ≠ null) {
                    continue;
                }

                Map<Locale, String> map = new HashMap<>();

                map.put(LocaleUtil.getDefault(), name);

                _sapEntryLocalService.addSAPEntry(
                    _userLocalService.getDefaultUserId(companyId),
                    allowedServiceSignatures, defaultSAPEntry, true, name, map,
                    new ServiceContext());
            }
    }

    ...

}
```

Click here to see the entire SyncSAPEntryActivator class. This class creates the policies when the module starts. Note that this module is included and enabled in Liferay DXP by default. You can access these and other policies in *Control Panel → Configuration → Service Access Policy*.

The sync-security module must then grant the appropriate policy when needed. Since every authenticated call to Liferay Sync's remote API requires access to com.liferay.sync.service.*, the module must grant the SYNC_TOKEN policy to such calls. The module does this with the method ServiceAccessPolicyThreadLocal.addActiveServiceAccessPolicyName, as shown in this code snippet:

```
if ((permissionChecker ≠ null) && permissionChecker.isSignedIn()) {
    ServiceAccessPolicyThreadLocal.addActiveServiceAccessPolicyName(
        String.valueOf(
            SyncSAPEntryActivator.SAP_ENTRY_OBJECT_ARRAYS[1][0]));
}
```

Now every authenticated call to Sync's remote API, regardless of authentication method, has access to com.liferay.sync.service.*. To see the full code example, click here.

Nice! Now you know how to integrate your apps with the Service Access Policies in Liferay DXP.

97.5 Using JSR Roles in a Portlet

Roles in Liferay DXP are the primary means for granting or restricting access to content. If you've decided *not* to use Liferay's permissions system, you can use the basic system offered by the JSR 168, 286, and 362 specifications that map Roles in a portlet to Roles provided by the portal.

JSR Portlet Security

The portlet specification defines a means to specify Roles used by portlets in their docroot/WEB-INF/portlet.xml descriptors. The Role names themselves, however, are not standardized. When these portlets run in Liferay DXP, the Role names defined in the portlet must be mapped to Roles that exist in the Portal.

For example, consider a Guestbook project that contains two portlets: The Guestbook portlet and the Guestbook Admin portlet. The WAR version of the Guestbook project's portlet.xml file references the *administrator*, *guest*, *power-user*, and *user* Roles:

```
<?xml version="1.0"?>
<portlet-app xmlns="http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="http:/
app_2_0.xsd http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd" version="2.0">

<portlet>
    <portlet-name>guestbook</portlet-name>
    <display-name>Guestbook</display-name>
    <portlet-class>
        com.liferay.docs.guestbook.portlet.GuestbookPortlet
    </portlet-class>
    <init-param>
        <name>view-template</name>
        <value>/html/guestbook/view.jsp</value>
    </init-param>
    <expiration-cache>0</expiration-cache>
    <supports>
        <mime-type>text/html</mime-type>
        <portlet-mode>view</portlet-mode>
    </supports>
    <portlet-info>
        <title>Guestbook</title>
        <short-title>Guestbook</short-title>
        <keywords></keywords>
    </portlet-info>
    <security-role-ref>
        <role-name>administrator</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>guest</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>power-user</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>user</role-name>
    </security-role-ref>
</portlet>
<portlet>
    <portlet-name>guestbook-admin</portlet-name>
    <display-name>Guestbook Admin</display-name>
    <portlet-class>
        com.liferay.docs.guestbook.portlet.GuestbookAdminPortlet
    </portlet-class>
    <init-param>
        <name>view-template</name>
        <value>/html/guestbookadmin/view.jsp</value>
    </init-param>
    <expiration-cache>0</expiration-cache>
    <supports>
        <mime-type>text/html</mime-type>
        <portlet-mode>view</portlet-mode>
    </supports>
    <portlet-info>
        <title>Guestbook Admin</title>
        <short-title>Guestbook Admin</short-title>
        <keywords></keywords>
    </portlet-info>
    <security-role-ref>
        <role-name>administrator</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>guest</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>power-user</role-name>
    </security-role-ref>
    <security-role-ref>
        <role-name>user</role-name>
    </security-role-ref>
</portlet>
```

An OSGi-based `guestbook-web` module project defines Roles without an XML file, in the portlet class's `@Component` annotation:

```
@Component(
    immediate = true,
    property = {
        "com.liferay.portlet.display-category=category.sample",
        "com.liferay.portlet.instanceable=true",
        "javax.portlet.init-param.template-path=/",
        "javax.portlet.init-param.view-template=/view.jsp",
        "javax.portlet.name=" + GuestbookPortletKeys.Guestbook,
        "javax.portlet.resource-bundle=content.Language",
        "javax.portlet.security-role-ref=power-user,user"
    },
    service = Portlet.class
)
```

If you are using an OSGi-based MVC Portlet, you must use Liferay's permissions system, as the only way to map JSR-362 Roles to Liferay Roles is to place them in the Liferay WAR file's `portlet.xml`.

Your `portlet.xml` Roles must be mapped to specific Roles that have been created. These mappings allow Liferay DXP to resolve conflicts between Roles with the same name that are from different portlets (e.g. portlets from different developers).

Note: Each Role named in a portlet's `<security-role-ref>` element is given permission to add the portlet to a page.

Mapping Portlet Roles to Portal Roles

To map the Roles to Liferay DXP, you must use the `docroot/WEB-INF/liferay-portlet.xml` Liferay-specific configuration file. For an example, see the mapping defined in the Guestbook project's `liferay-portlet.xml` file.

```
<role-mapper>
    <role-name>administrator</role-name>
    <role-link>Administrator</role-link>
</role-mapper>
<role-mapper>
    <role-name>guest</role-name>
    <role-link>Guest</role-link>
</role-mapper>
<role-mapper>
    <role-name>power-user</role-name>
    <role-link>Power User</role-link>
</role-mapper>
<role-mapper>
    <role-name>user</role-name>
    <role-link>User</role-link>
</role-mapper>
```

If a portlet definition references the Role `power-user`, that portlet is mapped to the Liferay Role called *Power User* that's already in Liferay's database.

As stated above, there is no standardization with portal Role names. If you deploy a portlet with Role names different from the above default Liferay names, you must add the names to the `system.roles` property in your `portal-ext.properties` file:

```
system.roles=my-role,your-role,our-role
```

This prevents Roles from being created accidentally.

Once Roles are mapped to the portal, you can use methods as defined in the portlet specification:

- `getRemoteUser()`
- `isUserInRole()`
- `getUserPrincipal()`

For example, you can use the following code to check if the current User has the `power-user` Role:

```
if (renderRequest.isUserInRole("power-user")) {
    // ...
}
```

By default, Liferay doesn't use the `isUserInRole()` method in any built-in portlets. Liferay uses its own permission system directly to achieve more fine-grained security. If you don't intend on deploying your portlets to other portal servers, we recommend using Liferay's permission system, because it offers a much more robust way of tailoring your application's permissions.

Chapter 98

Internationalization

Liferay DXP makes it easier than ever to localize content and design apps for different locales. You can centralize messages (language keys) and have manual and automatic translation, including localizing forms and setting text directionality from left-to-right or right-to-left. Customizing messages in apps is easy too. Internationalization is a snap with Liferay DXP!

98.1 Localizing Your Application

If you're writing a Liferay Application, you're probably a genius who is also really cool. Which means your application is going to be used throughout the entire world. At least, it will if the messages that appear to its users can be translated into their language. Thankfully, Liferay makes it easy to support translation of your application's language keys.

Note: Even if you don't think your application needs to be translated into multiple languages, use the localization pattern presented here for any messages displayed in your user interface. It's much easier to change the messages by updating a language properties file than by finding every instance of a message and replacing it in your JSPs and Java classes.

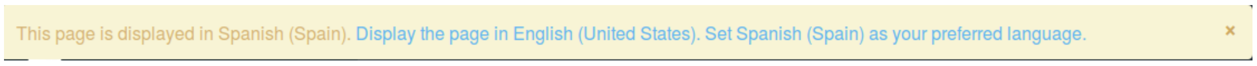
You just need to create a default language properties file (`Language.properties`) and one for each translation you'd like to support (for example, `Language_fr.properties` for your French translation), and put them in the correct location in your application. Use the two letter locale that corresponds to the language you want to translate in your file names (for example, `Language_es.properties` provides a Spanish translation for each key).

Application localization topics:

- What are Language Keys?
- What Locales are Available By Default?
- Where do I Put Language Files?
- Creating a Language Module
- Using a Language Module
- Using Global Language Properties

What are Language Keys?

Each language property file holds key/value pairs. The key is the same in all the language property files, while the value is translated in each file. You specify the key in your user interface code, and the appropriately translated message is returned automatically for your users, depending on the locale being used in Liferay. If you have Liferay running locally, append the URL with a supported locale to see how Liferay's language keys are translated (for example, enter `localhost:8080/es`).



This page is displayed in Spanish (Spain). Display the page in English (United States). Set Spanish (Spain) as your preferred language. ×

Figure 98.1: Append the locale to your running Liferay's URL and see Liferay's translation power in action.

Language keys are just keys you'll use in place of a hard coded, fully translated String value in your user interface code. For example, you can use a language key in your JSP via a `<liferay-ui:message />` tag.

The tag might be set up like this if you're not considering the need to translate your application's messages:

```
<liferay-ui:message key="Howdy, Partner!" />
```

In that case you'll get a properly capitalized and punctuated message in your application.

Alternatively, you can specify a simple key instead of the final value:

```
<liferay-ui:message key="howdy-partner" />
```

That way you can provide a translation of the key in a default language properties file (`Language.properties`):

```
howdy-partner=Howdy, Partner!
```

You'll get the same output in your application with either method above, but you have the flexibility to add additional language properties files that provide translations for your application's keys if you use the language properties approach. Use a key in your UI code, then provide the value (or translation) in your language properties file. You just need to make sure there's a locale that corresponds to your translation.

The values from your default `Language.properties` file will appear if no locale is specified. If a locale is specified, Liferay will try to find a file that corresponds to the locale. For example, if a Spanish translation is sought, a `Language_es.properties` file must be present to provide the proper values. If it isn't, the default language properties (from the `Language.properties` file) will be used.

What Locales are Available By Default?

There are a bunch of locales available by default in Liferay. Look in the `portal.properties` file file to find them.

```
locales=ar_SA,eu_ES,bg_BG,ca_AD,ca_ES,zh_CN,zh_TW,hr_HR,cs_CZ,da_DK,nl_NL,
    nl_BE,en_US,en_GB,en_AU,et_EE,fi_FI,fr_FR,fr_CA,gl_ES,de_DE,el_GR,
    iw_IL,hi_IN,hu_HU,in_ID,it_IT,ja_JP,ko_KR,lo_LA,lt_LT,nb_NO,fa_IR,
    pl_PL,pt_BR,pt_PT,ro_RO,ru_RU,sr_RS,sr_RS_latin,sl_SI,sk_SK,es_ES,
    sv_SE,tr_TR,uk_UA,vi_VN
```

To provide a translation for one of these locales, specify the locale in the file name where the translated keys will be (for example, `Langauge_es.properties` holds the Spanish translation).

Where do I Put Language Files?

In an application with only one module that holds all your application's views (for example, all its JSPs) and portlet components, just create a src/main/resources/content folder in that module, and place your Language.properties and Language_xx.properties files there.

After that, make sure any portlet components (the @Component annotation in your -Portlet classes) in the module include this property:

```
"javax.portlet.resource-bundle=content.Language"
```

Providing translated language properties files and specifying the javax.portlet.resource-bundle property in your portlet component is all you need to do to have your language keys translated. Then, when the locale is changed in Liferay DXP, your application's language keys will be automatically translated.

In a more complicated, well-modularized application, you might have language keys spread over multiple modules providing portlet components and JSP files. Moreover, there might be a fair number of duplicated language keys between the modules. Thankfully you don't need to maintain language properties files in each module.

Creating a Language Module

If you're crazy about modularity (and you should be), you might have an application with multiple modules that provide the view layer. These modules are often called web modules.

```
my-application/
my-application-web/
my-admin-application-web/
my-application-content-web/
my-application-api/
my-application-service/
```

Each of these modules can have language keys and translations to maintain, and there will probably be duplicate keys. You don't want to end up with different values for the same key, and you don't want to maintain language keys in multiple places. In this case, you need to go even crazier with modularity and create a new module, which we'll call a language module.

In the root project folder (the one that holds your service, API, and web modules), create a new module to hold your app's language keys. For example, here's the folder structure of a language module called my-application-lang.

```
my-application-lang/
    bnd.bnd
    src/
        main/
            resources/
                content/
                    Language.properties
                    Language_ar.properties
                    Language_bg.properties
                    ...
```

In the language module, create a src/main/resources/content folder. Put your language properties files here. A Language.properties file might look like this:

```
application=My Application
add-entity=Add Entity
```

Create any translations you want, adding the translation locale ID to the language file name. File Language_es.properties might look like this:

```
my-app-title=Mi Aplicación
add-entity=Añadir Entity
```

On building the language module, Liferay DXP's ResourceBundleLoaderAnalyzerPlugin detects the content/Language.properties file and adds a resource bundle *capability* to the module. A capability is a contract a module declares to Liferay DXP's OSGi framework. Capabilities let you associate services with modules that provide them. In this case, Liferay DXP registers a ResourceBundleLoader service for the resource bundle capability.

Next, you'll configure a web module to use the language module resource bundle.

Using a Language Module

A module or traditional Liferay plugin can use a resource bundle from another module and optionally include its own resource bundle. OSGi manifest headers Require-Capability and Provide-Capability make this possible, and it's especially easy in modules generated from Liferay project templates. Instructions for using a language module are divided into these environments:

- Using a Language Module from a Module
- Using a Language Module from a Traditional Plugin

If you're using bnd with Maven or Gradle, you need only specify Liferay's -liferay-aggregate-resource-bundle: bnd instruction–at build time, Liferay's bnd plugin converts the instruction to Require-Capability and Provide-Capability parameters automatically. Both approaches are demonstrated.

Using a Language Module from a Module

Modules generated from Liferay project templates have a Liferay bnd build time instruction called -liferay-aggregate-resource-bundles. It lets you use other resource bundles (e.g., including their language keys) along with your own. Here's how to do it:

1. Open your module's bnd.bnd file.

2. Add the -liferay-aggregate-resource-bundles: bnd instruction and assign it the bundle symbolic names of modules whose resource bundles to aggregate with the current module's resource bundle.

   ```
   -liferay-aggregate-resource-bundles: \
       [bundle.symbolic.name1],\
       [bundle.symbolic.name2]
   ```

For example, a module that uses resource bundles from modules com.liferay.docs.l10n.myapp1.lang and com.liferay.docs.l10n.myapp2.lang would set this in its bnd.bnd file:

```
-liferay-aggregate-resource-bundles: \
    com.liferay.docs.l10n.myapp1.lang,\
    com.liferay.docs.l10n.myapp2.lang
```

The current module's resource bundle is prioritized over those of the listed modules.

The Shared Language Key sample project is a working example that demonstrates aggregating resource bundles. You can deploy it in Gradle, Maven, and Liferay Workspace build environments.

At build time, Liferay's bnd plugin converts the bnd instruction to `Require-Capability` and `Provide-Capability` parameters automatically. In traditional Liferay plugins, you must specify the parameters manually.

Note: You can always specify the `Require-Capability` and `Provide- Capability` OSGi manifest headers manually, as the next section demonstrates.

Using a Language Module from a Traditional Plugin

To use a language module, from a traditional Liferay plugin you must specify the language module using `Require-Capability` and `Provide-Capability` OSGi manifest headers in the plugin's `liferay-plugin-package.properties` file.

Follow these steps to configure your traditional plugin to use a language module:

1. Open the plugin's `liferay-plugin-package.properties` file and add a `Require-Capability` header that filters on the language module's resource bundle capability. For example, if the language module's symbolic name is `myapp.lang`, you'd specify the requirement like this:

   ```
   Require-Capability: liferay.resource.bundle;filter:="(bundle.symbolic.name=myapp.lang)"
   ```

2. In the same `liferay-plugin-package.properties` file, add a `Provide-Capability` header that adds the language module's resource bundle *as* this plugin's (the `myapp.web` plugin) own resource bundle:

   ```
   Provide-Capability:\
   liferay.resource.bundle;resource.bundle.base.name="content.Language",\
   liferay.resource.bundle;resource.bundle.aggregate:String="(bundle.symbolic.name=myapp.lang)";bundle.symbolic.name=myapp.web;resource.bundle.base.nam
   servlet.context.name=myapp-web
   ```

In this case, the `myapp.web` plugin solely uses the language module's resource bundle—the resource bundle aggregate only includes language module `myapp.lang`.

Aggregating resource bundles comes into play when you want to use your a language module's resource bundle *in addition to* your plugin's resource bundle. These instructions show you how to do this, while prioritizing your current plugin's resource bundle over the language module resource bundle. In this way, the language module's language keys compliment your plugin's language keys.

For example, a portlet whose bundle symbolic name is `myapp.web` uses keys from language module `myapp.lang`, in addition to its own. The portlet's `Provide-Capability` and `Web-ContextPath` OSGi headers accomplish this.

```
Provide-Capability:\
liferay.resource.bundle;resource.bundle.base.name="content.Language",\
liferay.resource.bundle;resource.bundle.aggregate:String="(bundle.symbolic.name=myapp.web),(bundle.symbolic.name=myapp.lang)";bundle.symbolic.name=myapp.web
servlet.context.name=myapp-web
```

Let's examine the example `Provide-Capability` header.

1. `liferay.resource.bundle;resource.bundle.base.name="content.Language"` declares that the module provides a resource bundle whose base name is `content.language`.

2. The `liferay.resource.bundle;resource.bundle.aggregate:String=...` directive specifies the list of bundles whose resource bundles are aggregated, the target bundle, the target bundle's resource bundle name, and this service's ranking:

   - `"(bundle.symbolic.name=myapp.web),(bundle.symbolic.name=myapp.lang)"`: The service aggregates resource bundles from bundles `bundle.symbolic.name=myapp.web` (the current module) and `bundle.symbolic.name=myapp.lang`. Aggregate as many bundles as desired. Listed bundles are prioritized in descending order.
   - `bundle.symbolic.name=myapp.web;resource.bundle.base.name="content.Language"`: Override the `myapp.web` bundle's resource bundle named `content.Language`.
   - `service.ranking:Long="4"`: The resource bundle's service ranking is `4`. The OSGi framework applies this service if it outranks all other resource bundle services that target `myapp.web`'s `content.Language` resource bundle.
   - `servlet.context.name=myapp-web`: The target resource bundle is in servlet context `myapp-web`.

Now the language keys from the aggregated resource bundles compliment your plugin's language keys. Did you know that Liferay DXP's core language keys are also available to your module? They're up next.

Using Global Language Properties

If you have Liferay DXP's source code, you can check out Liferay DXP's core language properties by looking in the `portal-impl/src/main/content` folder. Otherwise, you can look in the `portal-impl.jar` that's in your Liferay bundle.

```
liferay-portal/portal-impl/src/content/Language_xx.properties
```

```
[Liferay Home]/tomcat-[version]/webapps/ROOT/WEB-INF/lib/portal-impl.jar
```

These keys are available at runtime, so when you use any of Liferay DXP's default keys in your user interface code, they're automagically swapped out for the appropriately translated value. Using Liferay DXP's keys where possible saves you time and ensures that your application follows Liferay's UI conventions.

If you want to generate language files for each supported locale automatically, or to configure your application to generate translations automatically using the Microsoft Translator API, check out the tutorial Automatically Generating Language Files.

98.2 Automatically Generating Language Files

If you already have a `Language.properties` file that holds language keys for your user interface messages, or even a language module that holds these keys, you're in the right place.

- Instead of manually creating a language properties file for each locale that's supported by Liferay, you can get them all automatically generated for you with one command. The same command also propagates the keys from the default language file to all translation files.

- You can also generate automatic translations using Microsoft's Translator Text API.

Generating Language Files for Supported Locales

If you want to generate files automatically for all locales supported by Liferay, you must make a small modification to your application's build file.

1. Make sure your module's build includes the `com.liferay.lang.builder` plugin, by putting the plugin in build script classpath.

2. Make sure you have a default `Language.properties` file in `src/main/resources/content`.

3. Run the `gradle buildLang` task from your project's root directory to generate default translation files.

   The generated files contain automatic copies of all the keys and values in your default `Language.properties` files. That way you don't have to copy your lanugage keys manually into all of the files. Run the `buildLang` task each time you change the default language file.

   When the task completes, it prints `BUILD SUCCESSFUL` with this log output:

   ```
   Translation is disabled because credentials are not specified
   ```

   See the next section to learn how to turn translation on and provide credentials.

Here's what a configuration of the `com.liferay.lang.builder` plugin looks in a `build.gradle` file:

```
buildscript {
    dependencies {
        classpath 'com.liferay:com.liferay.gradle.plugins.lang.builder:latest.release'
    }

    repositories {
        maven {
            url "http://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.lang.builder"

repositories {
    maven {
        url "http://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Now you can start translating your application's messages. If you want to configure your app to generate automatic translations using the Microsoft Translator Text API, keep reading.

Translating Language Keys Automatically

If you've configured the `com.liferay.lang.builder` plugin in your app, you're almost there. Now you have to configure Microsoft's Translator Text API so you can generate automatic translations of your language keys. You cannot, however, use Liferay's Lang Builder to automatically translate language keys containing HTML (e.g., `<em>`, `<b>`, `<code>`, etc.). Language keys containing HTML are automatically *copied* to all supported language files.

Note: These translations are best used as a starting point. A machine translation can't match the accuracy of a real person who is fluent in the language. Then again, if you only speak English and you need a Hungarian translation, this is better and faster than your attempts at a manual translation.

---

1. Generate a translation subscription key for the Microsoft Translator Text API. Follow the instructions here.

2. Make sure the buildLang task knows to use your subscription key for translation by setting the translateSubscriptionKey property:

   ```
   buildLang {
       translateSubscriptionKey = "my-key"
   }
   ```

   For security reasons you probably don't want to pass them directly in your application's build script. Instead, pass the credentials to a property that's stored in your local build environment, and pass the property into your application's build script.

   ```
    buildLang {
      translateSubscriptionKey = langTranslateSubscriptionKey
   }
   ```

So what would the complete buildLang configuration look like if you followed all the steps above?

```
buildscript {
    dependencies {
        classpath 'com.liferay:com.liferay.gradle.plugins.lang.builder:latest.release'
    }

    repositories {
        maven {
            url "http://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.lang.builder"

buildLang {
   translateSubscriptionKey = langTranslateSubscriptionKey
}

repositories {
    maven {
        url "http://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Great! You now know how to generate language files and provide automatic translations of your language keys.

98.3 Using Liferay's Language Settings

For a given locale, you can override Liferay's core UI messages. Modifying Language key values in Liferay provides a lot of localization flexibility in itself, but we're always looking for new ways to give you more control. There are language settings in Liferay's Language_xx.properties files that give you even more localization options.

- In the add and edit user forms, configure the name fields that are displayed and the field values available in select fields. For example, leave out the middle name field if you want, or alter the prefix selections.

- Control the directionality of content and messages in Liferay (left to right or right to left).

To see how these settings are configured, open Liferay's core `Language.properties` file in one of two ways:

1. From Liferay's source code, navigate to

   ```
   liferay-portal/portal-impl/src/content/Language.properties
   ```

2. From a Liferay bundle's `portal-impl.jar`.

   ```
   [Liferay Home]/tomcat-[version]/webapps/ROOT/WEB-INF/lib/portal-impl.jar
   ```

   Just open the `content` folder in the Jar to find the language files.

The first section in the `Language.properties` file is labeled *Language settings*:

```
##
## Language settings
##

lang.dir=ltr
lang.line.begin=left
lang.line.end=right
lang.user.name.field.names=prefix,first-name,middle-name,last-name,suffix
lang.user.name.prefix.values=Dr,Mr,Ms,Mrs
lang.user.name.required.field.names=last-name
lang.user.name.suffix.values=II,III,IV,Jr,Phd,Sr
```

Note: To use the language settings mentioned here, you need a module, which is like a magic carpet on which your code and resources ride triumphantly into Liferay's OSGi runtime. Refer to the tutorial on overriding language keys to set up a module with the following characteristics:

- Contains an implementation of `ResourceBundle` that is registered in the OSGi runtime.
- Contains a `Language.properties` file for the locale whose properties you want to override.

The user name properties are used to customize certain fields of the add and edit user forms based on a user's locale.

Localizing User Names

Liferay's customers come from all over the world, and we recognize that naming conventions are different between locales. Liferay's engineers have made several of the user name fields configurable in Liferay where user name information is entered or edited.

- Remove certain name fields and make others appear more than once. Some locale's need more than one last name, for example.

  ```
  lang.user.name.field.names=prefix,first-name,middle-name,last-name,suffix
  ```

- Change the prefix and suffix values for a locale.

```
lang.user.name.prefix.values=Dr,Mr,Ms,Mrs
lang.user.name.suffix.values=II,III,IV,Jr,Phd,Sr
```

- Specify which fields are required.

```
lang.user.name.required.field.names=last-name
```

Note: A user's first name is mandatory in Liferay. Because of this, take these two points into consideration when configuring a locale's user name settings:

1. The `first-name` field can't be removed from the field names list.

   ```
   lang.user.name.field.names=prefix,first-name,middle-name,last-name,suffix
   ```

2. Because first name is required, it's always implicitly included in the *required field names* property:

   ```
   lang.user.name.required.field.names=last-name
   ```

   Therefore, any fields you enter here are *in addition to* the first name field. Last name is required by default, but you can disable it by deleting its value from the property:

   ```
   lang.user.name.required.field.names=
   ```

   In that case, only first name would be required.

The properties for changing user name settings are those that begin with `lang.user.name` in the language settings section of a locale's language properties file.

For most of the locales enabled by default the user name properties are specifically tailored to that location.

```
locales.enabled=ca_ES,zh_CN,nl_NL,en_US,fi_FI,fr_FR,de_DE,iw_IL,hu_HU,ja_JP,pt_BR,es_ES
```

For example, these are the English (`Language_en.properties`) properties for setting user name fields:

```
lang.user.name.field.names=prefix,first-name,middle-name,last-name,suffix
lang.user.name.prefix.values=Dr,Mr,Ms,Mrs
lang.user.name.required.field.names=last-name
lang.user.name.suffix.values=II,III,IV,Jr,Phd,Sr
```

Compare those to the Spanish (`Language_es.properties`) settings:

```
lang.user.name.field.names=prefix,first-name,last-name
lang.user.name.prefix.values=Sr,Sra,Sta,Dr,Dra
lang.user.name.required.field.names=last-name
```

The biggest difference between the English and Spanish form fields in the images above is that the middle name and suffix fields are omitted in the Spanish configuration. Other differences include the specific prefix values.

¡Muy excelente! Localizing the forms for adding and editing users is accomplished using the same method by which Liferay's UI messages are localized: by overriding one of Liferay's `Lanuguage_xx.properties` files.

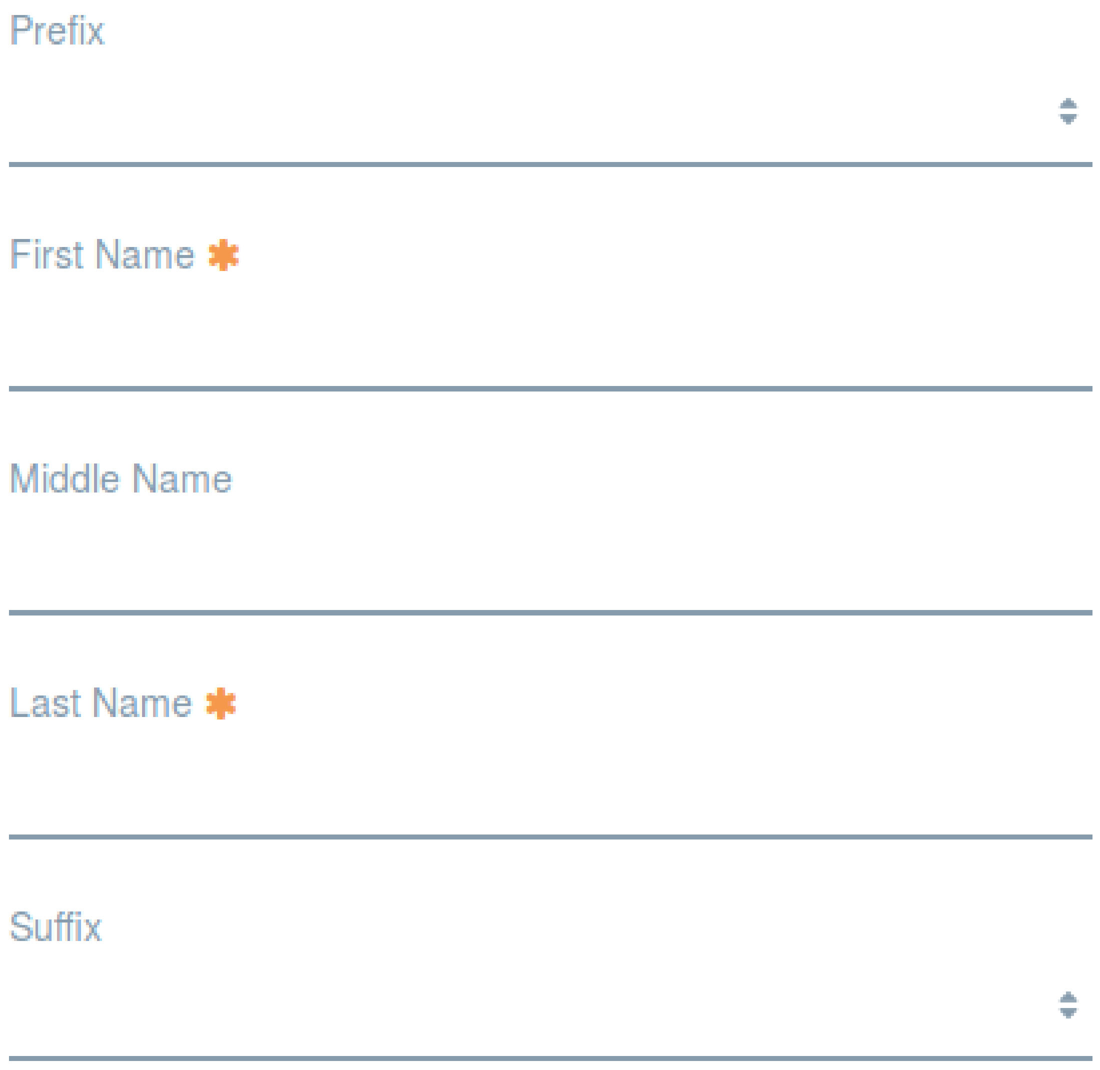


Figure 98.2: The user name settings impact the way user information and forms appear in Liferay.

Right to Left or Left to Right?

The first three properties in the language settings section are used for changing the direction in which the language's characters are displayed. Most languages are read from left to right, but other languages are meant to be read from right to left (Arabic, Hebrew, and Persian, for example). It can also be changed for languages that have been traditionally displayed left to right (like English) as a funny practical joke. Just don't tell anyone that you got the idea here.

Here's what the relevant language properties look like for a language that should be displayed from right to left:

```
lang.dir=rtl
lang.line.begin=right
lang.line.end=left
```

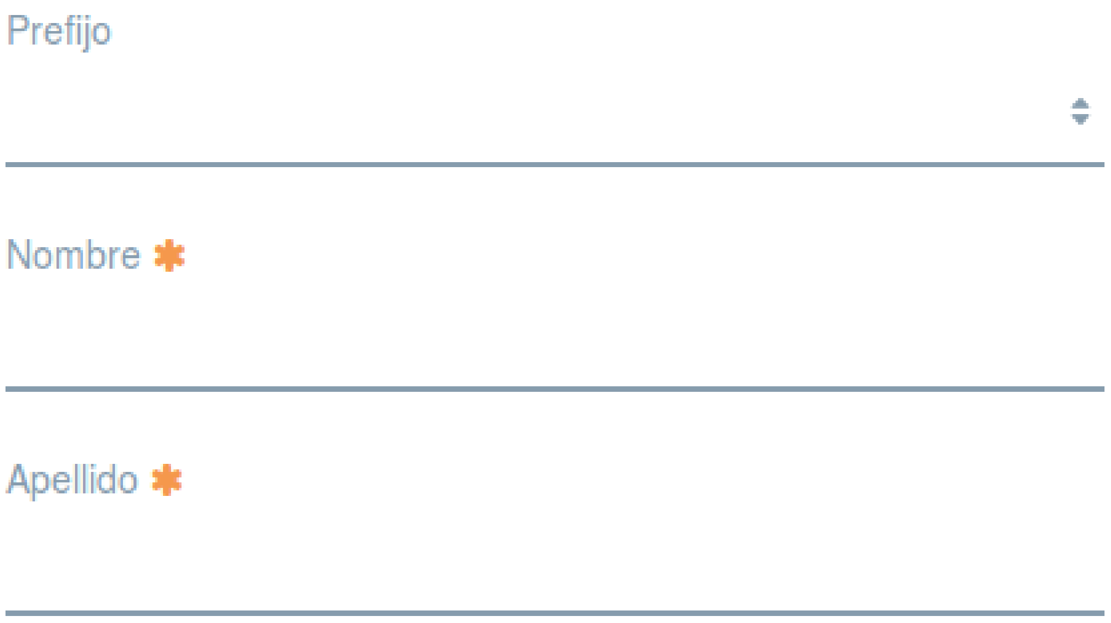

Figure 98.3: The Spanish user name settings omit the suffix and middle name fields entirely.

With these customizations yo can transform Liferay's UI into a user-friendly environment no matter where your users are from.

Chapter 99

WYSIWYG Editors

WYSIWYG editors are an important part of content creation. Liferay's platform supports several different editors, including CKEditor, TinyMCE, and our flagship, AlloyEditor. This section contains tutorials relating to WYSIWYG editors on the Liferay platform.

99.1 Adding a WYSIWYG Editor to a Portlet

It's easy to include WYSIWYG editors in your portlet, thanks to the `<liferay-ui:input-editor />` tag. Below is an example configuration:

```
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>

<div class="alloy-editor-container">
    <liferay-ui:input-editor
        contents="Default Content"
        cssClass="my-alloy-editor"
        editorName="alloyeditor"
        name="myAlloyEditor"
        placeholder="description"
        showSource="true" />
</div>
```

It is also possible to pass JavaScript functions through the `onBlurMethod`, `onChangeMethod`, `onFocusMethod`, and `onInitMethod` attributes. Here is an example configuration that uses the `onInitMethod` attribute to pass a JavaScript function called `OnDescriptionEditorInit`:

```
<%@ taglib prefix="aui" uri="http://liferay.com/tld/aui" %>
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>

<div class="alloy-editor-container">
    <liferay-ui:input-editor
        contents="Default Content"
        cssClass="my-alloy-editor"
        editorName="alloyeditor"
        name="myAlloyEditor"
        onInitMethod="OnDescriptionEditorInit"
        placeholder="description"
        showSource="true" />
</div>

<aui:script>
```

```
    function <portlet:namespace />OnDescriptionEditorInit() {
        <c:if test="<%= !customAbstract %>">
            document.getElementById('<portlet:namespace />myAlloyEditor').setAttribute('contenteditable', false);
        </c:if>
    }
</aui:script>
```

Below is an overview of the main attributes of the `<liferay-ui:input-editor />` tag:

Attribute	Type	Description
autoCreate	`java.lang.String`	Whether to show the HTML edit view of the editor initially
contents	`java.lang.String`	Sets the initial contents of the editor
contentsLanguageId	`java.lang.String`	Sets the language ID for the input editor's text
cssClass	`java.lang.String`	A CSS class for styling the component.
data	`java.util.Map`	Data that can be used as the editorConfig
editorName	`java.lang.String`	The editor you want to use (alloyeditor, ckeditor, tinymce, simple)
name	`java.lang.String`	A name for the input editor. The default value is `editor`.
onBlurMethod	`java.lang.String`	A function to be called when the input editor loses focus.
onChangeMethod	`java.lang.String`	A function to be called on a change in the input editor.
onFocusMethod	`java.lang.String`	A function to be called when the input editor gets focus.
onInitMethod	`java.lang.String`	A function to be called when the input editor initializes.
placeholder	`java.lang.String`	Placeholder text to display in the input editor.
showSource	`java.lang.String`	Whether to enable editing the HTML source code of the content. The default value is `true`.

See the taglibdocs for the complete list of supported attributes.

As you can see, it's easy to include WYSIWYG editors in your portlets!

Modifying an Editor's Configuration

Using the Liferay UI Taglib

99.2 Modifying an Editor's Configuration

Liferay DXP supports many different kinds of WYSIWYG editors that can be used in portlets to edit content. Depending on the content you're editing, you may want to modify the editor to provide a better configuration for your needs. In this tutorial, you'll learn how to extend your Liferay supported WYSIWYG editor to add new or modify existing configurations exactly how you'd like.

Extending the Editor's Configuration

To modify the editor's configuration, create a module that has a component that implements the `EditorConfigContributor` interface. When you implement this interface, your module will provide a service that modifies the editors you'd like to change. A simple example of this is provided below.

1. Create an OSGi module.

2. Create a unique package name in the module's `src` directory, and create a new Java class in that package. The class should extend the BaseEditorConfigContributor class.

3. Directly above the class's declaration, insert a component annotation:

```
@Component(
    property = {

    },

    service = EditorConfigContributor.class
)
```

   This annotation declares the implementation class of the Component and specifies the Component's properties. You should implement the `EditorConfigContributor` interface for this scenario. The `property` element is blank in the code snippet above. You need to insert properties that distinguish the editor's name, editor's configuration key, and/or the portlet name where the editor resides. These three properties can be specified independently or in any variation with each other. You can find out more about the available properties and how they should be used by reading the Javadoc provided in the EditorConfigContributor interface.

   The following code is a sample of what the `@Component` annotation could look like when modifying an editor's configuration:

```
@Component(
    property = {
        "editor.config.key=contentEditor", "editor.name=alloyeditor",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsPortlet",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsAdminPortlet",
        "service.ranking:Integer=100"
    },

    service = EditorConfigContributor.class
)
```

   This annotation declares that the following service is applied for the AlloyEditor identified by the `contentEditor` configuration key.

~~~~
**Note:** If you're targeting all editors for a portlet, the
`editor.config.key` is not required. For example, if you just want to target
the Web Content portlet's editors, you can provide the configuration below:

    @Component(
      property = {"editor.name=ckeditor",
      "javax.portlet.name=com_liferay_journal_web_portlet_JournalPortlet",
      "service.ranking:Integer=100"
    }
~~~~

~~~~
Two portlet names are specified (Blogs and Blogs Admin), which means the
service applies to all editors in those portlets. Lastly, the service
ranking is listed, which prioritizes this service over others that are
currently deployed in Liferay DXP.
~~~~

~~~~
**NOTE:** If you want to create a global configuration that applies to an
editor everywhere it's used, you must create two separate configurations:
one configuration that targets just the editor and a second configuration
that targets the Blogs and Blogs Admin portlets. For example, the two
separate configurations below apply the updates to AlloyEditor everywhere
it's used:

Configuration one:

```java
@Component(
    immediate = true,
    property = {
        "editor.name=alloyeditor",
        "service.ranking:Integer=100"
    },

    service = EditorConfigContributor.class
)
```

Configuration two:

```java
@Component(
    immediate = true,
    property = {
        "editor.name=alloyeditor",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsPortlet",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsAdminPortlet",
        "service.ranking:Integer=100"
    },

    service = EditorConfigContributor.class
)
```
~~~~

---

4. Now that you've specified which editor configurations you want to modify, you must specify what about them must change. Add the following method to your new class:

```
@Override
public void populateConfigJSONObject(
    JSONObject jsonObject, Map<String, Object> inputEditorTaglibAttributes,
```

```
        ThemeDisplay themeDisplay,
        RequestBackedPortletURLFactory requestBackedPortletURLFactory) {

    }
```

This method updates the original configuration JSON object with a new configuration. It can even update or delete the original configuration, or any other configuration introduced by another `EditorConfigContributor`. The configuration object contains the configuration to be directly used by the editor. This means that the configuration object used for this editor may differ from other editors used in Liferay DXP.

Currently, this method does nothing. You need to add some logic, which you'll do next.

5. In the `populateConfigJSONObject` method, you need to instantiate a JSONObject that holds the current configuration of the editor. For instance, you could do something like this:

   ```
   JSONObject toolbars = jsonObject.getJSONObject("toolbars");
   ```

   This gets the editor's toolbar.

```
**Note:** This toolbar configuration is only applicable for the AlloyEditor.
If you choose a configuration that is supported by multiple editors, you
could apply it to them all. To do this, you could specify all the editors
(e.g., `"editor.name=alloyeditor"`, `"editor.name=ckeditor"`,
`ckeditor_bbcode` etc.) in the `@Component` annotation  of your
`EditorConfigContributor` implementation, as you did in step 3. Use the
site links provided at the bottom of this tutorial to view each editor's
configuration options and requirements.
```

```
Now that you've retrieved the toolbar, you can modify it. You'll do this
next.
```

6. You'll modify the editor's toolbar by adding a camera button. To complete this, extract the *Add* buttons out of your toolbar configuration object as a JSONArray, and then add the button to that `JSONArray`. The following code adds a *Camera* button to the editor's toolbar:

   ```
   if (toolbars != null) {
       JSONObject toolbarAdd = toolbars.getJSONObject("add");

       if (toolbarAdd != null) {
           JSONArray addButtons = toolbarAdd.getJSONArray("buttons");

           addButtons.put("camera");
       }
   }
   ```

   The configuration JSON object is passed to the editor with the modifications you've implemented in the `populateConfigJSONObject` method.

Your Java class is complete! The only thing left to do is generate the module's JAR file and copy it to your Portal's `deploy` folder. Once the module is installed and activated in your Portal's service registry, your new editor configuration is available for use.

Liferay DXP supports several different types of WYSIWYG editors, which include (among others):

- AlloyEditor
- CKEditor
- TinyMCE

Make sure to visit each editor's configuration API to learn what each editor offers for configuration settings.

Developing Portlets

99.3 Adding New Behavior to an Editor

With the support of several kinds of WYSIWYG editors, Liferay gives you many options to support your users' editing needs. Sometimes, however, you can't get what you want with configuration alone. To help developers in these situations, Liferay provides a way to programmatically access the editor instance to create the editor experience you want.

This can be done by using the `liferay-util:dynamic-include` JavaScript extension point. This allows anyone to inject JavaScript code right after the editor instantiation to configure/change the editor.

Note: By default, the CKEditor strips empty <i> tags, such as those used for Font Awesome icons, from published content, when switching between the Code View and the Source View of the editor. You can disable this behavior by using the `ckeditor#onEditorCreate` or `alloyeditor#onEditorCreate` extension points to add the following code to the editor:

```
CKEDITOR.dtd.$removeEmpty.i = 0
```

In this tutorial, you'll learn how to use the JavaScript extension point in your Liferay supported WYSIWYG editor.

Injecting JavaScript into a WYSIWYG Editor

The `liferay-util:dynamic-include` extension point is available in the JSP files of Liferay DXP's configurable editors. This extension point serves as the gateway for injecting JavaScript into your editor instance. To take advantage of this extension point, you should follow these steps:

1. Create a JS file with the JavaScript code you'd like to execute in your editor. Create the JS file in a folder that makes sense to reference, since you'll need to register the file in your module. Also remember that the extension point is configured to inject the JavaScript code into the editor immediately following editor initialization.

   Some examples of JS files that are injected into the CKEditor are creole_dialog_definition.js, creole_dialog_show.js, and dialog_definition.js. These JS files are used by Liferay DXP to redefine which fields show in different dialogs, depending on what the selected language (HTML, BBCode, Creole) supports. For example, Creole doesn't support background color in table cells, so the table cells are removed from the options displayed to the user when running in Creole mode.

2. Create a module that can register your new JS file and inject it into your editor instance. The module should have a structure similar to this:

    - `bnd.bnd`
    - `build.gradle`
    - `gradle/`
        - `wrapper/`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `gradlew`
    - `gradlew.bat`
    - `src/main/`
        - `java/com/liferay/editor/myeditormodule/`
            - `constants/`
                - `MyEditorModulePortletKeys.java`
            - `internal/`
                - `CKEditorOnDialogDefinitionCreateDynamicInclude.java`
        - `resources/`
            - `META-INF/resources/ckeditor/extension/`
                - `ckeditor_dialog_definition.js`
            - `content/`
                - `Language.properties`

3. Create a unique package name in the module's src directory, and create a new Java class in that package. To follow naming conventions, your class name should begin with the editor you're modifying, followed by custom attributes, and ending with *DynamicInclude* (e.g., `CKEditorCreoleOnEditorCreateDynamicInclude.java`). Your Java class should implement the DynamicInclude interface.

4. Directly above the class's declaration, insert the following code:

    ```
    @Component(immediate = true, service = DynamicInclude.class)
    ```

    This annotation declares the implementation class of the Component, and specifies to immediately start the module once deployed to Portal.

5. If you have not yet inherited the abstract methods from `DynamicInclude`, do that now. You'll have two implemented methods to edit: `include(...)` and `register(...)`.

6. In the `include(...)` method, retrieve the bundle where your custom JS file resides. Then retrieve the JS file as a URL and inject the contents into the editor. You can view some example code below that does this for the `creole_dialog_definition.js` file:

   ```
   Bundle bundle = _bundleContext.getBundle();

   URL entryURL = bundle.getEntry(
       "/META-INF/resources/html/editors/ckeditor/extension" +
           "/creole_dialog_definition.js");

   StreamUtil.transfer(entryURL.openStream(), response.getOutputStream());
   ```

   In the `include(...)` method, you can also retrieve editor configurations and choose what JS file to inject based on the configuration selected by the user. For example, this would be applicable for the use case that was suggested previously dealing with Creole's deficiency with displaying background colors in table cells. You can look at how this could be done by looking at the `include(...)` method in the CKEditorCreoleOnEditorCreateDynamicInclude class.

7. Make sure you've instantiated your bundle's context so you can successfully retrieve your bundle. As a best practice, do this by creating an activation method and then setting the `BundleContext` as a private field. Here's an example:

   ```
   @Activate
   protected void activate(BundleContext bundleContext) {
       _bundleContext = bundleContext;
   }

   private BundleContext _bundleContext;
   ```

   This method uses the `@Activate` annotation, which specifies that it should be invoked once the service component has satisfied its requirements. For this default example, the `_bundleContext` was used in the `include(...)` method.

8. Now register the editor you're customizing. For example, if you were injecting JS code into the CKEditor's JSP file, the code would look like this:

   ```
   dynamicIncludeRegistry.register(
       "com.liferay.frontend.editor.ckeditor.web#ckeditor#onEditorCreate");
   ```

   This registers the CKEditor into the Dynamic Include registry and specifies that JS code will be injected into the editor once it's created.

   Just as you can configure individual JSP pages to use a specific implementation of the available WYSIWYG editors, you can use those same implementation options for the registration process. Visit the Editors section of `portal.properties` for more details. For example, to configure the Creole implementation of the CKEditor, you could use the following key:

   ```
   "com.liferay.frontend.editor.ckeditor.web#ckeditor_creole#onEditorCreate"
   ```

That's it! The JS code that you created is now injected into the editor instance you've specified. You're now able to use JavaScript to add new behavior to your Liferay supported WYSIWYG editor!

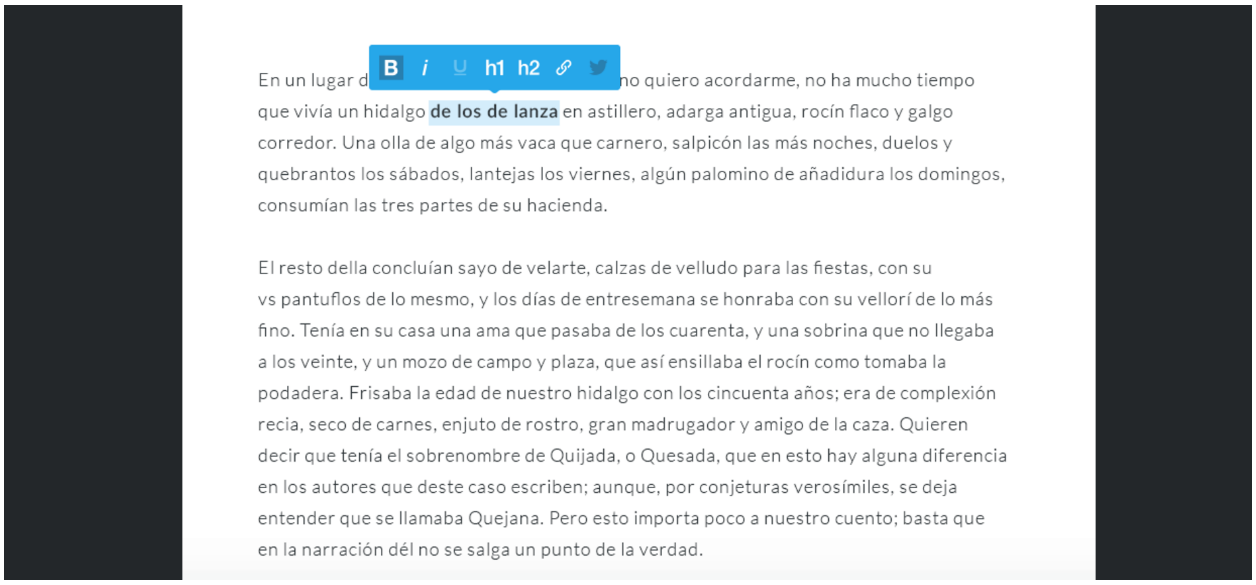
CHAPTER 100

AlloyEditor

AlloyEditor is a modern WYSIWYG editor built on top of CKEDITOR, designed to create modern and gorgeous web content.

As of Liferay DXP, AlloyEditor is the default WYSIWYG editor in Liferay DXP. Writing content is now enjoyable, and it has never been so easy!



En un lugar d no quiero acordarme, no ha mucho tiempo que vivía un hidalgo **de los de lanza** en astillero, adarga antigua, rocín flaco y galgo corredor. Una olla de algo más vaca que carnero, salpicón las más noches, duelos y quebrantos los sábados, lantejas los viernes, algún palomino de añadidura los domingos, consumían las tres partes de su hacienda.

El resto della concluían sayo de velarte, calzas de velludo para las fiestas, con su vs pantuflos de lo mesmo, y los días de entresemana se honraba con su vellorí de lo más fino. Tenía en su casa una ama que pasaba de los cuarenta, y una sobrina que no llegaba a los veinte, y un mozo de campo y plaza, que así ensillaba el rocín como tomaba la podadera. Frisaba la edad de nuestro hidalgo con los cincuenta años; era de complexión recia, seco de carnes, enjuto de rostro, gran madrugador y amigo de la caza. Quieren decir que tenía el sobrenombre de Quijada, o Quesada, que en esto hay alguna diferencia en los autores que deste caso escriben; aunque, por conjeturas verosímiles, se deja entender que se llamaba Quejana. Pero esto importa poco a nuestro cuento; basta que en la narración dél no se salga un punto de la verdad.

Figure 100.1: AlloyEditor is the new WYSIWYG editor by default, built on top of CKEditor.

100.1 Creating and Contributing new Buttons to AlloyEditor

It is possible to add additional AlloyEditor functionality through OSGi bundles. This tutorial demonstrates how to add a button to the editor.

Note: To use the syntax covered here, you must have AlloyEditor 2.11.0 or higher, which is included in Liferay DXP 7.0 Fix Pack 90 and Service Pack 13.

In this tutorial, you will learn how to

- Create an OSGi bundle for your own button
- Create a custom button for `AlloyEditor`
- Contribute your button to the list of available buttons
- Use your custom button in a toolbar in `AlloyEditor`

Go ahead and get started by creating the OSGi bundle next.

Creating the OSGi Bundle

AlloyEditor is built on `React.js` and uses `jsx` to render each button in the editor. Below is the folder structure for a module that adds a new button:

- `frontend-editor-my-button-web`
  - `src`
    - `main`
      - `java` - `com/liferay/frontend/editor/my/button/web/`
      - `editor`
      - `configuration`
      - `AlloyEditorMyButtonConfigContributor.java`
    - `servlet`
      - `taglib`
      - `AlloyEditorMyButtonDynamicInclude.java`
    - `resources`
      - `META-INF`
      - `resources`
      - `js`
      - `my_button.jsx`
  - `.babelrc` - needed since `JSX` is being compiled
  - `bnd.bnd`(example configuration shown below)

    Bundle-Name: Liferay Frontend Editor AlloyEditor My Button Web Bundle-SymbolicName: com.liferay.frontend.editor.alloyeditor.my.button.web Bundle-Version: 1.0.0 Liferay-Releng-Module-Group-Description: Liferay-Releng-Module-Group-Title: Rich Text Editors Web-ContextPath: /frontend-editor-alloyeditor-my-button-web

- `build.gradle`(contents shown below)

  configJSModules { enabled = false }

  dependencies { provided group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0" provided group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1" provided group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0" }

  transpileJS { bundleFileName = "js/buttons.js" globalName = "AlloyEditor.Buttons" modules = "globals" srcIncludes = "**/*.jsx" }

- `package.json`(contents shown below)

  { "devDependencies": { "babel-preset-react": "^6.11.1", "metal-cli": "^2.0.0" }, "name": "frontend-editor-alloyeditor-my-button-web", "version": "1.0.0" }

The contents of some of the files have been added as well, since the `build gradle` file requires some customizing.

Now that your OSGi bundle is configured, you can learn how to create buttons for the AlloyEditor next.

Creating the Button

Below is an example configuration for a JSX file that creates a new button:

```
/* global React, ReactDOM AlloyEditor */
(function() {
	'use strict';
	var React = AlloyEditor.React;
	var ButtonMyButton = React.createClass(
		{
			mixins: [AlloyEditor.Compat.ButtonStateClasses],
			displayName: 'ButtonMyButton',
			propTypes: {
				editor: React.PropTypes.object.isRequired
			},
			statics: {
				key: 'myButton'
			},
			/**
			 * Lifecycle. Renders the UI of the button.
			 *
			 * @method render
			 * @return {Object} The content which should be rendered.
			 */
			render: function() {
				var cssClass = 'ae-button ' + this.getStateClasses();
				return (
					<button className={cssClass}
					onClick={this._requestExclusive}
					tabIndex={this.props.tabIndex}>
						<small className="ae-icon small">
						Alt
						</small>
					</button>
				);
			},
			/**
			 * @protected
			 * @method  _doSomething
			 * @param {MouseEvent} event
			 */
			_doSomething: function(event) {
				console.log('do something!');
			}
```

```
                }
        );
        AlloyEditor.Buttons[ButtonMyButton.key] = AlloyEditor.ButtonMyButton
        = ButtonMyButton;
}());
```

The configuration above creates a new button called ButtonMyButton. The key aspects to note here are the lines that reference the global AlloyEditor. You can create your own JavaScript functions to interact with your button.

Now that you've seen how you can use a JSX file to create a new button, you can learn how to use your button in the editor next.

Contributing the Button

The next step is to add your button to the list of already available buttons. This can be achieved thanks to some smartly placed <liferay-util:dynamic-include /> tags in the editor's infrastructure. To make your button available in the AlloyEditor, you must extend the BaseDynamicInclude class. Below is an example configuration that extends this class:

```
package com.liferay.frontend.editor.alloyeditor.my.button.web.servlet.taglib;

import com.liferay.portal.kernel.servlet.taglib.BaseDynamicInclude;
import com.liferay.portal.kernel.servlet.taglib.DynamicInclude;
import com.liferay.portal.kernel.theme.ThemeDisplay;
import com.liferay.portal.kernel.util.PortalUtil;
import com.liferay.portal.kernel.util.StringBundler;
import com.liferay.portal.kernel.util.WebKeys;

import java.io.IOException;
import java.io.PrintWriter;

import javax.servlet.ServletContext;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

@Component(immediate = true, service = DynamicInclude.class)
public class AlloyEditorMyButtonDynamicInclude extends BaseDynamicInclude {

        @Override
        public void include(
                        HttpServletRequest request, HttpServletResponse response,
                        String key)
                throws IOException {

                ThemeDisplay themeDisplay = (ThemeDisplay)request.getAttribute(
                        WebKeys.THEME_DISPLAY);

                PrintWriter printWriter = response.getWriter();

                StringBundler sb = new StringBundler(7);

                sb.append("<script src=\"");
                sb.append(themeDisplay.getPortalURL());
                sb.append(PortalUtil.getPathProxy());
                sb.append(_servletContext.getContextPath());
                sb.append("/js/buttons.js");
                sb.append("\" ");
                sb.append("type=\"text/javascript\"></script>");

                printWriter.println(sb.toString());
```

```
	}

	@Override
	public void register(DynamicIncludeRegistry dynamicIncludeRegistry) {
		dynamicIncludeRegistry.register(
			"com.liferay.frontend.editor.alloyeditor.web#alloyeditor#" +
				"additionalResources");
	}

	@Reference(
		target = "(osgi.web.symbolicname=com.liferay.frontend.editor.alloyeditor.my.button.web)"
	)
	private ServletContext _servletContext;
}
```

Now that your button is included, you can learn how to make the button available in the editor's toolbar next.

Using the Button in a Toolbar

As explained in the Modifying an Editor's Configuration tutorial, you can configure which buttons show in the AlloyEditor toolbars by adding your own `EditorConfigContributor`. This file allows you to specify where in the toolbar your button should appear. The example configuration below doesn't specify a portlet name, so the button is added to the global AlloyEditor.

```
package com.liferay.frontend.editor.alloyeditor.my.button.web.editor.configuration;

import com.liferay.portal.kernel.editor.configuration.BaseEditorConfigContributor;
import com.liferay.portal.kernel.editor.configuration.EditorConfigContributor;
import com.liferay.portal.kernel.json.JSONArray;
import com.liferay.portal.kernel.json.JSONFactoryUtil;
import com.liferay.portal.kernel.json.JSONObject;
import com.liferay.portal.kernel.portlet.RequestBackedPortletURLFactory;
import com.liferay.portal.kernel.theme.ThemeDisplay;

import java.util.Map;
import java.util.Objects;

import org.osgi.service.component.annotations.Component;

@Component(
	property = {"editor.name=alloyeditor", "service.ranking:Integer=1000"},
	service = EditorConfigContributor.class
)
public class AlloyEditorMyButtonConfigContributor
	extends BaseEditorConfigContributor {

	@Override
	public void populateConfigJSONObject(
		JSONObject jsonObject, Map<String, Object> inputEditorTaglibAttributes,
		ThemeDisplay themeDisplay,
		RequestBackedPortletURLFactory requestBackedPortletURLFactory) {

		JSONObject toolbarsJSONObject = jsonObject.getJSONObject("toolbars");

		if (toolbarsJSONObject == null) {
			toolbarsJSONObject = JSONFactoryUtil.createJSONObject();
		}

		JSONObject stylesJSONObject = toolbarsJSONObject.getJSONObject(
			"styles");

		if (stylesJSONObject == null) {
			stylesJSONObject = JSONFactoryUtil.createJSONObject();
```

```
                }

                JSONArray selectionsJSONArray = stylesJSONObject.getJSONArray(
                        "selections");

                for (int i = 0; i < selectionsJSONArray.length(); i++) {
                        JSONObject selection = selectionsJSONArray.getJSONObject(i);

                        if (Objects.equals(selection.get("name"), "text")) {
                                JSONArray buttons = selection.getJSONArray("buttons");

                                buttons.put("myButton");
                        }
                }

                stylesJSONObject.put("selections", selectionsJSONArray);

                toolbarsJSONObject.put("styles", stylesJSONObject);

                jsonObject.put("toolbars", toolbarsJSONObject);
        }
}
```

There you have it. Now you know how to create and use custom buttons in the AlloyEditor!

Adding a WYSIWYG Editor to a Portlet

Modifying an Editor's Configuration

100.2 Using the Default CKEditor Plugins Bundled with AlloyEditor

You can customize an editor's configuration to include several modifications, such as adding new buttons and adding new behaviors. You can also use existing CKEditor plugins in AlloyEditor. Several CKEditor plugins are packaged with Liferay DXP's AlloyEditor, so you can use them with just a few configuration adjustments. This tutorial shows how to use the CKEditor plugins bundled with Liferay DXP's AlloyEditor. The `com.liferay.docs.myblogseditorconfigcontributor` module is used as an example throughout this tutorial.

Follow these steps:

1. Create a module to modify the AlloyEditor's configuration. The example boilerplate below modifies the AlloyEditor's configuration for the Blogs and Blogs Admin portlets:

```
@Component(
    immediate = true,
    property = {
        "editor.config.key=contentEditor",
        "editor.name=alloyeditor",
        "editor.name=ckeditor",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsPortlet",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsAdminPortlet",
        "service.ranking:Integer=100"
    },
    service = EditorConfigContributor.class
)
public class MyBlogsEditorConfigContributor
  extends BaseEditorConfigContributor {

    @Override
    public void populateConfigJSONObject(
      JSONObject jsonObject, Map<String, Object> inputEditorTaglibAttributes,
      ThemeDisplay themeDisplay,
      RequestBackedPortletURLFactory requestBackedPortletURLFactory) {

    }
  }
```

2. Add additional plugins to the AlloyEditor via the `extraPlugins` JSON object. To add a CKEditor plugin, extract the current list of `extraPlugins` from your editor configuration object as a `String`:

   ```
   String extraPlugins = jsonObject.getString("extraPlugins");
   ```

3. Choose the plugin(s) you want to use from the default CKEditor plugins bundled with Liferay DXP's AlloyEditor.

4. Add the CKEditor plugin(s) you want to use to the `extraPlugins` configuration. Liferay DXP's AlloyEditor also comes with several plugins to bridge the gap between the CKEditor's UI and the AlloyEditor's UI. These are prefixed with `ae_`. We recommend that you include them all to ensure compatibility. The example below checks for existing `extraPlugins` and adds the `font` CKEditor plugin along with its required Rich Combo plugin dependency and the remaining UI bridge plugins:

   ```
   if (Validator.isNotNull(extraPlugins)) {
     extraPlugins = extraPlugins + ",ae_uibridge,ae_autolink,ae_buttonbridge,ae_menubridge,ae_panelmenubuttonbridge,ae_placeholder,ae_richcombobridge,f
   }
   else {
     extraPlugins = "ae_uibridge,ae_autolink,ae_buttonbridge,ae_menubridge,ae_panelmenubuttonbridge,ae_placeholder,ae_richcombobridge,font";
   }

   jsonObject.put("extraPlugins", extraPlugins);
   ```

```
**Note:** Make sure the `ae_uibridge` plugin appears first, followed by
the remaining UI bridge plugins, and finally the CKEditor plugin(s).
```

---

5. If the plugin includes buttons, add them in the appropriate toolbar. The configuration below retrieves the Text Selection Toolbar's buttons and adds the `font` plugin's `Font` and `FontSize` buttons to it:

   ```
   JSONObject toolbarsJSONObject = jsonObject.getJSONObject("toolbars");

   if (toolbarsJSONObject == null) {
    toolbarsJSONObject = JSONFactoryUtil.createJSONObject();
   }

   JSONObject stylesJSONObject = toolbarsJSONObject.getJSONObject(
    "styles");

   if (stylesJSONObject == null) {
    stylesJSONObject = JSONFactoryUtil.createJSONObject();
   }

   JSONArray selectionsJSONArray = stylesJSONObject.getJSONArray(
    "selections");

   for (int i = 0; i < selectionsJSONArray.length(); i++) {
    JSONObject selection = selectionsJSONArray.getJSONObject(i);
   ```

```
            if (Objects.equals(selection.get("name"), "text")) {
             JSONArray buttons = selection.getJSONArray("buttons");

             buttons.put("Font");
             buttons.put("FontSize");
            }

        }

        stylesJSONObject.put("selections", selectionsJSONArray);

        toolbarsJSONObject.put("styles", stylesJSONObject);

        jsonObject.put("toolbars", toolbarsJSONObject);
```

Note: A plugin's buttons may not have the same name as the plugin. You can find the button names for a plugin by searching its `plugin.js` file for `editor.ui.addButton`. Note that button names are case sensitive and may be aliased in the `addButton()` method, such as the `clipboard` plugin's `Cut`, `Copy`, and `Paste` buttons.

Below is the full example `*EditorConfigContributor` class that adds the `font` plugin to the AlloyEditor for the Blogs and Blogs Admin portlets:

```
package com.liferay.docs.myblogseditorconfigcontributor;

import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import java.util.Objects;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

import com.liferay.portal.kernel.editor.configuration.BaseEditorConfigContributor;
import com.liferay.portal.kernel.editor.configuration.EditorConfigContributor;
import com.liferay.portal.kernel.json.JSONArray;
import com.liferay.portal.kernel.json.JSONFactoryUtil;
import com.liferay.portal.kernel.json.JSONObject;
import com.liferay.portal.kernel.portlet.RequestBackedPortletURLFactory;
import com.liferay.portal.kernel.theme.ThemeDisplay;
import com.liferay.portal.kernel.util.Portal;
import com.liferay.portal.kernel.util.Validator;

/**
 * @author liferay
 */
 @Component(
    immediate = true,
    property = {
        "editor.config.key=contentEditor",
        "editor.name=alloyeditor",
        "editor.name=ckeditor",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsPortlet",
        "javax.portlet.name=com_liferay_blogs_web_portlet_BlogsAdminPortlet",
        "service.ranking:Integer=100"
    },
    service = EditorConfigContributor.class
 )
 public class MyBlogsEditorConfigContributor
   extends BaseEditorConfigContributor {

   @Override
   public void populateConfigJSONObject(
     JSONObject jsonObject, Map<String, Object> inputEditorTaglibAttributes,
     ThemeDisplay themeDisplay,
     RequestBackedPortletURLFactory requestBackedPortletURLFactory) {

            String extraPlugins = jsonObject.getString("extraPlugins");

             if (Validator.isNotNull(extraPlugins)) {
                  extraPlugins = extraPlugins + ",ae_uibridge,ae_autolink,ae_buttonbridge,ae_menubridge,ae_panelmenubuttonbridge,ae_placeholder,ae_richcombo
                }
                else {
                  extraPlugins = "ae_uibridge,ae_autolink,ae_buttonbridge,ae_menubridge,ae_panelmenubuttonbridge,ae_placeholder,ae_richcombobridge,font";
                }

                jsonObject.put("extraPlugins", extraPlugins);

                JSONObject toolbarsJSONObject = jsonObject.getJSONObject("toolbars");

                if (toolbarsJSONObject == null) {
                 toolbarsJSONObject = JSONFactoryUtil.createJSONObject();
                }

                JSONObject stylesJSONObject = toolbarsJSONObject.getJSONObject(
                 "styles");

                if (stylesJSONObject == null) {
                 stylesJSONObject = JSONFactoryUtil.createJSONObject();
                }

                JSONArray selectionsJSONArray = stylesJSONObject.getJSONArray(
                 "selections");

                for (int i = 0; i < selectionsJSONArray.length(); i++) {
                 JSONObject selection = selectionsJSONArray.getJSONObject(i);

                        if (Objects.equals(selection.get("name"), "text")) {
                         JSONArray buttons = selection.getJSONArray("buttons");

                         buttons.put("Font");
                         buttons.put("FontSize");
                        }

                 }

                stylesJSONObject.put("selections", selectionsJSONArray);

                toolbarsJSONObject.put("styles", stylesJSONObject);

                jsonObject.put("toolbars", toolbarsJSONObject);
   }
 }
```

Now you know how to use Liferay DXP's bundled CKEditor plugins in its AlloyEditor!

Chapter 101

JavaScript Module Loaders

JavaScript modules encapsulate code into useful units that export their functions. Structuring an application this way makes it easier to work with in these ways:

- Other modules can explicitly require this piece of code.
- Structuring an application this way makes it easier to see the broader scope.
- Modular applications keep related functionality close together.
- Modularized code makes it easier to find what you're looking for.

This section contains tutorials relating to the different JavaScript Module Loaders included present on the Liferay platform.

101.1 Configuring Modules for Liferay DXP's Loaders

To load your modules in Liferay DXP, you need to know when they are needed, where they are located at build time, if you want to bundle them together or load them independently, and you must assemble them at runtime. Keeping track of all these tasks can be a hassle. Liferay DXP's module Loaders (YUI Loader and AMD Loader) provide a streamlined process that handles loading for you, which saves you time.

ES2015 `*.es.js` files are automatically transpiled to AMD modules and configured, so no additional work is needed for the Loader to recognize them. Other JavaScript modules, however, require more information to use Liferay DXP's Loaders.

Manual configuration is required for the following use cases:

- Custom AUI and YUI modules
- External libraries with named AMD modules
- External libraries with global exports that you want to load asynchronously or from other modules
- Initialization code

This tutorial covers these concepts:

- How to configure JavaScript modules to use Liferay DXP's Loaders
- How to use your loaded JavaScript modules in a portlet or a JavaScript

See the Preparing your JavaScript Files for ES2015 tutorial to learn how to use ES2015 in your JavaScript modules.

Get started by configuring your module next.

Configuring your Module

To use the loaders you must first define your modules. This metadata, known as the *module definition*, provides details such as dependencies, name and location, when they should be loaded, and more.

The module is defined using a configuration file. Liferay DXP uses `config.js` as a naming convention, but you can use whatever name you prefer.

You must specify your configuration file's location in your bundle's `bnd.bnd` file, so Liferay DXP knows where to access it. You'll learn how to do this next.

Configuring your Bundle's BND File

Follow these steps to configure your BND file:

1. Open your bundle's `bnd.bnd` file and add the `Liferay-JS-Config` header to point to the configuration file that contains the module's definition.

   For example, the header below points to a `config.js` file in the module's bundle:

   ```
   Liferay-JS-Config: /META-INF/resources/config.js
   ```

2. Next, add a web context path to retrieve resources for your module:

   ```
   Web-ContextPath: /my-bundle-name
   ```

Now that Liferay DXP knows how to find the file, you can write it next.

Writing the Configuration File

Follow these steps to define your module:

1. Create a configuration file, for example `config.js`, in the location you specified above.

   For example:

   ```
   src/main/resources/META-INF/resources
   ```

2. Identify the loader your module requires.

   The type of module you are configuring determines the loader you must use in your configuration file.

   YUI and AlloyUI modules: Use the `YUI.applyConfig` mechanism to provide the module information. Note that AUI modules use the AUI mechanism built on top of the existing YUI mechanism: `AUI().applyConfig`. You can also use this mechanism to override Liferay DXP's default YUI/AUI modules.

   AMD or global libraries: Use the `Liferay.Loader.addModule` mechanism to provide the module information.

   Initialization code: requires no loader mechanism. Simply add your code to the module's configuration file.

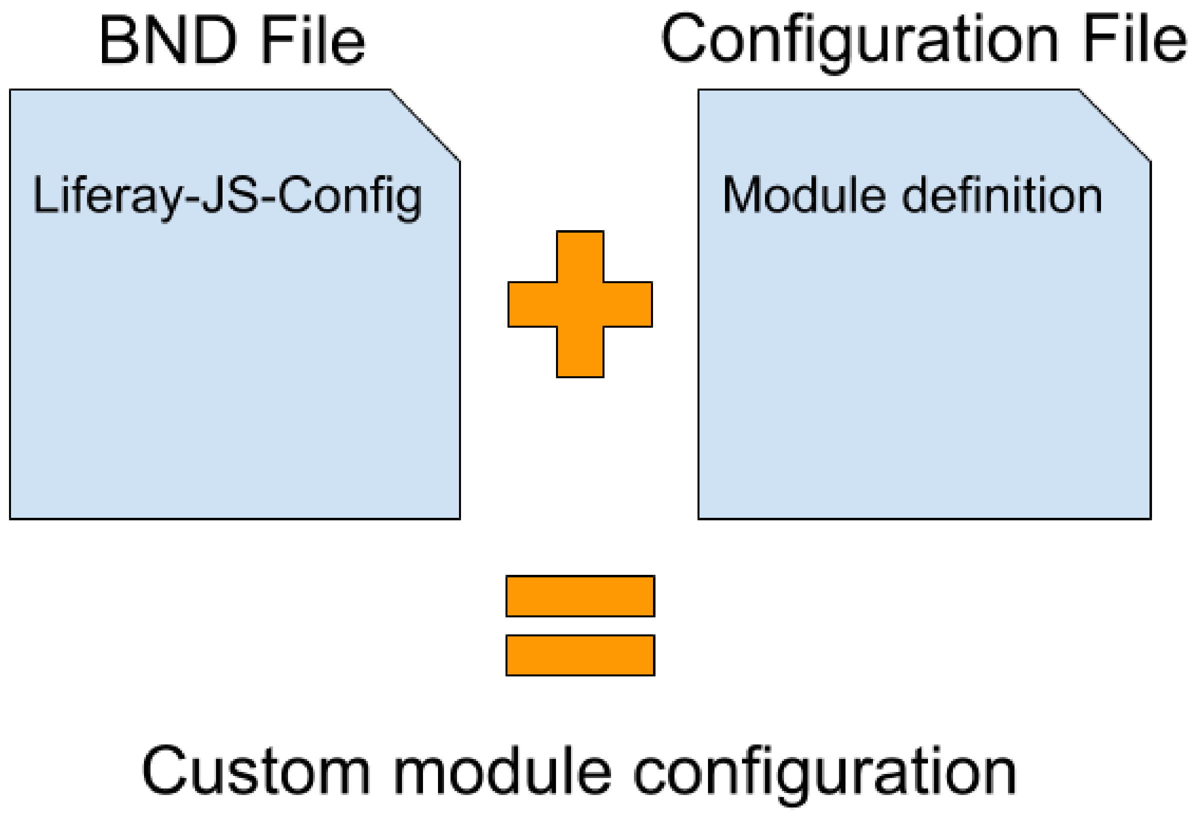

Figure 101.1: Custom JavaScript modules must use the `Liferay-JS-Config` BND header to point to a configuration file with the module definition.

3. Add the module's definition to the configuration file using the loader mechanism you identified in step 2.

   Below are some example configurations for each use case.

   Custom AUI module `config.js` example `com.liferay.map.common` module:

```
;(function() {
        AUI().applyConfig(
                {
                        groups: {
                                mapbase: {
                                        base: MODULE_PATH + '/js/',
                                        combine: Liferay.AUI.getCombine(),
                                        modules: {
                                                'liferay-map-common': {
                                                        path: 'map.js',
                                                        requires: [
                                                                'aui-base'
                                                        ]
                                                }
                                        },
                                        root: MODULE_PATH + '/js/'
                                }
                        }
                }
                );
        })();
```

Note: You can use the MODULE_PATH variable to reference your module's location in relative paths. This mechanism is more robust and reliable than hard coded paths in the event of modified system settings.

The parameters used in the AUI module example are defined below:

groups: A list of group definitions. Each group can contain definitions for base, comboBase, Combine, and a list of modules.

base: The base directory to fetch the module from.

combine: Whether to use a combo service to reduce the number of HTTP connections required to load your dependencies. Best practice is to use Liferay.AUI.getCombine() as the value, as Liferay DXP's own modules do. If js_fast_load in enabled in your theme, Liferay.AUI.getCombine() returns true, otherwise it returns false. Hard coding a value can result in odd or unexpected behavior, and is not recommended.

modules: A list of module definitions.

path: The path to the script from base. This parameter is required.

requires: An array of modules required by this component.

See the Loader.addModule method for a full list of the supported module metadata.

root: The root path to prepend to module names for the combo service. Ex: 2.5.2/build.

See the Loader class for a full list of available methods and properties.

Custom AMD module config.js example com.liferay.frontend.js.polyfill.babel.web module:

```
Liferay.Loader.addModule(
        {
                dependencies: [],
                exports: '_babelPolyfill',
                name: 'polyfill-babel',
                path: MODULE_PATH + 'browser-polyfill.min.js'
        }
);
```

The parameters used in the custom AMD module example are defined below:

dependencies: An array of module dependencies.

exports: The value, as a string, that the module exports to the global namespace. This is used for non-AMD modules. For example if your module exposes the global attribute window.MyLibrary, then you can set exports = 'MyLibrary' to let the loader know when this module is done loading.

name: The name of the module.

path: Sets the path of the module. If omitted, the module name value will be used as the path.

fullpath: Sets the full path to the module. This property should be used instead of the path property when the module isn't located in Portal. For example, you can use the fullpath property to load a library from an external CDN: fullPath: 'https://web/address/external-library.js'.

Library initialization code module config.js example com.liferay.frontend.js.metal.web module:

```
window.__METAL_COMPATIBILITY__ = {
        renderers: ['soy']
};
```

Although the example above contains library configuration code, you could add any initialization code that you require.

Liferay DXP automatically collects all the module definitions in a single request at startup, so you don't need to be concerned about the timing and placement of their configuration.

Now that your module is configured, you can learn how to use it in Liferay DXP next.

Using your Module

Once your module is configured, you have a few ways in which you can use it in Liferay DXP.

This example is configured to use a module in the JSP of a portlet, via the `aui:script`'s `require` attribute:

```
<aui:script require="relative/path/to/module/module-name">
  // variable `relativePathToModuleModuleName` is available here
</aui:script>
```

To adhere to JavaScript standards, references to the module within the script tag are named after the require value, in camel-case and with all invalid characters removed. For more information on using your module in a portlet, see the Using ES2015 Modules in your Portlet tutorial.

You can also use the module in a generic JavaScript:

```
<script>
Liferay.Loader.require('module-name', function (moduleName) {
  // variable `moduleName` is available here
});
</script>
```

Note: Using `Liferay.Loader.require` rather than just `require` is safer if you plan to hide the Loader by disabling the `exposeGlobal` option.

In Liferay DXP 7.1, `exposeGlobal` will be disabled by default.

Now you know how to load your custom JavaScript modules and global libraries in Liferay DXP!

Overriding Liferay DXP's Default YUI and AUI Modules

101.2 Using External Libraries

You can use external (i.e., anything but Metal.js, jQuery, or Lodash, which are included in Liferay DXP) JavaScript libraries in your portlets. There are a few methods you can use to make external libraries available. The method you should choose depends on the external libraries you plan to use and how you plan to use them (as modules or as browser globals).

This tutorial covers how to adapt external libraries for Liferay's JavaScript Loaders.

Go ahead and get started.

Configuring Libraries to Support UMD

If you're the owner of the library, you should make sure that it supports UMD (Universal Module Definition). You can configure your code to support UMD with the template shown below:

```
// Assuming your "module" will be exported as "mylibrary"
(function (root, factory) {
    if (typeof Liferay.Loader.define === 'function' && Liferay.Loader.define.amd) {
        // AMD. Register as a "named" module.
        Liferay.Loader.define('mylibrary', [], factory);
    } else if (typeof module === 'object' && module.exports) {
        // Node. Does not work with strict CommonJS, but
        // only CommonJS-like environments that support module.exports,
        // like Node.
        module.exports = factory();
    } else {
        // Browser globals (root is window)
        root.mylibrary = factory();
  }
}(this, function () {

    // Your library code goes here
    return {};
}));
```

Next you can learn how to load external libraries as browser globals.

Loading Libraries as Browser Globals

If you want to use a library that doesn't export itself as a named module (as is the case for many plugins) or load the library as a browser global, follow the steps in this section.

Note: These steps only apply to users on Liferay Portal CE 7.0 GA4, Liferay Digital Enterprise 7.0 SP2 (Fix Pack 8), or lower patch levels. If you're on a higher patch level, follow the steps in the Using Libraries that You Host section.

Follow these steps to load your libraries as browser globals:

1. Add a `<script>` tag with the following content before loading your module:

   ```
   <script>
       Liferay.Loader.define._amd = Liferay.Loader.define.amd;
       Liferay.Loader.define.amd = false;
   </script>
   ```

2. Next, add a `<script>` tag to load the module itself. Below is an example configuration:

   ```
   <script type="text/javascript" src="${javascript_folder}/library.js">
   </script>
   ```

3. Finally, cancel the change made in the previous step, by adding the following `<script>` tag:

   ```
   <script>
       Liferay.Loader.define.amd = Liferay.Loader.define._amd;
   </script>
   ```

This approach lets you load your modules as browser globals. Next, you can learn how to load libraries that you host.

Using Libraries That You Host

If you're hosting the library (and not loading it from a CDN), you must hide the Liferay AMD Loader to use your Library.

If you're running Liferay Portal CE 7.0 GA4, Liferay Digital Enterprise 7.0 SP2 (Fix Pack 8), or a higher patch level, you can hide the Liferay AMD Loader through the control panel. Follow these steps:

1. Open the Control Panel, navigate to *Configuration* → *System Settings*.
2. Click *JavaScript Loader* under the *Foundation* tab.
3. Uncheck the `expose global` option.

Note: Once this option is unchecked, you can no longer use the `Liferay.Loader.define` or `Liferay.Loader.require` functions in your app. Also, if you're using third party libraries that are AMD compatible, they could stop working after unchecking this option because they usually use global functions like `require()` or `define()`.

If you're running a lower patch level than Liferay Portal CE 7.0 GA4 or Liferay Digital Enterprise 7.0 SP2 (Fix Pack 8), follow these steps to hide the Liferay AMD Loader:

1. Name the library in the define function, as covered in the Configuring Libraries to Support UMD section. Below is an example configuration:

   ```
   Liferay.Loader.define('mylibrary', [], factory);
   ```

2. Remove the UMD wrapper `if (typeof Liferay.Loader.define === 'function' && Liferay.Loader.define.amd)` or update the UMD wrapper to match the one below:

   ```
   if (false && typeof Liferay.Loader.define === 'function' && Liferay.Loader.define.amd)
   ```

3. Configure your bundle's build task to run the `configJSModules` task over the library.

   This task names the library and generates the appropriate loader configuration for you.

Now you know how to adapt external libraries for Liferay's JavaScript Loaders.

Using ES2015 Modules in Your Portlet

101.3 Liferay AMD Module Loader

The Liferay AMD Module Loader is a JavaScript module loader.

What is a JavaScript module?

A JavaScript module encapsulates a piece of code into a useful unit that exports its capability/value. This makes it easy for other modules to explicitly require this piece of code. Structuring an application this way makes it easier to see the broader scope, easier to find what you're looking for, and keeps related pieces close together. This way of coding is a specification for the JavaScript language called Asynchronous Module Definition, or AMD.

Purpose of Liferay AMD Module Loader

A normal web page usually loads JavaScript files via HTML `script` tags. That's fine for small websites, but when developing large scale web applications, a more robust organization and loader is needed. A module loader allows an application to load dependencies easily by specifying a string that identifies the module name.

Now that you know the purpose of the Liferay AMD Module Loader, you can learn how to define modules next.

Defining a Module

The Liferay AMD Module loader works with JavaScript modules that are in the AMD format. Here is a basic example of the definition of an AMD module:

```
Liferay.Loader.define('my-dialog', ['my-node', 'my-plugin-base'], function(myNode, myPluginBase) {
    return {
        log: function(text) {
            console.log('module my-dialog: ' + text);
        }
    };
});
```

You can specify to load the module when another module is triggered or when a given condition is met:

```
Liferay.Loader.define('my-dialog', ['my-node', 'my-plugin-base'], function(myNode, myPluginBase) {
    return {
        log: function(text) {
            console.log('module my-dialog: ' + text);
        }
    };
}, {
    condition: {
        trigger: 'my-test',
        test: function() {
            var el = document.createElement('input');

            return ('placeholder' in el);
        }
    },
    path: 'my-dialog.js'
});
```

The configuration above specifies that this module should be loaded automatically, if the developer requests the `my-test` module under the given condition.

Next you can learn how to load a module.

Loading a Module

Loading a module is as easy as passing the module name to the `Liferay.Loader.require` method. The example below loads a module called `my-dialog`:

```
Liferay.Loader.require('my-dialog', function(myDialog) {
    // your code here
}, function(error) {
    console.error(error);
});
```

Next you can learn how to map module names.

Mapping Module Names

You can map module names to specific versions or other naming conventions. The example below maps the `liferay` and `liferay2` modules to `liferay@1.0.0`:

```
__CONFIG__.maps = {
    'liferay': 'liferay@1.0.0',
    'liferay2': 'liferay@1.0.0'
};
```

Mapping a module changes its name to the value specified in the map. Take this require value for example:

```
Liferay.Loader.require('liferay/html/js/autocomplete'...)
```

Under the hood, this is the same as the value shown below:

```
Liferay.Loader.require('liferay@1.0.0/html/js/autocomplete'...)
```

Using Liferay AMD Module Loader in Liferay DXP

Tools, like the Liferay AMD Module Config Generator, have been integrated into Liferay DXP to make it easy for developers to create and load modules. Here's how it works:

1. The Module Config Generator scans your code and looks for AMD module `Liferay.Loader.define(...)` statements.

2. It then names the module if it is not named already.

3. It uses that information, along with the listed dependencies, as well as any other configurations specified, to create a `config.json` file. Below is an example of a generated `config.json` file:

```
{
    "frontend-js-web@1.0.0/html/js/parser": {
        "dependencies": []
    },
    "frontend-js-web@1.0.0/html/js/list-display": {
        "dependencies": ["exports"]
    },
    "frontend-js-web@1.0.0/html/js/autocomplete": {
        "dependencies": ["exports", "./parser", "./list-display"]
    }
}
```

This configuration object tells the loader which modules are available, where they are, and what dependencies they require.

Now you know all about the Liferay AMD Module Loader!

Configuring Modules for Liferay Portal's Loaders

101.4 Loading Modules with AUI Script in Liferay DXP

The `aui:script` tag is a JSP tag that loads JavaScript in script tags on the page, while ensuring that certain resources are loaded before executing.

Using aui:script

The `aui:script` tag supports the following options:

- `require`: Requires an AMD module that will be loaded with the Liferay AMD Module Loader.
- `use`: Uses an AlloyUI/YUI module that is loaded via the YUI loader.
- `position`: The position the script tag is put on the page. Possible options are `inline` or `auto`.
- `sandbox`: Whether to wrap the script tag in an anonymous function. If set to `true`, in addition to the wrapping, `$` and `_` are defined for jQuery and underscore.

Next you can learn how to load ES2015 and Metal.js modules.

Loading ES2015 and Metal.js Modules

You can use `aui:script` to load your ES2015 and Metal.js modules like this:

```
<aui:script require="metal-clipboard/src/Clipboard">
    new metalClipboardSrcClipboard.default();
</aui:script>
```

This resolves the dependencies of the registered `Clipboard.js` and loads them in order until all of them are satisfied and the requested module can be safely executed.

In the browser, the `aui:script` translates to the full HTML shown below:

```
<script type="text/javascript">
    Liferay.Loader.require("metal-clipboard/src/Clipboard", function(metalClipboardSrcClipboard) {
        (function() {
            new metalClipboardSrcClipboard.default();
        })()
    }, function(error) {
        console.error(error)
    });
</script>
```

Next you can learn how to load AlloyUI modules.

Loading AlloyUI Modules

You can use the `use` attribute to load AlloyUI/YUI modules:

```
<aui:script use="aui-base">
    A.one('#someNodeId').on(
        'click',
        function(event) {
            alert('Thank you for clicking.')
        }
    );
</aui:script>
```

This loads the `aui-base` AlloyUI component and makes it available to the code inside the `aui:script`.

In the browser, the `aui:script` translates to the full HTML shown below:

```
<script type="text/javascript">
    AUI().use("aui-base",
        function(A){
            A.one('#someNodeId').on(
                'click',
                function(event) {
                    alert('Thank you for clicking.')
                }
            );
        }
    );
</script>
```

Next you can learn how to load AlloyUI modules together with ES2015 and Metal.js modules.

Loading AlloyUI Modules and ES2015 and Metal.js Modules Together

You may want to load an AUI module along with an ES2015 module or Metal.js module in an `aui:script`. The `aui:script` tag doesn't support both the `require` and `use` attributes in the same configuration. Not to worry though. You can use the `aui:script`'s `require` attribute to load the ES2015 and Metal.js modules, while loading the AUI module(s) with the `AUI().use()` function within the script. Below is an example configuration:

```
<aui:script require="path-to/metal/module">
 AUI().use(
    'liferay-aui-module',
    function(A) {
        let var = pathToMetalModule.default;
    }
);
</aui:script>
```

Now you know how to load modules with the `aui:script` tag!

Chapter 102

Liferay JavaScript APIs

The Liferay JavaScript object is populated with some helpful tools. This section contains a comprehensive list of some of the most useful utilities you can find inside the Liferay object.

102.1 Liferay ThemeDisplay

In Java, developers are used to being able to find lots of context information at runtime. You can learn about what user is browsing your application, what page it's on, what site it's in, and lots more. Wouldn't it be great if you could access that same information in JavaScript? You can! You can use Liferay DXP's ThemeDisplay JavaScript object!

It's a part of the Liferay global object that's automatically available to you in Liferay DXP at runtime. You can refer to the object as Liferay.ThemeDisplay. The ThemeDisplay object provides information on many aspects of a portal. It can identify the portal instance, the current user, the user's language, and the user's navigational context. It can tell you the paths to a portlet's scripts and images, a theme's images and files, and a portal's main folder. And it lets you know if a user is signed in and if the user is being impersonated. You can quickly assess your portal surroundings with ThemeDisplay.

This tutorial describes some of the most commonly used ThemeDisplay methods for getting IDs, paths, and user sign-in details.

Retrieving IDs

Using the ThemeDisplay methods below, you can grab IDs of various portal elements:

getCompanyId: Returns the company ID.

getLanguageId: Returns the user's language ID.

getScopeGroupId: Returns the group ID of the current site.

getUserId: Returns the user's ID.

getUserName: Returns the user's name.

Now that you know how to retrieve IDs of some of Liferay's key elements, you can learn how to get paths to various deployed entities in the portal.

Retrieving File Paths

The ThemeDisplay object has methods for retrieving commonly used file paths. Below are a few of the methods:

getPathImage: Returns the relative path of the portlet's image directory.

getPathJavaScript: Returns the relative path of the directory containing the portlet's JavaScript source files.

getPathMain: Returns the path of the portal instance's main directory.

getPathThemeImages: Returns the path of the current theme's image directory.

getPathThemeRoot: Returns the relative path of the current theme's root directory.

Now that you know how to retrieve paths to Liferay's deployed entities, you can next learn how to get information about the current user.

Retrieving Login Information

Here are a couple methods related to the current user.

isImpersonated: Returns `true` if the current user is being impersonated. Authorized administrative users can impersonate act as another user to test that user's account.

isSignedIn: Returns `true` if the user is logged in to the portal.

Below is JavaScript code that demonstrates using `ThemeDisplay`'s `isSignedIn` method:

```
if(Liferay.ThemeDisplay.isSignedIn()){
    alert('Hello ' + Liferay.ThemeDisplay.getUserName() + '. Welcome Back.')
}
else {
    alert('Hello Guest.')
}
```

The example above alerts a signed in user with a personalized greeting. Otherwise, it defaults to a guest greeting. Although this is a basic example, it shows how you can easily define unique user experiences with the `ThemeDisplay` object.

Liferay ThemeDisplay API

For completeness, you can find every available method inside the `Liferay.ThemeDisplay` object in the table below:

Method	Type	Description
getLayoutId	number	
getLayoutRelativeURL	string	
getLayoutURL	string	
getParentLayoutId	number	
isControlPanel	boolean	
isPrivateLayout	boolean	
isVirtualLayout	boolean	
getBCP47LanguageId	number	
getCDNBaseURL	string	
getCDNDynamicResourcesHost	string	
getCDNHost	string	
getCompanyGroupId	number	
getCompanyId	number	Returns the company ID
getDefaultLanguageId	number	
getDoAsUserIdEncoded	string	

Method	Type	Description
getLanguageId	number	Returns the user's language ID
getParentGroupId	number	
getPathContext	string	
getPathImage	string	Returns the relative path of the portlet's image directory
getPathJavaScript	string	Returns the relative path of the directory containing the

portlet's JavaScript source files |

getPathMain | string | Returns the path of the portal instance's main directory | getPathThemeImages | string | Returns the path of the current theme's image directory | getPathThemeRoot | string | Returns the relative path of the current theme's root

directory |

getPlid | string | | getPortalURL | string | | getScopeGroupId | number | Returns the group ID of the current site | getSiteGroupIdOrLiveGroupId | number | Returns the group ID of the live site. This is relevant for staging. | getSessionId | number | | getSiteGroupId | number | | getURLControlPanel | string | | getURLHome | string | | getUserId | number | Returns the user's ID | getUserName | string | Returns the user's name | isAddSessionIdToURL | boolean | | isFreeformLayout | boolean | | isImpersonated | boolean | Returns true if the current user is being impersonated. Authorized administrative users can impersonate act as another user to test that user's account | isSignedIn | boolean | Returns true if the user is logged in to the portal | isStateExclusive | boolean | | isStateMaximized | boolean | | isStatePopUp | boolean | |

102.2 Working with URLs in JavaScript

In Java, developers are able to create and work with URLs using their APIs. The `Liferay` global object offers some features to help you create and work with URLs.

This tutorial covers some of the most commonly used methods inside the `Liferay` global JavaScript object to manipulate URLs.

Liferay PortletURL

The `Liferay.PortletURL` class provides a way to create Liferay PortletURL's such as the `actionURL`, `renderURL`, and `resourceURL` through JavaScript. Below is an example configuration:

```
var portletURL = Liferay.PortletURL.createURL(themeDisplay.getURLControlPanel());

portletURL.setDoAsGroupId('true');
portletURL.setLifecycle(Liferay.PortletURL.ACTION_PHASE);
portletURL.setParameter('cmd', 'add_temp');
portletURL.setParameter('javax.portlet.action', '/document_library/upload_file_entry');
portletURL.setParameter('p_auth', Liferay.authToken);
portletURL.setPortletId(Liferay.PortletKeys.DOCUMENT_LIBRARY);
```

Liferay AuthToken

Below is an example configuration for the `Liferay.authToken`:

```
Liferay.authToken = '<%= AuthTokenUtil.getToken(request) %>';
```

Liferay CurrentURL

The `Liferay.currentURL` variable holds the path of the current URL from the server root.

For example, if checked from `my.domain.com/es/web/guest/home`, the value is `/es/web/guest/home`, as shown below:

```
// Inside my.domain.com/es/web/guest/home
console.log(Liferay.currentURL); // "/es/web/guest/home"
```

Liferay CurrentURLEncoded

The `Liferay.currentURLEncoded` variable holds the path of the current URL from the server root encoded in ASCII for safe transmission over the Internet.

For example, if checked from `my.domain.com/es/web/guest/home`, the value is `%2Fes%2Fweb%2Fguest%2Fhome`, as shown below:

```
// Inside my.domain.com/es/web/guest/home
console.log(Liferay.currentURLEncoded); // "%2Fes%2Fweb%2Fguest%2Fhome"
```

Now you know how to manipulate URLs using methods within the `Liferay` global JavaScript object.

102.3 Liferay DXP JavaScript Utilities

This tutorial explains some of the utility methods and objects inside the `Liferay` global JavaScript object.

Liferay Browser

The `Liferay.Browser` object contains methods that expose the current user agent characteristics without the need of accessing and parsing the global `window.navigator` object.

The available methods for the `Liferay.Browser` object are listed in the table below:

Method	Type	Description
acceptsGzip	boolean	
getMajorVersion	number	
getRevision	number	
getVersion	number	
isAir	boolean	
isChrome	boolean	
isFirefox	boolean	

Method	Type	Description
isGecko	boolean	
isIe	boolean	
isIphone	boolean	
isLinux	boolean	
isMac	boolean	
isMobile	boolean	
isMozilla	boolean	
isOpera	boolean	
isRtf	boolean	
isSafari	boolean	
isSun	boolean	
isWebKit	boolean	
isWindows	boolean

102.4 Invoking Liferay Services

Liferay DXP provides many web services out-of-the-box to you. These services include retrieving data and information about various assets, creating new assets, and even editing existing assets.

To see a comprehensive list of the available web services, start up a bundle and navigate to `http://localhost:8080/api/jsonws`. This list includes any custom web services that have been deployed to the bundle. These services are useful for creating single page applications, and can even be used to create custom front-ends, both inside and outside of Liferay DXP.

This tutorial explains how to invoke these web services using JavaScript.

Go ahead and get started.

Invoking Web Services via JavaScript

7.0 contains a global JavaScript object called `Liferay` that has many useful utilities. One method is `Liferay.Service`, which is used for invoking JSON web services.

The `Liferay.Service` method takes four possible arguments:

service {string|object}: Either the service name, or an object with the keys as the service to call, and the value as the service configuration object. (Required)

data {object|node|string}: The data to send to the service. If the object passed is the ID of a form or a form element, the form fields will be serialized and used as the data.

successCallback {function}: A function to execute when the server returns a response. It receives a JSON object as it's first parameter.

exceptionCallback {function}: A function to execute when the response from the server contains a service exception. It receives an exception message as it's first parameter.

One of the major benefits of using the `Liferay.Service` method versus using a standard AJAX request is that it handles the authentication for you.

Below is an example configuration of the `Liferay.Service` method:

```
Liferay.Service(
        '/user/get-user-by-email-address',
        {
                companyId: Liferay.ThemeDisplay.getCompanyId(),
                emailAddress: 'test@example.com'
        },
        function(obj) {
                console.log(obj);
        }
);
```

The example above retrieves information about a user by passing in the `companyId` and `emailAddress` of the user in question. The response data resembles the following JSON object:

```
{
        "agreedToTermsOfUse": true,
        "comments": "",
        "companyId": "20116",
        "contactId": "20157",
        "createDate": 1471990639779,
        "defaultUser": false,
        "emailAddress": "test@example.com",
        "emailAddressVerified": true,
        "facebookId": "0",
        "failedLoginAttempts": 0,
        "firstName": "Test",
        "googleUserId": "",
        "graceLoginCount": 0,
        "greeting": "Welcome Test Test!",
        "jobTitle": "",
        "languageId": "en_US",
        "lastFailedLoginDate": null,
        "lastLoginDate": 1471996720765,
        "lastLoginIP": "127.0.0.1",
        "lastName": "Test",
        "ldapServerId": "-1",
        "lockout": false,
        "lockoutDate": null,
        "loginDate": 1472077523149,
        "loginIP": "127.0.0.1",
        "middleName": "",
        "modifiedDate": 1472077523149,
        "mvccVersion": "7",
        "openId": "",
        "portraitId": "0",
        "reminderQueryAnswer": "test",
        "reminderQueryQuestion": "what-is-your-father's-middle-name",
        "screenName": "test",
        "status": 0,
        "timeZoneId": "UTC",
        "userId": "20156",
        "uuid": "c641a7c9-5acb-aa68-b3ea-5575e1845d2f"
}
```

Now that you know how to send an individual request, you're ready to run batch requests.

Batching Requests

Another format for invoking the `Liferay.Service` method is by passing an object with the keys as the service to call and the value as the service configuration object.

Below is an example configuration for a batch request:

```
Liferay.Service(
        {
                '/user/get-user-by-email-address': {
                        companyId: Liferay.ThemeDisplay.getCompanyId(),
                        emailAddress: 'test@example.com'
                }
        },
        function(obj) {
                console.log(obj);
        }
);
```

You can use this format to invoke multiple services with the same request by passing in an array of service objects. Here's an example:

```
Liferay.Service(
        [
                {
                        '/user/get-user-by-email-address': {
                                companyId: Liferay.ThemeDisplay.getCompanyId(),
                                emailAddress: 'test@example.com'
                        }
                },
                {
                        '/role/get-user-roles': {
                                userId: Liferay.ThemeDisplay.getUserId()
                        }
                }
        ],
        function(obj) {
                // obj is now an array of response objects
                // obj[0] == /user/get-user-by-email-address data
                // obj[1] == /role/get-user-roles data

                console.log(obj);
        }
);
```

Next you can learn how to nest your requests.

Nesting Requests

Nested service calls allow you to bind information from related objects together in a JSON object. You can call other services in the same HTTP request and conveniently nest returned objects.

You can use variables to reference objects returned from service calls. Variable names must start with a dollar sign ($).

The example in this section retrieves user data with `/user/get-user-by-id`, and uses the `contactId` returned from that service to then invoke `/contact/get-contact` in the same request.

Note: You must flag parameters that take values from existing variables. To flag a parameter, insert the `@` prefix before the parameter name.

Below is an example configuration that demonstrates the concepts covered in this section:

```
Liferay.Service(
        {
                "$user = /user/get-user-by-id": {
                        "userId": Liferay.ThemeDisplay.getUserId(),
                        "$contact = /contact/get-contact": {
                                "@contactId": "$user.contactId"
```

```
                    }
                }
        },
        function(obj) {
                console.log(obj);
        }
);
```

Here is what the response data would look like for the request above:

```
{
        "agreedToTermsOfUse": true,
        "comments": "",
        "companyId": "20116",
        "contactId": "20157",
        "createDate": 1471990639779,
        "defaultUser": false,
        "emailAddress": "test@example.com",
        "emailAddressVerified": true,
        "facebookId": "0",
        "failedLoginAttempts": 0,
        "firstName": "Test",
        "googleUserId": "",
        "graceLoginCount": 0,
        "greeting": "Welcome Test Test!",
        "jobTitle": "",
        "languageId": "en_US",
        "lastFailedLoginDate": null,
        "lastLoginDate": 1472231639378,
        "lastLoginIP": "127.0.0.1",
        [...]
        "screenName": "test",
        "status": 0,
        "timeZoneId": "UTC",
        "userId": "20156",
        "uuid": "c641a7c9-5acb-aa68-b3ea-5575e1845d2f",
        "contact": {
                "accountId": "20118",
                "birthday": 0,
                [...]
                "createDate": 1471990639779,
                "emailAddress": "test@example.com",
                "employeeNumber": "",
                "employeeStatusId": "",
                "facebookSn": "",
                "firstName": "Test",
                "lastName": "Test",
                "male": true,
                "middleName": "",
                "modifiedDate": 1471990639779,
                [...]
                "userName": ""
        }
}
```

Now that you know how to process requests, you can learn how to filter the results next.

Filtering Results

If you don't want all the properties returned by a service, you can define a whitelist of properties. This returns only the specific properties you request in the object.

Below is an example of whitelisting properties:

```
Liferay.Service(
        {
                '$user[emailAddress,firstName] = /user/get-user-by-id': {
                        userId: Liferay.ThemeDisplay.getUserId()
                }
        },
        function(obj) {
                console.log(obj);
        }
);
```

To specify whitelist properties, place the properties in square brackets (e.g., `[whiteList]`) immediately following the name of your variable. The example above requests only the `emailAddress` and `firstName` of the user.

Below is the filtered response:

```
{
        "firstName": "Test",
        "emailAddress": "test@example.com"
}
```

Next you can learn how to populate the inner parameters of the request.

Inner Parameters

When you pass in an object parameter, you'll often need to populate its inner parameters (i.e., fields).

Consider a default parameter `serviceContext` of type `ServiceContext`. To make an appropriate call to JSON web services you might need to set `serviceContext` fields such as`scopeGroupId`, as shown below:

```
Liferay.Service(
        '/example/some-web-service',
        {
                serviceContext: {
                        scopeGroupId: 123
                }
        },
        function(obj) {
                console.log(obj);
        }
);
```

Now you know how to invoke Liferay services!

Liferay JavaScript APIs

Chapter 103

Front-End Taglibs

Liferay DXP offers a powerful set of taglibs that are fully maintained and integrated. They provide common implementations for UI components and utilities to ensure that your apps, themes, and web content behave in a very clean and efficient way.

In this section of tutorials, you'll learn how to use Liferay DXP's taglibs to build awesome user interfaces.

103.1 Using the Liferay UI Taglib

You can create a lot of components using the Liferay UI taglibs. Liferay DXP's taglibs provide the following benefits to your markup:

- Consistent
- Responsive
- Accessible across your portlets

The full markup generated by the tags can be found in the JSPs of the tag's folder in the Liferay Github Repo.

Now that you know the benefits of Liferay DXP's tags, you can learn how to use them next.

Using Liferay UI Tags

A list of the available Liferay UI taglibs can be found here. To use the Liferay-UI taglib library in your apps, you must add the following declaration to your JSP:

```
<%@ taglib prefix="liferay-ui" uri="http://liferay.com/tld/ui" %>
```

The Liferay-UI taglib is also available via a macro for your FreeMarker theme and web content templates. Follow this syntax:

```
<@liferay_ui["tag-name"] attribute="string value" attribute=10 />
```

Now you're good to go!

Each taglib has a list of attributes that can be passed to the tag. Some of these are required and some are optional. See the taglibdocs to view the requirements for each tag.

The example below uses the `<liferay-ui:alert>` taglib to create a success alert that the user can close:

```
<liferay-ui:alert
        closeable="true"
        icon="exclamation-full"
        message="Here is our awesome alert example"
        type="success"
/>
```

Here is an example implementation of a `<liferay-ui:user-display>` taglib:

```
<liferay-ui:user-display
        markupView="lexicon"
        showUserDetails="true"
        showUserName="true"
        userId="<%= themeDisplay.getRealUserId() %>"
        userName="<%= themeDisplay.getRealUser().getFullName() %>"
/>
```

Now you know how to use Liferay-UI taglibs in your JSPs!

Related Topics

JavaScript Module Loaders
Loading Modules with the AUI Script in Liferay
Using the Liferay Util Taglib

103.2 Using the Liferay Util Taglib

The Liferay Util taglib is used to pull in other resources into a portlet or theme, it can be used to dictate which resources need to be inserted at the bottom or top of the HTML source.

Using Liferay Util Tags

A list of the available Liferay Util tags can be found here. To use the Liferay Util taglib library in your apps, you must add the following declaration to your JSP:

```
<%@ taglib prefix="liferay-util" uri="http://liferay.com/tld/util" %>
```

The Liferay Util taglib is also available via a macro for your FreeMarker theme and web content templates. Follow this syntax:

```
<@liferay_util["tag-name"] attribute="string value" attribute=10 />
```

Each taglib has a list of attributes that can be passed to the tag. Some of these are required and some are optional. See the taglibdocs to view the requirements for each tag.

Since each of the Liferay Util taglibs is unique, each tag is covered briefly in the sections that follow.

Using Liferay Util Body Bottom

The `<liferay-util:body-bottom>` tag is not a self-closing tag. The content placed between the opening and closing of this tag is moved to the bottom of the `body` tag. When something is passed using this taglib, the body_bottom.jsp is passed markup and outputs in this JSP. The attribute `outputKey` is the reference key for this content.

Below is an example configuration for the `<liferay-util:body-bottom>` tag:

```
<%@ taglib uri="http://liferay.com/tld/portlet" prefix="liferay-portlet" %>
<%@ taglib uri="http://liferay.com/tld/theme" prefix="liferay-theme" %>
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<%@ page import="com.liferay.portal.kernel.util.PortalUtil" %>
<%@ page import="com.liferay.product.navigation.product.menu.web.constants.ProductNavigationProductMenuPortletKeys" %>

<liferay-theme:defineObjects />

<%
String portletNamespace = PortalUtil.getPortletNamespace(ProductNavigationProductMenuPortletKeys.PRODUCT_NAVIGATION_PRODUCT_MENU);
%>

<liferay-util:body-bottom outputKey="productMenu">
        <div class="lfr-product-menu-panel sidenav-fixed sidenav-menu-slider"
        id="<%= portletNamespace %>sidenavSliderId">
                <div class="product-menu sidebar sidenav-menu">
                        <liferay-portlet:runtime portletName="<%= ProductNavigationProductMenuPortletKeys.PRODUCT_NAVIGATION_PRODUCT_MENU %>" />
                </div>
        </div>
</liferay-util:body-bottom>
```

Using Liferay Util Body Top

The `<liferay-util:body-top>` tag is not a self-closing tag. The content placed between the opening and closing of this tag is moved to the top of the `body` tag. When something is passed using this taglib the body_top.jsp is passed markup and outputs in this JSP. The attribute `outputKey` is the reference key for this content.

Below is an example configuration for the `<liferay-util:body-top>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:body-top outputKey="topContent">
        <div>
                <h1>I'm at the top of the page!</h1>
        </div>
</liferay-util:body-top>
```

Using Liferay Util Buffer

`<liferay-util:buffer>` is not a self-closing tag. The content placed between the opening and closing of this tag is saved to the value of the var attribute. This allows a developer to build a piece of markup that can be reused in a JSP.

Below is an example configuration for the `<liferay-util:buffer>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:buffer var="myBuffer">
        <small class="text-capitalize text-muted">
                This is my buffer content
        </small>
</liferay-util:buffer>

<div class="container">
        <h1>Welcome!</h1>

        <%= myBuffer %>
</div>

<div class="container">
        <h1>A Wonderful Title!</h1>
        <%= myBuffer %>
</div>
```

Using Liferay Util Dynamic Include

The `<liferay-util:dynamic-inlude>` tag allows you to register some content with the `DynamicIncludeRegistry`. You can read more about the OSGi Service Registry here. It's easier for modules using the OSGi registry to use the content that you include with this tag.

Below is an example configuration for the `<liferay-util:dynamic-inlude>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:dynamic-include key="/path/to/jsp#pre" />

<div>
        <p>And here we have our content</p>
</div>

<liferay-util:dynamic-include key="/path/to/jsp#post" />
```

Using Liferay Util Get URL

The `<liferay-util:get-url>` tag scrapes the URL provided by the `url` attribute. If a value is provided for the var attribute, the content from the screen scrape is scoped to that variable. Otherwise, the scraped content is displayed where the taglib is used.

Below is a basic example configuration for the `<liferay-util:get-url>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:get-url url="https://www.google.com/" />
```

Here is an example that uses the var attribute:

```
<liferay-util:get-url url="https://www.google.com/" var="google" />

<div>
        <h2>We stole <a href="https://www.google.com/">Google</a>, here it is.</h2>

        <div class="google">
                <%= google %>
        </div>
</div>
```

Using Liferay Util HTML Bottom

The `<liferay-util:html-bottom>` tag is not a self-closing tag. The content placed between the opening and closing of this tag will be moved to the bottom of the `html` tag. When something is passed using this taglib the bottom.jsp is passed markup and outputs in this JSP. The attribute `outputKey` is the reference key for this content.

Below is an example of using `<liferay-util:html-bottom>`. Commonly, JavaScript is passed to this tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:html-bottom outputKey="taglib_alert_user">
        <aui:script use="liferay-alert">
                new Liferay.Alert(
                        {
                                closeable: true,
                                message: 'Just saying hello from the
                                &lt;liferay-util:html-bottom&gt; taglib!',
                                type: 'success'
                        }
                ).render(#wrapper);
        </aui:script>
</liferay-util:html-bottom>
```

Using Liferay Util HTML Top

The `<liferay-util:html-top>` tag is not a self-closing tag. The content placed between the opening and closing of this tag is moved to the `head` tag. When something is passed using this taglib the top_head.jsp is passed markup and outputs in this JSP. The attribute `outputKey` is the reference key for this content.

Below is an example configuration for the `<liferay-util:html-top>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:html-top>
        <link data-senna-track="permanent" href="/path/to/style.css" rel="stylesheet" type="text/css" />
</liferay-util:html-top>
```

Using Liferay Util Include

The `<liferay-util:include>` tag can be used to include other JSP files in a portlet. This can increase readability as well as provide separation of concerns for JSP files.

Below is an explanation of some of the available attributes:

- `page`: This attribute is required. The value of this attribute is the path to the JSP or JSPF to be included.
- `servletContext`: Refers to the request context that the included JSP should use. Passing `<%= application %>` to this attribute allows the included JSP to use the same `request` object and other objects that might be set in the prior JSP.

Below is an example configuration for the `<liferay-util:include>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:include page="/path/to/view.jsp" servletContext="<%= application %>" />
```

Using Liferay Util Param

The `<liferay-util:param>` tag can be used to add a parameter value to a URL. This tag is best used when combined with the `<liferay-util:include>` tag for accessing new parameter values in another JSP.

Below is an example configuration for the `<liferay-util:param>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:include page="/path/to/answer.jsp" servletContext="<%= application %>">
        <liferay-util:param name="answer" value="42" />
</liferay-util:include>
```

The new parameter can then be used in `answer.jsp` like this:

```
<%@ page import="com.liferay.portal.kernel.util.ParamUtil" %>

<div>
        <p>The answer to life the universe and everything is
        <%= ParamUtil.getString(request, "answer") %></p>
</div>
```

Using Liferay Util Whitespace Remover

The `<liferay-util:whitespace-remover>` tag is used for removing all whitespace from whatever is included between the opening and closing of the tag.

Below is an example configuration for the `<liferay-util:whitespace-remover>` tag:

```
<%@ taglib uri="http://liferay.com/tld/util" prefix="liferay-util" %>

<liferay-util:whitespace-remover>
        <div class="input-container">
                <label for="myInput">
                        Is the &lt;liferay-util:whitespace-remover&gt; taglib
                        fantastic!
                </label>

                <input class="input" id="myInput" name="myInput" type="checkbox">
        </div>
</liferay-util:whitespace-remover>
```

Now you know how to use the Liferay-Util taglib!

Using the Liferay UI Taglib

CHAPTER 104

HTML FORMS

Forms are a must-have tool in any developer's UI bag. Rather than write your HTML from scratch, Liferay provides you with taglibs that offer everything standard HTML elements have, as well as some additional attributes that are Liferay specific. For a full list of all the available taglibs and attributes, look at Liferay's API docs on docs.liferay.com

Using a combination of Liferay's `AUI` taglibs and Lexicon classes, you can create forms in your app's JSPs. You can learn how to create an MVC portlet project in the using-the-mvc-portlet-template tutorial.

In this section of tutorials, you'll learn how to use the platform features to create forms with ease.

104.1 Forms and Validation

Creating forms is easy and flexible, thanks to Liferay DXP's form, input, and validation tags.

The `<aui:form>` tag sets up the necessary code (HTML, JS), uses Liferay JavaScript APIs, calls the validation framework, and submits the form data to the back-end.

The *input* tags (`<aui:input>`, `<liferay-ui:input-*>`, etc.) generate the necessary code (HTML, CSS, JS) to provide you with a consistent UI throughout your form. These tags also initialize the field's state (e.g. `value`, `disabled`, `readonly`, etc.).

The `<aui:validator>` tag lets you create validation rules for your form's input tags. This ensures that your users enter the proper data in the format you expect before it gets sent to the back-end for final validation and processing.

The following tags support validators natively:

- `<aui:input>`
- `<aui:select>`
- `<liferay-ui:input-date>`
- `<liferay-ui:input-search>`

All other fields can be validated using the method described in the Adding Custom Validators in JavaScript section below.

Get started by creating a basic form next.

Creating Your First Form

Below is an example configuration for a simple form in a JSP:

```
<aui:form action="<%= myActionURL %>" method="post" name="myForm">
        <aui:input label="My Text Input" name="myTextInput" type="text"
        value='<%= "My Text Value" %>' />

        <aui:button type="submit" />
</aui:form>
```

Although this form is simple, it provides all that's needed to pass the data to the back-end. The full HTML generated for this example is shown below:

```
<form action="http://localhost:8080/web/guest/home?p_p_id=my_portlet&amp;p_p_lifecycle=1&amp;p_p_state=normal&amp;p_p_mode=view&amp;p_p_col_id=column-
1&amp;p_p_col_count=3&amp;_my_portlet_javax.portlet.action=%2Fmy%2Faction&amp;_my_portlet_mvcRenderCommandName=%2Fmy%2Faction&amp;p_auth=WAxorpsN" class="fo
fm-namespace="_my_portlet_" id="_my_portlet_myForm" method="post" name="_my_portlet_myForm">
        <input class="field form-control" id="_my_portlet_formDate"
        name="_my_portlet_formDate" type="hidden" value="1472516415545">

        <div class="form-group input-text-wrapper">
                <label class="control-label"
                for="_my_portlet_myTextInput">My Text Input</label>

                <input class="field form-control" id="_my_portlet_myTextInput"
                name="_my_portlet_myTextInput" type="text"
                value="My Text Value">
        </div>

        <button class="btn  btn-primary btn-default" id="_my_portlet_kpyg"
        type="submit">
                <span class="lfr-btn-label">Save</span>
        </button>
</form>
```

As you can see, the tags provide all this to you for very little work! Next you can learn how to add validation to your forms.

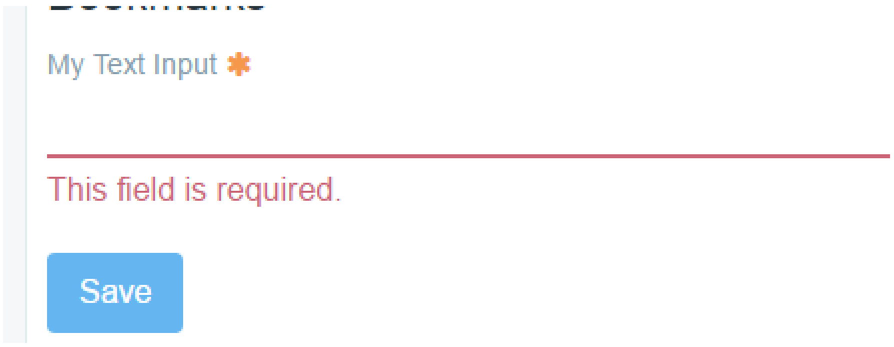
Adding Validation

What if you want to ensure the user enters the required data? Add validators.

An example configuration is shown below:

```
<aui:input label="My Text Input" name="myTextInput" type="text"
value='<%= "My Text Value" %>'>
        <aui:validator name="required" />
</aui:input>
```

This forces the user to enter something before the form is submitted.



This field is required.

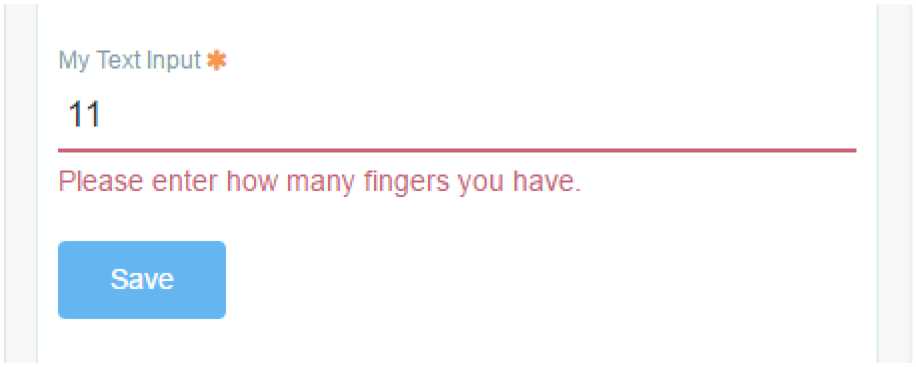
Figure 104.1: A field with a failed required validator.

What if you wanted to restrict the value to a number between `0` and `10`? There's a validator for that. Each of the validators shown below must pass to submit the form:

```
<aui:validator name="required" />
<aui:validator name="number" />
<aui:validator name="range">[0,10]</aui:validator>
```

You can even customize the error message, as shown below:

```
<aui:validator errorMessage="Please enter how many fingers you have."
name="range">[0,10]</aui:validator>
```



Please enter how many fingers you have.

Figure 104.2: A required validator with a custom error message.

Below is a list of all the available validation rules:

acceptFiles: Specifies that the field can contain only the file types given. Each file extension must be separated by a comma. For example `<aui:validator name="acceptFiles">'jpg,png,tif,gif'</aui:validator>`

alpha: Allows only alphabetic characters.

alphanum: Allows only alphanumeric characters.

date: Allows only a date.

digits: Allows only digits.

email: Allows only an email address.

equalTo: Allows only contents equal to some other field that has the specified field ID. The ID is declared in the opening and closing validator tags. For example `<aui:validator name="equalTo">'#<portlet:namespace />password'</aui:validator>`

max: Allows only an integer value less than the specified value. For example, a `max` value of `20` is specified here `<aui:validator name="max">20</aui:validator>`

maxLength: Allows a maximum field length of the specified size. The syntax is the same as `max`.

min: Allows only an integer value greater than the specified value. The syntax is the same as `max`.

minLength: Allows a field length longer than the specified size. The syntax is the same as `max`.

number: Allows only numerical values.

range: Allows only a number between the specified range. For example, a range between 1.23 and 10 is specified here `<aui:validator name="range">[1.23,10]</aui:validator>`

rangeLength: Allows a field length between the specified range. For example, a range between 3 and 8 characters long is specified here `<aui:validator name="rangeLength">[3,8]</aui:validator>`

required: Prevents a blank field.

url: Allows only a URL value.

Now that you know how to validate your forms, you can learn how to conditionally require user input next.

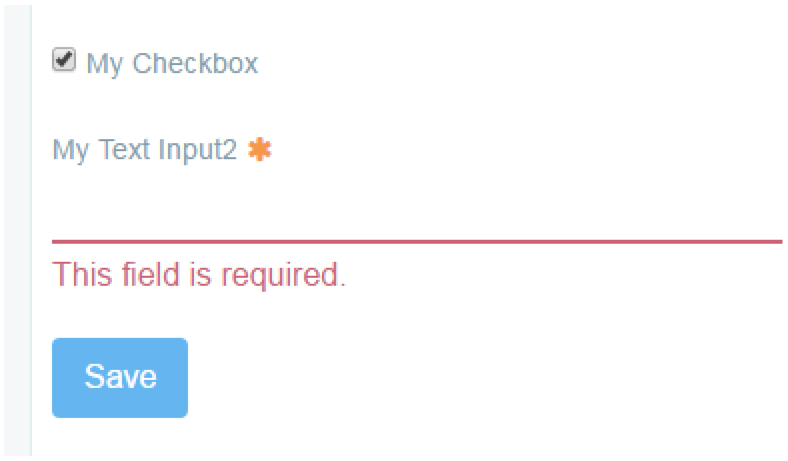
Conditionally Requiring A Field

Sometimes you'll want to validate a field based on the value of another field. You can do this by checking for that condition in a JavaScript function within the `required` validator's body.

Below is an example configuration:

```
<aui:input label="My Checkbox" name="myCheckbox" type="checkbox" />

<aui:input label="My Text Input" name="myTextInput" type="text">
        <aui:validator name="required">
                function() {
                        return AUI.$('#<portlet:namespace />myCheckbox').prop('checked');
                }
        </aui:validator>
</aui:input>
```



This field is required.

Figure 104.3: Fields can required based on other conditions.

Next you can learn how to add custom validators.

Adding Custom Validators

So far, you've only seen the default set of AUI validator rules. What if you need something that the default rules don't provide?

You can write your own validator and optionally supplement it with built-in validators, as shown below:

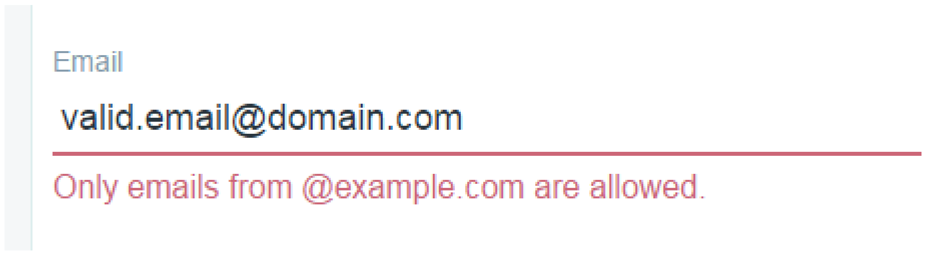
```
<aui:input label="Email" name="email" type="text">
        <aui:validator name="email" />

        <aui:validator errorMessage="Only emails from @example.com are allowed."
        name="custom">
                function(val, fieldNode, ruleValue) {
                        var regex = new RegExp(/@example\.com$/i);

                        return regex.test(val);
                }
        </aui:validator>
</aui:input>
```

This example runs the regular `email` validator, as well as a `custom` domain validator.

Next you can learn how to add custom validators in JavaScript.



Email

valid.email@domain.com

Only emails from @example.com are allowed.

Figure 104.4: You can write your own custom validations.

Adding Custom Validators in JavaScript

Sometimes you need to add additional validation dynamically after the page has rendered. Perhaps some additional fields were added to the DOM via an AJAX request.

To do this, you must access the `Liferay.Form` object, as demonstrated below:

```
<aui:script use="liferay-form">
        var form = Liferay.Form.get('<portlet:namespace />myForm');
        // ...
```

The `Liferay.Form` object allows you to `get()` and `set()` `fieldRules`.

`fieldRules` are the JavaScript equivalent of all the validators attached to the form.

This example below uses a `custom` validator and the built-in `number` validator.

```
<aui:script use="liferay-form">
        var form = Liferay.Form.get('<portlet:namespace />myForm');

        var oldFieldRules = form.get('fieldRules');

        var newFieldRules = [
                {
                        body: function (val, fieldNode, ruleValue) {
                                return (val !== '2');
                        },
                        custom: true,
                        errorMessage: 'must-not-equal-2',
                        fieldName: '<portlet:namespace />fooInput',
                        validatorName: 'custom_fooInput'
                },
                {
                        fieldName: '<portlet:namespace />fooInput',
                        validatorName: 'number'
                }
        ];

        var fieldRules = oldFieldRules.concat(newFieldRules);

        form.set('fieldRules', fieldRules);

</aui:script>
```

Notice that `newFieldRules` are combined with `oldFieldRules`, using `concat()`. You could leave this part out, and you'd have a whole new set of validators for the whole form.

Next you can learn how to validate your forms manually.

Manual Validation

You may need to execute validation on a field, based on some event not typical of user input. For instance, you may need to validate a related field at the same time.

To do this, you must access the `formValidator` object and call the `validateField()` method, passing the field's `name`. Below is an example configuration:

```
<aui:input label="Old Title" name="oldTitle" type="text">
        <aui:validator errorMessage="The New Title cannot match the Old Title"
        name="custom">
                function(val, fieldNode, ruleValue) {
                        <portlet:namespace />checkOtherTitle('<portlet:namespace />newTitle');

                        // check if old and new titles are a match

                        return !match;
                }
        </aui:validator>
</aui:input>

<aui:input label="New Title" name="newTitle" type="text">
        <!-- same custom validator -->
</aui:input>

<aui:script use="liferay-form">
        function <portlet:namespace />checkOtherTitle(fieldName) {
                var formValidator =
                Liferay.Form.get('<portlet:namespace />myForm').formValidator;

                formValidator.validateField(fieldName);
        }
</aui:script>
```

Now you know how to create and validate forms!

Front-End Taglibs

104.2 Creating Forms with Liferay's Taglibs

This tutorial demonstrates how to:

- Create a form using 7.0's taglibs in your application's JSPs

To begin, take a look at the Portlet Configuration application's add_configuration_template.jsp form for example:

```
<aui:form action="<%= updateArchivedSetupURL %>"
cssClass="container-fluid-1280" method="post" name="fm">
        <aui:input name="redirect" type="hidden" value="<%= redirect %>" />
        <aui:input name="portletResource" type="hidden"
        value="<%= portletResource %>" />

        <aui:fieldset-group markupView="lexicon">
                <aui:fieldset>

                        <%
                        String name = StringPool.BLANK;
                        boolean useCustomTitle =
                        GetterUtil.getBoolean(portletPreferences.getValue
                        ("portletSetupUseCustomTitle", null));
                        if (useCustomTitle) {
                                name = PortletConfigurationUtil.getPortletTitle
                                (portletPreferences, LocaleUtil.toLanguageId
                                (themeDisplay.getSiteDefaultLocale()));
                        }
                        %>

                        <aui:input name="name" placeholder="name"
                        required="<%= true %>" type="text" value="<%= name
                        %>">
                                <aui:validator name="maxLength">75
                                </aui:validator>
                        </aui:input>
                </aui:fieldset>
        </aui:fieldset-group>

        <aui:button-row>
                <aui:button type="submit" />

                <aui:button href="<%= redirect %>" type="cancel" />
        </aui:button-row>
</aui:form>
```

As you can see, a standard form uses quite a few taglibs. If you take a closer look, you'll notice that all of the taglibs are prefixed with aui. aui stands for AlloyUI, a JavaScript framework that uses Bootstrap to allow you to create UI components, easily and effectively. In order to use these AUI tags, you will need to have the AUI taglib declaration imported into your JSP. You'll take care of this next.

Adding the Taglib Declaration

The first thing you'll need to do is make sure you have the `<%@ taglib uri="http://liferay.com/tld/aui" prefix="aui"%>` declaration is in your JSP. This can be added to the main view of your app, `view.jsp` for example, or it can be added to a separate JSP file, such as `init.jsp`, and imported into the JSP in which you want to show the form. For example, the Portlet Configuration application includes the taglib declarations in its `init.jsp`, and then imports the `init.jsp` into its `view.jsp`, using the following line:

```
<%@ include file="/init.jsp"%>
```

Once the AUI taglib declaration is imported, you can move onto creating the form next.

Creating the Form

A form's design is determined by the input needed from the user. To that end, there are multiple design possibilities. The examples covered in the sections that follow are one possible design, and highlight some of the available attributes for the tags. The steps are laid out in a natural order, however you can jump to any section you wish.

For a full list of the available attributes for the form tags covered, checkout the API docs for the AUI Tags.

Go ahead and get started by adding the form tag next.

Adding the Form Wrapper

Start off by adding a `<aui:form>` tag to your jsp. Make sure to add a closing `<aui:form/>` tag, to wrap your form. This acts as a wrapper for your form and offers some additional styling and custom portlet namespacing for you to use. If you are familiar with HTML `<form>` tags, `<aui:form>` tags are configured the same way. For instance, the Bloggs Aggregator app has the following configuration:

```
<aui:form action="<%= configurationActionURL %>" method="post" name="fm">
```

The action attribute specifies where to send the form data when the form is submitted. The method attribute defines the method to use to send the form data(in most cases this will be post). Finally, the name attribute specifies the name for the form, as well as the ID for the component instance for the form. It's important to note that, by default, aui:form places the portlet namespace in front of the name and id attributes. This is also the default behavior for the aui:input tag as well.

You can find a full list of the available attributes for the <aui:form> tag in the AUI Form Taglib Docs.

Now that your form element is created, you can add your fieldsets next.

Adding the Fieldset Groups and Fieldsets

The next main element is the <aui:fieldset-group> tag. This tag creates a <div> to group fieldset elements of the form. Looking at the Portlet Configuration example, you can see the following pattern:

```
<aui:fieldset-group markupView="lexicon">
```

It's important to note the addition of the markupView="lexicon" attribute. This ensures that the lexicon HTML markup and CSS styles are used to render the element, rather than the standard markup.

Add the <aui:fieldset-group markupView="lexicon"> tag, just below the <aui:form> tag you just added. And make sure to add the closing </aui:fieldset-group> tag just before the closing </aui:form> tag. Your form should look something like this at this point:

```
<aui:form action="<%= ActionURL %>" method="post" name="fm">
    <aui:fieldset-group markupView="lexicon">

    </aui:fieldset-group>
</aui:form>
```

Now that your fieldset group is added, you can add your fieldset next. The <aui:fieldset> tag creates a <div> to group related form elements and offers some additional styling attributes as well.

Use the following pattern to add the <aui:fieldset> tag to your form:

```
<aui:fieldset >

</aui:fieldset>
```

Alternatively, if you have multiple fieldsets, you can update your tags to be collapsible, using the following pattern:

```
<aui:fieldset collapsed="<%= true %>" collapsible="<%= true %>" >

</aui:fieldset>
```

You can find a full list of the available attributes for the <aui:fieldset> tag in the AUI Fieldset Taglib Docs.

Next, you can add your input fields.

Adding the Input Fields

Each fieldset is used to group similar form elements together. In this section, you'll take a look at the different kinds of input fields you can use in your form.

AUI input fields use the following pattern:

```
<aui:input label="label" name="name" type="type" />
```

The `label` attribute sets the label for the input field. The `name` attribute sets the name for the field. Finally, the `type` attribute sets the type of input to use for the field.

The `type` attribute supports the following types:

- file: Adds a file browser.
- text: The default value if no `type` is specified. Adds a text input field.
- hidden: Adds a hidden text field.
- assetCategories: Adds a `liferay-ui:asset-categories-selector` component.
- assetTags: Adds a `liferay-ui:asset-tags-selector` component.
- textarea: Adds a textarea box.
- timeZone: Adds a `liferay-ui:input-time-zone` component.
- password: Adds a password input field.
- checkbox: Adds a checkbox.
- radio: Adds a radio button.
- color: Adds a HTML color picker.
- editor: Adds a `liferay-ui:input-editor` component.
- email: Adds an email input field.
- number: Adds a number selector.
- range: Adds a range slider.
- resource: Adds a `liferay-ui:input-resource` component.
- toggle-card: Adds a Toggle Card
- toggle-switch: Adds a Toggle Switch
- url: Adds a URL input field.

For a full list of all the attributes available for the `<aui:input>` tag, check out the AUI Input Taglib Docs.

Once you've added all of your input fields, you can move onto the form's buttons next.

Adding the Button Rows and Buttons

Taking a look at the portlet configuration application example once again, you can see that form buttons follow the pattern below:

```
<aui:button-row>
        <aui:button type="submit" />

        <aui:button href="<%= redirect %>" type="cancel" />
</aui:button-row>
```

The `<aui:button-row>` tags acts as a wrapper for the form's buttons, and offers some additional styling through the `cssClass` attribute.

The `<aui:button>` tag is a standard input button, with some additional attributes. It supports the `button`, `submit`(the default type), `cancel`, and `reset` types for the `type` attribute. Note that you if you wish to emphasize the button as a primary action, you can add the `primary="true"` attribute to your button:

```
<aui:button
    cssClass="btn-lg"
    id="submit"
    label="save"
    primary="<%= true %>"
    type="submit"
/>
```

For a full list of the attributes available for the `<aui:button>` tag, check out the AUI Button Taglib Docs.
Your form is complete!

104.3 Form Navigator Extensions

Some data-centric applications require the creation of large data-entry forms. Examples abound in healthcare, transportation, pharmaceutical, or any other heavily regulated industry. For these applications, you need an easy way to section off your forms into easily navigable groups.

Since 7.0, the Form Navigator framework enables you to add new sections and section categories dynamically to existing form navigation. The framework includes a well-described API and a powerful `liferay-ui` tag called `form-navigator`. It's easy to use and facilitates organizing large forms into sections of input and categories.

Form Navigators can be used in two ways: customizing a Form Navigator that already exists in the portal, and creating your own Form Navigator for your application. This tutorial demonstrates customizing an existing form. It references source code from an example portlet called the Form Nav Extension portlet. On GitHub, you can find its complete project called form-nav-extension-portlet. You can also download the Form Nav Extension portlet's bundle `form-nav-extension-portlet-1.0.jar`. To download it, go to its GitHub page and click the *View Raw* link.

Before extending a Form Navigator, you should understand the parts of the Form Navigator Framework and what they do.

Understanding the Parts of the Form Navigator Framework

Form Navigator implementations contain the following parts:

- **A JSP that contains a form**: The form must specify a `form-navigator` tag. All the form's input sections tie into the Form Navigator.
- **Sections**: A section (or entry) is a JSP that specifies inputs and a Java class that models the section and ties it into the Form Navigator.
- **Categories**: A category aggregates one or more sections. A Java class models it and ties it into the Form Navigator.
- **IDs**: A Form Navigator and its categories should be publicly identified. That is, they should all have IDs that can be looked up in a public API (e.g., Javadoc). A developer extending a Form Navigator must otherwise have access to the Form Navigator's source code in order to find the IDs.

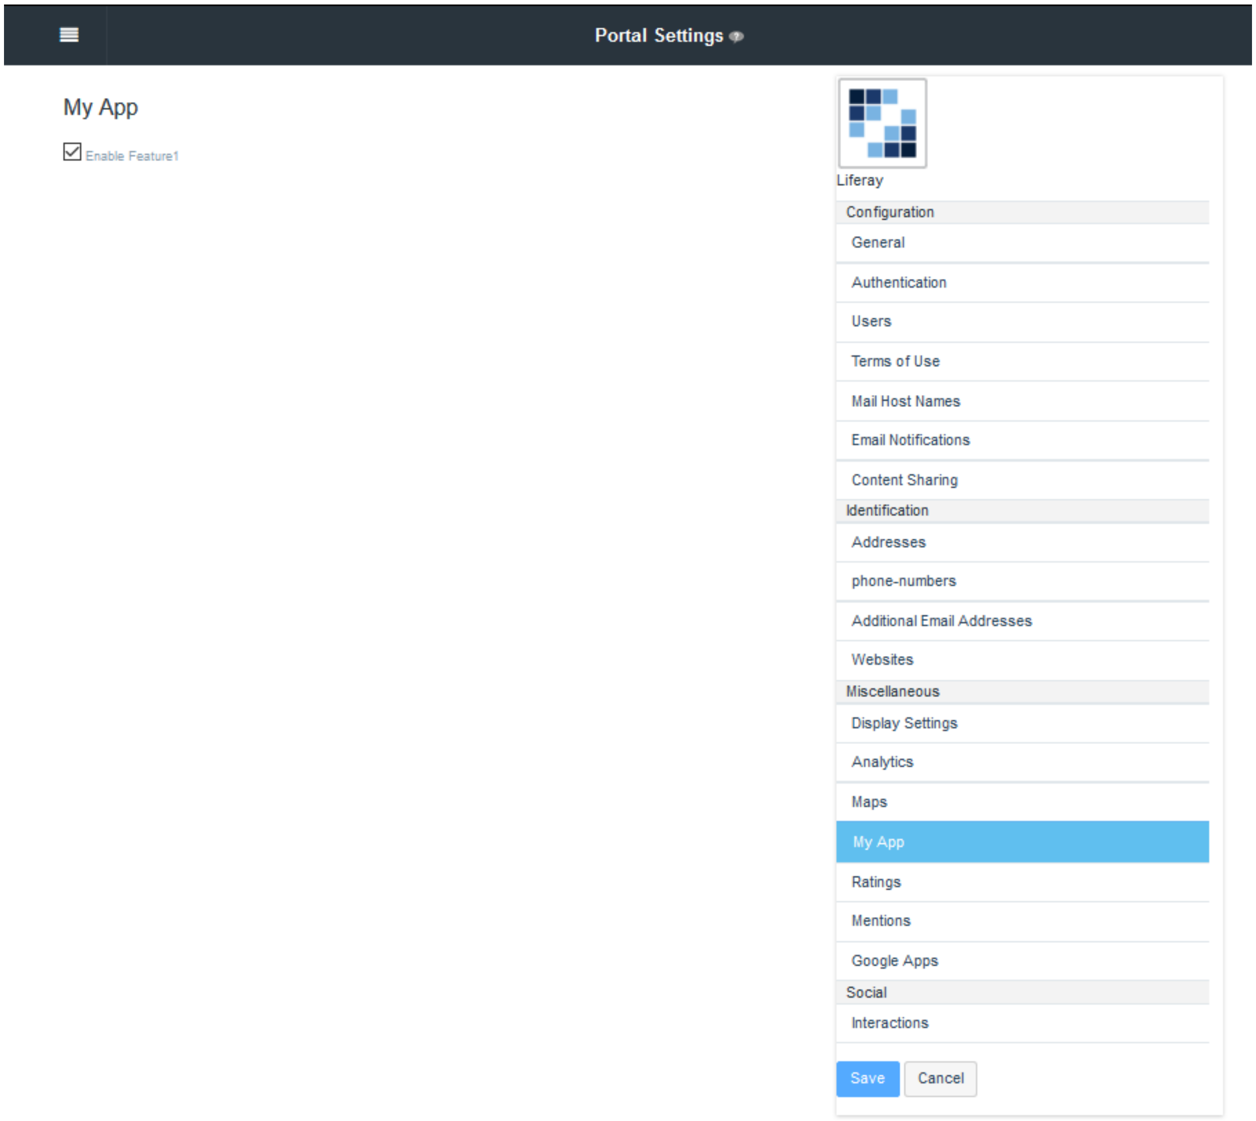

Figure 104.5: The Form Navigator framework lets you add your app's configuration forms to existing form navigators, like the one used in Portal Settings.

Liferay's Form Navigator implementations meet all these requirements. They're implemented similarly and their IDs are published in the Javadoc for the class `FormNavigatorConstants`.

Note: Form Navigator extensions implemented using portal properties and form navigation entry JSPs are deprecated but still supported in 7.0. All new Form Navigator extensions should be implemented as this tutorial describes.

Now that you know the parts of a Form Navigator, it'll be easier for you to extend one.

Extending a Form Navigator

Here's an overview of the steps to extend a Form Navigator:

- **Step 1: Implement a component portlet project to accommodate form navigation.**
- **Step 2: Create a JSP for each new section of inputs.**
- **Step 3: Identify the Form Navigator and category (if any) you're extending.**
- **Step 4: Create new categories.**
- **Step 5: Create new sections.**

Let's set up a component portlet project to support form navigation.

Step 1: Implement a component portlet project to accommodate form navigation

First, your component portlet must be implemented as an OSGi bundle. You can develop it in any environment that supports creating a bundle. Please refer to the 7.0 tutorial section Tooling to learn about development environments. The Form Nav Extension portlet was created with BLADE based on the `blade.portlet.jsp` template. This is also covered in the tutorial section linked above.

A Form Navigator extension bundle's metadata must do the following things:

- Specify the bundle's symbolic name for your servlet context to target
- Include your project's classes, JSPs, and resource bundles (for localization)
- Include the `JspAnalyzerPlugin` to generate generate metadata for the JSPs' dependencies
- Specify a web context path for the Form Navigator classes to associate with the JSPs

You should use a `bnd.bnd` file to specify this metadata. Your Bnd file should include definitions and directives similar to those specified in the Form Nav Extension portlet's `bnd.bnd` file:

```
Bundle-Name: Form Nav Extension Portlet
Bundle-SymbolicName: com.liferay.docs.formnavextensionportlet
Bundle-Version: 1.0.0
Include-Resource:\
        classes,\
        META-INF/resources=src/main/resources/META-INF/resources
-jsp: *.jsp,*.jspf
-plugin.jsp: com.liferay.ant.bnd.jsp.JspAnalyzerPlugin
Web-ContextPath: /formnavextensionportlet
```

The `Bundle-Name` value is arbitrary, but should be recognizable and unique. The `Bundle-SymbolicName` must be unique–the project's package path makes for a good symbolic name. For the `Include-Resource`, make sure to include your project's classes and the root path of its JSPs. The directive below includes all the project's `.jsp` and `.jspf` files:

```
-jsp: *.jsp,*.jspf
```

And the following directive to specify a plugin to include all the JSP dependencies:

```
-plugin.jsp: com.liferay.ant.bnd.jsp.JspAnalyzerPlugin
```

Lastly, the `Web-ContextPath` specifies the root of the portlet's web context.

As you progress through this tutorial, you'll refer to the metadata in your portlet's classes. Before diving into the Java classes, howerver, let's create JSPs for your sections' inputs.

Step 2: Create a JSP for each new section of inputs

The existing Form Navigator has a form, and each of its sections extend the form with sets of input. Your section will add its own inputs. You should create your section's JSP under the `META-INF/resources` property folder you defined in your `bnd.bnd` file's `Include-Resource` directive. The example Bnd file specified the folder like this:

```
META-INF/resources=src/main/resources/META-INF/resources
```

Under the folder, you can add a JSP for each section of inputs you want to add to the Form Navigator. Feel free to organize these with subfolders.

The Form Nav Extension portlet's JSP file `/portal_settings/my_app.jsp` provides a checkbox input to enable/disable My App's feature in the portal:

```
    <%@ taglib uri="http://java.sun.com/jsp/jstl/core" prefix="c" %>

    <%@ taglib uri="http://liferay.com/tld/aui" prefix="aui" %>
    <%@ taglib uri="http://liferay.com/tld/ui" prefix="liferay-ui" %>

    <%@ page import="com.liferay.docs.formnavextensionportlet.MyAppWebKeys" %>
    <%@ page import="com.liferay.portal.kernel.util.GetterUtil" %>
    <%@ page import="com.liferay.portal.kernel.util.ResourceBundleUtil" %>

    <%@ page import="java.util.ResourceBundle" %>

    <%
    boolean companyMyAppFeatureEnabled = GetterUtil.getBoolean(request.getAttribute(MyAppWebKeys.COMPANY_MY_APP_FEATURE_ENABLED));

    ResourceBundle resourceBundle = ResourceBundleUtil.getBundle("content.Language", request.getLocale(), getClass());
    %>

    <h3><liferay-ui:message key='<%= resourceBundle.getString("my-app-features") %>' /><h3>

    <aui:input checked="<%= companyMyAppFeatureEnabled %>" label='<%= resourceBundle.getString("enable-my-app-feature") %>' name="settings--
myAppFeatureEnabled--" type="checkbox" value="<%= companyMyAppFeatureEnabled %>" />
```

The input's name is `settings--myAppFeatureEnabled--`. So that the Form Navigator detects the inputs automatically, make sure to start each of your input's names with `settings--` and end them with `--`. Add all the inputs you need in each of your sets of inputs.

After creating section JSPs, you must find out the IDs of the existing Form Navigator and categories you're adding sections to. You refer to these IDs in the category and section classes you'll create to represent your Form Navigator extensions.

Step 3: Identify the form navigator and category you're extending

Liferay's class `FormNavigatorConstants` specifies constant values for all the portlet Form Navigators and categories. The identifiers follow the naming conventions below, where you substitue *FOO* for the navigator's or category's name:

- **Form navigator**: `FORM_NAVIGATOR_ID_FOO`
- **Category**: `CATEGORY_KEY_FOO`

Note the names of the constants that match the Form Navigator and categories you're extending–you'll refer to them in your Java classes in the next steps.

Step 4: Create new categories

To add a new category, create a class that implements the `FormNavigatorCategory` interface. The class needs a `@Component` annotation to register it as a service in Liferay's module framework. Here are the things your category class's component annotation should do:

- Declare that the component is of service type `FormNavigatorCategory.class`
- Request immediate loading
- Optionally, specify the category's entry order relative to the Form Navigator's other categories. The higher the category's order integer relative to the order of the other categories, the higher the category is listed in the form navigation.

Here's an example component annotation for a category:

```
@Component(
    immediate = true,
    property = {"form.navigator.category.order:Integer=20"},
    service = FormNavigatorCategory.class
)
```

Next, you implement the `FormNavigatorCategory` methods:

- `getFormNavigatorId`: Return the Form Navigator's constant you noted previously from `FormNavigatorConstants`
- `getKey`: Return an identifier for your category. You can optionally create a public class like `FormNavigatorConstants`, to publish your project's identifiers.
- `getLabel(Locale)`: Return the localized category label. You can create a `Language.properties` file in your project's `src/main/resources/content` folder and specify a key/value pair for the category label. You can then add the localized value of the property in language properties files for other locales.

For example, here's a Form Navigator category implementation for the *Social* Portal Setting category:

```
package com.liferay.portal.settings.web.internal.servlet.taglib.ui;

import com.liferay.portal.kernel.language.LanguageUtil;
import com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorCategory;
import com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorConstants;

import java.util.Locale;

import org.osgi.service.component.annotations.Component;

/**
 * @author Sergio González
 * @author Philip Jones
 */
@Component(
    immediate = true, property = {"form.navigator.category.order:Integer=20"},
    service = FormNavigatorCategory.class
)
public class CompanySettingsSocialFormNavigatorCategory
    implements FormNavigatorCategory {
```

```
    @Override
    public String getFormNavigatorId() {
        return FormNavigatorConstants.FORM_NAVIGATOR_ID_COMPANY_SETTINGS;
    }

    @Override
    public String getKey() {
        return FormNavigatorConstants.CATEGORY_KEY_COMPANY_SETTINGS_SOCIAL;
    }

    @Override
    public String getLabel(Locale locale) {
        return LanguageUtil.get(locale, "social");
    }

}
```

After you've implemented new Form Navigator categories, you can add new Form Navigator sections.

Step 5: Create new sections

To add a new section (entry) that uses a JSP, create a class that extends the abstract base class `BaseJSPFormNavigatorEntry` and implements the `FormNavigatorEntry` interface. The `BaseJSPFormNavigatorEntry` base class integrates the section's JSP with the Form Navigator. In both these parts of your class declaration, you must specify the Form Navigator's model bean class as the generic type on which they operate. For example, if your Form Navigator's model bean class is `User`, your decarlation would be like this:

```
public class MyEntry extends BaseJSPFormNavigatorEntry<User>
        implements FormNavigatorEntry<User>
```

There are a couple different ways to determine the model bean class. If you can access the Form Navigator's JSP source code, inspect the `form-navigator` element's `formModelBean` attribute value. The model bean class is the class type of the object passed in as the `form-navigator`'s `formModelBean` attribute.

You can also deduce the model bean class from the name of the ID's constant in `FormNavigatorConstants`. The word(s) right after `FORM_NAVIGATOR_ID_` in the constant's name hints at the class type. For example, if the navigator's ID is `FORM_NAVIGATOR_ID_USERS_SETTINGS`, then `User` is the model bean class; if the ID is `FORM_NAVIGATOR_ID_ORGANIZATIONS`, then `Organization` is the class; etc. Note: this is only a hint, and there are exceptions. For example, if the ID is is `FORM_NAVIGATOR_ID_SITES`, then `Group` is the class.

For example, here's a class declaration of a `FormNavigatorEntry`, from the Form Nav Extension portlet:

```
    @Component(
        immediate = true,
        property = {
            "form.navigator.entry.order:Integer=71"
        },
        service = FormNavigatorEntry.class
    )
    public class MyAppCompanySettingsFormNavigatorEntry
        extends BaseJSPFormNavigatorEntry<Company>
            implements FormNavigatorEntry<Company> {

            // ...

    }
```

It implements an entry on the `Company` model bean for the Portal Settings Form Navigator: the navigator identifed by the constant `FormNavigatorConstants.FORM_NAVIGATOR_ID_COMPANY_SETTINGS`.

The class also includes the @Component annotation, which is the next thing an entry must specify. An entry's @Component annotation registers the entry as a service in Liferay's module framework.

Here's what a Form Navigation entry's component annotation should do:

- Declare that the component is of service type FormNavigatorEntry.class
- Request immediate loading
- Optionally, specify a form.navigator.entry.order property for the entry relative to the other entries in the category. The higher the entry's order integer relative to the order of the category's other entries, the higher the entry is listed in the category. For example, @Component(property = {"form.navigator.entry.order:Integer=71"}, service = FormNavigatorEntry.class)

Except for your entry's order (optional), your entry's @Component annotation should look similar to the previous example's annotation. Next, you'll implement the entry class's methods.

The FormNavigatorEntry implementation must implement the following methods:

- getFormNavigatorId: Return the Form Navigator's constant you noted previously from FormNavigatorConstants

- getCategoryKey: Return the Form Navigator category constant you noted previously from FormNavigatorConstants

- getKey: Return an identifier for your entry. You can optionally create a public class like FormNavigatorConstants, to publish your project's identifiers.

- getLabel(Locale): Return the entry's localized label. You can create a Language.properties file in your project's src/main/resources/content folder and specify a key/value pair for the entry label.

- getJspPath: Return the path to the entry's JSP, starting from the path you specified previously for your bnd.bnd file's META-INF/resources property.

- include(HttpServletRequest, HttpServletResponse): Sets the request and response attributes for displaying the entry's HTML. You can retrieve the form's current settings and pass them to the request. You can optionally use a template (e.g., FreeMarker or Velocity) to render the form page, as long as you completely override BaseJSPFormNavigatorEntry's include method. The Form Nav Extension portlet's entry class's include method passes to the request the current settings that were saved as portlet preferences. It doesn't use a template language and instead calls BaseJSPFormNavigatorEntry's include method.

```
@Override
public void include(HttpServletRequest request, HttpServletResponse response)
        throws IOException {

    ThemeDisplay themeDisplay =
        (ThemeDisplay)request.getAttribute(WebKeys.THEME_DISPLAY);

    PortletPreferences companyPortletPreferences =
        PrefsPropsUtil.getPreferences(themeDisplay.getCompanyId(), true);

    boolean companyMyAppFeatureEnabled =
        PrefsParamUtil.getBoolean(
            companyPortletPreferences, request, "myAppFeatureEnabled",
            true);

    request.setAttribute(
        MyAppWebKeys.COMPANY_MY_APP_FEATURE_ENABLED,
        companyMyAppFeatureEnabled);
    super.include(request, response);
}
```

- setServletContext(ServletContext): In this method, you set the parent entry class's servlet context. Then, using a @Reference annotation, you unbind the servlet context from its current target and target it to your app's OSGi bundle. First, add the @Reference annotation. Next, unbind the servlet context by specifying unbind = "-". Finally, to target the servlet context to your app's OSGi bundle, specify as the target value the bundle's symbolic name–it's the value you specified for Bundle-SymbolicName in your bnd.bnd file.

  For example, here's the setServletContext(ServletContext) method from the Form Nav Extension portlet's entry class:

  ```
  @Override
  @Reference(
      target = "(osgi.web.symbolicname=com.liferay.docs.formnavextensionportlet)",
      unbind = "-"
  )
  public void setServletContext(ServletContext servletContext) {
      super.setServletContext(servletContext);
  }
  ```

The above method calls its parent's setServletContext(ServletContext) method. But look at what its @Reference annotation does. It unbinds the servlet context from its current binding and instead targets it to its own bundle–it targets the bundle symbolically named com.liferay.docs.formnavextensionportlet. That is the exact symbolic name defined by Bundle-SymbolicName: com.liferay.docs.formnavextensionportlet in the Form Nav Extension portlet's bnd.bnd file.

You've learned what's required to create a section class. You declared your class to extend the BaseJSPFormNavigatorEntry class and implement the FormNavigatorEntry interface, both with respect to your Form Navigator's form model bean class. Using annotations, you registered your entry class as an OSGi service. Then you implemented all the entry methods to relate your entry to a Form Navigator, category, and JSP, populate your entry's request object, and target the servlet context to your bundle.

If you're curious about what a working entry implementation looks like, check out the example entry class next.

Example Form Navigator Entry Class

Inspecting an example implementation can help you work out details in your implementation. Here's the Form Nav Extension portlet's entry class MyAppCompanySettingsFormNavigatorEntry:

```
package com.liferay.docs.formnavextensionportlet;

import java.io.IOException;
import java.util.Locale;
import java.util.ResourceBundle;

import javax.portlet.PortletPreferences;
import javax.servlet.ServletContext;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

import com.liferay.portal.kernel.servlet.taglib.ui.BaseJSPFormNavigatorEntry;
```

```
import com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorConstants;
import com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorEntry;
import com.liferay.portal.kernel.util.PrefsParamUtil;
import com.liferay.portal.kernel.util.PrefsPropsUtil;
import com.liferay.portal.kernel.util.ResourceBundleUtil;
import com.liferay.portal.kernel.util.WebKeys;
import com.liferay.portal.model.Company;
import com.liferay.portal.theme.ThemeDisplay;

@Component(
    immediate = true,
    property = {
        "form.navigator.entry.order:Integer=71"
    },
    service = FormNavigatorEntry.class
)
public class MyAppCompanySettingsFormNavigatorEntry
    extends BaseJSPFormNavigatorEntry<Company>
        implements FormNavigatorEntry<Company> {

    @Override
    public String getCategoryKey() {
        return FormNavigatorConstants.CATEGORY_KEY_COMPANY_SETTINGS_MISCELLANEOUS;
    }

    @Override
    public String getFormNavigatorId() {
        return FormNavigatorConstants.FORM_NAVIGATOR_ID_COMPANY_SETTINGS;
    }

    @Override
    protected String getJspPath() {
        return "/portal_settings/my_app.jsp";
    }

    @Override
    public String getKey() {
        return "my-app";
    }

    @Override
    public String getLabel(Locale locale) {
        ResourceBundle resourceBundle = ResourceBundleUtil.getBundle(
            "content.Language", locale, getClass());

        return resourceBundle.getString("my-app");
    }

    @Override
    public void include(HttpServletRequest request, HttpServletResponse response)
            throws IOException {

        ThemeDisplay themeDisplay =
            (ThemeDisplay)request.getAttribute(WebKeys.THEME_DISPLAY);

        PortletPreferences companyPortletPreferences =
            PrefsPropsUtil.getPreferences(themeDisplay.getCompanyId(), true);

        boolean companyMyAppFeatureEnabled =
            PrefsParamUtil.getBoolean(
                companyPortletPreferences, request, "myAppFeatureEnabled",
                true);

        request.setAttribute(
            MyAppWebKeys.COMPANY_MY_APP_FEATURE_ENABLED,
            companyMyAppFeatureEnabled);

        super.include(request, response);
    }

    @Override
    @Reference(
        target = "(osgi.web.symbolicname=com.liferay.docs.formnavextensionportlet)",
        unbind = "-"
    )
    public void setServletContext(ServletContext servletContext) {
        super.setServletContext(servletContext);
    }

}
```

The above class is declared an OSGi component that provides a `FormNavigatorEntry.class` service. Since the entry adds a JSP to Portal Settings, the class extends `BaseJSPFormNavigatorEntry` and implements `FormNavigatorEntry` on the `Company` model bean class. The class specifies that the entry belongs to the *Miscellaneous* portal settings category, by returning navigator key `FormNavigatorConstants.FORM_NAVIGATOR_ID_COMPANY_SETTINGS` from method `getFormNavigatorId` and category key `FormNavigatorConstants.CATEGORY_KEY_COMPANY_SETTINGS_MISCELLANEOUS` from method `getCategoryKey`. The entry's method `getKey` returns *my-app* as its own key and method `getJspPath` maps the class to the entry's JSP by returning its JSP file path `/portal_settings/my_app.jsp`.

The entry's `include` method retrieves a boolean portlet preference variable `myAppFeatureEnabled` that specifies whether My App's feature is enabled for the portal. It then sets the preference's value as an attribute on the request. The Form Nav Portlet's language keys for the entry's name, input screen title, and input label are defined in its `src/main/content/Language.properties` file. The method `getLabel(Locale)` uses language key `my-app` to return the entry's localized label. In summary, the `MyAppCompanySettingsFormNavigatorEntry` class meets all of the Form Navigation framework's section entry requirements.

There you have it! You learned all the parts of the Form Navigator framework and worked through all the steps to implement new categories and sections. To recap, you prepared your project's `bnd.bnd` file to support form navigator extension, created JSPs for your new form sections, identified the targeted form navigator and categories, created new categories, and created new entry implementations. You did it all! You now know what it takes to extend Liferay Form Navigators.

104.4 Creating Form Navigator Contexts

Form Navigator System Settings let you specify what categories and sections are visible in your forms. You can learn how to set Form Navigator System Settings in Configuring Form Navigator Forms. Form Navigator configurations let you specify an optional context which defines the circumstances for which the configuration is applied. The following Form Navigator contexts are available by default:

- `add`: Denotes that the form is viewed when new content is being created. For example, you could use the `add` context to specify the visible form sections when someone creates a new site.
- `update`: Denotes that the form is viewed when content is being edited. For example, you could use the `update` context to specify the visible form sections when someone edits a site.

Although the default contexts cover most use cases, you may want to provide additional contexts for users. For example, you may want a custom configuration for a form when it's viewed by an administrator. This tutorial covers how to create additional contexts for Form Navigators.

Your first step is to manage the dependencies.

Adding the Form Navigator Dependency

Open your module's `build.gradle` file and add the following dependency:

```
dependencies {
    compileOnly group: "com.liferay.portal", name:
    "com.liferay.frontend.taglib.form.navigator", version: "1.0.2"
}
```

Now that you have the Form Navigator taglib dependency added, you can create the component class.

Implementing the Context Provider Class

Follow these steps to create a Form Navigator Context:

1. Create a component class that implements the `FormNavigatorContextProvider` service:

   ```
   @Component(
       service = FormNavigatorContextProvider.class
   )
   ```

2. Set the `FormNavigatorContextConstants.FORM_NAVIGATOR_ID` property to the form associated with the context. The example configuration below specifies the Users form, using a constant provided by the `com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorConstants` class:

   ```
   @Component(
       property = FormNavigatorContextConstants.FORM_NAVIGATOR_ID + "=" +
     FormNavigatorConstants.FORM_NAVIGATOR_ID_USERS,
       service = FormNavigatorContextProvider.class
   )
   ```

3. Implement the `FormNavigatorContextProvider` interface, specifying the Form Navigator's model bean class as a generic type. The example below sets the Users form's `User` model bean class as the generic type:

   ```
   public class UsersFormNavigatorContextProvider
       implements FormNavigatorContextProvider<User> {
       ...
     }
   ```

   You can determine the model bean class from the name of the ID's constant in `FormNavigatorConstants`. The word(s) right after `FORM_NAVIGATOR_ID_` in the constant's name hints at the class type. If you can access the Form Navigator's JSP source code, you can find the model bean from the `form-navigator` tag's `formModelBean` attribute value. You can locate the constant in the Liferay Portal repository using the following pattern: `id="<%= FormNavigatorConstants.[CONSTANT]`.

   For example, if the form navigator's ID is `FORM_NAVIGATOR_ID_USERS`, then you would search for `id="<%= FormNavigatorConstants.FORM_NAVIGATOR_ID_USERS`; Make sure that the `form-navigator` tag's `formModelBean` attribute's value isn't a reference to another class. For example, the web content form navigator's `formModelBean` attribute value is `article`, but upon further inspection, it's clear that `article` is a reference variable to the true model bean class: `JournalArticle`.

4. Override the *ContextProvider's getContext() method. This method also takes the Form Navigator's model bean class as a generic type and defines the logic for the new context. The example configuration below creates a new context called my.account for the Users form:

   ```
   @Override
   public String getContext(User selectedUser) {
       if (PortletKeys.MY_ACCOUNT.equals(_getPortletName())) {
           return "my.account";
       }

       if (selectedUser == null) {
           return FormNavigatorContextConstants.CONTEXT_ADD;
       }

       return FormNavigatorContextConstants.CONTEXT_UPDATE;
   }
   ```

   If you are viewing the Users form from the com_liferay_my_account_web_portlet_MyAccountPortlet portlet, the my.account context is returned. You also need to specify under what circumstances the add and update contexts are returned. In the example above, if the user doesn't exist (i.e. you are creating a new user), the add context is returned. Otherwise it defaults to the update context (edit view).

The new context is ready to use in your Form Navigator configurations.
A full *ContextProvider example class is provided next.

Context Provider Example class

Below is an example configuration for the com.liferay.users.admin.web.servlet.taglib.ui.UsersFormNavigatorContextProvic class:

```
package com.liferay.users.admin.web.servlet.taglib.ui;

import com.liferay.frontend.taglib.form.navigator.constants.FormNavigatorContextConstants;
import com.liferay.frontend.taglib.form.navigator.context.FormNavigatorContextProvider;
import com.liferay.portal.kernel.model.User;
import com.liferay.portal.kernel.service.ServiceContext;
import com.liferay.portal.kernel.service.ServiceContextThreadLocal;
import com.liferay.portal.kernel.servlet.taglib.ui.FormNavigatorConstants;
import com.liferay.portal.kernel.theme.PortletDisplay;
import com.liferay.portal.kernel.theme.ThemeDisplay;
import com.liferay.portal.kernel.util.PortletKeys;

import org.osgi.service.component.annotations.Component;

/**
 * @author Alejandro Tardín
 */
@Component(
    property = FormNavigatorContextConstants.FORM_NAVIGATOR_ID + "=" + FormNavigatorConstants.FORM_NAVIGATOR_ID_USERS,
    service = FormNavigatorContextProvider.class
)
public class UsersFormNavigatorContextProvider
    implements FormNavigatorContextProvider<User> {

    @Override
    public String getContext(User selectedUser) {
        if (PortletKeys.MY_ACCOUNT.equals(_getPortletName())) {
            return "my.account";
        }

        if (selectedUser == null) {
```

```
            return FormNavigatorContextConstants.CONTEXT_ADD;
        }

        return FormNavigatorContextConstants.CONTEXT_UPDATE;
    }

    private String _getPortletName() {
        ServiceContext serviceContext =
            ServiceContextThreadLocal.getServiceContext();

        ThemeDisplay themeDisplay = serviceContext.getThemeDisplay();

        PortletDisplay portletDisplay = themeDisplay.getPortletDisplay();

        return portletDisplay.getPortletName();
    }

}
```

Now you know how to create a Form Navigator context!

Chapter 105

Themes and Layout Templates

Do you want to transform the look and feel of your Liferay DXP? Create your own user interface with a Liferay Theme! Create a layout template to specify where content can be placed on a page! Define a custom look and feel for your portlets! All these customizations and more are possible with Liferay DXP!

In this section of tutorials, you'll learn how to develop themes and layout templates, customize portlets, and more.

Chapter 106

Themes

A Liferay Theme is the overall look and feel for a site. Themes are a combination of CSS, JavaScript, HTML, and FreeMarker templates. Although the default themes are nice, you may wish to create your own custom look and feel for your site. Liferay DXP provides several tools and environments that you can use to create themes:

- Theme Builder Gradle Plugin
- The Liferay Theme Generator
- @ide@
- Blade CLI's Theme Template

What if you only wish to make a minor change to the overall look and feel? Let's say you just want to change a menu animation. Instead of creating an entire theme for this single modification, you can create a Themelet. Themelets are modular, customizable, reusable, shareable pieces of code that extend a theme. They enable reusable code for themes. Instead of rewriting the code each time, you can use the same themelet in each theme.

Liferay has its own set of base themes, called styled and unstyled that create the default look and feel you see at first start. The *styled* theme inherits from the *unstyled* theme, and simply adds some additional styling on top. These same base themes are used to create a custom theme. See the User Profile Theme, which uses the *styled* theme as its base. Using a base theme as your foundation, you can then make your customizations to the theme files. To modify the theme, mirror the folder structure of the files you wish to change and copy them into your theme. Place the modified files in the `src` folder of your theme if using the Liferay Theme Generator, or copy them into the `webapp` folder of your theme if using Liferay @ide@. Build the theme to apply the changes.

Once your theme is developed it is packaged as a WAR (Web application ARchive) file and can be deployed to the server, either manually or using build tools. Apply your theme to your pages through the Look and Feel menu. The only limitation is your imagination.

106.1 Liferay Theme Generator

The Liferay Theme Generator is an easy-to-use command-line wizard that streamlines the theme creation process. It is independent of the Liferay Plugins SDK, and generates themes for Liferay Portal 6.2, 7.0, and up. It is just one of Liferay JS Theme Toolkit. This tutorial focuses on using the Liferay Theme Generator to create themes. In just a few steps, you'll have a working Liferay theme.

Note: The Liferay Theme Generator is unsupported. The tool is still in development and is not guaranteed to work on all platforms and environments.

This tutorial demonstrates how to:

- Install the Liferay Theme Generator
- Generate a theme

The first step is to install the Liferay Theme Generator.

Installing the Theme Generator

The Liferay Theme Generator has several dependencies. Follow these steps to install them:

1. Install Node.js, if it's not already installed. We recommend installing v6.6.0, which is the version Liferay Portal 7.0 supports.

   To test your Node.js installation, execute the following command:

   ```
   node -v
   ```

   The resulting output should look similar to this:

   ```
   v4.2.2
   ```

   Note: To avoid any potential compatibility issues, we recommend installing the Long Term Support (LTS) version of Node.js–at the time of this writing, the LTS version is v4.2.2.

   Node Package Manager (npm) is installed along with Node.js.

2. Set up your npm environment.

   First, create an `.npmrc` file in your user's home directory. This helps you bypass npm permission-related issues.

   In the `.npmrc` file, specify a `prefix` property like this one:

   ```
   prefix=/Users/[username]/.npm-packages
   ```

   Set the `prefix` value based on your user's home directory. The location you specify is where global npm packages are to be installed.

   Next, set the `NPM_PACKAGES` system environment variable to the `prefix` value you just specified:

   ```
   NPM_PACKAGES=/Users/[username]/.npm-packages (same as prefix value)
   ```

   As a last npm configuration, since npm installs Yeoman and gulp executables to `${NPM_PACKAGES}/bin` on UNIX and to `%NPM_PACKAGES%` on Windows, make sure to add the appropriate directory to your system path. For example, on UNIX you'd set this:

```
PATH=${PATH}:${NPM_PACKAGES}/bin
```

3. Install Yeoman and gulp globally by executing the following command:

   ```
   npm install -g yo gulp
   ```

   You've completed installing the Liferay Theme Generator's dependencies.

4. Install the Liferay Theme Generator. 7.x.x versions of the Theme Generator create themes for 6.2 and 7.0. 8.x.x versions create themes for 7.0 and 7.1. 9.x.x versions create themes for 7.2 and up.

   To create themes for **6.2** or **7.0**, run the following command:

   ```
   npm install -g generator-liferay-theme@7.x.x
   ```

   To create themes for **7.0** or **7.1** versions of Liferay DXP, run this command:

   ```
   npm install -g generator-liferay-theme@8.x.x
   ```

If you are on Windows, you must do additional setup for generated themes to use Sass.

Installing Sass on Windows

To use Sass on Windows, you must use either Sass from node-sass or Sass from Ruby. By default, the generator creates theme projects to use node-sass; but you can reconfigure them to use Ruby based Sass and Compass. Since node-sass indirectly requires Visual Studio, developers who are not already using Visual Studio may opt to use Ruby based Sass and Compass instead of node-sass.

Note: If your theme was built with an older version of the Liferay Theme Generator and specifies the `"liferay-theme-deps-7.0": "1.0.0"` dependency in its `package.json`, `npm install` may fail in Liferay DXP due to its dependency on node-sass `v3.13.1`. To fix this issue, change the dev dependency in your `package.json` to `"liferay-theme-deps-7.0": "7.0.0"` and rebuild your theme. We recommend that you use the latest 7.x.x version of the Theme Generator and dependencies in your `package.json` to ensure full compatibility.

This section explains both Sass installations.

Installing Sass from node-sass By default, the generator uses Sass from node-sass. node-sass requires node-gyp, which in turn requires Python and Visual Studio. The node-gyp installation instructions explain how to set up node-gyp, Python, and Visual Studio. Since Visual Studio is a particularly large dependency, if you aren't already using Visual Studio you might want to consider using Ruby Sass instead of node-sass.

Installing Ruby Sass and Compass As an alternative to using Sass from node-sass, you can use Sass from Ruby. Liferay themes require using Compass along with Ruby based Sass. In order to install and use Sass and Compass, you must install Ruby via the Ruby installer.

Note: Sass version 3.5 has compatibility issues with Compass. We recommend that you install Sass version 3.4.0 as shown in the command below.

The following commands install the Sass and Compass gems:

```
gem install sass -v "=3.4.0"

gem install compass
```

After creating a theme project in the next section, you'll learn how to configure a project to use Ruby based Sass and Compass.

Now that you've installed the Liferay Theme Generator and theme dependencies, you can generate a theme.

Running the Liferay Theme Generator

When you installed the Liferay Theme Generator, you also installed three sub-generators with it: a layout template creator, a themelet creator, and a theme importer. For the purposes of this tutorial, the focus will be on the default Liferay Theme Generator.

Note: If you run into permissions issues during theme generation, make sure you have read/write access to all folders on your system.

From a directory in which you want to create a theme, run the following command:

```
yo liferay-theme
```

Note: Some theme options are deprecated for 7.0 (such as Velocity theme templates). To view the deprecated options, run the generator with the `--deprecated` flag:

```
 yo liferay-theme --deprecated
```

The Liferay Theme Generator prompts you for the following things:

1. Enter a name for your theme.

2. Enter a theme ID, or press *enter* to accept the default.

3. Select the version of your Liferay instance (e.g., 7.0).

4. Choose a template language. Note that Freemarker is used by default; you can only select Velocity if you run the generator with the `--deprecated` flag.

   Based on the inputs up to this point, the default generator starts installing additional required software and creating your theme project.

5. When prompted, enter your app server's path. The information you provide is added to the `liferay-theme.json` in your theme's root folder. you can change the path in that file if you change app servers.

6. Finally, enter your Liferay instance's URL, or press *enter* to accept the default `localhost:8080`.

The generator creates a new theme project in your current directory. The theme inherits styles from the liferay-theme-styled theme. Note that you can switch to using a different base theme by executing the `gulp extend` command.

Note: The liferay-theme-styled and liferay-theme-unstyled themes are base themes. They're analogous to Java APIs. Liferay's Classic theme and other themes that use liferay-theme-styled or liferay-theme-unstyled as a base theme are analogous to API implementations–they're not meant to be extended. Extending Liferay's Classic theme is strongly discouraged.

Important: By default, your theme is based off of the styled theme and uses lib-sass/bourbon, instead of Compass. If, however, you are on Windows and are using the Ruby version of Sass, you must configure the theme to support Compass. To do so, follow these steps:

1. Open the `package.json` file found in the root folder of your theme, and locate the `rubySass` property and change it from `false` to `true`.

   Now that your theme is set to support Compass, you must install the Ruby Sass middleware and save it as a dependency for your theme.

2. Run the following command to install the Ruby Sass middleware:

   ```
   npm i --save gulp-ruby-sass
   ```

   The `--save` flag adds Ruby Sass to the list of dependencies in your theme's `package.json` file. Your theme is ready to use.

3. Run the `gulp build` task to generate the base files for your theme. Open the `build` folder of your theme to view the base files.

There you have it! You now have a working theme. At the moment, the theme is a bit bare bones, but you have everything you need to develop it.

The generated theme's structure differs slightly from a theme created in the Liferay Plugins SDK. In a theme generated in the Liferay Plugins SDK, you put changes in a `_diffs` folder. In a theme generated by the Liferay Theme Generator, you put changes in the `src` folder.

To develop your theme, copy the build files into your `src` folder. For instance to make a change to the `portal_normal.ftl` theme template, you would create a `templates` folder in your `src` folder, and copy the `portal_normal.ftl` file from the `build/templates` folder into the `src/templates` folder. This gives you the base template to build on. It is important that you mirror the folder structure in order for the changes to be applied.

Another noticeable difference in the generator created theme is that all CSS files have been converted to Sass SCSS files. Sassy CSS (SCSS) is the new main syntax which allows you to use the latest CSS3 styles and leverage Sass syntax advantages, such as nesting and variables.

To deploy your theme to your configured Liferay DXP instance, execute this command:

```
gulp deploy
```

You can apply your theme by following the instructions found in the Creating and Managing Pages User Guide.

Note: By default theme images are cached by the browser. If you need to update images in the theme, it is best practice to use versioning in the image URL. For example, `background-image:url("../images/image.jpg?v=1")` . You can then just update the version each time you update the image, which will remove the potential for any caching issues.

Now that you've created a theme and deployed it, you can use the theme project's gulp tasks to further develop and manage your theme. These offer basic functions, such as `build` and `deploy`, as well as more complex interactions, such as auto deploying when a change is made and setting the base theme.

There you have it! You're ready to design a terrific theme!

Theme Gulp Tasks

Themelets

Importing Resources with a Theme

106.2 Themelets

Themelets are small, extendable, and reusable pieces of code. Whereas themes require multiple components, a themelet only requires the files you wish to extend. This creates a more modular approach to theme design, that lends itself well to collaboration, and reduces the need for duplicated code in your theme.

Themelets let developers easily share code snippets across their themes with other developers. A themelet can consist of CSS and JavaScript. Themelets **do not support** theme templates.

Themelets are very flexible, and therefore they have a number of possible uses. You can make a themelet to modify the appearance of 7.0 admin tools, or a themelet that uses a custom JavaScript component for responsive embedded videos. For example, take a look at the Liferay Product Menu Animation Themelet. This themelet simply alters the animation for Liferay's Product Menu.

If there is something you find yourself coding over and over again for themes, it's a good candidate for a themelet.

This tutorial demonstrates how to:

- Create a themelet to extend your theme
- Install a Themelet

To create a themelet, you need a theme to extend and the Liferay Theme Generator and dependencies installed, as explained in the Liferay Theme Generator tutorial.

Creating a Themelet

Follow these steps to create a themelet:

1. Open the Command Line and navigate to the directory you want to create your themelet in.
2. Run `yo liferay-theme:themelet` and follow the prompts to generate the themelet.
3. The generated themelet contains a `package.json` file with configuration information and a `src/css` folder that contains a `_custom.scss` file. Just like a theme, add your CSS changes to the `src/css` folder, and add your JavaScript changes to the `src/js` folder.
4. To use your themelet, you must install it globally first. This makes the themelet visible to the generator. To install your themelet globally, navigate into its root folder and run `npm link`. Note, you may need to run the command using `sudo npm link`. This creates a globally-installed symbolic link for the themelet in your npm packages folder. Now your themelet is available to install in your themes.

Now that your themelet is developed, you can install it in your theme.

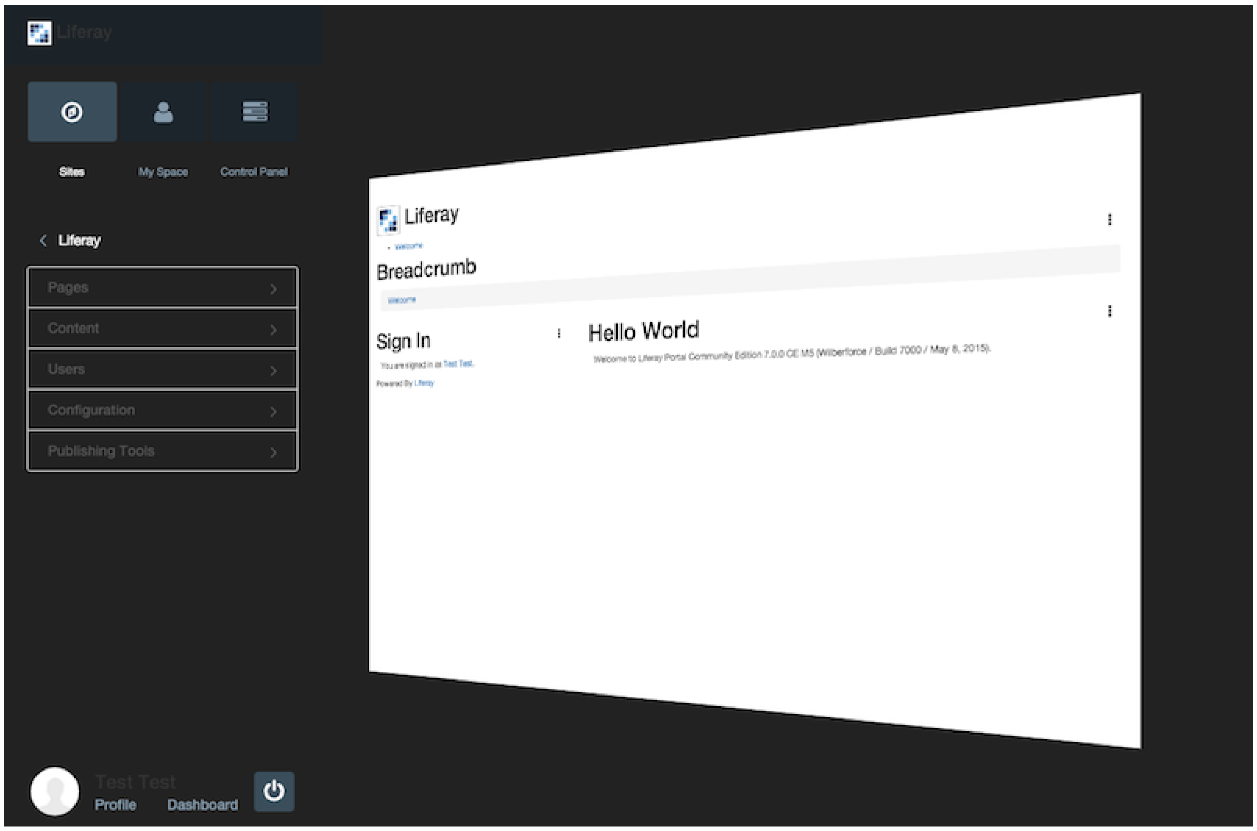

Figure 106.1: Themelets can be used to modify one aspect of the UI, that you can then reuse in your other themes.

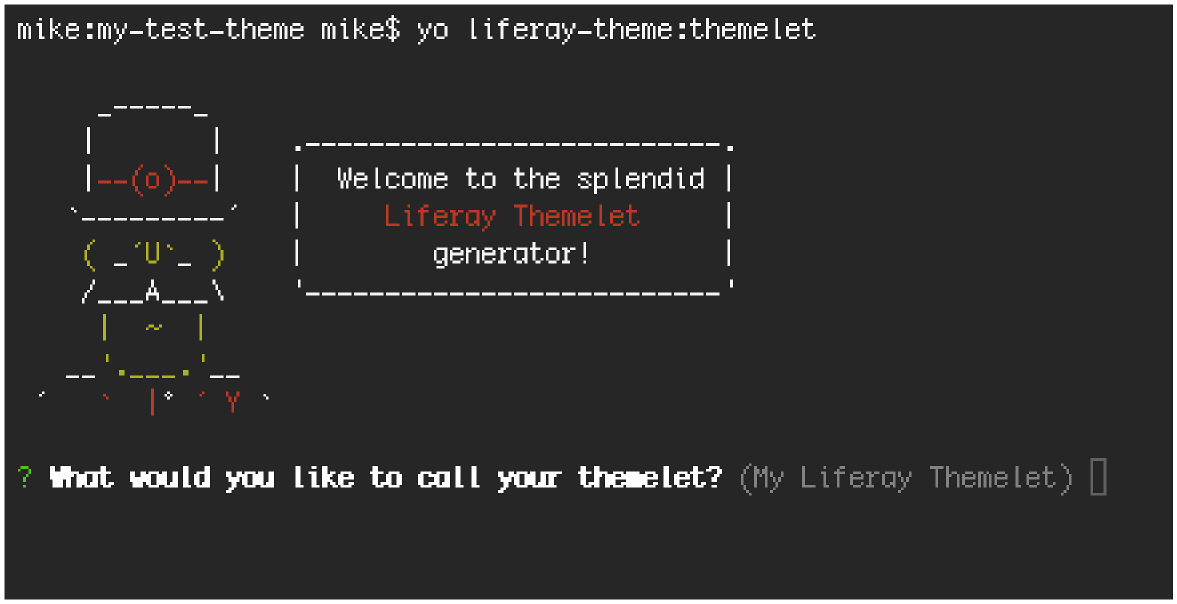


```
mike:my-test-theme mike$ yo liferay-theme:themelet

      _-----_
     |       |    .--------------------------.
     |--(o)--|    |  Welcome to the splendid |
    `---------´   |     Liferay Themelet     |
     ( _´U`_ )    |        generator!        |
     /___A___\    '--------------------------'
      |  ~  |
    __'.___.'__
  ´   `  |° ´ Y `

? What would you like to call your themelet? (My Liferay Themelet)
```

Figure 106.2: The Themelet sub-generator automates the themelet creation process, making it quick and easy.

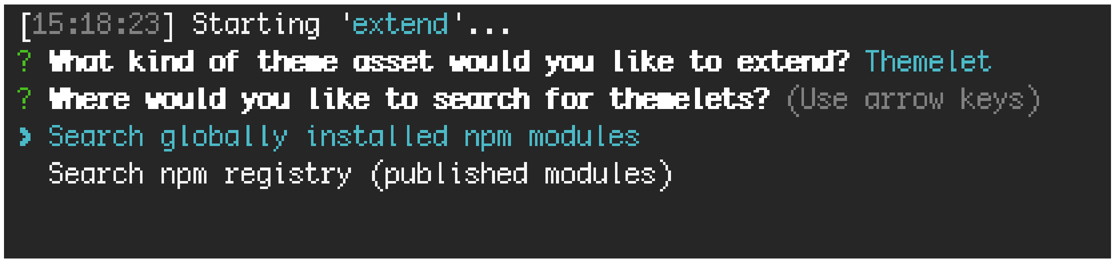
Installing a Themelet

After you've developed your themelet, follow the steps below to install it into your theme.

1. Navigate to your theme's root directory and run the following command:

   ```
   gulp extend
   ```

2. Choose *Themelet* as the theme asset to extend.
3. Select *Search globally installed npm modules*.



```
[15:18:23] Starting 'extend'...
? What kind of theme asset would you like to extend? Themelet
? Where would you like to search for themelets? (Use arrow keys)
❯ Search globally installed npm modules
  Search npm registry (published modules)
```

Figure 106.3: You can extend your theme using globally installed npm modules or published npm modules.

4. Highlight your themelet, press spacebar to activate it, and press *Enter* to install it.
5. Run `gulp deploy` to build and deploy your theme with the new themelet updates.

Your themelet is installed! As you can see, themelets are a handy tool to add to your theme development bag o' tricks.

Liferay Theme Generator

106.3 Importing Resources with a Theme

A theme without content is like an empty house. If you're trying to sell an empty house, it may be difficult for prospective buyers to see its full beauty. However, staging the house with some furniture and decorations helps prospective buyers imagine what the house might look like with their belongings. Liferay's resources importer module is a tool that allows a theme developer to have files and web content automatically imported into Liferay DXP when a theme is deployed. Usually, the resources are imported into a site template but they can also be imported directly into a site. Liferay Administrators can use the site or site template created by the resources importer to showcase the theme. This is a great way for theme developers to provide a sample context that optimizes the design of their theme. In fact, all standalone themes that are uploaded to Liferay Marketplace must use the resources importer. This ensures a uniform experience for Marketplace users: a user can download a theme from Marketplace, install it on Liferay DXP, go to Sites or Site Templates in the Control Panel and immediately see their new theme in action. In this tutorial, we explain how to include resources with your theme.

Note: The resources importer has undergone some changes that affect the properties, class names, and structures that were referred to in versions prior to 7.0. Please read through the steps below to see the updates. In previous versions of Liferay, you had to deploy the resources importer if you declared it as a dependency in your theme's `liferay-plugin-package.properties` file. In 7.0 and up, this is no longer a requirement. The resources importer is now an OSGi module, and is deployed to your instance by default.

When you create a new theme using the Liferay Theme Generator, check your theme's `src/WEB-INF/liferay-plugin-package.properties` file for the developer mode entry:

```
resources-importer-developer-mode-enabled=true
```

This is a convenience feature for theme developers. With this setting enabled, importing resources to a site or site template that already exists, recreates the site or site template. Importing resources into a site template reapplies the site template and its resources to the sites that are based on the site template. Without `resources-importer-developer-mode-enabled=true`, you have to manually delete the sites or site templates built by the resources importer, each time you want to apply changes from your theme's `src/WEB-INF/src/resources-importer` folder.

Warning: the `resources-importer-developer-mode-enabled=true` setting can be dangerous since it involves *deleting* (and re-creating) the affected site or site template. It's only intended to be used during development. Never use it in production.

If you'd like to import your theme's resources directly into a site, instead of into a site template, you can specify the following in your `liferay-plugin-package.properties` file:

```
resources-importer-target-class-name=com.liferay.portal.kernel.model.Group

resources-importer-target-value=[site-name]
```

If you're using the `resources-importer-target-value=[site-name]` property, double check the site name that you're specifying. If you specify the wrong value, you could end up deleting (and re-creating) the wrong site!

Warning: It's safer to import theme resources into a site template than into an actual site. The `resources-importer-target-class-name=com.liferay.portal.kernel.model.Group` setting can be handy for development and testing but should be used cautiously. Don't use this setting in a theme that will be deployed to a production Liferay instance or a theme that will be submitted to Liferay Marketplace. To prepare a theme for deployment to a production Liferay instance, use the default setting so that the resources are imported into a site template. You can do this explicitly by setting `resources-importer-target-class-name=com.liferay.portal.kernel.model.LayoutSetPrototype` or implicitly by commenting out or removing the `resources-importer-target-class-name` property.

All of the resources a theme uses with the resources importer go in the `[theme-name]/src/WEB-INF/src/resources-importer` folder. The assets to be imported by your theme should be placed in the following directory structure:

- `[theme-name]/src/WEB-INF/src/resources-importer/`

    - `sitemap.json` - defines the pages, layout templates, and portlets
    - `assets.json` - (optional) specifies details on the assets

- document_library/
    * documents/ - contains documents and media files
- journal/
    * articles/ - contains web content (HTML) and folders grouping web content articles (XML) by template. Each folder name must match the file name of the corresponding template. For example, create folder Template 1/ to hold an article based on template file Template 1.ftl.
    * structures/ - contains structures (JSON) and folders of child structures. Each folder name must match the file name of the corresponding parent structure. For example, create folder Structure 1/ to hold a child of structure file Structure 1.json.
    * templates/ - groups templates (VM or FTL) into folders by structure. Each folder name must match the file name of the corresponding structure. For example, create folder Structure 1/ to hold a template for structure file Structure 1.json.

The following is the XML file for a basic web content article:

```
<?xml version="1.0"?>

<root available-locales="en_US" default-locale="en_US">
    <dynamic-element name="content" type="text_area" index-type="keyword" index="0">
        <dynamic-content language-id="en_US">
            <![CDATA[
                <center>
                <p><img alt="" src="[$FILE=space-program-history.jpg$]" /></p>
                </center>

                <p>In the mid-20th century, after two of the
                most violent wars in history, mankind turned
                its gaze upwards to the stars. Instead of
                continuing to strive against one another,
                man choose instead to strive against the
                limits that we had bound ourselves to. And
                so the Great Space Race began.</p>

                <p>At first the race was to reach space--get
                outside the earth's atmosphere, and when
                that had been reached, we shot for the moon.
                After sending men to the moon, robots to
                Mars, and probes beyond the reaches of our
                solar system, it seemed that there was
                nowhere left to go.</p>

                <p>The Space Program aims to change that.
                Beyond national boundaries, beyond what
                anyone can imagine that we can do. The sky
                is not the limit.</p>
            ]]>
        </dynamic-content>
    </dynamic-element>
</root>
```

You can view an article's XML by going to its source.

When you create a new theme using the Liferay Theme Generator, a default sitemap.json file is created and a default liferay-plugin-package.properties file is created in the WEB-INF folder.

You have two options for specifying resources to be imported with your theme. The recommended approach is to add resource files to the folders outlined above and to specify the contents of the site or site template in a `sitemap.json` file (described below). Alternatively, you can use an `archive.lar` file to package the resources you'd like your theme to deploy. To create such an `archive.lar`, just export the contents of a site from Liferay Portal using the site scope. Then place the `archive.lar` file in your theme's `[theme-name]/src/WEB-INF/src/resources-importer` folder. If you choose to use an archive file to package all of your resources, you won't need a `sitemap.json` file or any other files in your `[theme-name]/src/WEB-INF/src/resources-importer` folder. Note, however, a LAR file is version-specific; it won't work on any version of Liferay other than the one from which it was exported. For this reason, using a `sitemap.json` file to specify resources is the most flexible approach. If you're developing themes for Liferay Marketplace, you should use the `sitemap.json` to specify resources to be imported with your theme.

The `sitemap.json` in the `[theme-name]/src/WEB-INF/src/resources-importer` folder specifies the site pages, layout templates, web content, assets, and portlet configurations provided with the theme. This file describes the contents and hierarchy of the site for Liferay to import as a site or site template.

Note: Site templates only support the importing of either public page sets or private page sets.

If you want to import both public and private page sets, as shown in the example `sitemap.json` below, you must import your resources into a site.

Even if you're not familiar with JSON, the `sitemap.json` file is easy to understand. Let's examine a sample `sitemap.json` file:

```
{
"layoutTemplateId": "2_columns_ii",
"privatePages": [
    {
        "friendlyURL": "/private-page",
    "name": "Private Page",
    "title": "Private Page"
    }
],
"publicPages": [
        {
            "columns": [
                [
                    {
                        "portletId": "com_liferay_login_web_portlet_LoginPortlet"
                    },
                    {
                        "portletId": "com_liferay_site_navigation_menu_web_portlet_SiteNavigationMenuPortlet"
                    },
                    {
                        "portletId": "com_liferay_journal_content_web_portlet_JournalContentPortlet",
                        "portletPreferences": {
                            "articleId": "Without Border.html",
                            "groupId": "${groupId}",
                            "portletSetupPortletDecoratorId": "borderless"
                        }
                    },
                    {
                        "portletId": "com_liferay_journal_content_web_portlet_JournalContentPortlet",
                        "portletPreferences": {
                            "articleId": "Custom Title.html",
                            "groupId": "${groupId}",
                            "portletSetupPortletDecoratorId": "decorate",
                            "portletSetupTitle_en_US": "Web Content Display with Custom Title",
                            "portletSetupUseCustomTitle": "true"
                        }
                    }
                ],
                [
                    {
```

```
                "portletId": "com_liferay_hello_world_web_portlet_HelloWorldPortlet"
            },
            {
                "portletId": "com_liferay_site_navigation_menu_web_portlet_SiteNavigationMenuPortlet_INSTANCE_${groupId}",
                "portletPreferences": {
                    "displayStyle": "[custom]",
                    "headerType": "root-layout",
                    "includedLayouts": "all",
                    "nestedChildren": "1",
                    "rootLayoutLevel": "3",
                    "rootLayoutType": "relative"
                }
            },
            "Web Content with Image.html",
            {
                "portletId": "com_liferay_nested_portlets_web_portlet_NestedPortletsPortlet",
                "portletPreferences": {
                    "columns": [
                        [
                            {
                                "portletId": "com_liferay_journal_content_web_portlet_JournalContentPortlet",
                                "portletPreferences": {
                                "articleId": "Child Web Content 1.xml",
                                "groupId": "${groupId}",
                                "portletSetupPortletDecoratorId": "decorate",
                                "portletSetupTitle_en_US": "Web Content Display with Child Structure 1",
                                    "portletSetupUseCustomTitle": "true"
                                }
                            }
                        ],
                        [
                            {
                                "portletId": "com_liferay_journal_content_web_portlet_JournalContentPortlet",
                                "portletPreferences": {
                                "articleId": "Child Web Content 2.xml",
                                "groupId": "${groupId}",
                                "portletSetupPortletDecoratorId": "decorate",
                                "portletSetupTitle_en_US": "Web Content Display with Child Structure 2",
                                    "portletSetupUseCustomTitle": "true"
                                }
                            }
                        ]
                    ],
                    "layoutTemplateId": "2_columns_i"
                }
            }
        ]
    ],
    "friendlyURL": "/home",

                        "portletId": "com_liferay_hello_world_web_portlet_HelloWorldPortlet"
                    }
                ]
            ],
            "friendlyURL": "/parent-page",
            "layouts": [
                {
                    "friendlyURL": "/child-page-1",
                    "name": "Child Page 1",
                    "title": "Child Page 1"
                },
                {
                    "friendlyURL": "/child-page-2",
                    "name": "Child Page 2",
                    "title": "Child Page 2"
                }
            ],
            "name": "Parent Page",
            "title": "Parent Page"
        },
        {
            "friendlyURL": "/url-page",
            "name": "URL Page",
            "title": "URL Page",
            "type": "url"
        },
        {
            "friendlyURL": "/link-page",
            "name": "Link to another Page",
            "title": "Link to another Page",
            "type": "link_to_layout",
            "typeSettings": "linkToLayoutId=1"
        },
        {
            "friendlyURL": "/hidden-page",
            "name": "Hidden Page",
            "title": "Hidden Page",
            "hidden": "true"
        }
    ]
}
```

The first thing you should declare in your `sitemap.json` file is a default layout template ID so the target site or site template can reference the layout template to use for its pages. You can also specify different layout templates to use for individual pages. You can find layout templates in your Liferay installation's `/layouttpl` folder. Next, you have to declare the layouts, or pages, that your site template should use. Note that pages are called *layouts* in Liferay DXP's code. You can specify a name, title, and friendly URL for a page, and you can set a page to be hidden. To declare that web content should be displayed on a page, simply specify an XML file. You can declare portlets by specifying their portlet IDs, which can be found in the App Manager of the Control Panel. Select the suite that the App is located in, click the App, click the App web link, and open the *Portlets* tab that appears. The portlet ID is displayed below the name of the App. You can find a full list of the default portlet IDs for Liferay in the Portlet ID quick reference. You can also specify portlet preferences for each portlet.

The following properties are available in the `sitemap.json`:

colorSchemeId: Specifies a different color scheme (by ID) than the default color scheme to use for the layout.

columns: Specifies the column contents for the layout.

friendlyURL: Sets the layout's friendly URL.

hidden: Sets whether the layout is hidden.

layoutCss: Sets custom CSS for the layout to load after the theme.

layoutPrototypeLinkEnabled: Sets whether the layout inherits changes made to the page template (if the layout has one).

layoutPrototypeName: Specifies the page template (by name) to use for the layout. If this is defined, the page template's UUID is retrieved using the name, and `layoutPrototypeUuid` is not required.

layoutPrototypeUuid: Specifies the page template (by UUID) to use for the layout. If `layoutPrototypeName` is defined, this is not required.

layoutTemplateId: When defined outside the scope of a portlet, sets the default layout template for the theme's layouts. When placed inside a layout, sets the layout template for the layout.

layouts: Specifies child pages for a layout set (`publicPages` || `privatePages`).

name: The layout's name.

nameMap: Passes a name object with multiple name key/value pairs. As shown in the example sitemap above, you can use this to pass language keys for layout names.

portletPreferences: Specifies the portlet's preferences. See note below for more information.

portletSetupPortletDecoratorId: Specifies the portlet decorator to use for the portlet (`borderless` || `barebone` || `decorate`). See the Portlet Decorators tutorial for more info.

portlets: specifies the portlets to display in the layout's column. To nest portlets, recursively use columns as shown in the example `sitemap.json` above for the `com_liferay_nested_portlets_web_portlet_NestedPortletsPortlet` portlet.

privatePages: Specifies private layouts.

publicPages: Specifies public layouts.

themeId: Specifies a different theme (by ID) than the default theme bundled with the `sitemap.json` to use for the layout.

title: The layout's title.

type: Sets the layout type. The default value is `portlet` (empty page). Possible values are `copy` (copy of a page of this site), `embedded`, `full_page_application`, `link_to_layout`, `node` (page set), `panel`, `portlet`, and `url` (link to URL).

typeSettings: Specifies settings (using key/value pairs) for the layout `type`.

Note: Portlet preferences set in `sitemap.json` are saved in the database to the column: `portletPreferences.preferences`. To determine the proper key:value pair for a portlet preference, there are a couple approaches you can take.

You can manually set the portlet preference in Liferay DXP, and then check the values in this column of the database as a hint for what to configure in your `sitemap.json`. For example, you can configure the Asset Publisher to display assets that match the specified asset tags, using the following configuration:

```
"queryName0": "assetTags",
"queryValues0": "MyAssetTagName"
```

Alternatively, you can search each app in your Liferay DXP bundle for the keyword `preferences--`. This returns some of the app's JSPs that have the portlet preferences defined for the portlet.

You can use a combination of both of these approaches to determine the key/value pairs for the portlet preferences.

Note that portlet preferences that require an existing configuration, such as a tag or category, may require you to create the configuration on the Global site first, so that the Resources Importer finds a match when deployed with the theme.

Tip: You can specify an application display template (ADT) for a portlet in the `sitemap.json` file by setting the `displayStyle` and `displayStyleGroupId` portlet preferences. For example:

```
"portletId": "com_liferay_asset_publisher_web_portlet_AssetPublisherPortlet",
    "portletPreferences": {
        "displayStyleGroupId": "10197",
        "displayStyle": "ddmTemplate_6fe4851b-53bc-4ca7-868a-c836982836f4",
}
```

To learn more about ADTs, visit the Styling Apps with Application Display Templates chapter.

Optionally, you can create an `assets.json` file in your `[theme-name]/src/WEB-INF/src/resources-importer` folder. While the `sitemap.json` file defines the pages of the site or site template to be imported, along with the layout templates, portlets, and portlet preferences of these pages, the `assets.json` file specifies details about the assets to be imported. Tags can be applied to any asset. Abstract summaries and small images can be applied to web content articles. For example, the following `assets.json` file specifies two tags for the `company_logo.png` image, one tag for the `Custom Title.xml` web content article, and an abstract summary and small image for the `Child Web Content 1.json` article structure:

```
{
    "assets": [
        {
            "name": "company_logo.png",
            "tags": [
                "logo",
                "company"
            ]
        },
        {
            "name": "Custom Title.xml",
            "tags": [
                "web content"
            ]
        },
        {
            "abstractSummary": "This is an abstract summary.",
            "name": "Child Web Content 1.xml",
            "smallImage": "company_logo.png"
        }
    ]
}
```

Now that you've learned about the directory structure for your resources, the `sitemap.json` file for referencing your resources, and the `assets.json` file for describing the assets of your resources, it's time to put resources into your theme. You can create resources from scratch and/or bring in resources that you've already created in Liferay. Let's go over how to leverage your HTML (basic web content), JSON (structures), or VM or FTL (templates) files from Liferay:

Note: In previous versions of Liferay, basic web content could be added without the need of a structure or template. In 7.0 and above, all web content articles require a structure and template.

- **web content:** Edit the article, and copy the content from the *Source* view. Create a folder for the article under `resources-importer/journal/articles/`, copy the contents into an XML file, named as desired, and place it into the folder for the article. The web content article's XML fills in the data required by the structure.
- **structure:** Edit the structure by clicking the link under *Structure and Template*, and copy and paste its contents into a new JSON file for the structure in the `resources-importer/journal/structures/` folder. The structure JSON sets a wireframe, or blueprint, for an article's data.
- **template:** Create a folder for the template under `resources-importer/journal/templates/`. Edit the template by clicking the link under *Structure and Template*, and copy and paste its contents into a new FTL file for the template, and place it into the folder for the template. The template defines how the data should be displayed.

Here is an outline of steps you can use in developing your theme and its resources:

1. Create your theme.
2. Add your resources under the `[theme-name]/src/WEB-INF/src/resources-importer` folder and its sub-folders.
3. Create a `sitemap.json` file in your `resources-importer/` folder. In this file, define the pages of the site or site template to be imported, along with the layout templates, portlets, and portlet preferences of these pages.
4. Create an `assets.json` file in your `resources-importer/` folder. In this file, specify details of your resource assets.
5. In your `liferay-plugin-package.properties` file, set `resources-importer-developer-mode-enabled=true`:

   ```
   resources-importer-developer-mode-enabled=true
   ```

6. Set the `resources-importer-target-value` property to the name of the site or site template into which you are importing, or comment it out to use the theme's name.

   For example, the following configuration sets the target value to the name of an existing site or site template:

   ```
   resources-importer-target-value = site/site template name
   ```

   Alternatively, this configuration uses the theme's name as the target value:

```
#resources-importer-target-value
```

```
**Note:** By default resources are imported into a new site template named
after the theme. If you want your resources to be imported into an existing
site or site template, you must specify a value for the
`resources-importer-target-value` property.
```

---

7. Comment out the `resources-importer-target-class-name` property to import into a site template or set it to `com.liferay.portal.kernel.model.Group` to import directly into a site.

   As mentioned above the example `sitemap.json`, **you must import your resources into a site, if you define both public and private page sets in your `sitemap.json`.**

If you don't specify a value for the `resources-importer-target-class-name` property, your resources will be imported into a site template.

8. Deploy your theme into your Liferay instance.

9. View your theme, and its resources, from within Liferay. Log in to your portal as an administrator and check the Sites or Site Templates section of the Control Panel to make sure that your resources were deployed correctly. From the Control Panel you can easily view your theme and its resources:

   - If you imported into a site template, select its *Actions* → *View Pages* to see it.
   - If you imported directly into a site, select its *Actions* → *Go to Public Pages* to see it.

You can go back to any of the beginning steps in this outline to make refinements. It's just that easy to develop a theme with resources intact!

106.4 Using Developer Mode with Themes

Do you want to develop Liferay DXP themes without having to redeploy to see your modifications? Use Liferay DXP's Developer Mode! In Developer Mode, all caches are removed, so any changes you make are visible right away. Also, you don't have to reboot the server as often in Developer Mode.

How does Developer Mode let you see your changes more quickly? By default, Liferay DXP is optimized for performance. Developer mode optimizes your configuration for development instead. Here is a list of Developer Mode's key behavior changes and the Portal Property override settings that trigger them (if applicable):

- CSS files are loaded individually rather than being combined and loaded as a single CSS file (`theme.css.fast.load=false`).
- Layout template caching is disabled (`layout.template.cache.enabled=false`).
- The server does not launch a browser when starting (`browser.launcher.url=`).

- FreeMarker Templates for themes and web content are not cached, so changes are applied immediately (via the system setting in your Liferay DXP instance).
- Minification of CSS and JavaScript resources is disabled (`minifier.enabled=false`).

Note: There are two known issues LPS-71350 and LPS-70364 that prevent CSS changes from being applied to the page and the Control Panel and Product Menu to break when using Developer Mode. Both these issues are fixed in Liferay Portal CE 7.0.3 GA4 and Liferay DXP 7.0 Fixpack DE 13.

Individual file loading of your styling and behaviors, combined with disabled caching for layout and FreeMarker templates, lets you see your changes more quickly.

These developer settings are defined in the `portal-developer.properties` file. To use these settings, you can include them in your `portal-ext.properties` file or copy them over to your `portal-ext.properties` file and override specific properties as needed. These configurations are covered in this tutorial.

First, you can explore how it's done in @ide@.

Setting Developer Mode for Your Server in @ide@

To enable Developer Mode for your server in @ide@, follow these steps:

1. Double-click on your server in the *Servers* window and open the *Liferay Launch* section.

2. Select *Custom Launch Settings* and check the *Use developer mode* option.

3. Save the changes and start your server.

Warning: Only change the Server settings from the runtime environment's Liferay Launch section.

For Liferay Portal servers below version 6.2 (e.g., Liferay v6.1 CE Server, Liferay v6.0 CE Server), @ide@ enables Developer Mode by default. When starting your Liferay DXP server for the first time, it creates a `portal-ext.properties` file in your server's directory. This properties file contains the property setting `include-and-override=portal-developer.properties`, which enables Developer Mode.

Most of the configuration is provided by the `portal-developer.properties` file, but you still have to configure the FreeMarker template setting. Follow the steps in the Configuring FreeMarker System Settings section to configure the FreeMarker template cache.

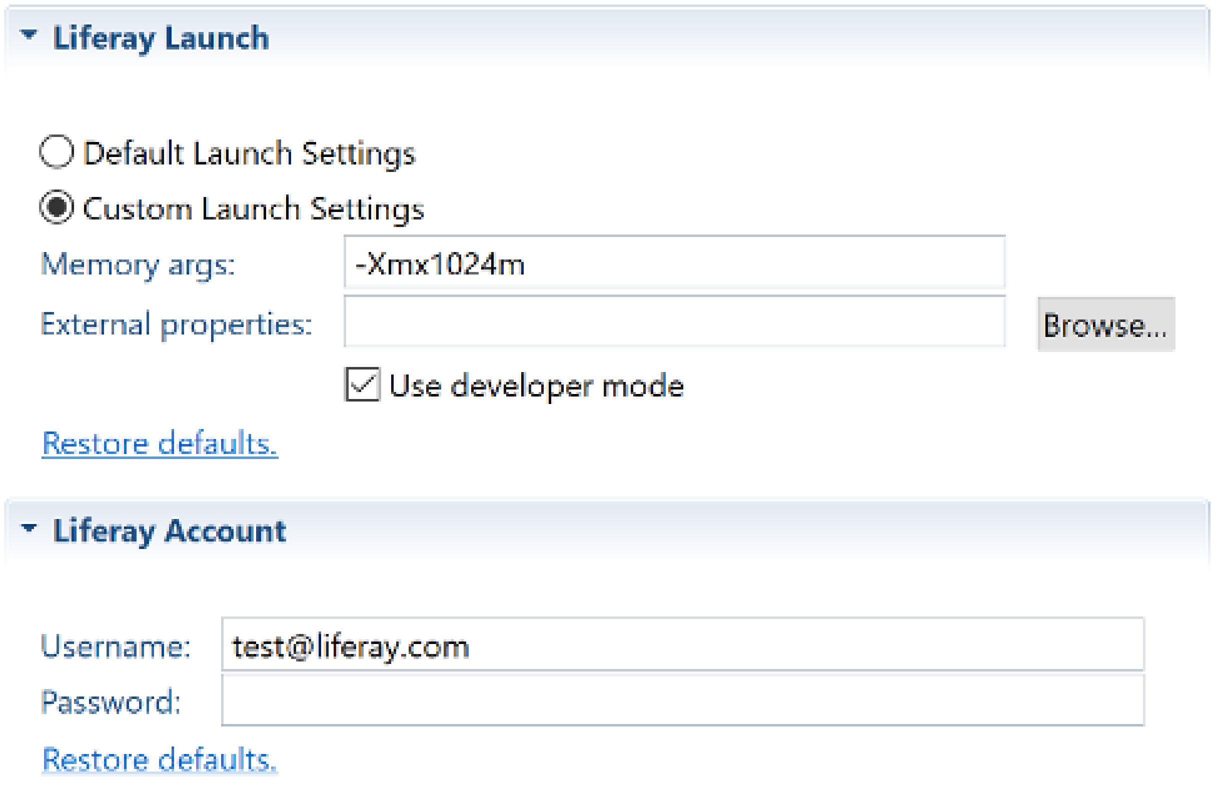
If you're not using @ide@, manual configuration for Developer Mode is covered next.

Setting Developer Mode for Your Server Using portal-developer.properties

To set Developer Mode manually, you must point to `portal-developer.properties` as shown in the last section. Add the `portal-ext.properties` file to the root folder of your app server's bundle and add the following line:

```
include-and-override=portal-developer.properties
```

Developer Mode is enabled upon starting your app server. `portal-developer.properties` provides the majority of the settings you'll need for smooth development. To disable the cache for FreeMarker templates, you must update the System Setting covered in the next section.



Liferay Launch

( ) Default Launch Settings
(●) Custom Launch Settings

Memory args: -Xmx1024m
External properties:
[✓] Use developer mode

Restore defaults.

Liferay Account

Username: test@liferay.com
Password:

Restore defaults.

Figure 106.4: The *Use developer mode* option lets you enable Developer Mode for your server in @ide@.

Configuring FreeMarker System Settings

FreeMarker Templates for themes and web content are cached by default. Therefore, any changes you make to your FreeMarker theme templates aren't immediately displayed. You can change this behavior through System Settings. Follow these steps:

1. Open the Control Panel and go to *Configuration* → *System Settings*.
2. Click the *Foundation* tab and select *FreeMarker Engine*.
3. By default, the *Resource modification check* (the time in milliseconds that the template is cached) is set to `60`. Set this value to `0` to disable caching.

Your FreeMarker templates are ready for development. Next you can learn how you can improve JavaScript file loading for development.

JavaScript Fast Loading

By default, JavaScript fast loading is enabled in Developer Mode (`javascript.fast.load=true`). This loads the packed version of files listed in the Portal Properties `javascript.barebone.files` or `javascript.everything.files`. You can, however, disable JavaScript fast loading for easier debugging for development. Just set `javascript.fast.load` to `false` in your `portal.properties`, or you can disable fast loading by setting the URL parameter `js_fast_load` to `0`.

Note: JavaScript fast loading is retrieved from one of three places: the request (determined by the current URL: `http://localhost:8080/web/guest/home?js_fast_load=1`(on) or `...?js_fast_load=0`(off)), the Session, or the Portal Property (`javascript.fast.load=true`). Liferay DXP gives preference in the order of request, session, and then Portal Properties. This lets you change `js_fast_load`'s value from the default in `portal.properties` without having to manually re-enter `js_fast_load` into the URL upon every new page load.

Great! You've set up your Liferay DXP server for Developer Mode. Now, when you modify your theme's file directly in your bundle, you can see your changes applied immediately on redeploying your theme!

Creating Layout Templates Manually

Creating Themes with @ide@

106.5 Theme Contributors

If you want to package UI resources independent of a specific theme and include them on a Liferay DXP page, Theme Contributors are your best option. If, instead, you'd like to include separate UI resources on a Liferay DXP page that are attached to a theme, you should look into themelets.

A Theme Contributor is a module that contains UI resources to use in Liferay DXP. Once a Theme Contributor is deployed to Liferay DXP, it's scanned for all valid CSS and JS files, and then its resources are included on the page. You can, therefore, style these UI components as you like, and the styles are applied for the current theme.

This tutorial demonstrates how to

- Identify a Theme Contributor module.
- Create a Theme Contributor module.

Next, you'll learn how to create a Theme Contributor.

Creating Theme Contributors

In Liferay versions prior to 7.0, the standard UI for User menus and navigation (the Dockbar) was included in the theme template. Starting in Liferay DXP 7.0, these standard UI components are packaged as Theme Contributors.

For example, the Control Menu, Product Menu, and Simulation Panel are packaged as Theme Contributor modules in Liferay, separating them from the theme. This means that these UI components must be handled outside the theme.

If you want to edit or style these standard UI components, you'll need to create your own Theme Contributor and add your modifications on top. You can also add new UI components to Liferay DXP by creating a Theme Contributor.

To create a Theme Contributor module, follow these steps:

1. Create a generic OSGi module using your favorite third party tool, or use Blade CLI. You can also use the Blade Template to create your module, in which case you can skip step 2.

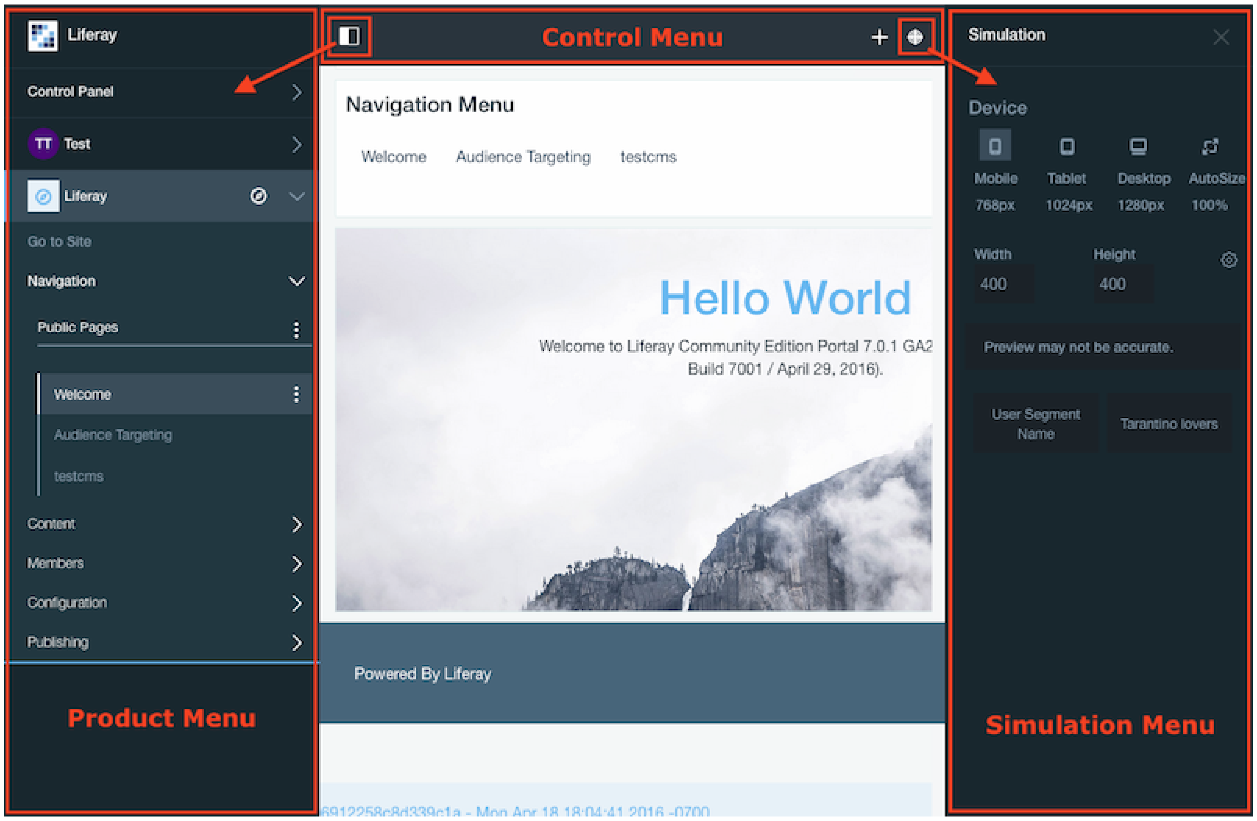

Figure 106.5: The Control Menu, Product Menu, and Simulation Panel are packaged as Theme Contributor modules.

2. To identify your module as a Theme Contributor, add the `Liferay-Theme-Contributor-Type` and `Web-ContextPath` headers to your module's `bnd.bnd` file. For example, see the Control Menu Theme Contributor module's `bnd.bnd`:

```
Bundle-Name: Liferay Product Navigation Control Menu Theme Contributor
Bundle-SymbolicName: com.liferay.product.navigation.control.menu.theme.contributor
Bundle-Version: 1.0.0
Liferay-Releng-Module-Group-Description:
Liferay-Releng-Module-Group-Title: Product Navigation
Liferay-Theme-Contributor-Type: product-navigation-control-menu
Web-ContextPath: /product-navigation-control-menu-theme-contributor
-include: ../../../../../marketplace/web-content-management/bnd.bnd
```

   The Theme Contributor type helps Liferay DXP better identify your module. For example, if you're creating a Theme Contributor to override an existing Theme Contributor, you should try to use the same type to maximize compatibility with future developments. The `Web-ContextPath` header sets the context from which the Theme Contributor's resources are hosted.

3. Because you'll often be overriding CSS of another Theme Contributor, you should load your CSS after theirs. You can do this by setting a weight for your Theme Contributor. In your `bnd.bnd` file, add the following header:

```
Liferay-Theme-Contributor-Weight: [value]
```

The higher the value, the higher the priority. If your Theme Contributor has a weight of 100, it will be loaded after one with a weight of 99, allowing your CSS to override theirs.

4. Create a `src/main/resources/META-INF/resources` folder in your module and place your resources (CSS and JS) in that folder.

5. Build and deploy your module to see your modifications applied to Liferay DXP pages and themes.

That's all you need to do to create a Theme Contributor for your site. Remember, with great power comes great responsibility, so use Theme Contributors wisely. The UI contributions affect every page and aren't affected by theme deployments.

Theme Contributor Template

106.6 Context Contributors

JSP templates are the predominant templating framework in Liferay DXP. Themes, application display templates (ADTs), DDM templates, and more make use of JSPs as a templating engine. JSPs, however, are not the only templating language supported by Liferay DXP. Since many developers prefer other templating frameworks (e.g., FreeMarker and Velocity), Liferay enables you to use other template formats by offering the Context Contributors framework.

Because JSPs are "native" to Java EE, they have access to all the contextual objects inherent to the platform, like the request and the session. Through these objects, developers can normally obtain Liferay-specific context information by accessing container objects like `themeDisplay` or `serviceContext`.

Template formats like FreeMarker aren't native to Java EE, so they don't have access to these objects. If your template needs contextual information such as the current user, the page, or anything else, Java EE won't make it available to the template like it does for JSPs: you must inject it yourself into the template. Liferay, however, gives you a head start by injecting a `contextObjects` map of common variables (e.g., `themeDisplay`, `locale`, `user`, etc.) by default into FreeMarker templates (e.g., themes). This map is usually referred to as the *context* of a template. If you need to access some other context object that Liferay doesn't provide by default, you must modify or add to a template's context. To do that, you create a context contributor.

Context contributors modify a template's context by injecting variables and functionality usable by the template framework. This lets you use non-JSP templating languages for themes, ADTs, and any other templates used in Liferay DXP. For example, suppose you want your theme to change color based on the user's organization. You could create a context contributor to inject the user's organization to your theme's context, and then determine the theme's color based on that information.

Context contributors are already used in Liferay DXP by default. Liferay's Product Menu display is determined by a variable injected by a context contributor. You'll learn more about this later.

First, you'll learn how to create your own context contributor, and then you'll examine one example of how Liferay DXP uses context contributors.

1. Create a generic OSGi module using your favorite third party tool, or use Blade CLI.

2. Create a unique package name in the module's src directory and create a new Java class in that package. To follow naming conventions, begin the class name with the entity you want to inject context-specific variables for, followed by *TemplateContextContributor* (e.g., `ProductMenuTemplateContextContributor`).

3. Directly above the class's declaration, insert the following annotation:

   ```
   @Component(
       immediate = true,
       property = {"type=" + TemplateContextContributor.[Type of Contributor]},
       service = TemplateContextContributor.class
   )
   ```

   The `immediate` element instructs the module to start immediately once deployed to Liferay DXP. The `type` property should be set to one of the two fields defined in the TemplateContextContributor interface: `TYPE_GLOBAL` or `TYPE_THEME`. The `TYPE_THEME` field should be set if you only wish to inject context-specific variables for your theme; otherwise, setting the `TYPE_GLOBAL` field affects every context execution in Liferay DXP, like themes, ADTs, DDM templates, etc. Finally, your `service` element should be set to `TemplateContextContributor.class`.

   The `ProductMenuTemplateContextContributor` class's `@Component` annotation follows a similar layout:

   ```
   @Component(
       immediate = true,
       property = {"type=" + TemplateContextContributor.TYPE_THEME},
       service = TemplateContextContributor.class
   )
   ```

4. Implement the TemplateContextContributor interface in your `-TemplateContextContributor` class. This only requires implementing the `prepare(Map<String,Object>, HttpServletRequest)` method.

   Notice that the `prepare` method receives the `contextObjects` map as a parameter. This is your template's context that was described earlier. This method should be used to edit the context by injecting new or modified variables into the `contextObjects` map.

For a quick example of how you can implement the `TemplateContextContributor` interface to inject variables into a template's context, you'll examine the `ProductMenuTemplateContextContributor` class used by Liferay DXP by default. This class injects variables into Liferay's FreeMarker theme and determines whether the Product Menu is displayed in the current theme.

The `ProductMenuTemplateContextContributor` class implements the `prepare(...)` method, which injects a modified variable (`bodyCssClass`) and a new variable (`liferay_product_menu_state`) into the theme context:

```
@Override
public void prepare(
    Map<String, Object> contextObjects, HttpServletRequest request) {

    if (!isShowProductMenu(request)) {
        return;
    }

    String cssClass = GetterUtil.getString(
        contextObjects.get("bodyCssClass"));
    String productMenuState = SessionClicks.get(
        request,
        ProductNavigationProductMenuWebKeys.
            PRODUCT_NAVIGATION_PRODUCT_MENU_STATE,
        "closed");
```

```
    contextObjects.put(
        "bodyCssClass", cssClass + StringPool.SPACE + productMenuState);

        contextObjects.put("liferay_product_menu_state", productMenuState);
}
```

This method prepares the context contributor to inject variables into the theme to be used by the Product Menu. For this example, the `cssClass` and `productMenuState` variables are defined and then placed in the `contextObjects` map. By doing this, these variables have been injected into the theme context, making them accessible to the theme. Specifically, the `cssClass` variable provides styling for the Product Menu and the `productMenuState` variable determines whether the visible Product Menu should be open or closed.

Note: In previous versions of Liferay, if you needed to inject variables into themes, you were forced to create those variables in the `init.ftl` file of every theme. This forced theme developers to keep that logic updated in every theme version of every theme they developed. With context contributors, you can inject variables into existing frameworks without forcing theme developers to update their `init.ftl` files.

The `prepare` method above also determines whether to show the Product Menu or not with the following if statement:

```
if (!isShowProductMenu(request)) {
    return;
}
```

The `isShowProductMenu(...)` method injects functionality into the theme's context by providing an option to show/hide the Product Menu. This method is also included in the `ProductMenuTemplateContextContributor` class:

```
protected boolean isShowProductMenu(HttpServletRequest request) {
    ThemeDisplay themeDisplay = (ThemeDisplay)request.getAttribute(
        WebKeys.THEME_DISPLAY);

    if (themeDisplay.isImpersonated()) {
        return true;
    }

    if (!themeDisplay.isSignedIn()) {
        return false;
    }

    User user = themeDisplay.getUser();

    if (!user.isSetupComplete()) {
        return false;
    }

    return true;
}
```

The `ProductMenuTemplateContextContributor` provides an easy way to inject variables into Liferay DXP's theme directly related to the Product Menu. You can do the same with your custom context contributor. With the power to inject additional variables to any context in Liferay, you're free to fully harness the power of your chosen templating language.

106.7 Macros

Macros let you assign theme template fragments to a variable. This keeps your theme templates from becoming cluttered and makes them easier to read. Liferay DXP defines several FreeMarker macros in `FTL_liferay.ftl` template that you can use in your FreeMarker theme templates to include theme resources, standard portlets, and more. Likewise, Velocity macros are available in `VM_liferay.vm` template Liferay DXP also exposes its taglibs as FreeMarker macros. See the corresponding taglib tutorial for more information on using the taglib in your FreeMarker templates. This tutorial shows how to use Liferay DXP's macros in your FreeMarker and Velocity theme templates.

Note that **Velocity templates are supported, but deprecated as of Liferay Portal CE 7.0 and Liferay DXP 7.0**. We recommend that you convert your Velocity theme templates to FreeMarker at your earliest convenience to avoid future issues. This tutorial covers both FreeMarker and Velocity template macros to help with your conversion process.

The syntax for a macro is straightforward. A macro directive is defined containing the template fragment. For example, below is the macro directive for Liferay DXP's Control Menu:

FreeMarker:

```
<#macro control_menu>
	<#if themeDisplay.isImpersonated() || (is_setup_complete && is_signed_in)>
		<@liferay_product_navigation["control-menu"] />
	</#if>
</#macro>
```

Velocity:

```
#macro (control_menu)
	#if ($themeDisplay.isImpersonated() || ($is_setup_complete && $is_signed_in))
	    $theme.runtime(
	        "com.liferay.admin.kernel.util.PortalProductNavigationControlMenuApplicationType$ProductNavigationControlMenu",
	        $portletProviderAction.VIEW
	    )
	#end
#end
```

Note: Liferay DXP's default FreeMarker macro calls are namespaced with `liferay` (for example, `<@liferay.macro_variable_name />`). If you create custom macros, they can be called with the explicit variable name.

To include the template fragment in your theme templates, call the macro using the variable name:

FreeMarker:

```
<@liferay.control_menu />
```

Velocity:

```
#control_menu()
```

The macro is replaced with the template fragment when the page is rendered. That's all there is to a basic macro.

Macros can also be passed arguments. For example Liferay DXP's `language` macro has a language key parameter:

FreeMarker:

```
<#macro language
       key
>
${languageUtil.get(locale, key)}
</#macro>
```

Velocity:

```
#macro (language $lang_key)
$languageUtil.get($locale, $lang_key)
#end
```

You can pass an argument in the macro call like this:

FreeMarker:

```
<@liferay.language key="powered-by" />
```

Velocity:

```
#language ("powered-by")
```

You can read more about FreeMarker macros and Velocity macros at freemarker.org and velocity.apache.org.

Liferay DXP provides several macros that you can use in your theme templates. These are covered next.

Liferay DXP Macros

There are several default macros defined in the `FTL_Liferay.ftl` template that you can use in your FreeMarker theme templates. Likewise, VM_liferay.vm defines the default macros for Velocity. The table below lists the available macros and parameters:

Macro	Parameters	Description
breadcrumbs	default preferences	Adds the Breadcrumbs portlet with optional preferences
control_menu	N/A	Adds the Control Menu portlet
css	filename	Adds an external stylesheet with the specified file name location
date	format	Prints the date in the current locale with the given format
js	filename	Adds an external JavaScript file with the specified file name source
language	key	Prints the specified language key in the current locale

Macro	Parameters	Description
language_format	argumentskey	Formats the given language key with the specified arguments. For example, passing `go-to-x` as the key and `Mars` as the arguments prints *Go to Mars*.
languages	default preferences	Adds the Languages portlet with optional preferences
navigation_menu	default preferencesinstance ID	Adds the Navigation Menu portlet with optional preferences and instance ID. `${freeMarkerPortletPreferences}` or `$velocityPortletPreferences.toString()` is a common value for default preferences.
search	default preferences	Adds the Search portlet with optional preferences
user_personal_bar	N/A	Adds the User Personal Bar portlet

Now you know how to use Liferay DXP's macros in your theme templates!

Theme Reference Guide

106.8 Theme Builder

Liferay's Theme Builder gives developers who aren't using Liferay's Theme Generator (e.g., Gradle or Maven) a way to compile and build a theme WAR file. To use the Theme Builder, you must apply it to your project. If you're unsure how to structure themes for Liferay DXP, see the Introduction to Themes tutorial.

Follow the instructions below to apply the Theme Builder plugin and build your theme WAR.

Step 1: Apply the Theme Builder Plugin to Your Theme Project

Liferay provides two Theme Builder plugins depending on your build tool:

- com.liferay.portal.tools.theme.builder (Ant, Maven, etc.)
- com.liferay.gradle.plugins.theme.builder (Gradle)

If you want to apply the Theme Builder plugin to an Ant project, examine the `build.xml` file as an example below:

```
<?xml version="1.0"?>
<!DOCTYPE project>

<project>
    <path id="theme.builder.classpath">
        <fileset dir="[PATH_TO_THEME_BUILDER_JAR]" includes="com.liferay.portal.tools.theme.builder-*.jar" />
    </path>

    <taskdef classpathref="theme.builder.classpath" resource="com/liferay/portal/tools/theme/builder/ant/taskdefs.properties" />

    <target name="build-theme">
        <build-theme
            diffsDir="diffs"
            outputDir="../dist"
            parentDir="[PATH_TO_STYLED_THEME]/classes/META-INF/resources/_styled"
            parentName="_styled"
            unstyledDir="[PATH_TO_UNSTYLED_THEME]/classes/META-INF/resources/_unstyled"
        />
    </target>
</project>
```

You should first supply the path to the Theme Builder JAR. The above code configures the literal path to the JAR on your local machine. As an alternative, you could configure Ivy to do this for you behind the scenes. Then create an Ant target (e.g., `build-theme`) that configures the required parameters to build your theme.

For assistance applying the Theme Builder plugin for a Gradle or Maven project, see the Theme Builder Gradle Plugin or Building Themes in a Maven Project articles, respectively.

Step 2: Build Your Theme

Execute the appropriate command based on your build tool:

- *Ant:* `ant build-theme`
- *Gradle:* `gradlew buildTheme`
- *Maven:* `mvn verify`

The WAR is generated in the following folder, depending on the build tool you used:

- *Ant:* `/dist`
- *Gradle:* `/build`
- *Maven:* `/target`

That's it! You've successfully configured and leveraged the Theme Builder in your project. You can also use the Theme Builder to migrate a Plugins SDK theme to Liferay Workspace. See the Migrating a Theme from the Plugins SDK to Workspace tutorial for details.

106.9 Creating a Theme Thumbnail

Theme thumbnails help users quickly identify your theme. It's especially important to provide thumbnails when your theme offers color schemes.

Here's how to create a proper thumbnail image for your theme:

1. Create a thumbnail image. Make sure it's 150 pixels wide by 120 pixels high. You may want to take a snapshot of your theme and re-size it to these dimensions. **Your thumbnail must be these exact dimensions** or the image won't display properly.

2. Save the image as a .png file named thumbnail.png and place it in the theme's images folder (create this folder if it doesn't already exist). On redeployment, the thumbnail.png file automatically becomes the theme's thumbnail.

Note: The Theme Builder Gradle plugin doesn't recognize a thumbnail.png file. If you're using this plugin to build your theme instead, you must create a screenshot.png file in your theme's images folder that is 1080 pixels high by 864 pixels wide. The thumbnail is automatically generated from the screenshot for you when the theme is built.

Now, when you apply the theme, its thumbnail displays along with the other themes that are available to your site.

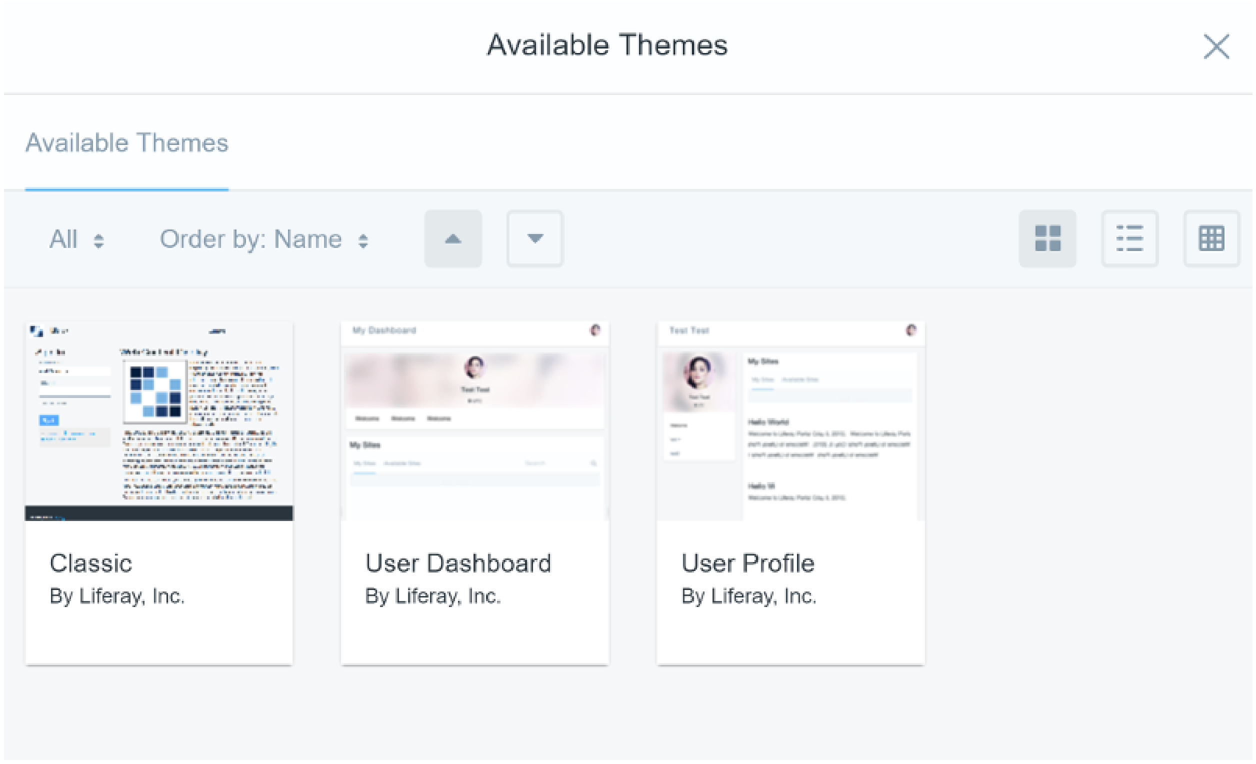

Figure 106.6: Your theme thumbnail is displayed with the rest of the available themes.

Congrats! Now you know how to create a thumbnail image for your theme!

Liferay Theme Generator Specifying Color Schemes in Your Theme

106.10 Specifying Color Schemes in your Theme

You can provide various "flavors" of your theme by creating color schemes. Color schemes let you keep the styles and overall design for your theme, while giving a new look for your users to enjoy. You specify color schemes with a CSS class name, which also lets you choose different background images, different border colors, and more.

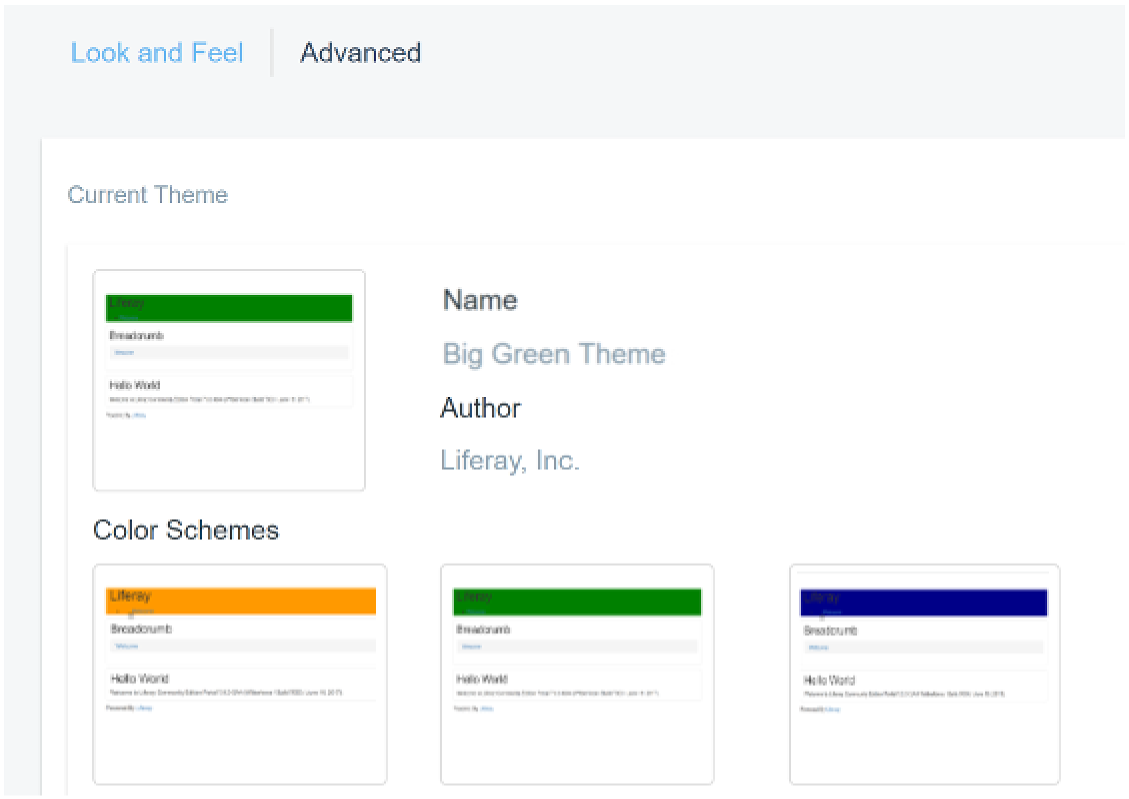

Figure 106.7: You can offer eye-pleasing color schemes for your themes.

Follow these steps to create color schemes for your theme:

1. Create a folder to hold color schemes (`color_schemes` for example) in the theme's css folder.

2. Create an `.scss` file in the color schemes folder for each color scheme your theme supports. If you don't specify a `.scss` file for a color scheme, the theme's default color scheme is used.

3. Prefix all CSS styles with the name of your color scheme. The color scheme CSS class is placed on the page's `<body>` element, so you can use it to identify your styling. For example, you'd prefix all the styles with the word *day* in a color scheme CSS file named `_day.scss`:

```
body.day { background-color: #DDF; }
.day a { color: #66A; }
```

```
**Note:** The default color scheme does not require a prefix, as it uses
the theme's `_custom.scss` for styling.
```

---

4. Import the color scheme `.scss` files into the `_custom.scss` file. The example below imports `_day.scss` and `_night.scss` files:

```
@import "color_schemes/day";
@import "color_schemes/night";
```

5. Open the theme's `liferay-look-and-feel.xml` file and add the default color scheme for the theme. Pass the default color scheme's CSS class name (the name of the CSS file) in the `<css-class>` element. If the default color scheme styling is in the theme's `_custom.scss` file, use `default` for the `<css-class>`:

   ```
   <theme id="my-theme-id" name="My Theme Name">
      <color-scheme id="01" name="My Default Color Scheme Name">
          <default-cs>true</default-cs>
          <css-class>default</css-class>

          <color-scheme-images-path>
              ${images-path}/my_color_schemes_folder_name/${css-class}
          </color-scheme-images-path>
      </color-scheme
      ...
   </theme>
   ```

   A default color scheme lets users return to the theme's default look and feel. Note that the color scheme's `name` is arbitrary. Only the color scheme's `css-class` element must match the name of the color scheme's CSS class.

   Note that color schemes are sorted alphabetically by `name` rather than `id`. For example, a color scheme named `Day` and `id` `02` would be selected by default over a color scheme named `Clouds` with `id` `01`. The `<default-cs>` element overrides the alphabetical sorting and sets the color scheme that is selected by default, when the theme is chosen. Adding this element to the default color scheme ensures that it is selected when the theme is chosen.

   The `<color-scheme-images-path>` element specifies theme thumbnail image location. Place this element in the first color scheme to affect them all. For example you could use the folders `/images/color_schemes/default`, `/images/color_schemes/day`, and `/images/color_schemes/night`.

6. Add the remaining color schemes to the `liferay-look-and-feel.xml` using the pattern below:

   ```
   <color-scheme id="02" name="my-color-scheme-name">
      <css-class>my-color-scheme-css-class-name</css-class>
   </color-scheme>
   ```

   The example below defines a *Day* color scheme and a *Night* color scheme for a theme named *Big Green*. Here's the code as specified in the `liferay-look-and-feel.xml` file:

   ```
   <theme id="big-green" name="Big Green">
       <color-scheme id="01" name="Default">
           <default-cs>true</default-cs>
           <css-class>default</css-class>
           <color-scheme-images-path>
               ${images-path}/color_schemes/${css-class}
           </color-scheme-images-path>
       </color-scheme>
       <color-scheme id="02" name="Day">
           <css-class>day</css-class>
       </color-scheme>
       <color-scheme id="03" name="Night">
           <css-class>night</css-class>
       </color-scheme>
   </theme>
   ```

7. Place a `thumbnail.png` and `screenshot.png` file in each of the color scheme's folders. Make sure thumbnail images follow the specifications defined in the Creating a Theme Thumbnail tutorial.

There you have it. Now you can go color scheme crazy with your themes!

Layout Templates with the Theme Generator

Creating a Theme Thumbnail

106.11 Making Themes Configurable with Settings

Theme settings let site administrators control the look and feel of certain aspects of a theme. For example, you can create a theme setting to control the visibility of theme elements, such as only showing a site banner when the user is logged in. You can also create a theme setting to configure an element, such as a title or a background image. The Settings API is built flexibly to meet your needs. The sky's the limit.

This tutorial covers how to create theme settings for a theme.

Making configurable theme settings involves a multi-step process:

- Add the settings to `liferay-look-and-feel.xml`
- Assign the settings to variables in `init_custom.ftl`
- Use the settings variables in your theme templates

Follow these steps to create theme settings:

1. Open `liferay-look-and-feel.xml` from the theme's `WEB-INF` folder. Settings placed here appear in the *Look and Feel* menu of Liferay DXP's *Site Administration*. If your project doesn't have this file, create it in the `WEB-INF` folder and add the following XML content (make sure to replace the theme `id` and `name` with your theme's):

```
<?xml version="1.0"?>
<!DOCTYPE look-and-feel PUBLIC "-//Liferay//DTD Look and Feel 7.0.0//EN"
"http://www.liferay.com/dtd/liferay-look-and-feel_7_0_0.dtd">

<look-and-feel>
    <compatibility>
        <version>7.0.0+</version>
    </compatibility>
    <theme id="your-theme-name" name="Your Theme Name">
        <template-extension>ftl</template-extension>
    <portlet-decorator id="barebone" name="Barebone">
            <portlet-decorator-css-class>portlet-barebone</portlet-decorator-css-class>
        </portlet-decorator>
        <portlet-decorator id="borderless" name="Borderless">
            <portlet-decorator-css-class>portlet-borderless</portlet-decorator-css-class>
        </portlet-decorator>
        <portlet-decorator id="decorate" name="Decorate">
            <default-portlet-decorator>true</default-portlet-decorator>
            <portlet-decorator-css-class>portlet-decorate</portlet-decorator-css-class>
        </portlet-decorator>
    </theme>
</look-and-feel>
```

2. Add `<settings></settings>` tags before the opening `<portlet-decorator>` tag.

3. Add a `<setting/>` element between the `<settings></settings>` tags for each setting the theme requires. Below is an example pattern along with the available attributes:

   ```
   <setting configurable="true" key="my-setting-language-key"
   options="true,false" type="select" value="false" />
   ```

   The following attributes are available for theme settings:

   configurable: whether the setting is configurable or static. **key:** the language key that identifies the theme setting. **options:** sets the options for the select menu if the `type` is `select`. **type:** the type of UI to render to control the theme setting. Possible values are `checkbox`, `select`, `text`, or `textarea`. **value:** sets the default value for the theme setting.

   You can find more information about setting attributes and all other configurations for the `liferay-look-and-feel.xml` in its DTD docs.

4. Open `init_custom.ftl` and assign the settings to variables using the patterns below.

   Use the following pattern for settings that return a `Boolean` (for example a select box with the options `true` and `false` or a toggle-switch checkbox with values `yes` and `no`):

   ```
   <#assign my_variable_name =
   getterUtil.getBoolean(theme_settings["theme-setting-key"])>
   ```

   Use the following pattern for settings that return a `String` (for example, a text input or textarea input):

   ```
   <#assign footer_text =
   getterUtil.getString(theme_settings["theme-setting-key"])/>
   ```

5. Use the theme setting variable in the theme template. For example, you can use the variable to check a condition, print a value, or even display a theme template. Examples of each case are shown below.

   This configuration is used in `portal_normal.ftl` to show the navigation breadcrumbs element if the `show_breadcrumbs` theme setting is `true`:

   `liferay-look-and-feel.xml`:

   ```
   <setting configurable="true" key="show-breadcrumbs" type="checkbox"
   value="false" />
   ```

   `init_custom.ftl`:

   ```
   <#assign show_breadcrumbs =
   getterUtil.getBoolean(theme_settings["show-breadcrumbs"])>
   ```

   `portal_normal.ftl`:

   ```
   <#if show_breadcrumbs>
     <nav id="breadcrumbs">
       <@liferay.breadcrumbs />
     </nav>
   </#if>
   ```

```
This example configuration prints a text input's value in a `<p>` element,
or defaults to *Hello Text* if no value is given:

`liferay-look-and-feel.xml`:
```

```
    <setting configurable="true" key="custom-text" type="text"
    value="Hello Text"/>

`init_custom.ftl`:

    <#assign custom_text =
    getterUtil.getString(theme_settings["custom-text"])/>

`portal_normal.ftl`:

    <p>${custom_text}</p>

This example renders the brief header template or detailed header
template based on the theme setting:

`liferay-look-and-feel.xml`:

    <setting configurable="true" key="header-type" type="select"
    options="brief,detailed" value="brief"/>

`init_custom.ftl`:

    <#assign header_type =
    getterUtil.getString(theme_settings["header-type"])/>

`header_brief.ftl`: brief header template

`header_detailed.ftl`: detailed header template

`portal_normal.ftl`:

    <#if header_type == "brief">
      <#include "${full_templates_path}/header_brief.ftl" />
    <#elseif header_type == "detailed">
      <#include "${full_templates_path}/header_detailed.ftl" />
    </#if>
```

6. Make sure the theme is installed. Open the *Control Menu* → *Site Administration* → *Navigation* → *Public Pages* and select the *Configure* option. Configure the theme settings from the *Look and Feel* section to see your changes. You can set the theme settings for an individual page by selecting the *Configure Page* option from the page's Actions menu and selecting the *Define a Specific look and feel for this page* option under the *Look and Feel* section.

Now you know how to make configurable theme settings for your themes!

CHAPTER 107

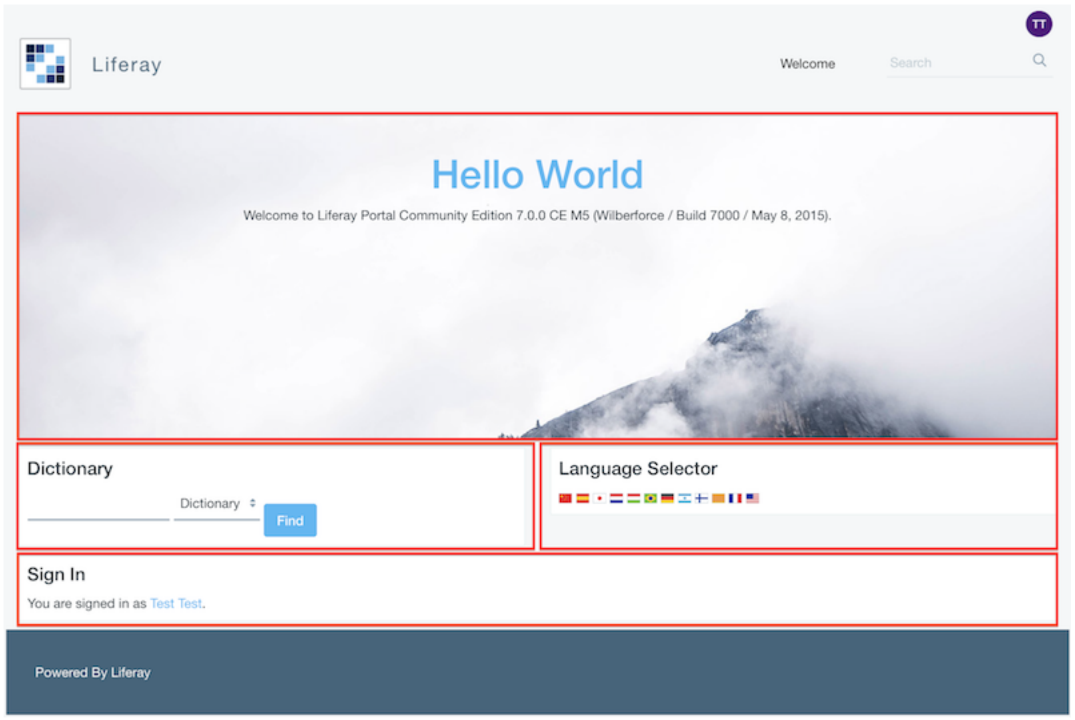
LAYOUT TEMPLATES

Are you craving more than Liferay DXP's default page layouts? Do you have a special use case that a default layout template doesn't meet? Well, look no further. Create your own Layout Template! Layout templates allow you to set the rows and columns of a page and determine where content can be placed.

In this section of tutorials, you'll learn how to develop layout templates for Liferay DXP.

107.1 Layout Templates with the Liferay Theme Generator

Layout Templates specify how content is arranged on your site pages in Liferay DXP. For example, take a look at the *1-2-1 Columns Layout CE* layout shown below:



TT
Liferay
Welcome
Search
Hello World
Welcome to Liferay Portal Community Edition 7.0.0 CE M5 (Wilberforce / Build 7000 / May 8, 2015).

You are signed in as Test Test.
Powered By Liferay

Figure 107.1: The *1-2-1 Columns Layout CE* page layout creates a nice flow for your content.

7.0 and DXP provide several layout templates out-of-the-box for you to choose from. You can change the layout for your page, and view the installed layout templates, by opening the `Edit` menu for your page, under the `Navigation` heading of the `Product Menu` and scrolling down to the *Layouts* heading.

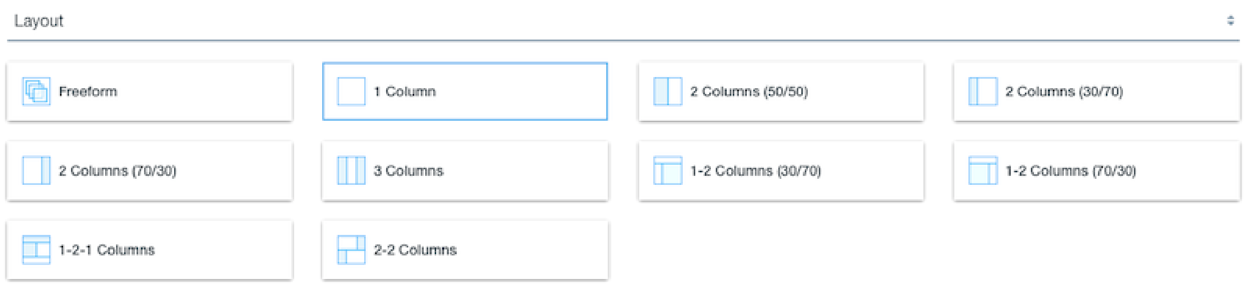

Figure 107.2: Liferay provides several layout templates out-of-the-box for you to use.

If you'd like to create your own custom layout templates, you've come to the right place.
This tutorial demonstrates how to:

- Create a Layout Template with the Layouts Sub-generator
- Create a Thumbnail for a Layout Template

In order to create a layout template with the Layouts Sub-generator, you will need the Node.js build tools installed. The Liferay Theme Generator tutorial explains how to install these tools and how to create a theme.
Once you have the Liferay Theme Generator installed you can go ahead and get started.

Creating a Layout Template with the Layouts Sub-generator

Follow these steps to create a layout template:

1. Open the Command Line and navigate to the directory you want to create your layout template in.

2. Run `yo liferay-theme:layout` to start the layouts sub-generator.

   Note: If you run the layout sub-generator from the root directory of a theme created with the themes generator, it will add the layout template as a part of the theme in the `src/layouttpl` directory.

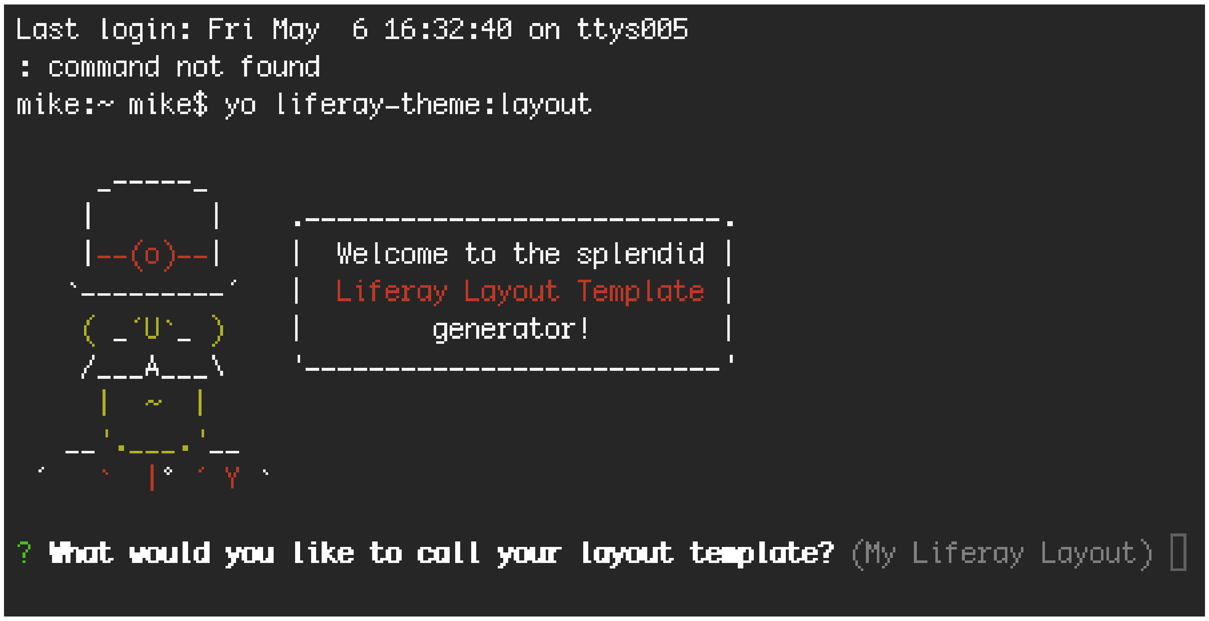
3. Enter a name and ID for your layout template, or press Enter to accept the default values.

4. Choose your Liferay version and press Enter to continue.

   At this point the layout template design process begins. As the generator states, Layout templates implement Bootstrap's grid system. Every row consists of 12 sections, so columns range in size from 1 to 12. The sub-generator is user-friendly, allowing you to add and remove rows and columns as you design.

5. Enter the number of columns you would like for `row 1`.

   Once you've entered a value, the generator asks how wide you want your row and column to be, and presents you with the available width(s).



```
Last login: Fri May  6 16:32:40 on ttys005
: command not found
mike:~ mike$ yo liferay-theme:layout

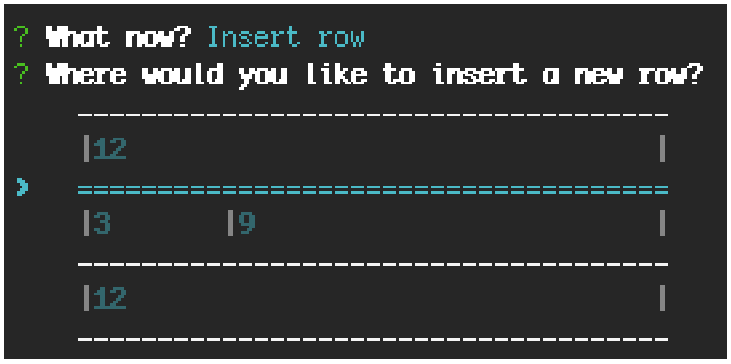
     _-----_
    |       |    .--------------------------.
    |--(o)--|    |  Welcome to the splendid |
   `---------´   |  Liferay Layout Template |
    ( _´U`_ )    |        generator!        |
    /___A___\    '--------------------------'
     |  ~  |
   __'.___.'__
 ´   `  |° ´ Y `

? What would you like to call your layout template? (My Liferay Layout)
```

Figure 107.3: The Layout Template sub-generator automates the layout creation process.

6. Choose from the available option(s) with your arrow keys and press Enter to make your selection. If you have remaining space, the generator will repeat this step for the remaining columns. Once you're done configuring your row, you are presented with a few options:

   - Add a row: Adds a row below the last row.
   - Insert row: Displays a vi to insert your row. Use your arrow keys to choose where to insert your row, highlighted in blue, then press Enter to insert the row.

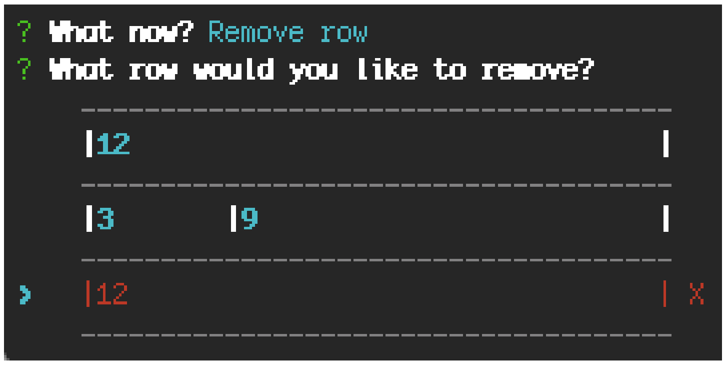


```
? What now? Insert row
? Where would you like to insert a new row?
    -------------------------------------
    |12                                 |
  > =====================================
    |3        |9                        |
    -------------------------------------
    |12                                 |
    -------------------------------------
```

Figure 107.4: Rows can be inserted using the layout vi.

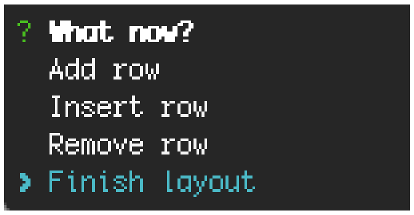
   - Remove row: Displays a vi to remove your row. Use your arrow keys to select the row you want to remove, highlighted in red, then press Enter to remove the row.

   Once you are done designing your layout you can move onto the next step.



```
? What now? Remove row
? What row would you like to remove?
    ----------------------------------------
    |12                                    |
    ----------------------------------------
    |3        |9                           |
    ----------------------------------------
>   |12                                    | X
    ----------------------------------------
```

Figure 107.5: Rows are removed using the layout vi.



```
? What now?
  Add row
  Insert row
  Remove row
> Finish layout
```

Figure 107.6: Select the *Finish layout* option to complete your design.

7. Select *Finish layout* to complete your layout's design.

   Your layout template files are generated for you in the current directory.

8. Enter the path to your app server directory, or press Enter to accept the default.

9. Enter the URL to your server or press Enter to accept the default `http://localhost:8080` development site.

   Your layout template is generated, but you still need to include it in your `liferay-look-and-feel.xml` file.

```
**Note:** Currently the Liferay Theme Generator does not add the layout
template configuration to your `liferay-look-and-feel.xml`. This feature
will be added in a future release. For now you must add this manually next.
```

---

10. Add your custom layout template to your `liferay-look-and-feel.xml` using the `<layout-templates>` tag. Below is an example configuration for the Porygon theme's' layout templates:

    ... /layouttpl/custom/porygon_70_30_width_limited.tpl /layouttpl/custom/porygon_70_30_width_limited.png /layouttpl/custom/porygon_50_50_width_limited.tpl /layouttpl/custom/porygon_50_50_width_limited.png

```
The `<layout-template>` tag's `id` attribute must match the ID you gave in
step 3 (the TPL file name).
```

When your layout template was generated, a default thumbnail was created. You can learn how to create a custom thumbnail in the next section.

Creating a Custom Thumbnail for Your Layout Template

To create your own thumbnail follow the steps below:

1. Navigate to the `docroot` directory of the layout template you just created.

   Note: if you created the layout template in your existing themes generator theme, the thumbnail is located in your theme's `src/layouttpl/custom` directory.

2. Replace the `layout-name.png` file with your own custom thumbnail PNG.

3. navigate back to the layout's root directory and run `gulp deploy` to re-build and deploy the template to your app server.

   Note: If your layout template was added as part of your themes generator theme, the layout template will deploy when the theme is deployed.

```
**Note:** Currently the Liferay Theme Generator does not add the thumbnail
configuration to your `liferay-look-and-feel.xml`. This feature will be
added in a future release. For now you must add this manually next.
```

---

4. Specify the thumbnail's location in your `liferay-look-and-feel.xml` using the `<thumbnail-path>` tag. Below is an example configuration for the Porygon theme:

```
<layout-template id="porygon_50_50_width_limited"
name="Porygon 2 Columns (50/50) width limited">
    <template-path>
        /layoutttpl/custom/porygon_50_50_width_limited.tpl
    </template-path>
    <thumbnail-path>
        /layoutttpl/custom/porygon_50_50_width_limited.png
    </thumbnail-path>
</layout-template>
```

Your layout template is complete! As you can see, the layouts sub-generator makes creating a layout template a piece of cake.

Edit a page on your site and select your new layout template to use it.

107.2 Creating Layout Templates Manually

You can use the Liferay Theme Generator to generate Layout Templates automatically. This is covered in the Layout Templates with the Liferay Theme Generator tutorial. You may, however, want to create or modify your layout templates manually.

In this tutorial you'll learn how to create or modify a Layout Template manually.

You can see the HTML markup for a basic layout template next.

Basic Layout Template

Below is an example of a basic Layout Template `.tpl` file:

```
<div class="my-liferay-layout" id="main-content" role="main">
        <div class="portlet-layout row">
                <div class="col-md-4 portlet-column portlet-column-first"
                id="column-1">
                        $processor.processColumn("column-1",
                        "portlet-column-content portlet-column-content-first")
                </div>
                <div class="col-md-8 portlet-column portlet-column-last" id="column-2">
                        $processor.processColumn("column-2",
                        "portlet-column-content portlet-column-content-last")
                </div>
        </div>
        <div class="portlet-layout row">
                <div class="col-md-12 portlet-column portlet-column-only" id="column-3">
                        $processor.processColumn("column-3",
                        "portlet-column-content portlet-column-content-only")
                </div>
        </div>
        <div class="portlet-layout row">
                <div class="col-md-4 portlet-column portlet-column-first" id="column-4">
                        $processor.processColumn("column-4",
                        "portlet-column-content portlet-column-content-first")
                </div>
                <div class="col-md-4 portlet-column" id="column-5">
                        $processor.processColumn("column-5", "portlet-column-content")
                </div>
                <div class="col-md-4 portlet-column portlet-column-last" id="column-6">
                        $processor.processColumn("column-6",
                        "portlet-column-content portlet-column-content-last")
                </div>
        </div>
</div>
```

The column elements and classes are described in more detail next.

Column Elements and Classes

To understand how the layout template works, you must look closely at how the HTML is structured. This section uses the first column of the example above to demonstrate the key elements and classes of a layout template:

```
<div class="col-md-4 portlet-column portlet-column-first" id="column-1">
        $processor.processColumn("column-1", "portlet-column-content
        portlet-column-content-first")
</div>
```

You can learn more about the column container next.

Column Container

Below is a description of each of the column container classes:

`column-1`: A unique identifier for the column that matches the ID passed to `$processor.processColumn`.

`col-md-4`: This class comes from Bootstrap's grid system and determines two things: the percentage based width of the element, and the media query breakpoint for when this element expands to 100% width. 12 is the maximum amount, so `col-md-4` indicates `4/12` width, or `33.33%`.

portlet-column portlet-column-first: All column containers must use the portlet-column class. For rows with more than one column, the first column must have portlet-column-first and the last must have portlet-column-last. For rows with only one column, use the portlet-column-only class.

Next you can learn more about the $processor.processColumn.

Processor ProcessColumn

$processor.processColumn takes these arguments:

column-1: A unique identifier. This should match the ID of the parent div.

portlet-column-content portlet-column-content-first: Additional classes added to the content element. These classes must match the parent div's classes with -content appended.

Next you can learn how to modify template breakpoints.

Modifying Template Breakpoints

When looking at the example template, you'll notice this Bootstrap grid class is used on every column:

```
col-md-{size}
```

The different sizes available are xs, sm, md, and lg. The medium size is used by default, but the others can be used in layout templates as well.

For example, setting the column classes to col-lg-{size} means the columns would expand to 100% width at a larger screen width than col-md-{size}.

These classes can also be mixed to achieve more advanced layouts, as shown below:

```
<div class="portlet-layout row">
        <div class="col-md-4 col-sm-6 portlet-column portlet-column-first"
        id="column-1">
                $processor.processColumn("column-1",
                "portlet-column-content portlet-column-content-first")
        </div>
        <div class="col-md-8 col-sm-6 portlet-column portlet-column-last"
        id="column-2">
                $processor.processColumn("column-2",
                "portlet-column-content portlet-column-content-last")
        </div>
</div>
```

In the example row above, on medium sized view, ports column-1 are 33.33% width and column-2 are 66.66% width, but on small sized view ports both column-1 and column-2 are 50% width.

Place the completed layout in your theme's src/layouttpl folder if you created your theme with Theme's Generator, or place it in your theme's docroot/layouttpl/custom folder if using the Plugins SDK.

Next you can learn how to include layout templates in a theme.

Including Layout Templates with a Theme

You can deploy a layout template with a theme by specifying it in the theme's liferay-look-and-feel.xml file.

Add your custom layout template to your liferay-look-and-feel.xml using the <layout-templates> tag. Below is an example configuration using the basic layout template example shown above:

```
<theme id="my-theme-name" name="My Theme Name">
    ...
      <layout-templates>
        <custom>
          <layout-template id="my_liferay_layout_template"
          name="My Liferay Layout Template">
            <template-path>
                /layoutttpl/custom/my_liferay_layout_template.tpl
            </template-path>
            <thumbnail-path>
                /layoutttpl/custom/my_liferay_layout_template.png
            </thumbnail-path>
          </layout-template>
        </custom>
      </layout-templates>
    ...
</theme>
```

The `<layout-template>` tag's `id` attribute must match the layout template's filename. The template and thumbnail paths shown above are for files in the `layouttpl/custom` folder. If you created your layout template with the Liferay Theme Generator, your file paths may differ.

There you have it. Now you know how to create and modify layout templates manually and how to include them with a theme!

Layout Templates with the Liferay Theme Generator

Liferay Theme Generator

Chapter 108

Portlets and Themes

Liferay DXP gives you complete control over the look and feel of your portlets. You can provide custom styles for portlets, create style configuration options via portlet decorators, and embed portlets in themes and layout templates.

All these topics are covered in this section of tutorials.

Chapter 109

Portlet Decorators

In previous versions of Liferay DXP, administrators could display or hide the application borders through the *Show Borders* option of the look and feel configuration menu. In 7.0 this option has been replaced with Portlet Decorators, a more powerful mechanism to customize the style of the application wrapper.

If you inspect the markup of your Liferay application when it's on a page you'll observe that it is wrapped by two layers. Among other things, these layers provide some common basic features like the drag and drop and the application border style. In order to protect these features, you can't modify the markup of these layers directly with a theme.

Portlet Decorators provide a mechanism to add a CSS class to one of these wrapping layers via a user's setting. By defining styles for this class in your theme, you can change the look and feel of the application instances where the Portlet Decorator is applied, including its wrapper.

The figure below shows the markup of the layers wrapping a Liferay application when the *Decorate* Portlet Decorator is applied:

Application Decorators
Decorate

Figure 109.2: Portlet Decorators can be applied through the Look and Feel Configuration menu

Your portlet's decor is now in your hands.

109.1 Adding Portlet Decorators to a Theme

Portlet Decorators are associated with a particular theme. If your theme does not define any portlet decorators, none are available. It is recommended that you provide a few decorators for your portlets, to cover the basic use cases.

For example, the Liferay Portal CE 7.0 Classic theme includes three Portlet Decorators:

- Decorate: this is the default Application Decorator when using the Classic theme. When this decorator is applied, the portlet is wrapped in a white box with a border and the portlet title is displayed at the top.
- Borderless: when this decorator is applied, the portlet is no longer wrapped in a white box, but the portlet title is displayed at the top.
- Barebone: when this decorator is applied, neither the wrapping box nor the custom portlet title are shown. This option is recommended when you only want to display the bare portlet content.

Note: Upgrading to Liferay DXP will assign the *borderless* decorator automatically to those portlets that had the *Show Borders* option set to false in previous versions of Liferay.

As mentioned, you should consider updating your Liferay DXP Themes to provide at least one for the *decorate*, *borderless* and *barebone* use cases.

This tutorial demonstrates how to

- Add Portlet Decorators to your theme
- Affect theme markup with Portlet Decorators

Now that you know why you should have Portlet Decorators in your theme, you can learn how to add them to your theme.

Adding Portlet Decorators to a Theme

Adding Portlet Decorators to your theme is similar to adding Color Schemes. You just have to follow these steps:

1. Configure your theme's `liferay-look-and-feel.xml`
2. Define the Application Decorator CSS styles
3. Optional: Add conditions to your theme's markup

Figure 109.4: The Classic theme's Borderless Application Decorator displays the application's custom title.

Configuring liferay-look-and-feel.xml

The first thing you must do is declare the Portlet Decorators in your theme's `liferay-look-and-feel.xml`.

The Document Type Definition for the liferay-look-and-feel.xml in Liferay DXP contains the information and rules to add Portlet Decorators (in the code referred as portlet-decorators) to your theme.

Here is how the classic theme defines Portlet Decorators in its `liferay-look-and-feel.xml`:

```
<?xml version="1.0"?>
<!DOCTYPE look-and-feel PUBLIC "-//Liferay//DTD Look and Feel 7.0.0//EN" "http://www.liferay.com/dtd/liferay-look-and-feel_7_0_0.dtd">

<look-and-feel>
    <compatibility>
        <version>7.0.0+</version>
    </compatibility>
    ...
        <theme id="classic" name="Classic">
        ...
        <portlet-decorator id="barebone" name="Barebone">
```

Figure 109.5: The Classic theme's Barebone Application Decorator displays only the application's content.

```
            <portlet-decorator-css-class>portlet-barebone</portlet-decorator-css-class>
        </portlet-decorator>
        <portlet-decorator id="borderless" name="Borderless">
            <portlet-decorator-css-class>portlet-borderless</portlet-decorator-css-class>
        </portlet-decorator>
        <portlet-decorator id="decorate" name="Decorate">
            <default-portlet-decorator>true</default-portlet-decorator>
            <portlet-decorator-css-class>portlet-decorate</portlet-decorator-css-class>
        </portlet-decorator>
        </theme>
</look-and-feel>
```

The `portlet-decorator` element contains all the information about the Application Decorator:

- id: this required attribute contains a unique string that identifies this specific Application Decorator. This is the value that is stored when applying an Application Decorator, and it can be used to refer to this decorator in your theme templates.
- name: this required attribute is a user friendly identifier for the Application Decorator to be displayed in the Look and Feel UI.
- portlet-decorator-css-class: this required element contains the name of the CSS class that is added to the application wrapping layer when this Application Decorator is applied.
- default-portlet-decorator: use this optional element to identify the default Application Decorator for your theme.

You can define as many Portlet Decorators as you want, but it's recommended to include at least one for the *decorate*, *borderless* and *barebone* use cases.

Define the Styles for Your Application Decorator CSS Class

Once you've declared your Portlet Decorators, it's time to define their effect in the application look and feel. While the previous step was straightforward, this depends on your creativity.

As an example, look at the `_portlet_decorator.scss` of the Classic theme:

```
.portlet-decorate .portlet-content {
    background: #FFF;
    border: 1px solid #DEEEEE;
}

.portlet-barebone .portlet-content {
    padding: 0;
}
```

Once your CSS styles are written, make sure to import the CSS file into your `_custom.scss`:

```
@import "portlet_decorator"
```

That's all that is required to add Portlet Decorators to your theme. If you want to modify your application's markup with your Portlet Decorators, read the next section.

Changing Your Application Markup with Portlet Decorators

So far you've seen how to use Portlet Decorators to change the look and feel of an application with styles.

It's possible to go a step further and alter the markup of your application based on the Application Decorator applied. For this, you must edit the `portlet.ftl` template for your theme, retrieve the `portletDecoratorId` of the current Application Decorator from the `portlet_display` object, and make some decisions based on it.

For example, this is how the Classic theme shows the application title when the *barebone* Application Decorator is not applied:

```
<#if portlet_display.getPortletDecoratorId() != "barebone">
        <h2 class="portlet-title-text">${portlet_title}</h2>
</#if>
```

There you have it! Now you know how to add Portlet Decorators to your theme. Let your creativity be your guide.

Themelets

Making Your Applications Configurable

109.2 Applying Portlet Decorators to Embedded Portlets

Once you have installed a theme that contains Portlet Decorators, site administrators can apply them to a portlet instance by selecting the Application Decorator in the Look and Feel Configuration dialog.

If your theme contains embedded portlets, it's also possible to apply an Application Decorator other than the default one by setting its preferences.

This tutorial demonstrates how to apply Portlet Decorators to Embedded Portlets in your theme.

Setting Application Decorator Preferences

To define a default Application Decorator for your theme's embedded portlets, you must set a default decorator in the portlet preferences.

For example, the Classic theme declares an Application Decorator with Id `barebone` and applies it to the embedded Navigation Menu portlet and Search portlet in its `navigation.ftl`:

```
<#assign VOID =
freeMarkerPortletPreferences.setValue("portletSetupPortletDecoratorId",
"barebone")>

<div aria-expanded="false" class="collapse navbar-collapse"
id="navigationCollapse">
    <#if has_navigation && is_setup_complete>
        <nav class="${nav_css_class} site-navigation"
        id="navigation" role="navigation">
            <div class="navbar-form navbar-right" role="search">
                <@liferay.search default_preferences=
                "${freeMarkerPortletPreferences}" />
            </div>

            <div class="navbar-right">
                <@liferay.navigation_menu default_preferences=
                "${freeMarkerPortletPreferences}" />
            </div>
        </nav>
    </#if>
</div>

<#assign VOID = freeMarkerPortletPreferences.reset()>
```

To set the default decorator for your embedded portlets, follow these steps:

1. Set the value for the `portletSetupPortletDecoratorId` to the Id of the Application Decorator you want to use:

   ```
   <#assign VOID =
   freeMarkerPortletPreferences.setValue("portletSetupPortletDecoratorId",
   "barebone")>
   ```

2. Next, set the `default_preferences` attribute of the portlet's tag to the `freeMarkerPortletPreferences` variable you just defined:

   ```
   <@liferay.search default_preferences= "${freeMarkerPortletPreferences}" />
   ```

Your embedded portlets now have a custom default Application Decorator!

Embedding Portlets in Themes

Providing Portlets to Manage Requests

109.3 Theming Portlets

Liferay DXP themes can provide additional styles to a portlet. You can change the markup for the portlet containers by modifying the `portlet.ftl` file.

This tutorial demonstrates how to style portlets with your themes.

Portlet FTL

Here is a quick look at the default `portlet.ftl` that's included in the default theme of 7.0:

```
<#assign
	portlet_display = portletDisplay

	portlet_back_url = htmlUtil.escapeHREF(portlet_display.getURLBack())
	portlet_content_css_class = "portlet-content"
	portlet_display_name = htmlUtil.escape(portlet_display.getPortletDisplayName())
	portlet_display_root_portlet_id = htmlUtil.escapeAttribute(portlet_display.getRootPortletId())
	portlet_id = htmlUtil.escapeAttribute(portlet_display.getId())
	portlet_title = htmlUtil.escape(portlet_display.getTitle())
/>
```

An explanation of each variable used in `portlet.ftl` is shown below:

- `portletDisplay`: is fetched from the `themeDisplay` object and contains information about the portlet.
- `portlet_back_url`: URL to return to the previous page with portlet `WindowState` is maximized.
- `portlet_display_name`: The "friendly" name of the portlet as displayed in the GUI.
- `portlet_display_root_portlet_id`: Sets the
- `portlet_id`: The ID of the portlet (not the same as the portlet namespace)
- `portlet_title`: The portlet name set in the portlet Java class (usually from a `Keys.java` class).

The following condition checks if the portlet header should be displayed. If the portlet has a portlet toolbar (Configuration, Permissions, Look and Feel), the condition is true:

```
<#if portlet_display.isPortletDecorate() && !portlet_display.isStateMax()
&& portlet_display.getPortletConfigurationIconMenu()??
&& portlet_display.getPortletToolbar()??>
```

Portlet title menus are used in portlets that allow you to add resources (Web Content Display, Media Gallery, Documents and Media). This is used to build a menu of items for adding resources:

```
portlet_title_menus = portlet_toolbar.getPortletTitleMenus(portlet_display_root_portlet_id, renderRequest, renderResponse)
```

The configuration below contains the information for the configuration menu (Configuration, Permissions, Look and Feel):

```
portlet_configuration_icons = portlet_configuration_icon_menu.getPortletConfigurationIcons(portlet_display_root_portlet_id, renderRequest, renderResponse)
```

The rest of the file contains the HTML markup for the portlet topper and the portlet content. It is possible to add CSS classes, change markup, or add custom information to the `portlet.ftl`. To provide a default style for all portlets, use the CSS classes found in this file, in conjunction with the portlet decorators to achieve the desired look and feel.

Portlet Decorators are explained in more detail next.

Portlet Decorators

In previous versions of Liferay DXP, administrators could display or hide the application borders through the Show Borders option of the look and feel configuration menu. In 7.0 this option has been replaced with Portlet Decorators, a more powerful mechanism to customize the style of the application wrapper.

The default portlet decorators are covered next.

Default Portlet Decorators

Themes come bundled with three default portlet decorators in their `liferay-look-and-feel.xml`. These are listed below:

- `Barebone`: when this decorator is applied, neither the wrapping box nor the custom application title are shown. This option is recommended when you only want to display the bare application content.
- `Borderless`: when this decorator is applied, the application is no longer wrapped in a white box, but the application custom title is displayed at the top.
- `Decorate`: this is the default Portlet Decorator when using the Classic theme. When this decorator is applied, the application is wrapped in a white box with a border and the application custom title is displayed at the top.

You can learn how to create and apply your own portlet decorators in the section dedicated to Portlet Decorators.

Now you know how to make your portlets stylish!

Themes and Layout Templates

109.4 Embedding Portlets in Themes

One thing developers often want to do is embed a portlet in a theme. This makes the portlet visible on all pages where the theme is used. In the past, this was only possible by hard-coding a specific portlet into place, which has many drawbacks. Liferay DXP provides the *Portlet Providers* framework that requires you only specify the entity type and action to be displayed. Based on the given entity type and action, Liferay DXP determines which deployed portlet to use. This increases the flexibility and modularity of embedding portlets in Liferay DXP.

In this tutorial, you'll learn how to declare an entity type and action in a custom theme, and you'll create a module that finds the correct portlet to use based on those given parameters. You'll first learn how to embed portlets into a theme.

Adding a Portlet to a Custom Theme

The first thing you should do is open the template file for which you want to declare an embedded portlet. For example, the `portal_normal.ftl` template file is a popular place to declare embedded portlets. There are two ways two embed a portlet in a theme: by class name or by portlet name. Both methods are covered in this section.

Embedding a Portlet by Class Name

To embed a portlet by class name, insert the following declaration wherever you want to embed the portlet:

```
<@liferay_portlet["runtime"]
    portletProviderAction=ACTION
    portletProviderClassName="CLASS_NAME"
/>
```

This declaration expects two parameters: the type of action and the class name of the entity type the portlet should handle. Here's an example of an embedded portlet declaration that uses the class name:

```
<@liferay_portlet["runtime"]
    portletProviderAction=portletProviderAction.VIEW
    portletProviderClassName="com.liferay.portal.kernel.servlet.taglib.ui.LanguageEntry"
/>
```

This declares that the theme is requesting to view language entries. Liferay DXP determines which deployed portlet to use in this case by providing the portlet with the highest service ranking.

Note: In some cases, a default portlet is already provided to fulfill certain requests. You can override the default portlet with your custom portlet by specifying a higher service rank. To do this, set the following property in your class' `@Component` declaration:

```
property= {"service.ranking:Integer=20"}
```

Make sure you set the service ranking higher than the default portlet being used.

There are five different kinds of actions supported by the Portlet Providers framework: `ADD`, `BROWSE`, `EDIT`, `PREVIEW`, and `VIEW`. Specify the entity type and action in your theme's runtime declaration.

Great! Your theme declaration is complete. However, the Portal is not yet configured to handle this request. You must create a module that can find the portlet that fits the theme's request.

1. Create an OSGi module.

2. Create a unique package name in the module's src directory, and create a new Java class in that package. To follow naming conventions, name the class based on the entity type and action type, followed by *PortletProvider* (e.g., `SiteNavigationLanguageEntryViewPortletProvider`). The class should extend the `BasePortletProvider` class and implement the appropriate portlet provider interface based on the action you chose in your theme (e.g., ViewPortletProvider, BrowsePortletProvider, etc.).

3. Directly above the class's declaration, insert the following annotation:

   ```
   @Component(
       immediate = true,
       property = {"model.class.name=CLASS_NAME"},
       service = INTERFACE.class
   )
   ```

   The `property` element should match the entity type you specified in your theme declaration (e.g., `com.liferay.portal.kernel.servlet.taglib.ui.LanguageEntry`). Also, your `service` element should match the interface you're implementing (e.g., `ViewPortletProvider.class`). You can view an example of a similar `@Component` annotation in the RolesSelectorEditPortletProvider class.

4. Specify the methods you want to implement. Make sure to retrieve the portlet ID and page ID that should be provided when this service is called by your theme.

   A common use case is to implement the `getPortletId()` and `getPlid(ThemeDisplay)` methods. You can view the SiteNavigationLanguageViewPortletProvider for an example of how these methods can be implemented to provide a portlet for embedding in a theme. This example module returns the portlet ID of the Language portlet specified in SiteNavigationLanguagePortletKeys. Furthermore, it returns the PLID, which is the ID that uniquely identifies a page used by your theme. By retrieving these, your theme will know which portlet to use, and which page to use it on.

The only thing left to do is generate the module's JAR file and copy it to your Portal's `osgi/modules` directory. Once the module is installed and activated in your Portal's service registry, your embedded portlet is available for use wherever your theme is used.

You successfully requested a portlet based on the entity and action types required, and created and deployed a module that retrieves the portlet and embeds it in your theme.

Embedding a Portlet by Portlet Name

If you'd like to embed a specific portlet in the theme, you can hard code it by providing its instance ID and name:

```
<@liferay_portlet["runtime"]
    instanceId="INSTANCE_ID"
    portletName="PORTLET_NAME"
/>
```

Note: If your portlet is instanceable, an instance ID must be provided; otherwise, you can remove this line. To set your portlet to non-instanceable, set the property `com.liferay.portlet.instanceable` in the component annotation of your portlet to `false`.

The portlet name must be the same as `javax.portlet.name`'s value.

Here's an example of an embedded portlet declaration that uses the portlet name to embed a web content portlet:

```
<@liferay_portlet["runtime"]
    portletName="com_liferay_journal_content_web_portlet_JournalContentPortlet"
/>
```

You can also set default preferences for an application. This process is covered next.

Setting Default Preferences for an Embedded Portlet

Follow these steps to set default portlet preferences for an embedded portlet:

1. Temporarily assign the `VOID` variable to set portlet preferences using the `freeMarkerPortletPreferences` object as shown in the example below:

   ```
   <#assign VOID = freeMarkerPortletPreferences.setValue(
   "portletSetupPortletDecoratorId", "barebone") />
   ```

2. Set the `defaultPreferences` attribute to use the `freeMarkerPortletPreferences` object you just configured:

   ```
   <@liferay_portlet["runtime"]
       defaultPreferences="${freeMarkerPortletPreferences}"
       portletName="com_liferay_login_web_portlet_LoginPortlet"
   />
   ```

3. Once the preferences are set and passed to your portlet, reset the `freeMarkerPortletPreferences` object so it can be fresh for the next portlet:

   ```
   <#assign VOID = freeMarkerPortletPreferences.reset() />
   ```

Now you know how to set default preferences for embedded portlets! Next you can see the additional attributes you can use for your embedded portlets.

Additional Attributes for Portlets

Below are some additional attributes you can define for embedded portlets:

defaultPreferences: A string of Portlet Preferences for the application. This includes look and feel configurations.

instanceId: The instance ID for the app, if the application is instanceable.

persistSettings: Whether to have an application use its default settings, which will persist across layouts. The default value is *true*.

settingsScope: Specifies which settings use for the application. The default value is `portletInstance`, but can be set to `group` or `company`.

Now you know how to embed a portlet in your theme by class name and by portlet name and how to configure your embedded portlet!

CHAPTER 110

LEXICON CSS AND THEMES

Lexicon CSS is an extension of Bootstrap's CSS Framework. Bootstrap is by far the most popular CSS framework on the web. Also, it's open source, so anyone can use it. Built with Sass, Lexicon CSS fills the front-end gaps between Bootstrap and the specific needs of Liferay DXP.

These tutorials look briefly at Lexicon CSS and show you how to use it in your Liferay DXP themes.

110.1 Importing Lexicon CSS into a Theme

As mentioned before, Lexicon CSS fills the gaps between Bootstrap and the specific needs of Liferay DXP. Bootstrap features have been extended to cover more use cases. Here are some of the new components added by Lexicon CSS:

- Aspect Ratio
- Cards
- Dropdown Wide and Dropdown Full
- Figures
- Nameplates
- Sidebar / Sidenav
- Stickers
- SVG Icons
- Timelines
- Toggles

Several reusable CSS patterns have also been added to help accomplish time consuming tasks such as these:

- truncating text
- content filling the remaining container width
- truncating text inside table cells
- table cells filling remaining container width and table cells only being as wide as their content
- open and close icons inside collapsible panels
- nested vertical navigations
- slide out panels

- notification icons/messages
- vertical alignment of content

Next you can learn more about Lexicon's structure.

Lexicon CSS Structure

Lexicon CSS is bundled with two sub-themes: Lexicon Base and Atlas. Lexicon Base is Liferay DXP's Bootstrap API extension. It is also the theme that is used in Liferay DXP's Styled Theme. It adds all the features and components you need and inherits Bootstrap's styles. As a result, Lexicon Base is fully compatible with third party themes that leverage Bootstrap's Sass variable API. As a best practice, you should use the Lexicon Base as your base theme to integrate third party themes into Liferay DXP.

Atlas is Liferay DXP's custom Bootstrap theme that is used in the Classic Theme. Its purpose is to overwrite and manipulate Bootstrap and Lexicon Base to create Liferay DXP's classic look and feel. Atlas is equivalent to installing a Bootstrap third party theme.

Note: It is not recommended to integrate third party themes with Atlas, as it adds variables and styles that are outside the scope of Bootstrap's API.

You can learn how to customize the Atlas theme next.

Customizing Atlas in Liferay DXP

If you want to include all the Classic Theme's files, you can skip these steps and move on to the next section.

Follow these steps to customize the Atlas theme:

1. In your theme's `/src/css` directory (for legacy ant themes, place in `/_diff/css`) add a file named `aui.scss` with the code below and save:

```
@import "aui/lexicon/atlas";
```

2. Add a file named `_imports.scss` with the code below and save:

```
@import "bourbon";
@import "mixins";
@import "aui/lexicon/atlas-variables";
@import "aui/lexicon/bootstrap/mixins";
@import "aui/lexicon/lexicon-base/mixins";
@import "aui/lexicon/atlas-theme/mixins";
```

3. Add a file named `_aui_variables.scss` with the code below and save:

```
// Icon paths

$FontAwesomePath: "aui/lexicon/fonts/alloy-font-awesome/font";
$font-awesome-path: "aui/lexicon/fonts/alloy-font-awesome/font";
$icon-font-path: "aui/lexicon/fonts/";
```

All your Atlas, Bootstrap, and Lexicon Base variable modifications must be placed in this file.

4. Add a file named `_custom.scss` with the code below and save:

```
    /* Use these inject tags to dynamically create imports for
    themelet styles. You can place them where ever you like in this file. */

    /* inject:imports */
    /* endinject */

    /* This file allows you to override default styles in one central
    location for easier upgrade and maintenance. */
```

Place your custom CSS in this file. Next you can learn how to extend Atlas with the Classic theme.

Extending Atlas with the Classic Theme

To extend the Atlas theme with the Classic theme, copy all the files located in these directories into your theme:

```
frontend-theme-classic/src/css
frontend-theme-classic/src/images
frontend-theme-classic/src/js
frontend-theme-classic/src/templates
```

You can also automatically copy these files into your theme using the Liferay Theme Tasks module gulp kickstart command and following the prompts.

Next you can learn how to customize the Lexicon Base.

Customizing Lexicon Base

You can customize Lexicon Base with just a few imports.

In your custom theme's `/src/css` directory (for legacy ant themes, place in `/_diff/css`) add a file named `_aui_variables.scss` with the code below and save:

```
// Icon paths

    $FontAwesomePath: "aui/lexicon/fonts/alloy-font-awesome/font";
    $font-awesome-path: "aui/lexicon/fonts/alloy-font-awesome/font";
    $icon-font-path: "aui/lexicon/fonts/";
```

All your Atlas, Bootstrap, and Lexicon Base variable modifications must be placed in this file.

As mentioned earlier, any custom CSS should be placed in `_custom.scss`.

You can learn how to add third party themes in Liferay DXP next.

Adding a Third Party Theme

Third party themes must be built with Sass to be compatible with Liferay DXP. **Make sure the Sass files are included before making any theme purchase.**

Follow these steps to add a third party theme:

1. Follow the steps above in the Customizing Lexicon Base section.

2. Create a folder inside `/src/css` (for legacy ant themes, `/_diff/css`) that contains your third party theme (e.g. `/src/css/awesome-theme` or `/_diff/css/awesome-theme`)

3. Copy the contents of the theme to the folder you just created.

4. In `_aui_variables.scss`, import the file containing the theme variables. For example, `@import "awesome-theme/variables.scss";`

```
**Note:** You may omit the leading underscore when importing Sass files.
```

---

5. In `_custom.scss`, import the file containing the CSS. For example, `@import "awesome-theme/main.scss";`
6. Deploy your theme with `gulp deploy` (for legacy ant themes, use `ant deploy`)

Now you know how to use Lexicon CSS in your theme!

Applying Lexicon Styles to Your App

Chapter 111

Product Navigation

Liferay's product navigation consists of the main menus you use to customize, configure, and navigate your Liferay instance. Whether you edit a page, switch to a different site scope, access a user's credentials, etc., you're constantly using the default navigation menus. Liferay's product navigation is designed to be intuitive and extensive, but often times, providing a customization to a default menu is necessary to give your Liferay instance that unique touch you're searching for. Liferay allows developers to extend and customize the default product navigation to fit their needs.

There are four main sections of Liferay's product navigation that you can extend: Product Menu, Control Menu, Simulation Menu, and User Personal Bar.

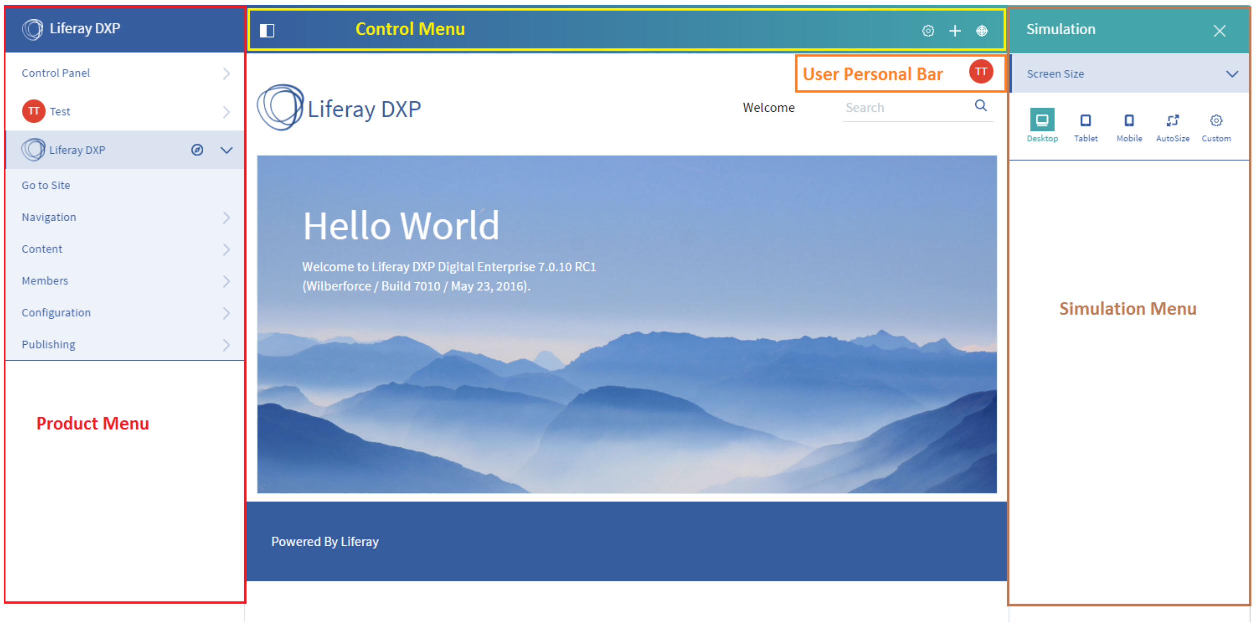

Figure 111.1: The main product navigation menus include the Product Menu, Control Menu, Simulation Menu, and User Personal Bar.

As you can see from the figure above, the Product Menu is the menu to the left that displays your's instance's Control Panel, user account settings, and Site Administration functionality. The Control Menu is the top menu offering navigation to the Product Menu, Simulation Menu (the right menu), and *Add* button.

When certain settings are enabled (e.g., Staging, Page Customization, etc.) more tools are offered. The Simulation Menu offers options to simulate your site's look for different scenarios (devices, user segments, etc.). Lastly, the User Personal Bar is used to hold selectable items that aid with a user's own account settings.

In this section of tutorials, you'll learn about the various ways you can extend and customize Liferay's product navigation to fit your needs.

111.1 Customizing the Product Menu

Liferay's Product Menu comes with three major sections to choose from, by default: the Control Panel, User Settings, and Site Administration. These options are called panel categories, which is the term used to differentiate between sections of the menu. For instance, the Control Panel is a single panel category, and when clicking on it, you're presented with four other child panel categories: *Users*, *Sites*, *Apps*, and *Configuration*. It you click on one of these child panel categories, you're presented with panel apps.

Note: The Product Menu cannot be changed by applying a new theme. To change the layout/style of the Product Menu, you must create and deploy a theme contributor. See the Theme Contributors tutorial for more details.

This construction of the Product Menu was designed to be intuitive and easy to use. For your instance of Liferay, however, you may want to add other panel categories with custom panel apps. Also, you may desire to change the order of your panel categories and/or apps. In this tutorial, you'll learn how to provide your own custom or modify existing panel categories and panel apps for the Product Menu.

Adding Custom Panel Categories

Liferay provides an easy way to extend the Product Menu and customize it to display what is most helpful in your particular situation. First, you'll learn how to add a panel category.

1. Create a generic OSGi module using your favorite third party tool, or use Blade CLI. Blade CLI offers a Panel App template, which you can use to generate a basic panel category and panel app.

2. Create a unique package name in the module's src directory and create a new Java class in that package. To follow naming conventions, give your class a unique name followed by *PanelCategory* (e.g., `ControlPanelCategory`).

3. Directly above the class's declaration, insert the following annotation:

```
@Component(
    immediate = true,
    property = {
        "panel.category.key=" + [Panel Category Key],
        "panel.category.order:Integer=[int]"
    },
    service = PanelCategory.class
)
```

   The `property` element designates two properties that should be assigned for your category. The `panel.category.key` specifies the parent category for your custom category. You can find popular parent categories to assign in the PanelCategoryKeys class. For instance, if you wanted to create a child category in the Control Panel, you could assign `PanelCategoryKeys.CONTROL_PANEL`. Likewise, if you wanted to create a root category, like the Control Panel or Site Administration, you could assign `PanelCategoryKeys.ROOT`.

The `panel.category.order:Integer` property specifies the order in which your category is displayed. The higher the number (integer), the lower your category is listed among other sibling categories assigned to a parent.

Lastly, your `service` element should specify the `PanelCategory.class` service. You can view an example of a similar `@Component` annotation for the `UserPanelCategory` class below.

```
@Component(
    immediate = true,
    property = {
        "panel.category.key=" + PanelCategoryKeys.ROOT,
        "panel.category.order:Integer=200"
    },
    service = PanelCategory.class
)
```

4. Implement the `PanelCategory` interface. A popular way to do this is by extending the BasePanelCategory or BaseJSPPanelCategory abstract classes. Typically, the `BasePanelCategory` is extended for basic categories (e.g., the Control Panel category) that only display the category name or other simple functionality. If you'd like to provide a custom UI for your panel, you can do so using any frontend technology, you only need to implement the methods `include()` or `includeHeader()` from the `PanelCategory` interface. The `includeHeader` method is used to render the header of the section and the `include` method is used to render the body. Implementing a custom UI gives you the flexibility to add more complex functionality. If you are going to use JSPs as the frontend technology, a base class called `BaseJSPPanelCategory` can be extended that already implements the methods `include()` and `includeHeader()` for you. This will be elaborated on more extensively later.

```
**Note:** In this tutorial, JSPs are used to describe how to provide
functionality to panel categories and apps. JSPs, however, are not the only
way to provide frontend functionality to your categories/apps. You can
create your own class implementing `PanelCategory` to use other
technologies, such as FreeMarker.
```

---

5. Since you're implementing the PanelCategory interface, you'll need to implement its methods if you're not extending a base class:

    - `getNotificationCount`: returns the number of notifications to be shown in the panel category.
    - `include`: renders the body of the panel category.
    - `includeHeader`: renders the panel category header.
    - `isActive`: whether the panel is selected.
    - `isPersistState`: whether to persist the panel category's state to the database. This is used to save the state of the panel category when navigating away from the menu.

6. Add any other methods that are necessary to create your custom panel category. As you learned earlier, you can extend the `BasePanelCategory` and `BaseJSPPanelCategory` abstract classes to implement `PanelCategory`.

If you'd like to provide something simple for your panel category like a name, extending `BasePanelCategory` is probably sufficient. For example, the ControlPanelCategory extends `BasePanelCategory` and specifies a `getLabel` method to set and display the panel category name.

```
@Override
public String getLabel(Locale locale) {
    return LanguageUtil.get(locale, "control-panel");
}
```

If you'd like to provide functionality that is more complex, you can use JSPs or any other similar technology to render the panel category. You can easily do this by extending `BaseJSPPanelCategory`. For example, the SiteAdministrationPanelCategory specifies the `getHeaderJspPath` and `getJspPath` methods. You could create a JSP with the UI you'd like to render and specify its path in methods like these:

```
@Override
public String getHeaderJspPath() {
    return "/sites/site_administration_header.jsp";
}

@Override
public String getJspPath() {
    return "/sites/site_administration_body.jsp";
}
```

One JSP is responsible for rendering the panel category's header (displayed when panel is collapsed) and the other for its body (displayed when panel is expanded).

You will also need to specify the servlet context from where you are loading the JSP files. If this is inside an OSGi module, make sure your `bnd.bnd` file has defined a web context path:

```
Bundle-SymbolicName: com.sample.my.module.web
Web-ContextPath: /my-module-web
```

And then reference the Servlet context using the symbolic name of your module like this:

```
@Override
@Reference(
    target = "(osgi.web.symbolicname=com.sample.my.module.web)",
    unbind = "-"
)
public void setServletContext(ServletContext servletContext) {
    super.setServletContext(servletContext);
}
```

Excellent! You've successfully created a custom panel category to display in the Product Menu. In many cases, a panel category holds panel apps for users to access. You'll learn about how to add a panel app to a panel category next.

Adding Custom Panel Apps

Just as adding panel categories is straight-forward and dynamic, so too is the process for adding panel apps. Panel apps are, by default, links provided in a panel category that allow you to access an application. For instance, if you navigate to the Site Administration → *Content* panel category, you can select the *Web Content* option, which is a panel app that allows you to access web content. Panel apps can also have a custom UI in the same way Panel categories could have a more complex UI.

Follow the steps below to add a panel app to your Liferay instance's Product Menu.

1. Create a generic OSGi module using your favorite third party tool, or use Blade CLI. Blade CLI offers a Panel App template, which you can use to generate a basic panel category and panel app.

2. Create a unique package name in the module's `src` directory and create a new Java class in that package. To follow naming conventions, give your class a unique name followed by *PanelApp* (e.g., `JournalPanelApp`).

3. Directly above the class's declaration, insert the following annotation:

```
@Component(
    immediate = true,
    property = {
        "panel.app.order:Integer=INTEGER"
        "panel.category.key=" + PANEL_CATEGORY_KEY,
    },
    service = PanelApp.class
)
```

   These properties and attributes are very similar to the ones discussed for panel categories. The `panel.app.order:Integer` property specifies the order your panel app is listed among other panel apps in the same category. The `panel.category.key` specifies the panel category your panel app will reside in. For example, if you want to add a panel app to Site Administration → *Content*, you would add the following property:

```
"panel.category.key=" + PanelCategoryKeys.SITE_ADMINISTRATION_CONTENT
```

   Visit the PanelCategoryKeys class for keys you can use to specify default panel categories in Liferay.

   Lastly, be sure to set the `service` attribute to `PanelApp.class`. You can view an example of a similar `@Component` annotation for the `JournalPanelApp` class below.

```
@Component(
    immediate = true,
    property = {
        "panel.app.order:Integer=100",
        "panel.category.key=" + PanelCategoryKeys.SITE_ADMINISTRATION_CONTENT
    },
    service = PanelApp.class
)
```

4. Implement the `PanelApp` interface. A popular way to do this is by extending the BasePanelApp abstract class. Just as you learned in the previous sub-section on panel categories, if you need to create a more complex UI to render in the panel, you can do so. If you want to use JSPs to render that UI, you can extend an additional abstract class which extends `BasePanelApp` called BaseJSPPanelApp. This provides

additional methods you can use to incorporate JSP functionality into your app's listing in the Product Menu.

JSPs are not the only way to provide frontend functionality to your panel apps. You can create your own class implementing `PanelCategory` to use other technologies, such as FreeMarker.

5. Since you're implementing the PanelApp interface, you must implement its methods if you're not extending a base class. The `BlogsPanelApp` is a simple example of how to specify your portlet as a panel app. This class extends the `BasePanelApp`, overriding the `getPortletId` and `setPortlet` methods. These methods specify and set the Blogs portlet as a panel app.

   Each panel app must belong to a portlet and each portlet can have at most one panel app. If more than one panel app is needed, another custom portlet must be created. By default, the panel app will only be shown if the user has permission to view the associated portlet.

   This is how those methods look for the Blogs portlet:

```
@Override
public String getPortletId() {
    return BlogsPortletKeys.BLOGS_ADMIN;
}

@Override
@Reference(
    target = "(javax.portlet.name=" + BlogsPortletKeys.BLOGS_ADMIN + ")",
    unbind = "-"
)
public void setPortlet(Portlet portlet) {
    super.setPortlet(portlet);
}
```

   Liferay DXP also lets you customize your panel app's appearance in the Product Menu. As you learned before, the `BaseJSPPanelApp` abstract class can be extended to provide further functionality with JSPs. For instance, the Navigation category in Site Administration offers a dynamic Pages panel app that provides much more than a simple link to access a portlet. This is accomplished by extending `BaseJSPPanelApp` in the GroupPagesPanelApp class, which provides this functionality in the Product Menu.

   In `GroupPagesPanelApp`, notice that the portlet ID is still returned similarly to the previous `BlogsPanelApp` example, but a `getJspPath` method is also called, which gives the panel app much more functionality provided by the `layouts_tree` JSP file:

```
@Override
public String getJspPath() {
    return "/panel/app/layouts_tree.jsp";
}
```

   Since you're including custom JSPs in your module, you'll also need to set the right `ServletContext`.

```
@Override
@Reference(
    target = "(osgi.web.symbolicname=com.liferay.layout.admin.web)",
    unbind = "-"
)
public void setServletContext(ServletContext servletContext) {
    super.setServletContext(servletContext);
}
```

Now you know how to add or modify a panel app in the Product Menu. Not only does Liferay provide a simple solution to add new panel categories and apps, it also gives you the flexibility to add a more complex UI to the Product Menu using any technology.

111.2 Customizing the Control Menu

The Control Menu is the most visible and accessible menu in Liferay. It is visible to the user in most places, always displaying helpful text or options at the top of the page. For example, on your home page, the Control Menu offers default options for accessing the Product Menu, Simulation Menu, and Add Menu. You can think of this menu as the gateway to configuring options in Liferay.

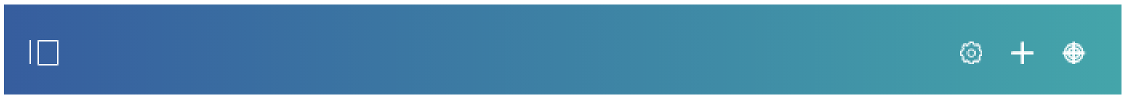

Figure 111.2: The Control Menu has three configurable areas: left, right, and middle.

If you navigate away from the home page, the Control Menu adapts and provides helpful functionality for what ever option you're using. For example, if you navigated to Site Administration → *Content* → *Web Content*, you'd be displayed a Control Menu with different functionality tailored for that option.

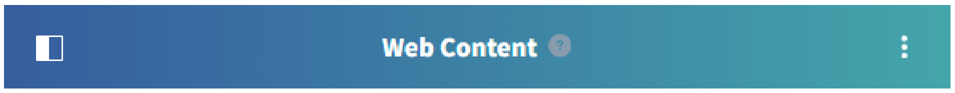

Figure 111.3: When switching your context to web content, the Control Menu adapts to provide helpful options for that area.

The default Control Menu is made up of three categories that represent the left, middle, and right portions of the menu. You can create navigation entries for each category, which can provide options or further navigation for the particular screen you're on.

Note: You can add the Control Menu to a custom theme by adding the following snippet into your `portal_normal.ftl`:

```
<@liferay.control_menu />
```

The other product navigation menus (e.g., Product Menu, Simulation Menu) are included in this tag, so specifying the above snippet will embed all three menus into your theme. Embedding the User Personal Bar is slightly different. Visit the Providing the User Personal Bar tutorial for more information.

You can reference a sample Control Menu Entry by visiting the Control Menu Entry article.

In this tutorial, you'll learn how to create your own entries to customize the Control Menu. Make sure to read the Adding Custom Panel Categories before beginning this tutorial. This tutorial assumes you have knowledge on creating a panel category. You'll begin by creating an entry for the Control Menu.

1. Create a generic OSGi module using your favorite third party tool, or use Blade CLI. Your module must contain a Java class, `bnd.bnd` file, and build file (e.g., `build.gradle` or `pom.xml`). You'll create your Java class next if your project does not already define one.

2. Create a unique package name in the module's src directory and create a new Java class in that package. To follow naming conventions, give your class a unique name followed by *ProductNavigationControlMenuEntry* (e.g., `StagingProductNavigationControlMenuEntry`).

3. Directly above the class's declaration, insert the following annotation:

```
@Component(
    immediate = true,
    property = {
        "product.navigation.control.menu.category.key=" + [Control Menu Category],
        "product.navigation.control.menu.category.order:Integer=[int]"
    },
    service = ProductNavigationControlMenuEntry.class
)
```

The `product.navigation.control.menu.category.key` property specifies the category your entry should reside in. As mentioned previously, the default Control Menu provides three categories: Sites (left portion), Tools (middle portion), and User (right portion).

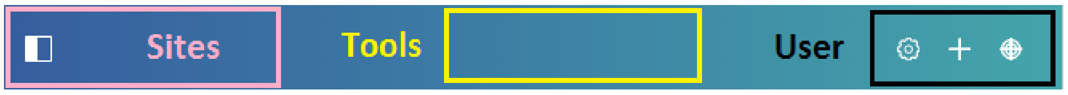

Figure 111.4: This image shows where your entry will reside depending on the category you select.

To specify the category, reference the appropriate key in the ProductNavigationControlMenuCategoryKeys class. For example, the following property would place your entry in the middle portion of the Control Menu:

```
"product.navigation.control.menu.category.key=" + ProductNavigationControlMenuCategoryKeys.TOOLS
```

Similar to panel categories, you'll also need to specify an integer for the order in which your entry will be displayed in the category. Entries are ordered from left to right. For example, an entry with order 1 will be listed to the left of an entry with order 2. If the order is not specified, it's chosen at random based on which service was registered first in the OSGi container. Lastly, your service element should specify the `ProductNavigationControlMenuEntry.class` service.

4. Implement the ProductNavigationControlMenuEntry interface. You can also extend the BaseProductNavigationControlMenuEntry or BaseJSPProductNavigationControlMenuEntry abstract classes. Typically, the `BaseProductNavigationControlMenuEntry` is extended for basic entries (e.g., `IndexingProductNavigationControlMenuEntry`) that only display a link with text or a simple icon. If you'd like to provide a more complex UI, like buttons or a sub-menu, you can do so by overriding the `include()` and `includeBody()` methods. If you are going to use JSPs for generating the UI, you can extend `BaseJSPProductNavigationControlMenuEntry` to save time. This will be elaborated on more extensively in the next step.

5. Define your Control Menu entry. You'll explore two examples to discover some options you have available for defining your entry. First, let's take a look at a simple example for providing text and an icon. The IndexingProductNavigationControlMenuEntry extends the `BaseProductNavigationControlMenuEntry` class and is used when Liferay is indexing. For this process, the indexing entry is displayed in the *Tools* (middle) area of the Control Menu with a *Refresh* icon and text stating *The Portal is currently indexing*. The icon is defined by calling the following method:

```
@Override
public String getIcon(HttpServletRequest request) {
    return "reload";
}
```

By default, Lexicon icons are expected to be returned. This is because the `BaseProductNavigationControlMenuEntry.getMa` method returns `lexicon`. To view all the Lexicon icons available, see https://liferay.github.io/clay /content/icons-lexicon/. You can also return FontAwesome icons, but you must implement the ProductNavigationControlMenuEntry.getMarkupView(...) method in your class and have it return `null`. Then you can return FontAwesome icons for the `getIcon(...)` method. To view all the FontAwesome icons available, see the FontAwesome 4.6.1 docs.

You can also provide a label for the Control Menu entry that displays when hovering over it with your pointer. This label is stored in the module's resource bundle, which you can learn more about in the Internationalization tutorials.

```
@Override
public String getLabel(Locale locale) {
    ResourceBundle resourceBundle = ResourceBundleUtil.getBundle(
        "content.Language", locale, getClass());

    return LanguageUtil.get(
        resourceBundle, "the-portal-is-currently-reindexing");
}
```

To do this, you'll need to create a `Language.properties` for your module.

You also have the option to provide a Lexicon or CSS icon in your `*ControlMenuEntry`. To use a Lexicon icon, you should override the methods in `ProductMenuProductNavigationControlMenuEntry` like the following:

```
public String getIconCssClass(HttpServletRequest request) {
    return "";
}

public String getIcon(HttpServletRequest request) {
    return "lexicon-icon";
}

public String getMarkupView(HttpServletRequest request) {
    return "lexicon";
}
```

Likewise, you can use a CSS icon by overriding the `ProductMenuProductNavigationControlMenuEntry` methods like the following:

```
public String getIconCssClass(HttpServletRequest request) {
    return "icon-css";
}

public String getIcon(HttpServletRequest request) {
    return "";
}

public String getMarkupView(HttpServletRequest request) {
    return "";
}
```

The icons used in the two examples for Lexicon and CSS icons can be found in the icons-lexicon and icons-font-awesome components, respectively.

The ProductMenuProductNavigationControlMenuEntry is a more advanced example. This entry displays in the *Sites* (left) area of the Control Menu, but unlike the previous example, it extends the

BaseJSPProductNavigationControlMenuEntry class. This provides several more methods that lets you use JSPs to define your entry's UI. There are two methods to pay special attention to:

```
@Override
public String getBodyJspPath() {
    return "/portlet/control_menu/product_menu_control_menu_entry_body.jsp";
}

@Override
public String getIconJspPath() {
    return "/portlet/control_menu/product_menu_control_menu_entry_icon.jsp";
}
```

The `getIconJspPath()` method provides the Product Menu icon (◧ → ◨) and the `getBodyJspPath()` method adds the UI body for the entry outside of the Control Menu. The latter method must be used when providing a UI outside the Control Menu. You can easily test this when you open and close the Product Menu on the home page.

Lastly, if you're planning on providing functionality that will stay exclusively inside the Control Menu, the `StagingProductNavigationControlMenuEntry` class calls its JSP like this:

```
@Override
public String getIconJspPath() {
    return "/control_menu/entry.jsp";
}
```

In particular, the `entry.jsp` is returned, which embeds the Staging Bar portlet into the Control Menu.

You will also need to specify the servlet context from where you are loading the JSP files. If this is inside an OSGi module, make sure your `bnd.bnd` file has defined a web context path:

```
Bundle-SymbolicName: com.sample.my.module.web
Web-ContextPath: /my-module-web
```

And then reference the Servlet context using the symbolic name of your module like this:

```
@Override
@Reference(
    target = "(osgi.web.symbolicname=com.sample.my.module.web)",
    unbind = "-"
)
public void setServletContext(ServletContext servletContext) {
    super.setServletContext(servletContext);
}
```

6. Define when to display your new entry in the Control Menu. As you've learned already, the Control Panel displays different entries depending on the page you've navigated to. You can specify when your entry should display using the `isShow(HttpServletRequest)` method.

   For example, the `IndexingProductNavigationControlMenuEntry` class queries the number of indexing jobs when calling `isShow`. If the query count is 0, then the indexing entry is not displayed in the Control Menu:

```
@Override
public boolean isShow(HttpServletRequest request) throws PortalException {
    int count = _indexWriterHelper.getReindexTaskCount(
        CompanyConstants.SYSTEM, false);

    if (count == 0) {
        return false;
    }

    return super.isShow(request);
}
```

The `StagingProductNavigationControlMenuEntry` class is selective over which pages to display for. The staging entry is configured to never display if the page is an administration page (e.g., *Site Administration*, *My Account*, etc.):

```
@Override
public boolean isShow(HttpServletRequest request) throws PortalException {
    ThemeDisplay themeDisplay = (ThemeDisplay)request.getAttribute(
        WebKeys.THEME_DISPLAY);

    Layout layout = themeDisplay.getLayout();

    // This controls if the page is an Administration Page

    if (layout.isTypeControlPanel()) {
        return false;
    }

    // This controls if Staging is enabled

    if (!themeDisplay.isShowStagingIcon()) {
        return false;
    }

    return true;
}
```

7. Define the dependencies for your Control Menu Entry. This should be completed in your build file (e.g., `build.grade` or `pom.xml`). For example, some popular dependencies (in Gradle format) are defined below:

```
dependencies {
    compileOnly group: "com.liferay", name: "com.liferay.product.navigation.control.menu.api", version: "[VERSION]"
    compile group: "com.liferay", name: "com.liferay.product.navigation.taglib", version: "[VERSION]"
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "[VERSION]"
    compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "[VERSION]"
    compile group: "javax.servlet.jsp", name: "javax.servlet.jsp-api", version: "[VERSION]"
    compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "[VERSION]"
}
```

Your project may require more dependencies, depending on your module's functionality.

Excellent! You've created your entry in one of the three default panel categories in the Control Menu. You learned a basic way and an advanced way of providing that entry, and learned how to apply both.

111.3 Extending the Simulation Menu

When testing how Liferay pages and apps will appear for users, it's critical to simulate their views on as many useful ways as possible. By default, Liferay provides the Simulation Menu on the right-side of the main page. What if, however, you'd like to simulate something in Liferay that is not provided by the Simulation Menu? You'll need to extend the Simulation Menu, of course! Luckily, Liferay offers a simple way to extend and customize the Simulation Menu so you can test what you need. In this tutorial, you'll learn how to add additional functionality to the menu so you can do more simulating and less wondering.

The first thing you'll need to do is get accustomed to using panel categories/apps. This is covered in detail in the Customizing The Product Menu tutorial. Once you know the difference between panel categories and panel apps, and know how to create them, continue on in this tutorial.

There are few differences between the Simulation Menu and Product Menu, mostly because they extend the same base classes. The Simulation Menu, by default, is made up of only one panel category and one panel app. Liferay provides the SimulationPanelCategory class, which is a hidden category needed to hold the `DevicePreviewPanelApp`. This is the app and functionality you see in the Simulation Menu by default.

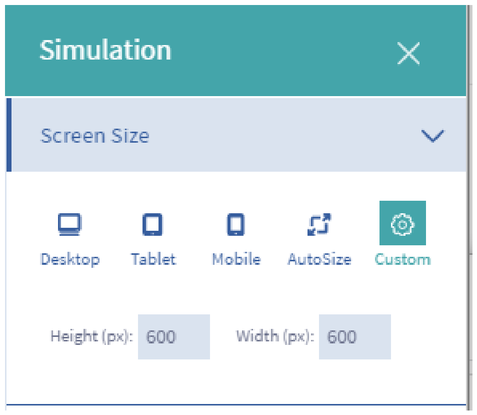

Figure 111.5: The Simulation Menu offers a device preview application.

To provide your own functionality in the Simulation Menu, you'll need to create a panel app in the `SimulationPanelCategory`. If you're looking to add extensive functionality, you can even create additional panel categories in the menu to divide up your panel apps. This tutorial will cover the simpler case of creating a panel app for the already present hidden category.

1. Follow the steps documented in the Adding Custom Panel Apps section for creating custom panel apps. Once you've created the foundation of your panel app, move on to learn how to tweak it so it customizes the Simulation Menu.

   You can easily generate a Simulation Panel App by using Blade CLI's Simulation Panel Entry template. You can also refer to the Simulation Panel App sample for a working example.

2. Since this tutorial assumes you're providing more functionality to the existing simulation category, set the simulation category in the `panel.category.key` of the `@Component` annotation:

   ```
   "panel.category.key=" + SimulationPanelCategory.SIMULATION
   ```

   In order to use this constant, you need to add a dependency on com.liferay.product.navigation.simulation. Be sure to also specify the order you'd like to display your new panel app, which was explained in the Adding Custom Panel Apps section.

3. This tutorial assumes you're using JSPs for creating a complex UI. Therefore, you should extend the BaseJSPPanelApp abstract class. This class implements the PanelApp interface and also provides additional methods necessary for specifying JSPs to render your panel app's UI. Remember that you can also implement your own `include()` method to use any frontend technology you want, if you'd like to use a technology other than JSP (e.g., FreeMarker).

4. Define your simulation view. For instance, in `DevicePreviewPanelApp`, the `getJspPath` method points to the `simulation-device.jsp` file in the `resources/META-INF/resources` folder, where the device simulation interface is defined. Optionally, you can also add your own language keys, CSS, or JS resources in your simulation module.

   The right servlet context is also provided implementing this method:

   ```
   @Override
   @Reference(
       target = "(osgi.web.symbolicname=com.liferay.product.navigation.simulation.device)",
       unbind = "-"
   )
   public void setServletContext(ServletContext servletContext) {
       super.setServletContext(servletContext);
   }
   ```

   As explained in Customizing The Product Menu, a panel app should be associated with a portlet. This makes the panel app visible only when the user has permission to view the portlet. This panel app is associated to the Simulation Device portlet using these methods:

   ```
   @Override
   public String getPortletId() {
       return ProductNavigationSimulationPortletKeys.
           PRODUCT_NAVIGATION_SIMULATION;
   }

   @Override
   @Reference(
       target = "(javax.portlet.name=" + ProductNavigationSimulationPortletKeys.PRODUCT_NAVIGATION_SIMULATION + ")",
       unbind = "-"
   )
   public void setPortlet(Portlet portlet) {
       super.setPortlet(portlet);
   }
   ```

   Audience Targeting also provides a good example of how to extend the Simulation Menu. When the Audience Targeting app is deployed, the Simulation Menu is extended to offer more functionality, in particular, for Audience Targeting User Segments and Campaigns. You can simulate particular scenarios for campaigns and users directly from the Simulation Menu. Its panel app class is very similar to `DevicePreviewPanelApp`, except it points to a different portlet and JSP.

5. You can combine your simulation options with the device simulation options by interacting with the device preview iFrame. To retrieve the device preview frame in an `aui:script` block of your custom simulation view's JavaScript, you can use the following:

   ```
   var iframe = A.one('#simulationDeviceIframe');
   ```

   Then you can modify the device preview frame URL like this:

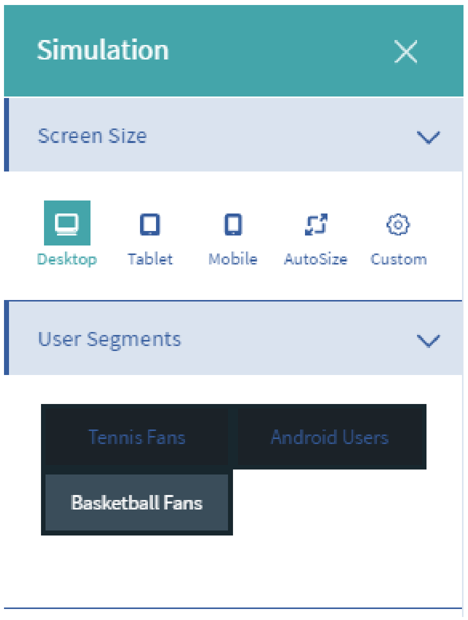

Figure 111.6: The Audience Targeting app extends the Simulation Menu to help simulate different users and campaign views.

```
    iframe.setAttribute('src', newUrlWithCustomParameters);
```

Now that you know how to extend the necessary panel categories and panel apps to modify the Simulation Menu, go ahead and create a module of your own and customize the Simulation Menu so it's most helpful for your needs.

111.4 Providing the User Personal Bar

Liferay offers a touch of personability with the User Personal Bar. This navigation menu is used to display options that are unique to the current logged in user. By default, Liferay displays this menu as a simple avatar button that expands the User Settings sub-menu in the Product Menu.

Although Liferay's default usage of the User Personal Bar is bare-bones, you can add more functionality to the user bar to fit your needs. Unlike other product navigation menus (e.g., Product Menu), the User Personal Bar does not require the extension/creation of panel categories and panel apps. It uses another common Liferay framework for providing functionality: Portlet Providers. Be sure to visit the linked tutorial to learn about how the Portlet Providers framework works in Liferay.

The User Personal Bar can be seen as a placeholder in every Liferay theme. By default, Liferay provides one sample *User Personal Bar* portlet that fills that placeholder, but the portlet Liferay provides can be easily replaced by other portlets.

Note: You can add the User Personal Bar to a custom theme by adding the following snippet into your `portal_normal.ftl`:

```
<@liferay.user_personal_bar />
```

In this tutorial, you'll learn how to customize the User Personal Bar. You'll create a single Java class where you'll specify a portlet to replace the existing default portlet.

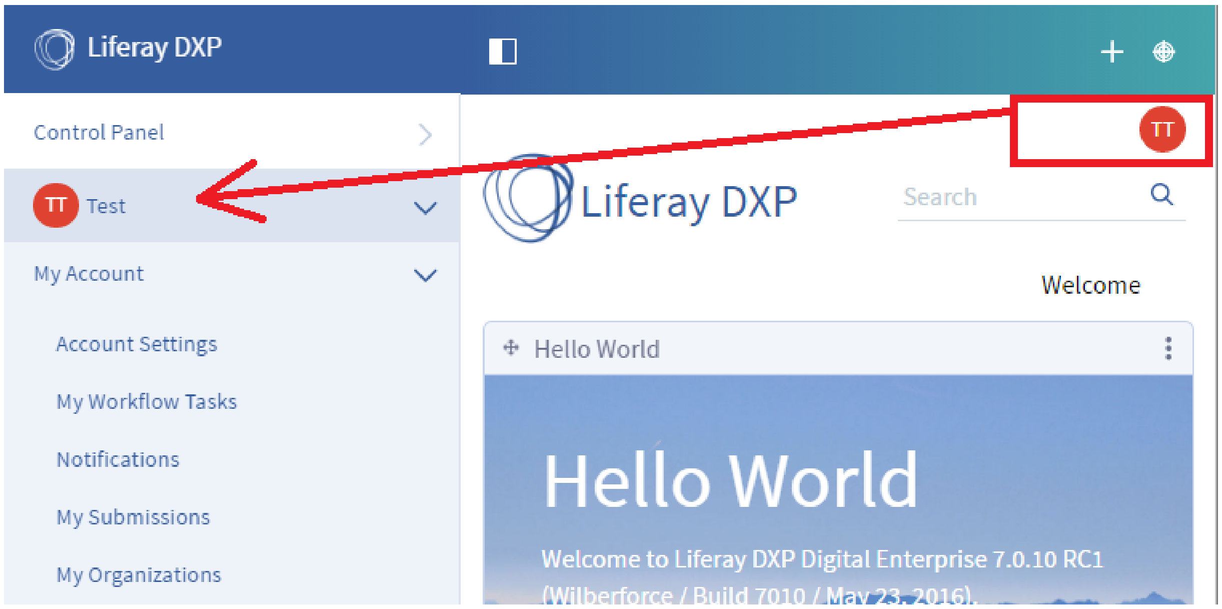

Figure 111.7: By default, the User Personal Bar contains the signed-in user's avatar, which navigates to the Product Menu when selected.

1. Create an OSGi module.

2. Create a unique package name in the module's src directory and create a new Java class in that package.

3. Directly above the class's declaration, insert the following annotation:

```
@Component(
    immediate = true,
    property = {
        "model.class.name=" + PortalUserPersonalBarApplicationType.UserPersonalBar.CLASS_NAME,
        "service.ranking:Integer=10"
    },
    service = ViewPortletProvider.class
)
```

   The `model.class.name` property must be set to the class name of the entity type you want the portlet to handle. In this case, you want your portlet to be provided based on whether or not it can be displayed in the User Personal Bar. You may recall from the Portlet Providers tutorial that you can request portlets in several different ways (e.g., *Edit*, *Browse*, etc.).

   You should also specify the service rank for your new portlet so it overrides the default one provided by Liferay DXP. Make sure to set the `service.ranking:Integer` property to a number that is ranked higher than the portlet being used by default.

   Since you're only wanting the User Personal Bar to display your portlet, you'll always have the service element be `ViewPortletProvider.class`.

4. Update the class's declaration to extend the BasePortletProvider abstract class and implement `ViewPortletProvider`:

```
public class ExampleViewPortletProvider extends BasePortletProvider implements ViewPortletProvider {
```

5. Specify the portlet you'd like to provide in the User Personal Bar by declaring the following method in your class:

   ```
   @Override
   public String getPortletName() {
       return PORTLET_NAME;
   }
   ```

   You should replace the `PORTLET_NAME` text with the portlet you want to provide Liferay when it requests one to be viewed in the User Personal Bar. For example, Liferay declares `com_liferay_product_navigation_user_personal_` for its default User Personal Bar portlet.

You've successfully provided a portlet to be displayed in the User Personal Bar. If you'd like to inspect the entire module used for Liferay's default User Personal Bar, see product-navigation-user-personal-bar-web. Besides the `*ViewPortletProvider` class, this module contains two classes defining constants and a portlet class defining the default portlet to provide. Although these additional classes are not required, your module should have access to the portlet you want to provide.

Chapter 112

Testing

Assuring top quality is paramount in producing awesome software. Test driven development plays a key role in this process. Liferay's tooling and integration with standard test frameworks support test driven development and help you reach quality milestones. Here are the ways Liferay facilitates testing:

- Unit testing: Using JUnit to unit test Liferay DXP modules in Gradle and Maven build environments and in IDEs that have JUnit plugins is seamless.
- Integration testing: The Arquillian Extension for Liferay lets you spin up a Liferay DXP instance, deploy modules whose components provide and consume services, and exercise their APIs. Liferay's `@Inject` annotation allows you to inject service instances into tests.
- Functional testing: Selenium and the Arquillian Extension for Liferay support functional UI testing.
- Code Coverage: JaCoCo analyzes and reports test code coverage.
- Slim Runtime: Liferay Slim Runtime facilitates testing modules (including Service Builder modules) in a fast, lightweight environment.

Unit testing is the first step in test driven development.

112.1 Unit Testing with JUnit

Test driven development is a best practice for any developer. Unit tests verify and validate functionality of classes and methods in isolation by "mocking" external dependencies. One of the most widely-used tools for test driven development on the Java platform is JUnit. You can use the JUnit framework to write unit tests for Liferay DXP applications.

JUnit integrates with build environments such as Maven and Gradle. JUnit plugins are available in IDEs such as Eclipse, IntelliJ, and NetBeans. And of course, Liferay Workspace supports running JUnit tests.

This tutorial covers the following topics:

- Writing good tests
- JUnit annotations
- Creating JUnit test classes
- Running JUnit tests

You'll start by learning best practices for writing unit tests.

Writing Good Tests

To write good tests, developers must understand assertions and follow best practices.

Assertion: an executable specification of the expected behavior of the software under test (SUT) given a scenario. The tests define the behavior in the scenario using several methods: a test setup method, a class setup method, and a test method. It's *executable* because it programmatically checks behavior and tracks requirements.

Best Practices for Unit Tests:

Rule	Description
A test should have only one reason to fail.	Resolving failures from a single root cause is easiest.
A test should check just one thing.	Tests that verify or validate one thing are easier to understand and maintain. Focusing on multiple things can lead to multiple failure points, thus breaking the *one reason to fail* rule.
Avoid conditional logic in tests.	Conditional test logic that uses loops or if/else clauses increases the probability of test bugs.
A test that asserts nothing or cannot fail is worthless.	Tests that can't fail create a false sense of security.Here's example test code that can't fail:`File f = new File ("foo");Assert.assertTrue(f ≠ null);`
A test that inaccurately advertises what it asserts is untrustworthy	A test's name should accurately express what it tests. A name that's inaccurate or that promises more than what the test does creates confusion. `@Testpublic void testAddUser() { // do something not related to user creation }`

Next, you'll learn JUnit's annotations for test methods.

Understanding JUnit Annotations

The following table describes the JUnit method annotations.

Method signature	Description
`@BeforeClasspublic static void method()`	The method is invoked once, before the class's entire suite of tests is executed. It should prepare the general test environment.
`@Beforepublic void method()`	The method is invoked before each test. It should prepare the environment for each test.
`@Testpublic void method()`	Marks the method as a test.
`@Test (expected = SomeException.class)public void method()`	The test fails if the method doesn't throw the exception.
`@Afterpublic void method()`	The method is invoked after each test. It should clean up the environment.
`@AfterClasspublic static void method()`	The method is invoked once, after the class's entire suite of tests is executed. It should cleanup the general test environment.
`@Ignore or @Ignore("Why disabled")public void method()`	The method is skipped. Adding the `@Ignore` annotation is an easy way to skip a test. The message (optional) can explain why the test is being ignored.

JUnit follows the algorithm below to execute the test class's methods.

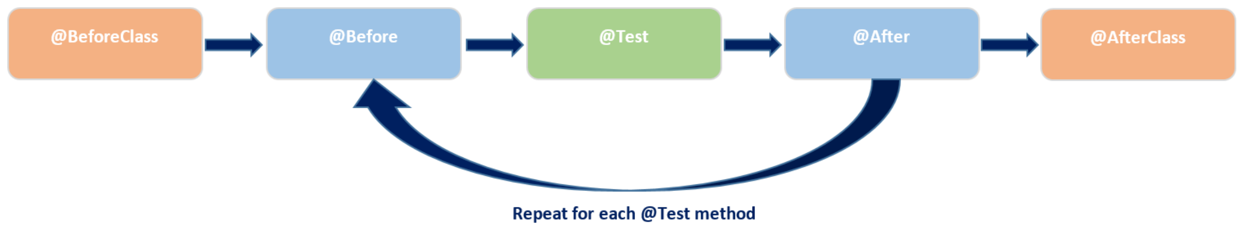

Figure 112.1: JUnit executes the annotated methods following this algorithm.

Let's create a JUnit test class.

Creating a JUnit Test Class

Here you'll create a JUnit test class and fill it with methods that both set up/clean up the test environment and assert the software's expected behavior.

To help illustrate creating unit tests, here's an example class to test:

```
public class MySampleNameClass {

   public MySampleNameClass(String firstName, String middleName, String lastName) {
      _firstName = firstName;
      _middleName = middleName;
      _lastName = lastName;
   }

   public int fullNameLength() {
      return _firstName.length() + _middleName.length() + _lastName.length();
   }

   public String getMiddleInitial() {
      return _middleName.charAt(0) + ".";
   }

   @Override
   public String toString() {
      return _firstName + " " + getMiddleInitial() + " " + _lastName;
   }

   private String _firstName;
   private String _middleName;
   private String _lastName;

}
```

In the sections that follow, you'll see setup, cleanup, and test methods that relate to this example class. Create a test class:

1. Open the module of the class you're testing.
2. Add a `src/test/java/` folder to the module.
3. In that folder, create a package path (ending in `test`) that mirrors the package path of the class you're testing.

   For example, if the class is in package `com.sample`, add a test package `com.sample.test`.
4. In that package, create a test class that ends in `Test` (e.g., `SomeTest.java`).

Your new test class is ready for test methods.

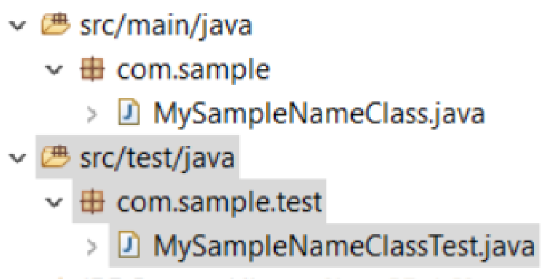

Figure 112.2: In this example module, the JUnit test class is in the same module of the class it tests. The test class resides in a source folder and package following standard test structure conventions.

Now create methods in the order of test flow execution.

@BeforeClass

Identify resources or computationally expensive tasks that must be completed prior to running all the tests. Create a method that initializes these resources and invokes these tasks. Apply the `@BeforeClass` annotation to the method.

@Before

Consider what needs to be done before running each individual test. Create a method that makes small preparations before each test case. Add the `@Before` annotation to the method.

For example, each of the tests for the class `MySampleNameClass` operate on a populated `MySampleNameClass` object. Implementing a method that instantiates such an object beforehand is appropriate. Adding the `@Before` annotation to the method ensures it's executed before each individual test.

Here's what the `MySampleNameClassTest` class might look like with such a method:

```
public class MySampleNameClassTest {

   @Before
   public void setUp() {
      _mySampleNameClass = new MySampleNameClass("Brian", "Edward", "Greenwald");
   }

   private MySampleNameClass _mySampleNameClass;

}
```

Note: Since this example class is immutable, it might make more sense to instantiate the object once in the `@BeforeClass` method and forgo the `@Before` method. It's probably more typical, however, that you'll be testing methods that change an object's state; so pretend this example object must be instantiated anew before each `@Test` method.

Now that you've instantiated objects each test needs, you can add `@Test` methods to assert expected output from the object's methods.

@Test

JUnit's `Assert` utility class contains static methods for comparing actual test results with expected results. When an assertion fails, an `AssertionException` is thrown and the test fails. If a test method completes execution without throwing an exception, the test succeeds.

For tests that contain a large amount of logic it's typically a best practice to use multiple assertions within the test to better identify the earliest point of failure. But since the example class is fairly simple, it's better to create a test for each of its methods:

```
@Test
public void testFullNameLength() {
   int length = _mySampleNameClass.fullNameLength();

   Assert.assertEquals(20, length);
}

@Test
public void testGetMiddleInitial() {
   String middleInitial = _mySampleNameClass.getMiddleInitial();

   Assert.assertEquals("E.", middleInitial);
}

@Test
```

```
public void testToString() {
   String fullName = _mySampleNameClass.toString();

   Assert.assertEquals("Brian E. Greenwald", fullName);
}
```

Since you know the test input (e.g., the parameters passed into the `MySampleNameClass` constructor), you can easily determine expected output. You can compare the computed value each method invocation returns with the expected value.

To test that a method throws a particular exception when given certain invalid inputs, add an `expected` attribute to the `@Test` annotation and assign the attribute the expected exception's class name. Important: refrain from making any assertions in the test method.

```
@Test(expected = MySampleException.class)
public void testToString() {
   String fullName = _mySampleNamenClass.toString();
}
```

Warning: Each test method should be independent. Since JUnit doesn't guarantee test order, you can't rely on a test being run before or after other tests.

@After

On finishing each individual test, you should clean up anything that was created or modified. Implement the cleanup instructions in a method and add the `@After` annotation to it.

@AfterClass

On finishing the entire set of tests, you should clean up any remaining test environment resources. Implement the final cleanup instructions in a method and add the `@AfterClass` annotation to it.

It's time to compile and run your JUnit tests.

Running JUnit Tests

Unit testing involves these things:

- Resolving test dependencies
- Executing the tests
- Analyzing test results

Add JUnit as a dependency. Here's a dependency on JUnit in Gradle:

```
testCompile group: "junit", name: "junit", version: "4.12"
```

If your tests require accessing classes outside the module, declare them as `testCompile` dependencies in the module's `build.gradle` file. Here's an example `testCompile` dependency.

```
testCompile group: "com.sample", name: "com.sample.external", version: "1.0.0"
```

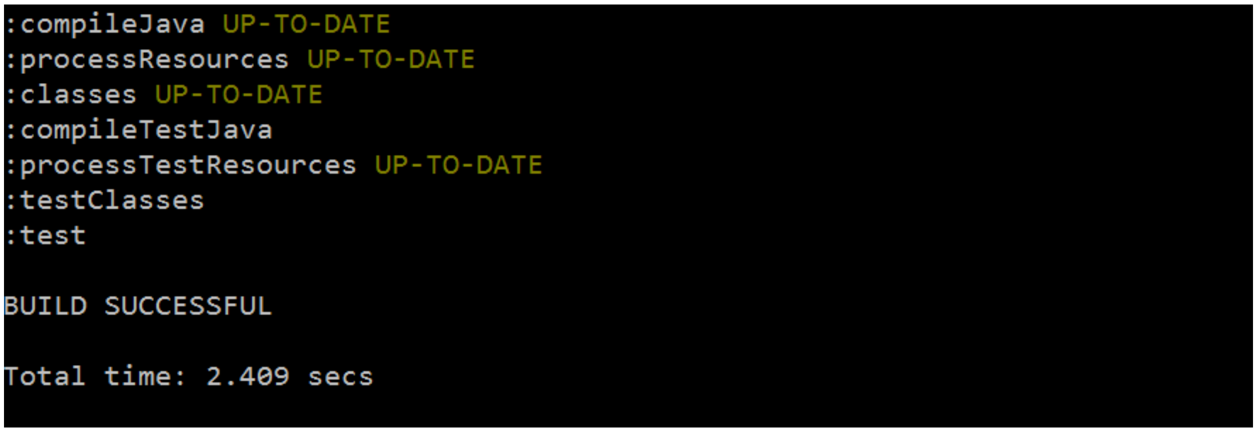
Because unit tests run independent of any running Liferay DXP instance, you can use external modules in tests but can't access their services.

Gradle and Maven commands execute module unit tests:

Gradle: `./gradlew test`

Maven: `mvn test`

The module's classes and tests compile and its tests run. The following figure shows command output for a successful test execution.



```
:compileJava UP-TO-DATE
:processResources UP-TO-DATE
:classes UP-TO-DATE
:compileTestJava
:processTestResources UP-TO-DATE
:testClasses
:test

BUILD SUCCESSFUL

Total time: 2.409 secs
```

Figure 112.3: Command output of successful test execution looks like this.

Reports are generated to module subfolders based on the build environment and/or reporting mechanism.

Gradle:

- HTML report `build/reports/tests/index.html`
- XML report file in `build/test-results/`

Maven:

- SureFire plugin generates XML and text report files in `targets/surefire-reports/`

Gradle's HTML report, for example, shows overall test metrics and organizes test results by package. Clicking on a package name lists test class results. Clicking on a test class name lists test method results.

While it's certainly helpful to see successful test results, it's even more helpful to see results of failing tests.

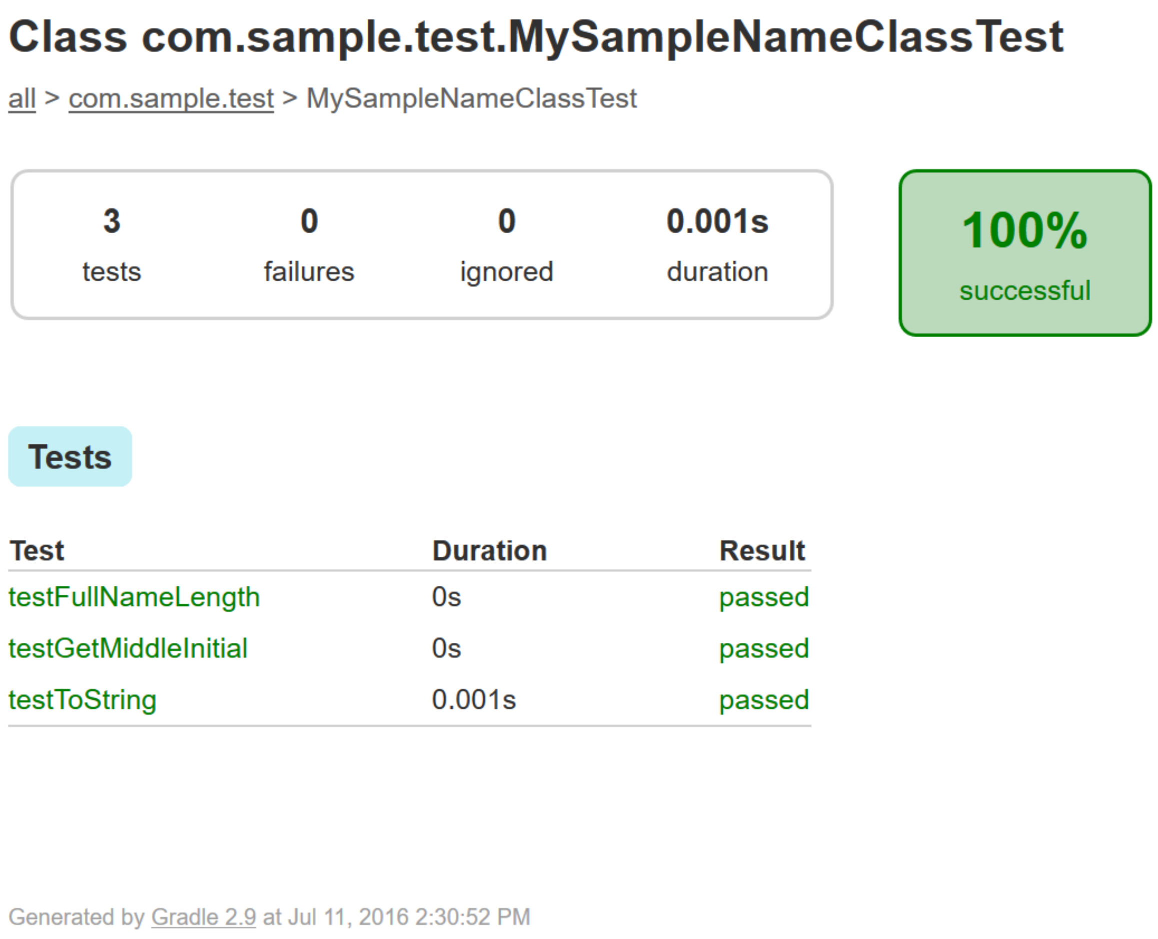
As an experiment, change the expected values of a test's assertions to force the test to fail and rerun the tests to yield the respective failures.

The command output shows the class and method name of each failed test, the JUnit assertion type, and the assertion's line number.

The generated HTML report shows each failing test's stack trace.

Stack traces show exactly why the test failed. They're essential for determining whether the failure is the result of faulty business logic or an incorrect expected value in the assertion. Using this information the developer can resolve the issue.

Congratulations on creating and executing unit tests with JUnit!



Class com.sample.test.MySampleNameClassTest

Arquillian Extension for Liferay Example

Arquillian is an extensible Java testing platform that's designed to make integration testing easy. Arquillian manages the lifecycle of setting up, starting, or connecting to a container (e.g., Tomcat), packaging your test cases and any dependent classes or resources, deploying them to the container, running the tests in the container, and capturing and reporting the results. The Arquillian Extension for Liferay is a set of tools designed to help developers test their Liferay plugins.

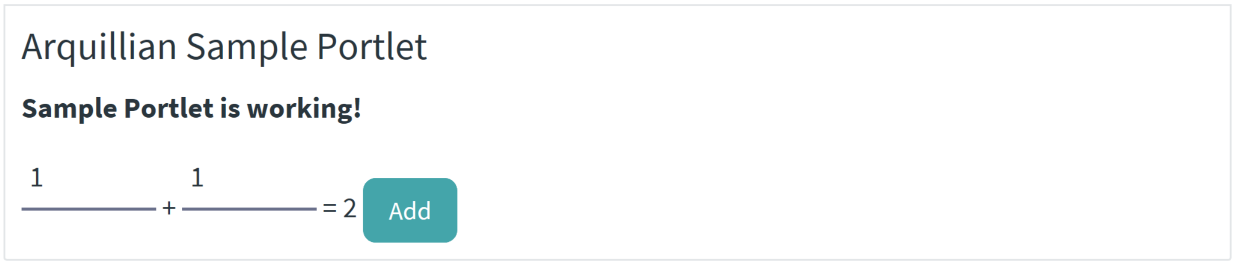
The Arquillian Blade Example project demonstrates performing integration and functional tests using the Arquillian Liferay Extension. Additionally it measures code coverage using JaCoCo. In this tutorial, you'll learn how the Arquillian Liferay Extension and JaCoCo work. You can download the Arquillian Blade Example project here or access its latest code on GitHub.

Here are the tutorial sections:

- Arquillian Sample Portlet
- Arquillian Integration Test Example
- Arquillian Functional Test Example
- JaCoCo Code Coverage Example
- Running the Arquillian Example

113.1 Arquillian Example Sample Portlet

The sample portlet calculates the sum of two numbers.



Arquillian Sample Portlet

Sample Portlet is working!

1 + 1 = 2

Figure 113.1: The Arquillian Sample Portlet calculates the sum of two numbers.

The portlet project comprises a portlet class, service classes, and JSPs. It follows the standard OSGi module folder structure with Java files in src/main/java/, resource files in src/main/resources/META-INF/resources, and build files in the project root.

Here are the primary files:

- SampleService.java: Provides an interface that defines method public long add(final int addend1, final int addend2) for returning the sum of two numbers.
- SampleServiceImpl.java: Uses OSGi Declarative Services to implement the SampleService interface.
- SamplePortlet.java: Extends Liferay MVCPortlet and processes portlet action commands and renders the result of executing the add service.
- bnd.bnd: Specifies the module's name, symbolic name, and version.
- init.jsp: Imports classes and tag libraries for the view layer.
- view.jsp: Provides a form for calculating the sum of two numbers.

You'll examine the tests next.

113.2 Arquillian Integration Test Example

Integration tests exercise module interaction. The following integration test validates the sample portlet using its API. Although the example's BasicPortletIntegrationTest class demonstrates invoking the sample module's SampleService.add method only, an Arquillian integration test could just as easily invoke many methods to test behavior across many modules. The test classes are in the src/testIntegration/java folder and test resources are in the src/testIntegration/resources folder.

Here's the BasicPortletIntegrationTest class:

```
package com.liferay.arquillian.test;

import com.google.common.io.Files;

import com.liferay.arquillian.containter.remote.enricher.Inject;
import com.liferay.arquillian.sample.service.SampleService;
import com.liferay.portal.kernel.exception.PortalException;

import java.io.File;
import java.io.IOException;

import org.jboss.arquillian.container.test.api.Deployment;
import org.jboss.arquillian.junit.Arquillian;
import org.jboss.shrinkwrap.api.ShrinkWrap;
import org.jboss.shrinkwrap.api.spec.JavaArchive;

import org.junit.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

@RunWith(Arquillian.class)
public class BasicPortletIntegrationTest {

    @Deployment
    public static JavaArchive create() throws Exception {
        final File tempDir = Files.createTempDir();

        String gradlew = "./gradlew";
        String osName = System.getProperty("os.name", "");
        if (osName.toLowerCase().contains("windows")) {
            gradlew = "./gradlew.bat";
        }

        final ProcessBuilder processBuilder = new ProcessBuilder(
            gradlew, "jar", "-Pdir=" + tempDir.getAbsolutePath());

        final Process process = processBuilder.start();

        process.waitFor();

        final File jarFile = new File(
            tempDir.getAbsolutePath() +
                "/com.liferay.arquillian.sample-1.0.0.jar");

        return ShrinkWrap.createFromZipFile(JavaArchive.class, jarFile);
    }

    @Test
    public void testAdd() throws IOException, PortalException {
        final long result = _sampleService.add(1, 3);

        Assert.assertEquals(4, result);
    }

    @Inject
    private SampleService _sampleService;

}
```

JUnit annotation `@RunWith(Arquillian.class)` marks the class for Arquillian to execute.

The `create` method packages the test class and resources in a Java archive (JAR). Invoking the project's `jar` Gradle task creates the test JAR Arquillian executes.

```
@Deployment
public static JavaArchive create() throws Exception {
    final File tempDir = Files.createTempDir();

    final ProcessBuilder processBuilder = new ProcessBuilder(
        "./gradlew", "jar", "-Pdir=" + tempDir.getAbsolutePath());

    final Process process = processBuilder.start();

    process.waitFor();

    final File jarFile = new File(
        tempDir.getAbsolutePath() +
            "/com.liferay.arquillian.sample-1.0.0.jar");

    return ShrinkWrap.createFromZipFile(JavaArchive.class, jarFile);
}
```

JUnit annotation `@Test` designates the `testAdd` method as a test. The method invokes the `SampleService` object's `add` method and asserts its result.

```
@Test
public void testAdd() throws IOException, PortalException {
    final long result = _sampleService.add(1, 3);

    Assert.assertEquals(4, result);
}
```

The Liferay Arquillian Extension injects the `_sampleService` field with a `SampleService` implementation (i.e., a `SampleServiceImpl` instance).

```
@Inject
private SampleService _sampleService;
```

The integration test has some dependencies, of course.

Dependencies

The project's `build.gradle` file specifies this test's dependencies on Liferay's Arquillian container, JUnit, and an Arquillian JUnit test container:

```
testIntegrationCompile group: "com.liferay.arquillian", name: "com.liferay.arquillian.arquillian-container-liferay", version: "1.0.6"
testIntegrationCompile group: "junit", name: "junit", version: "4.12"
testIntegrationCompile group: "org.jboss.arquillian.junit", name: "arquillian-junit-container", version: "1.1.11.Final"
```

Arquillian tests are configurable too.

Arquillian Configuration

Arquillian configuration file `src/testIntegration/resources/arquillian.xml` uses property `deploymentExportPath` (optional) to write a test archive (e.g., JAR file) to a folder before deploying the tests. You can inspect all the test files from this archive. To highlight the `deploymentExportPath` property, here's an abbreviated view of the `arquillian.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<arquillian xmlns="http://jboss.org/schema/arquillian"
            xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:schemaLocation="http://jboss.org/schema/arquillian http://jboss.org/schema/arquillian/arquillian_1_0.xsd">

    <!-- More content here -->

    <engine>
        <property name="deploymentExportPath">build/deployments</property>
    </engine>
</arquillian>
```

The project uses Java Management Extensions (JMX) to deploy OSGi modules to Liferay DXP. Enabling JMX for the application server is next.

JMX Settings

Apache Aries JMX exposes the JMX API that Arquillian uses to install/deploy/start the modules. Since DXP Digital Enterprise 7.0 Fix Pack 16 and Liferay CE 7.0 GA4, Liferay Workspace's `startTestableTomcat` Gradle task installs the Apache Aries JMX modules automatically. In case you're using an earlier Liferay DXP version or haven't already installed the Aries modules, here's their group ID, artifact ID, and version information. You can install them using Apache Felix GoGo Shell:

```
"org.apache.aries.jmx:org.apache.aries.jmx:1.1.5"
"org.apache.aries:org.apache.aries.util:1.1.3"
```

JMX is enabled on the application server via Java runtime options. The following Apache Tomcat environment script excerpts demonstrate enabling JMX (without authentication) on port 8099.

`setenv.sh` JMX Settings

```
JMX_OPTS="-Dcom.sun.management.jmxremote -Dcom.sun.management.jmxremote.authenticate=false -Dcom.sun.management.jmxremote.port=8099 -
Dcom.sun.management.jmxremote.ssl=false"

CATALINA_OPTS="${CATALINA_OPTS} ${JMX_OPTS}"
```

`setenv.bat` JMX Settings

```
set "JMX_OPTS=-Dcom.sun.management.jmxremote -Dcom.sun.management.jmxremote.authenticate=false -Dcom.sun.management.jmxremote.port=8099 -
Dcom.sun.management.jmxremote.ssl=false"

set "CATALINA_OPTS=%CATALINA_OPTS% %JMX_OPTS%"
```

Apache Tomcat's guide *Enabling JMX Remote* has more JMX configuration details.

You've seen how setting up the example integration test class is straightforward. Next, you'll discover how fun it is to develop functional browser-based tests using Arquillian.

113.3 Arquillian Functional Test Example

Where the integration test invokes the `SampleService`'s `add` method directly, the functional test invokes the `add` method indirectly using a web browser. The Arquillian Blade Example's functional tests interact with the portlet UI to verify content and validate behavior. The test classes are in the `src/testIntegration/java` folder and test resources are in the `src/testIntegration/resources` folder.

The example functional tests operate on the following view parameters:

- `firstParameter`: First number to add
- `secondParameter`: Second number to add
- `result`: Sum of the two numbers

The JSP file `view.jsp` and portlet class `BasicPortletFunctionalTest` use these parameters. Here's the `view.jsp` code:

```
<%@ include file="/init.jsp" %>

<%@ page import="com.liferay.portal.kernel.util.ParamUtil" %>

<%
int firstParameter = ParamUtil.getInteger(request, "firstParameter", 1);
int secondParameter = ParamUtil.getInteger(request, "secondParameter", 1);
int result = ParamUtil.getInteger(request, "result");
%>

<portlet:actionURL name="add" var="portletURL" />

<p>
<b>Sample Portlet is working!</b>
</p>

<aui:form action="<%= portletURL %>" method="post" name="fm">
<aui:input inlineField="<%= true %>" label="" name="firstParameter" size="4" type="int" value="<%= firstParameter %>" />
<span> + </span>
<aui:input inlineField="<%= true %>" label="" name="secondParameter" size="4" type="int" value="<%= secondParameter %>" />
<span> = </span>
<span class="result"><%= result %></span>

<aui:button type="submit" value="add" />
</aui:form>
```

Users enter numbers in the `firstParameter` and `secondParameter` input fields and click on the add button to show the sum to the `result` field.

Functional test class `BasicPortletFunctionalTest` uses Selenium to interact with the portlet's UI. Here's the `BasicPortletFunctionalTest` class:

```
package com.liferay.arquillian.test;

import com.google.common.io.Files;

import com.liferay.arquillian.portal.annotation.PortalURL;
import com.liferay.portal.kernel.exception.PortalException;

import java.io.File;
import java.io.IOException;

import java.net.URL;

import org.jboss.arquillian.container.test.api.Deployment;
import org.jboss.arquillian.container.test.api.RunAsClient;
import org.jboss.arquillian.drone.api.annotation.Drone;
import org.jboss.arquillian.junit.Arquillian;
import org.jboss.shrinkwrap.api.ShrinkWrap;
import org.jboss.shrinkwrap.api.spec.JavaArchive;

import org.junit.Assert;
import org.junit.Test;
import org.junit.runner.RunWith;

import org.openqa.selenium.OutputType;
import org.openqa.selenium.TakesScreenshot;
import org.openqa.selenium.WebDriver;
import org.openqa.selenium.WebElement;
import org.openqa.selenium.support.FindBy;

@RunAsClient
@RunWith(Arquillian.class)
public class BasicPortletFunctionalTest {

    @Deployment
    public static JavaArchive create() throws Exception {
        final File tempDir = Files.createTempDir();

        String gradlew = "./gradlew";

        String osName = System.getProperty("os.name", "");
        if (osName.toLowerCase().contains("windows")) {
            gradlew = "./gradlew.bat";
        }

        final ProcessBuilder processBuilder = new ProcessBuilder(
            gradlew, "jar", "-Pdir=" + tempDir.getAbsolutePath());

        final Process process = processBuilder.start();

        process.waitFor();

        final File jarFile = new File(
            tempDir.getAbsolutePath() +
                "/com.liferay.arquillian.sample-1.0.0.jar");

        return ShrinkWrap.createFromZipFile(JavaArchive.class, jarFile);
    }

    @Test
    public void testAdd()
        throws InterruptedException, IOException, PortalException {
```

```
        _browser.get(_portlerURL.toExternalForm());

        _firstParamter.clear();

        _firstParamter.sendKeys("2");

        _secondParameter.clear();

        _secondParameter.sendKeys("3");

        _add.click();

        Thread.sleep(5000);

        Assert.assertEquals("5", _result.getText());
    }

    @Test
    public void testInstallPortlet() throws IOException, PortalException {
        _browser.get(_portlerURL.toExternalForm());

        final String bodyText = _browser.getPageSource();

        Assert.assertTrue(
            "The portlet is not well deployed",
            bodyText.contains("Sample Portlet is working!"));
    }

    @FindBy(css = "button[type=submit]")
    private WebElement _add;

    @Drone
    private WebDriver _browser;

    @FindBy(css = "input[id$='firstParameter']")
    private WebElement _firstParamter;

    @PortalURL("arquillian_sample_portlet")
    private URL _portlerURL;

    @FindBy(css = "span[class='result']")
    private WebElement _result;

    @FindBy(css = "input[id$='secondParameter']")
    private WebElement _secondParameter;

}
```

Arquillian annotation `@RunAsClient` and JUnit annotation `@RunWith` mark the class as a web client that runs on Arquillian.

Similar to the integration test class, this class's create method packages the test as a JAR file for Arquillian to execute.

Method `testInstallPortlet` verifies portlet content.

```
@Test
public void testInstallPortlet() throws IOException, PortalException {
    _browser.get(_portlerURL.toExternalForm());

    final String bodyText = _browser.getPageSource();

    Assert.assertTrue(
        "The portlet is not well deployed",
        bodyText.contains("Sample Portlet is working!"));
}
```

This test class uses the following fields:

- `_browser`: Arquillian annotation `@Drone` sets this field as a Selenium `WebDriver` (browser).

  ```
  @Drone
  private WebDriver _browser;
  ```

- `_portlerURL`: Liferay Arquillian annotation `@PortalURL` assigns the portlet's URL to this field.

  ```
  @PortalURL("arquillian_sample_portlet")
  private URL _portlerURL;
  ```

- `_firstParamter` and `_secondParameter`: JavaScript selectors and Selenium annotation `@FindBy` map these fields to the form's inputs.

  ```
  @FindBy(css = "input[id$='firstParameter']")
  private WebElement _firstParamter;

  @FindBy(css = "input[id$='secondParameter']")
  private WebElement _secondParameter;
  ```

- `_add`: The form's `submit` button.

  ```
  @FindBy(css = "button[type=submit]")
  private WebElement _add;
  ```

- `_result`: Sum of the two numbers.

  ```
  @FindBy(css = "span[class='result']")
  private WebElement _result;
  ```

Using the `*Parameter` fields, the `testAdd` method injects numbers `2` and `3` into the form, submits the form, and asserts `5` as the result.

```
@Test
public void testAdd()
    throws InterruptedException, IOException, PortalException {

    _browser.get(_portlerURL.toExternalForm());

    _firstParameter.clear();

    _firstParameter.sendKeys("2");

    _secondParameter.clear();

    _secondParameter.sendKeys("3");

    _add.click();

    Thread.sleep(5000);

    Assert.assertEquals("5", _result.getText());
}
```

Testing portlets via a web client is that simple!

Functional tests typically require more setup than integration tests.

Dependencies

In addition to the Liferay Arquillian container, JUnit, and an Arquillian JUnit test container artifacts that the integration test required, the `BasicPortletFunctionalTest` class requires Arquillian's Graphine extension to use the web client. Here's the dependency from the Gradle file `build.gradle`:

```
testIntegrationCompile group: "org.jboss.arquillian.graphene", name: "graphene-webdriver", version: "2.1.0.Final"
```

Note: To learn more about functional testing using Graphine, see this guide.

The test requires additional Arquillian configuration elements too.

Arquillian Configuration

In addition to the `deploymentExportPath` property introduced with the integration test, this functional test specifies the browser type using `phantomjs` and the portal's URL. Here's the project's `arquillian.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<arquillian xmlns="http://jboss.org/schema/arquillian"
            xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
            xsi:schemaLocation="http://jboss.org/schema/arquillian http://jboss.org/schema/arquillian/arquillian_1_0.xsd">

    <extension qualifier="webdriver">
        <property name="browser">phantomjs</property>
    </extension>

    <extension qualifier="graphene">
        <property name="url">http://localhost:8080</property>
    </extension>

    <engine>
        <property name="deploymentExportPath">build/deployments</property>
    </engine>
</arquillian>
```

Note: The Arquillian Liferay Extension provides these options for injecting the URL of the container (e.g., Apache Tomcat):

1. In a test class deployment method or field, use the annotation `@ArquillianResource` to designate the URL.
2. Configure Arquillian using the graphene URL property (via `arquillian.xml`, `arquillian.properties`, or System Properties).

You should use Portal properties to prevent Liferay DXP from launching a browser and the Setup Wizard.

Portal Properties

The Arquillian Blade Example specifies the following Portal properties in file `src/testIntegration/resources/portal-ext.properties`:

```
browser.launcher.url=
setup.wizard.enabled=false
```

Browsers other than the ones the functional tests launch can interfere with tests. Setting `browser.launcher.url` to an empty value prevents Liferay DXP from launching a browser on its own. You don't need Liferay DXP's setup wizard either. Setting `setup.wizard.enabled=false` bypasses launching the Setup Wizard.

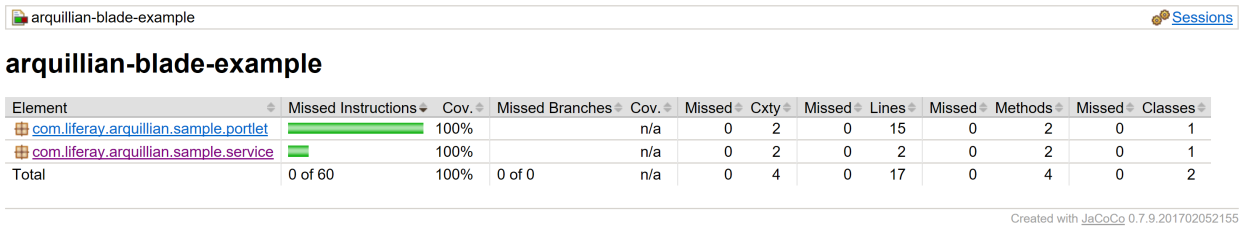
The example project's Gradle task `copyPortalExt`, copies the Portal properties file into the Liferay DXP installation.

As you develop tests, you might want to track the parts of the product your tests cover. The example project uses JaCoCo to measure code coverage. JaCoCo is explained next.

If you'd rather launch the Arquillian Blade Example before investigating JaCoCo, skip to Running the Arquillian Example. Otherwise, jump into JaCoCo!

113.4 JaCoCo Code Coverage Example

JaCoCo measures Java code coverage. The Arquillian Blade Example uses JaCoCo to report parts and percentages of the product code the tests execute.



arquillian-blade-example Sessions

arquillian-blade-example

Element	Missed Instructions	Cov.	Missed Branches	Cov.	Missed	Cxty	Missed	Lines	Missed	Methods	Missed	Classes
com.liferay.arquillian.sample.portlet	🟩	100%		n/a	0	2	0	15	0	2	0	1
com.liferay.arquillian.sample.service	🟩	100%		n/a	0	2	0	2	0	2	0	1
Total	0 of 60	100%	0 of 0	n/a	0	4	0	17	0	4	0	2

Created with JaCoCo 0.7.9.201702052155

Figure 113.2: JaCoCo reports lines of code tests execute in methods and classes.

Enabling JaCoCo

JaCoCo requires attaching an agent to the JVM. To attach the JaCoCo agent, append the following JaCoCo options to the Tomcat environment script's `CATALINA_OPTS` variable.

`setenv.sh` JaCoCo Settings

```
JACOCO_OPTS="-javaagent:PATH_TO_JACOCO_AGENT_JAR/jacocoagent.jar=destfile=JACOCO_EXEC_FILE,output=file,append=true,jmx=true"

CATALINA_OPTS="${CATALINA_OPTS} ${JACOCO_OPTS}"
```

`setenv.bat` JaCoCo Settings

```
set "JACOCO_OPTS=-javaagent:PATH_TO_JACOCO_AGENT_JAR/jacocoagent.jar=destfile=JACOCO_EXEC_FILE,output=file,append=true,jmx=true"

set "CATALINA_OPTS=%CATALINA_OPTS% %JACOCO_OPTS%"
```

Replace `PATH_TO_JACOCO_AGENT_JAR` with the path to the `jacocoagent.jar` file and `JACOCO_EXEC_FILE` with the path to the JaCoCo result dump file.

JaCoCo Build Instructions

The Gradle build file `build.gradle` specifies several JaCoCo-related instructions:

1. Apply the plugin to the build:

```
apply plugin: 'jacoco'

jacoco {
    toolVersion = '0.7.9'
}
```

2. Copy the JaCoCo agent into the project build.

```
task copyJacocoAgent(type: Copy) {
println configurations.jacocoAgent

    configurations.jacocoAgent.asFileTree.each {
        from(zipTree(it))
    }

    into "${rootDir}/build/jacoco"
}
```

3. Dump the code coverage data:

```
task dumpJacoco {
    doLast {
        def serverUrl = 'service:jmx:rmi:///jndi/rmi://localhost:8099/jmxrmi'
        String beanName = "org.jacoco:type=Runtime"
        def server = JmxFactory.connect(new JmxUrl(serverUrl)).MBeanServerConnection
        def gmxb = new GroovyMBean(server, beanName)

        println "Connected to:\n$gmxb\n"
        println "Executing dump()"
        gmxb.dump(true)
    }
}
```

4. Generate JaCoCo reports:

```
jacocoTestReport {
    dependsOn dumpJacoco
    group = "Reporting"
    reports {
        xml.enabled true
        csv.enabled false
        html.destination "${buildDir}/reports/coverage"
    }
    executionData = files("${rootDir}/build/jacoco/testIntegration.exec")
}
```

JaCoCo code coverage reporting runs as part of the project's `testIntegration` Gradle task. You'll run the tests and JaCoCo next.

113.5 Running the Arquillian Example

You're ready to run the Arquillian Blade Example tests. Open a terminal to the project root and execute the following command:

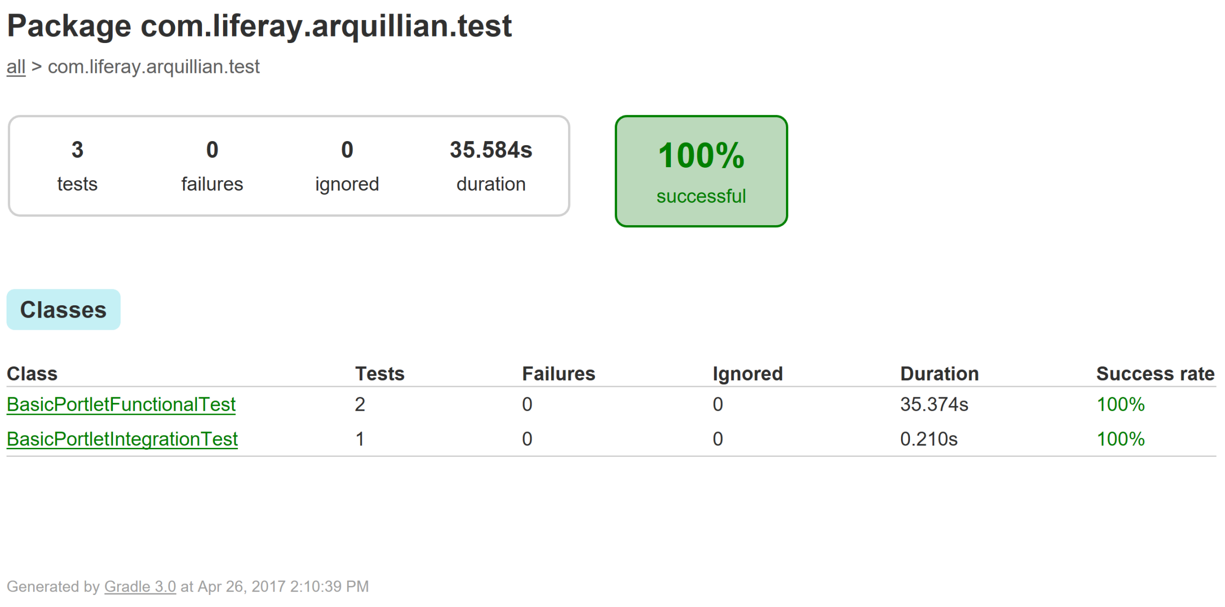
```
gradlew testIntegration
```

The command does these things:

1. Downloads and installs 7.0 bundled with Apache Tomcat
2. Starts a 7.0 server
3. Runs the tests, including the functional browser-based tests
4. Shuts down the server
5. Reports test and code coverage results

For `testIntegration` task details, examine the `build.gradle` file in the project root. The command can take several minutes to execute because of all it does. Test results are found in these locations:

- *Tests*: `build\reports\tests\testIntegration\index.html`
- *Code Coverage*: `build\reports\coverage\index.html`



Package com.liferay.arquillian.test

all > com.liferay.arquillian.test

3	0	0	35.584s
tests	failures	ignored	duration

100% successful

Classes

Class	Tests	Failures	Ignored	Duration	Success rate
BasicPortletFunctionalTest	2	0	0	35.374s	100%
BasicPortletIntegrationTest	1	0	0	0.210s	100%

Generated by Gradle 3.0 at Apr 26, 2017 2:10:39 PM

Figure 113.3: Open the test reports to analyze the results.

Note: before rerunning the tests, you must delete the `build/reports/` and `build/test-results/` folders.

Now that you've examined Arquillian functional and integration tests and JaCoCo code coverage capabilities, you can create similar tests and improve test code coverage in your projects.

Liferay's Slim Runtime
Unit Testing with JUnit

113.6 Liferay Slim Runtime

The Liferay Slim Runtime provides the bare necessities for running Service Builder modules. It's useful for testing applications quickly in a Liferay runtime environment free of Liferay add-ons.

The Liferay Slim Runtime provides

- Caching infrastructure
- Database infrastructure
- HTTP support
- JAX-RS support
- Limited set of Liferay utility classes
- OSGi framework for running modules
- Service Builder runtime for Service Builder modules
- Spring infrastructure
- Transaction infrastructure

It does **not** provide

- Authentication/Authorization layers
- Layout templates
- Permissions
- Portlet support (no portlet container)
- Sites
- Themes
- etc.

Building and launching a Liferay Slim Runtime is much quicker than a typical Liferay DXP bundle. Because of decreased build and startup times, the Slim Runtime provides a great environment for testing. You'll learn how to build one next.

Build

To build the Slim Runtime, you must have the liferay-portal Github repository forked and cloned to your local machine. Navigate to the repository's root folder and execute the following Ant command:

```
ant all -Dbuild.profile=slim
```

It's built in the server directory specified by the `app.server.properties` file's `app.server.parent.dir` property. Note that the Slim Runtime only supports Apache Tomcat 8+. This limitation simplifies packaging and configuration.

Launch

To launch the Slim Runtime, run the Tomcat start scripts found in the runtime's `<tomcat>/bin` directory:

```
./startup.[sh|bat]
```

Deploying Modules

You can deploy modules from any of the default directories the portal.properties file defines (see properties below) or from a custom auto-deploy directory you add to the `module.framework.auto.deploy.dirs` property.

```
module.framework.base.dir=${liferay.home}/osgi

module.framework.configs.dir=${module.framework.base.dir}/configs
module.framework.marketplace.dir=${module.framework.base.dir}/marketplace
module.framework.modules.dir=${module.framework.base.dir}/modules
module.framework.war.dir=${module.framework.base.dir}/war

module.framework.auto.deploy.dirs=\
    ${module.framework.configs.dir},\
    ${module.framework.marketplace.dir},\
    ${module.framework.modules.dir},\
    ${module.framework.war.dir}
```

By default, a pristine Slim Runtime has no UI or apps. Requests to it result in 404 errors. The modules you add provide all the functionality.

Adding Functionality

A web endpoint is the simplest type of function.

The following snippet demonstrates a simple servlet that responds to all requests to `http://localhost:8080[/*]`:

```
package web.sample;

import java.io.IOException;
import java.io.PrintWriter;

import javax.servlet.Servlet;
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.http.whiteboard.HttpWhiteboardConstants;

@Component(
    immediate = true,
    property = {
        HttpWhiteboardConstants.HTTP_WHITEBOARD_SERVLET_PATTERN + "=/*"
    },
    service = Servlet.class
)
public class SampleServlet extends HttpServlet {

    private static final long serialVersionUID = 1L;

    @Override
    protected void service(
            HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {

        response.setContentType("text/html");

        PrintWriter writer = response.getWriter();

        writer.println("<h2>Hello You!</h2>");
    }

}
```

The Database

The Slim Runtime creates the database schema automatically the first time it runs.

```
MariaDB [lportal]> show tables;
+------------------+
```

```
 Tables_in_lportal|
```

---+——————+

```
 ClassName_       |
 Configuration_   |
 Counter          |
 Release_         |
 ServiceComponent |
```

---+——————+ 5 rows in set (0.00 sec)

Only the following core services are available:

- `ClassNameLocalService`
- `CounterLocalService`
- `ReleaseLocalService`
- `ServiceComponentLocalService`

The Slim Runtime provides no other services! To test your services, therefore, you must deploy modules that provide the capabilities they depend on.

Service Builder

The Service Builder runtime bootstraps all deployed Service Builder services (API and service modules).

For example, deploying the `com.liferay.contacts.api` and `com.liferay.contacts.service` modules adds the `Contacts_Entry` table to the database:

```
MariaDB [lportal]> show tables;
+------------------+
```

```
 Tables_in_lportal|
```

---+——————+

```
 ClassName_       |
 Configuration_   |
 Contacts_Entry   |
 Counter          |
 Release_         |
 ServiceComponent |
```

---+——————+ 6 rows in set (0.00 sec)

A Basic Service Builder Web App

The servlet in the following snippet implements a simple web app that uses the contacts service.

```
package web.sample;

import java.io.IOException;
import java.io.PrintWriter;
import java.util.List;

import javax.servlet.Servlet;
import javax.servlet.ServletException;
import javax.servlet.http.HttpServlet;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;
import org.osgi.service.http.whiteboard.HttpWhiteboardConstants;

import com.liferay.contacts.model.Entry;
import com.liferay.contacts.service.EntryLocalService;
import com.liferay.counter.kernel.service.CounterLocalService;
import com.liferay.portal.kernel.dao.orm.DynamicQuery;
import com.liferay.portal.kernel.dao.orm.QueryUtil;
import com.liferay.portal.kernel.dao.orm.RestrictionsFactoryUtil;
import com.liferay.portal.kernel.util.ParamUtil;
import com.liferay.portal.kernel.util.Validator;

@Component(
    immediate = true,
    property = {
        HttpWhiteboardConstants.HTTP_WHITEBOARD_SERVLET_PATTERN + "=/*"
    },
    service = Servlet.class
)
public class SampleServlet extends HttpServlet {

    private static final long serialVersionUID = 1L;

    @Override
    protected void service(
            HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {

        response.setContentType("text/html");

        PrintWriter writer = response.getWriter();

        String fullNameParameter = ParamUtil.getString(request, "fullName");

        if (Validator.isNull(fullNameParameter)) {
            writer.println("<h2>Hello You!</h2>");
            writer.println("Do you want to sign up for this thing?<br/>");
            writer.println("<form action='/join' method='post'>");
            writer.println("<input type='text' name='fullName' placeholder='Full Name'><br>");
            writer.println("<input type='text' name='emailAddress' placeholder='Email Address'><br>");
            writer.println("<input type='submit' value='Sign Up'><br>");
            writer.println("</form>");

            List<Entry> entries = _entryLocalService.getEntries(QueryUtil.ALL_POS, QueryUtil.ALL_POS);

            if (entries.isEmpty()) {
                writer.println("I'm so lonely! :(<br/>");
            }
            else {
                writer.println("Here's a list of others who've already signed up:<br/>");
                for (Entry entry : _entryLocalService.getEntries(QueryUtil.ALL_POS, QueryUtil.ALL_POS)) {
                    writer.println(String.format("%s &lt;%s><br/>", entry.getFullName(), entry.getEmailAddress()));
                }
            }

            return;
        }

        String emailAddressParameter = ParamUtil.getString(request, "emailAddress");

        if (Validator.isNull(emailAddressParameter)) {
            writer.println(String.format("Ooops! %s, you forgot your emailAddress :(<br/>", fullNameParameter));
            writer.println("<a href='/'>Retry?</a>");

            return;
        }

        DynamicQuery dynamicQuery = _entryLocalService.dynamicQuery();

        dynamicQuery.add(RestrictionsFactoryUtil.eq("emailAddress", emailAddressParameter));

        long count = _entryLocalService.dynamicQueryCount(dynamicQuery);

        if (count > 0) {
            writer.println(String.format("Ooops! Someone already registered with the email address &lt;%s> :(<br/>", emailAddressParameter));
            writer.println("<a href='/'>Retry?</a>");

            return;
        }

        long entryId = _counterLocalService.increment();

        Entry entry = _entryLocalService.createEntry(entryId);

        entry.setFullName(fullNameParameter);
        entry.setEmailAddress(emailAddressParameter);

        _entryLocalService.updateEntry(entry);

        writer.println(String.format("Great! Thanks for signing up %s :D<br/>", fullNameParameter));
        writer.println("<a href='/'>Go Back!</a>");
    }

    @Reference
    private CounterLocalService _counterLocalService;

    @Reference
    private EntryLocalService _entryLocalService;

}
```

Note how it uses OSGi Declarative Services to reference an instance of Portal Kernel's `CounterLocalService` and Contacts API's `EntryLocalService`.

113.7 Injecting Service Components into Tests

You can use Liferay DXP's `@Inject` annotation to inject service components into a test, like you use the `@Reference` annotation to inject service components into a module component.

`@Inject` uses reflection to inject a field with a service component object matching the field's interface. Test rule `LiferayIntegrationTestRule` provides this annotation. The annotation accepts `filter` and `type` parameters, which you can use separately or together.

DXP Digital Enterprise 7.0 Fix Pack 30 and Liferay CE Portal 7.0 GA5 introduced the `@Inject` annotation.

To fill a field with a particular implementation or sub-class object, set the `type` with it.

```
@Inject(type = SubClass.class)
```

Replace `SubClass` with the name of the service interface to inject.

Here's an example test class that injects a `DDLServiceUpgrade` object into an `UpgradeStepRegistrator` interface field:

```
public class Test {

    @ClassRule
    @Rule
    public static final AggregateTestRule aggregateTestRule =
        new LiferayIntegrationTestRule();

    @Test
    public void testSomething() {
        // your test code here
    }

    @Inject(
        filter = "(&(objectClass=com.liferay.dynamic.data.lists.internal.upgrade.DDLServiceUpgrade))"
    )
    private static UpgradeStepRegistrator _upgradeStepRegistrator;

}
```

Here's how to inject a service component into a test class:

1. In your test class, add a rule field of type `com.liferay.portal.test.rule.LiferayIntegrationTestRule`. For example,

   ```
   @ClassRule
   @Rule
   public static final AggregateTestRule aggregateTestRule =
       new LiferayIntegrationTestRule();
   ```

2. Add a field to hold a service component. Making the field static improves efficiency, because the container injects static fields once before test runs and nulls them after all tests run. Non-static fields are injected before each test run but stay in memory till all tests finish.

3. Annotate the field with an `@Inject` annotation. By default, the container injects the field with a service component object matching the field's type.

4. Optionally add a `filter` string or `type` parameter to further specify the service component object to inject.

At runtime, the `@Inject` annotation blocks the test until a matching service component is available. The block has a timeout and messages are logged regarding the test's unavailable dependencies.

Important: If you're publishing the service component you are injecting, the test might never run. If you must publish the service component from the test class, use Service Trackers to access service components.

Great! Now you can inject service components into your tests.

Chapter 114

Modularity and OSGi

Things we use every day are made of carefully designed, created, and tested subsystems. For example, a car has an engine, suspension, and air conditioner. Teams of engineers, machinists, and technicians make these subsystems the best they can be separately before combining them to create a high quality car. This is modularity in action–creating things from smaller well-designed, well-tested parts.

Liferay DXP is modular too. It comprises code modules created and tested independently and in parallel. It's a platform on which modules and modular applications are installed, started, used, stopped, and uninstalled. Liferay DXP's components use the OSGi modularity standard.

These tutorials demonstrate developing OSGi services and components to customize Liferay DXP and create applications on it. As Liferay's developers used modules to create Liferay DXP and its applications, you and your teammates can enjoy developing your own modules, applications, and customizations in parallel on Liferay DXP.

114.1 The Benefits of Modularity

Dictionary.com defines modularity as *the use of individually distinct functional units, as in assembling an electronic or mechanical system*. The distinct functional units are called *modules*.

NASA's Apollo spacecraft, for example, comprised three modules, each with a distinct function:

- *Lunar Module*: Carried astronauts from the Apollo spacecraft to the moon's surface and back.
- *Service Module*: Provided fuel for propulsion, air conditioning, and water.
- *Command Module*: Housed the astronauts and communication and navigation controls.

The spacecraft and its modules exemplified these modularity characteristics:

- **Distinct functionality**: Each module provides a distinct function (purpose); modules can be combined to provide an entirely new collective function.

  The Apollo spacecraft's modules were grouped together for a distinct collective function: take astronauts from the Earth's atmospheric rim, to the moon's surface, and back to Earth. The previous list identifies each module's distinct function.

- **Dependencies**: Modules can require capabilities other modules satisfy.

  The Apollo modules had these dependencies:

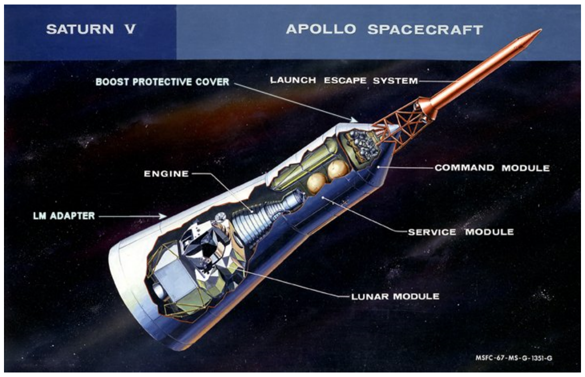

Figure 114.1: The Apollo spacecraft's modules collectively took astronauts to the moon's surface and back to Earth.

  - Lunar Module depended on the Service Module to get near the moon.
  - Command Module depended on the Service Module for power and oxygen.
  - Service Module depended on the Command Module for instruction.

- **Encapsulation**: Modules hide their implementation details but publicly define their capabilities and interfaces.

  Each Apollo module was commissioned with a contract defining its capabilities and interface, while each module's details were encapsulated (hidden) from other modules. NASA integrated the modules based on their interfaces.

- **Reusability**: A module can be applied to different scenarios.

  The Command Module's structure and design were reusable. NASA used different versions of the Command Module, for example, throughout the Apollo program, and in the Gemini Program, which focused on Earth orbit.

NASA used modularity to successfully complete over a dozen missions to the moon. Can modularity benefit software too? Yes! The following sections show you how:

- Modularity benefits for software
- Example: How to design a modular application

Modularity Benefits for Software

Java applications have predominantly been monolithic: they're developed in large code bases. In a monolith, it's difficult to avoid tight coupling of classes. Modular application design, conversely, facilitates loose coupling, making the code easier to maintain. It's much easier and more fun to develop small amounts of cohesive code in modules. Here are some key benefits of developing modular software.

Distinct Functionality

It's natural to focus on developing one piece of software at a time. In a module, you work on a small set of classes to define and implement the module's function. Keeping scope small facilitates writing high quality, elegant code. The more cohesive the code, the easier it is to test, debug, and maintain. Modules can be combined to provide a new function, distinguishable from each module's function.

Encapsulation

A module encapsulates a function (capability). Module implementations are hidden from consumers, so you can create and modify them as you like. Throughout a module's lifetime, you can fix and improve the implementation or swap in an entirely new one. You make the changes behind the scenes, transparent to consumers. A module's contract defines its capability and interface, making the module easy to understand and use.

Dependencies

Modules have requirements and capabilities. The interaction between modules is a function of the capability of one satisfying the requirement of another and so on. Modules are published to artifact repositories, such as Maven Central. Module versioning schemes let you specify dependencies on particular module versions or version ranges.

Reusability

Modules that do their job well are hot commodities. They're reusable across projects, for different purposes. As you discover helpful reliable modules, you'll use them again and again.

It's time to design a modular application.

Example: Designing a Modular Application

Application design often starts out simple but gets more complex as you determine capabilities the application requires. If a third party library already provides the capability, you can deploy it with your app. You can otherwise implement the capability yourself.

As you design various aspects of your app to support its function, you must decide how those aspects fit into the code base. Putting them in a single monolithic code base often leads to tight coupling, while designating separate modules for each aspect fosters loose coupling. Adopting a modular approach to application design lets you reap the modularity benefits.

For example, you can apply modular design to a speech recognition app. Here are the app's function and required capabilities:

Function: interface with users to translate their speech into text for the computer to understand.

Required capabilities: - Translates user words to text - Uses a selected computer voice to speak to users. - Interacts with users based on a script of instructions that include questions, commands, requests, and confirmations.

You could create modules to provide the required capabilities:

- *Speech to text*: Translates spoken words to text the computer understands.
- *Voice UI*: Interacts with users based on stored questions, commands, and confirmations.
- *Instruction manager*: Stores and provides the application's questions, commands, and confirmations.
- *Computer voice*: Stores and provides computer voices for users to choose from.

The following diagram contrasts a monolithic design for the speech recognition application with a modular design.

Designing the app as a monolith lumps everything together. There are no initial boundaries between the application aspects, whereas the modular design distinguishes the aspects.

Developers can create the modules in parallel, each one with its own particular capability. Designing applications that comprise modules fosters writing cohesive pieces of code that represent capabilities. Each module's capability can potentially be *reused* in other scenarios too.

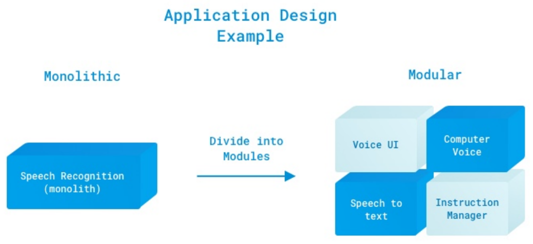

Figure 114.2: The speech recognition application can be implemented in a single monolithic code base or in modules, each focused on a particular function.

For example, the *Instruction manager* and *Computer voice* modules can be *reused* by a navigation app.

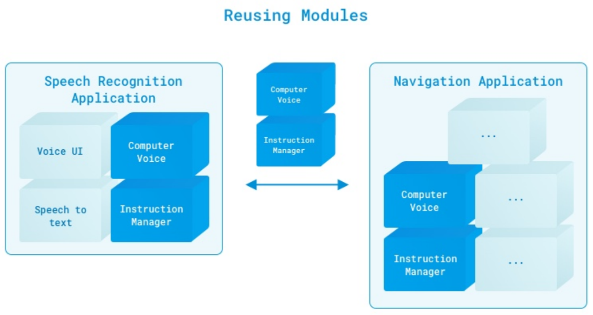

Figure 114.3: The *Instruction manager* and *Computer voice* modules designed for the speech recognition app can be used (or *reused*) by a navigation app.

Here are the benefits of designing the speech recognition app as modules:

- Each module represents a capability that contributes to the app's overall function.
- The app depends on modules, that are easy to develop, test, and maintain.
- The modules can be reused in different applications.

In conclusion, modularity has literally taken us to the moon and back. It benefits software development too. The example speech recognition application demonstrated how to design an app that comprises modules.

Next you'll learn how OSGi facilitates creating modules that provide and consume services.

114.2 OSGi and Modularity

Modularity makes writing software, especially as a team, fun! Here are some benefits to modular development on DXP:

- Liferay DXP's runtime framework is lightweight, fast, and secure.
- The framework uses the OSGi standard. If you have experience using OSGi with other projects, you can apply your existing knowledge to developing on DXP.
- Modules publish services to and consume services from a service registry. Service contracts are loosely coupled from service providers and consumers, and the registry manages the contracts automatically.
- Modules' dependencies are managed automatically by the container, dynamically (no restart required).

- The container manages module life cycles dynamically. Modules can be installed, started, updated, stopped, and uninstalled while Liferay DXP is running, making deployment a snap.
- Only a module's classes whose packages are explicitly exported are publicly visible; OSGi hides all other classes by default.
- Modules and packages are semantically versioned and declare dependencies on specific versions of other packages. This allows two applications that depend on different versions of the same packages to each depend on their own versions of the packages.
- Team members can develop, test, and improve modules in parallel.
- You can use your existing developer tools and environment to develop modules.

There are many benefits to modular software development with OSGi, and we can only scratch the surface here. Once you start developing modules, you might find it hard to go back to developing any other way.

Modules

It's time to see what module projects look like and see Liferay DXP's modular development features in action. To keep things simple, only project code and structure are shown: you can create modules like these anytime.

These modules collectively provide a command that takes a String and uses it in a greeting. Consider it "Hello World" for modules.

API

The API module is first. It defines the contract that a provider implements and a consumer uses. Here is its structure:

- `greeting-api`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/greeting/api`
      - `Greeting.java`
  - `bnd.bnd`
  - `build.gradle`

Very simple, right? Beyond the Java source file, there are only two other files: a Gradle build script (though you can use any build system you want), and a configuration file called `bnd.bnd`. The `bnd.bnd` file describes and configures the module:

```
Bundle-Name: Greeting API
Bundle-SymbolicName: com.liferay.docs.greeting.api
Bundle-Version: 1.0.0
Export-Package: com.liferay.docs.greeting.api
```

The module's name is *Greeting API*. Its symbolic name–a name that ensures uniqueness–is `com.liferay.docs.greeting.api`. Its semantic version is declared next, and its package is *exported*, which means it's made available to other modules. This module's package is just an API other modules can implement.

Finally, there's the Java class, which in this case is an interface:

```
package com.liferay.docs.greeting.api;

import aQute.bnd.annotation.ProviderType;

@ProviderType
public interface Greeting {

        public void greet(String name);

}
```

The interface's `@ProviderType` annotation tells the service registry that anything implementing the interface is a provider. The interface's one method asks for a `String` and doesn't return anything.

That's it! As you can see, creating modules is not very different from creating other Java projects.

Provider

An interface only defines an API; to do something, it must be implemented. This is what the provider module is for. Here's what a provider module for the Greeting API looks like:

- `greeting-impl`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/greeting/impl`
      - `GreetingImpl.java`
  - `bnd.bnd`
  - `build.gradle`

It has the same structure as the API module: a build script, a `bnd.bnd` configuration file, and an implementation class. The only differences are the file contents. The `bnd.bnd` file is a little different:

```
Bundle-Name: Greeting Impl
Bundle-SymbolicName: com.liferay.docs.greeting.impl
Bundle-Version: 1.0.0
```

The bundle name, symbolic name, and version are all set similarly to the API.

Finally, there's no `Export-Package` declaration. A client (which is the third module you'll create) just wants to use the API: it doesn't care how its implementation works as long as the API returns what it's supposed to return. The client, then, only needs to declare a dependency on the API; the service registry injects the appropriate implementation at runtime.

Pretty cool, eh?

All that's left, then, is the class that provides the implementation:

```
package com.liferay.docs.greeting.impl;

import com.liferay.docs.greeting.api.Greeting;

import org.osgi.service.component.annotations.Component;

@Component(
    immediate = true,
    property = {
    },
    service = Greeting.class
)
public class GreetingImpl implements Greeting {

    @Override
    public void greet(String name) {
        System.out.println("Hello " + name + "!");
    }

}
```

The implementation is simple. It uses the `String` as a name and prints a hello message. A better implementation might be to use Liferay DXP's API to collect all the names of all the users in the system and send each user a greeting notification, but the point here is to keep things simple. You should understand, though, that there's nothing stopping you from replacing this implementation by deploying another module whose Greeting implementation's `@Component` annotation specifies a higher service ranking property (e.g., `"service.ranking:Integer=100"`).

This `@Component` annotation defines three options: `immediate = true`, an empty property list, and the service class that it implements. The `immediate = true` setting means that this module should not be lazy-loaded; the service registry loads it as soon as it's deployed, instead of when it's first used. Using the `@Component` annotation declares the class as a Declarative Services component, which is the most straightforward way to create components for OSGi modules. A component is a POJO that the runtime creates automatically when the module starts.

To compile this module, the API it's implementing must be on the classpath. If you're using Gradle, you'd add the `greetings-api` project to your `dependencies { ... }` block. In a Liferay Workspace module, the dependency looks like this:

```
compileOnly project (':modules:greeting-api')
```

That's all there is to a provider module.

Consumer

The consumer or client uses the API that the API module defines and the provider module implements. DXP has many different kinds of consumer modules. Portlets are the most common consumer module type, but since they are a topic all by themselves, this example stays simple by creating an command for the Apache Felix Gogo shell. Note that consumers can, of course, consume many different APIs to provide functionality.

A consumer module has the same structure as the other module types:

- `greeting-command`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/greeting/command`
      - `GreetingCommand.java`
  - `bnd.bnd`
  - `build.gradle`

Again, you have a build script, a `bnd.bnd` file, and a Java class. This module's `bnd.bnd` file is almost the same as the provider's:

```
Bundle-Name: Greeting Command
Bundle-SymbolicName: com.liferay.docs.greeting.command
Bundle-Version: 1.0.0
```

There's nothing new here: you declare the same things you declared for the provider.

Your Java class has a little bit more going on:

```
package com.liferay.docs.greeting.command;

import org.osgi.service.component.annotations.Component;
import org.osgi.service.component.annotations.Reference;

import com.liferay.docs.greeting.api.Greeting;

@Component(
    immediate = true,
    property = {
        "osgi.command.scope=greet",
        "osgi.command.function=greet"
    },
    service = Object.class
)
public class GreetingCommand {

    public void greet(String name) {
        Greeting greeting = _greeting;

        greeting.greet(name);
    }

    @Reference
    private Greeting _greeting;

}
```

The `@Component` annotation declares the same attributes, but specifies different properties and a different service. As in Java, where every class is a subclass of `java.lang.Object` (even though you don't need to specify it by default), in Declarative Services, the runtime needs to know the type of class to register. Because you're not implementing any particular type, your parent class is `java.lang.Object`, so you must specify that class as the service. While Java doesn't require you to specify `Object` as the parent when you're creating a class that doesn't inherit anything, Declarative Services does.

The two properties define a command scope and a command function. All commands have a scope to define their context, as it's common for multiple APIs to have similar functions, such as `copy` or `delete`. These properties specify you're creating a command called `greet` in a scope called `greet`. While you get no points for imagination, this sufficiently defines the command.

Since you specified `osgi.command.function=greet` in the `@Component` annotation, your class must have a method named `greet`, and you do. But how does this `greet` method work? It obtains an instance of the `Greeting` OSGi service and invokes its `greet` method, passing in the `name` parameter. How is an instance of the `Greeting` OSGi service obtained? The `GreetingCommand` class declares a private service bean, `_greeting` of type `Greeting`. This is the OSGi service type that the provider module registers. The `@Reference` annotation tells the OSGi runtime to instantiate the service bean with a service from the service registry. The runtime binds the `Greeting` object of type `GreetingImpl` to the private field `_greeting`. The `greet` method uses the `_greeting` field value.

Just like the provider, the consumer needs to have the API on its classpath in order to compile, but at runtime, since you've declared all the dependencies appropriately, the container knows about these dependencies, and provides them automatically.

If you were to deploy these modules to a DXP instance, you'd be able to attach to the Gogo Shell and execute a command like this:

```
greet:greet "Captain\ Kirk"
```

The shell would then return your greeting:

```
Hello Captain Kirk!
```

This most basic of examples should make it clear that module-based development is easy and straightforward. The API-Provider-Consumer contract fosters loose coupling, making your software easy to manage, enhance, and support.

A Typical Liferay Application

If you look at a typical application from Liferay DXP's source, you'll generally find at least four modules:

- An API module
- A Service (provider) module
- A Test module
- A Web (consumer) module

This is exactly what you'll find for some smaller applications, like the Mentions application that lets users mention other users with the `@username` nomenclature in comments, blogs, or other applications. Larger applications like the Documents and Media library have more modules. In the case of the Documents and Media library, there are separate modules for different document storage back-ends. In the case of the Wiki, there are separate modules for different Wiki engines.

Encapsulating capability variations as modules facilitates extensibility. If you have a document storage back-end that Liferay DXP doesn't yet support, you can implement Liferay's document storage API for your solution by developing a module for it and thus extend Liferay's Documents and Media library. If there's a Wiki dialect that you like better than what Liferay's wiki provides, you can write a module for it and extend Liferay's wiki.

Are you excited yet? Are you ready to start developing? Here are some resources for you to learn more.

OSGi Basics for Liferay Development

Liferay leverages the OSGi framework to provide a development environment for modular applications. There are many OSGi best practices that Liferay DXP follows to provide an easy-to-develop-for platform. Here, you're introduced to some OSGi basics and common Liferay best practices for your bundle's (module) development.

115.1 Liferay Portal Classloader Hierarchy

All Liferay DXP applications live in its OSGi container. Portal is a web application deployed on your application server. Portal's Module Framework bundles (modules) live in the OSGi container and have class loaders. All the classloaders from Java's Bootstrap classloader to classloaders for bundle classes and JSPs are part of a hierarchy.

This tutorial explains Liferay DXP's classloader hierarchy and describes how it works in the following contexts:

- Web application, such as Liferay Portal, deployed on the app server
- OSGi bundle deployed in the Module Framework

The following diagram shows Liferay DXP's classloader hierarchy.

Here are the classloader descriptions:

- **Bootstrap**: The JRE's classes (from packages `java.*`) and Java extension classes (from `$JAVA_HOME/lib/ext`). No matter the context, loading all `java.*` classes is delegated to the Bootstrap classloader.
- **System**: Classes configured on the `CLASSPATH` and or passed in via the application server's Java classpath (`-cp` or `-classpath`) parameter.
- **Common**: Classes accessible globally to web applications on the application server.
- **Web Application**: Classes in the application's `WEB-INF/classes` folder and `WEB-INF/lib/*.jar`.
- **Module Framework**: Liferay DXP's OSGi module framework classloader which is used to provide controlled isolation for the module framework bundles.
- **bundle**: Classes from a bundle's packages or from packages other bundles export.

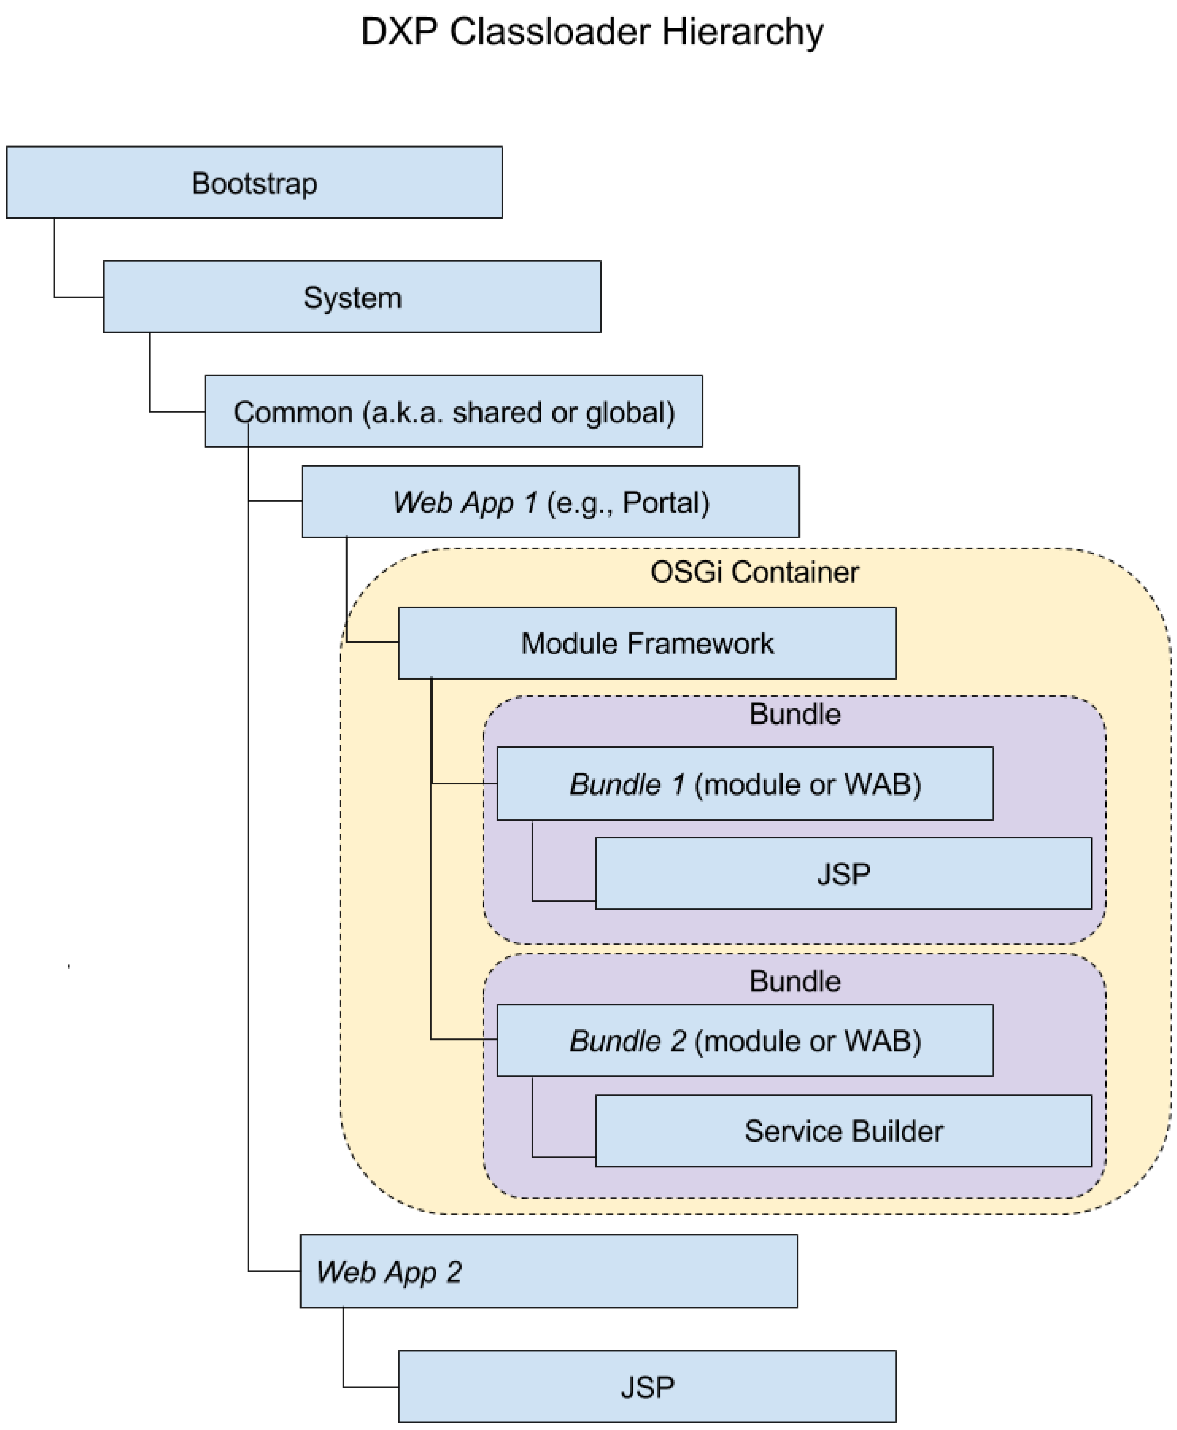

Figure 115.1: 0: Here is Liferay DXP's classloader hierarchy.

- **JSP**: A classloader that aggregates the following bundle and classloaders:
  - Bundle that contains the JSPs' classloader
  - JSP servlet bundle's classloader
  - Javax Expression Language (EL) implementation bundle's classloader
  - Javax JSTL implementation bundle's classloader
- **Service Builder**: Service Builder classes

The classloader used depends on context. Classloading rules vary between application servers. Classloading in web applications and OSGi bundles differs too. In all contexts, however, the Bootstrap classloader loads classes from `java.*` packages.

Classloading from a web application perspective is up next.

Web Application Classloading Perspective

Application servers dictate where and in what order web applications, such as Liferay DXP, search for classes and resources. Application servers such as Apache Tomcat enforce the following default search order:

1. Bootstrap classes
2. Web app's `WEB-INF/classes`
3. web app's `WEB-INF/lib/*.jar`
4. System classloader
5. Common classloader

First, the web application searches Bootstrap. If the class/resource isn't there, the web application searches its own classes and JARs. If the class/resource still isn't found, it checks the System classloader and then Common classloader. Except for the web application checking its own classes and JARs, it searches the hierarchy in parent-first order.

Application servers such as Oracle WebLogic and IBM WebSphere have additional classloaders. They may also have a different classloader hierarchy and search order. Consult your application server's documentation for classloading details.

Other Classloading Perspectives

The Bundle Classloading Flow tutorial explains classloading from an OSGi bundle perspective.

Classloading for JSPs and Service Builder classes is similar to that of web applications and OSGi bundle classes.

You now know Liferay DXP's classloading hierarchy, understand it in context of web applications, and have references to information on other classloading perspectives.

Related Topics

Bundle Classloading Flow

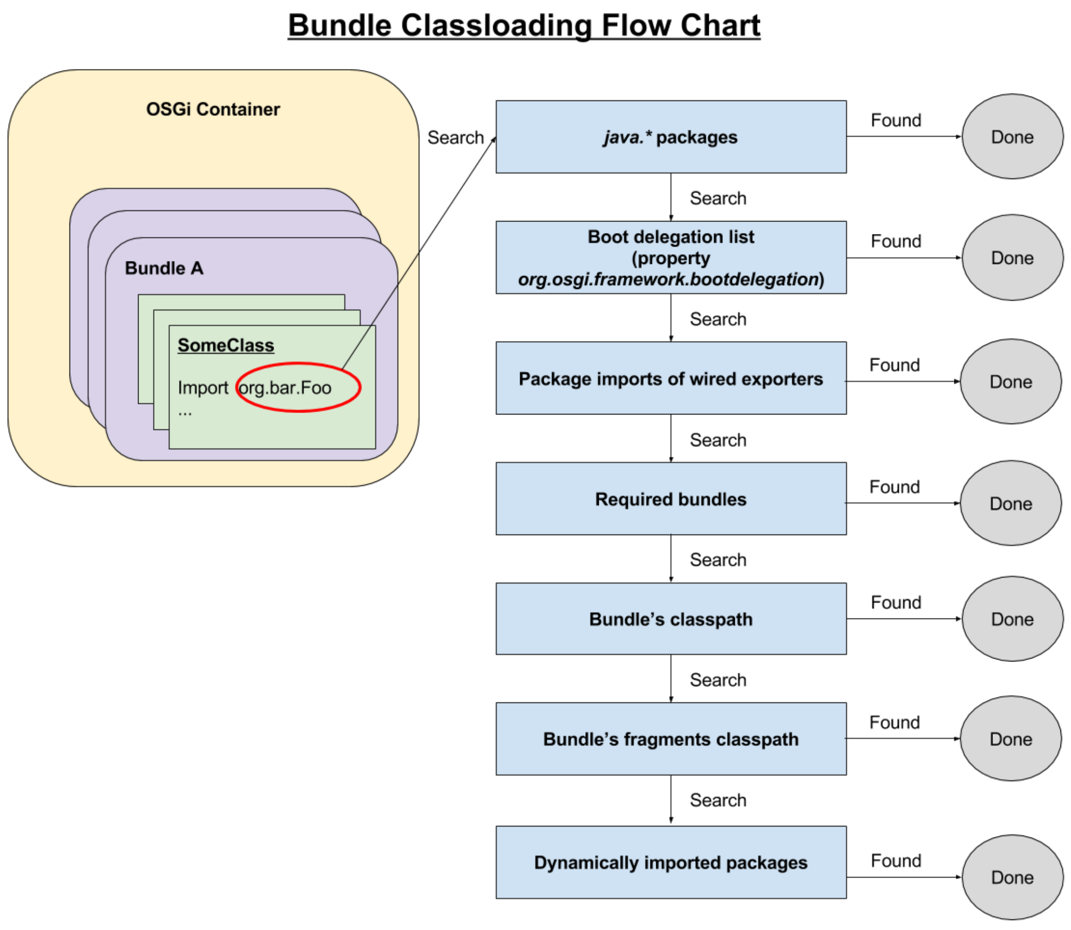

Figure 115.2: 0: This flow chart illustrates classloading in a bundle.

115.2 Bundle Classloading Flow

The OSGi container searches several places for imported classes. It's important to know where it looks and in what order. Liferay DXP's classloading flow for OSGi bundles follows the OSGi Core specification. It's straightforward, but complex. The figure below illustrates the flow and this tutorial walks you through it.

Here is the algorithm for classloading in a bundle:

1. If the class is in a `java.*` package, delegate loading to the parent classloader. Otherwise, continue.

2. If the class is in the OSGi Framework's boot delegation list, delegate loading to the parent classloader. Otherwise, continue.

3. If the class is in one of the packages the bundle imports from a wired exporter, the exporting bundle's classloader loads it. A *wired exporter* is another bundle's classloader that previously loaded the package. If the class isn't found, continue.

4. If the class is imported by one of the bundle's required bundles, the required bundle's classloader loads it.

5. If the class is in the bundle's classpath (manifest header `Bundle-ClassPath`), the bundle's classloader loads it. Otherwise, continue.

6. If the class is in the bundle's fragments classpath, the bundle's classloader loads it.

7. If the class is in a package that's dynamically imported using `DynamicImport-Package` and a wire is established with the exporting bundle, the exporting bundle's classloader loads it. Otherwise, the class isn't found.

Congratulations! Now you know how Liferay DXP finds and loads classes OSGi bundles use.

115.3 Resolving Third Party Library Package Dependencies

The OSGi framework lets you build applications composed of multiple modules. The modules must resolve their Java package dependencies for the framework to assemble the modules into a working system. In a perfect world, every Java library would be an OSGi bundle (module), but many libraries aren't. So how do you resolve the packages your OSGi module needs from non-OSGi third party libraries?

Here is the main workflow for resolving third party Java library packages:

Step 1 - Find an OSGi module of the library: Projects, such as Eclipse Orbit and ServiceMix Bundles, convert hundreds of traditional Java libraries to OSGi modules. Their artifacts are available at these locations:

- Eclipse Orbit
- ServiceMix Bundles

Deploying the module to Liferay's OSGi framework lets you share it on the system. If you find a module for the library you need, deploy it. Then add a `compileOnly` (Gradle) or `<scope>provided</scope>` (Maven) dependency for it in your module. When you deploy your module, the OSGi framework wires the dependency module to your module. If there's no OSGi module based on the Java library, go to Step 2.

Tip: Refrain from embedding library JARs that provide the same packages that Liferay DXP or existing modules provide already.

Note: If you're developing a WAR that requires a different version of a third-party package that Liferay DXP or another module exports, specify that package in your `Import-Package:` list. If the package provider is an OSGi module, publish its exported packages by deploying that module. Otherwise, rename the third-party library (not an OSGi module) differently from the JAR that the WAB generator excludes and embed the JAR in your project.

Step 2 - Resolve the Java packages privately in your module: You can copy required library packages into your OSGi module or embed them wholesale, if you must. The rest of the tutorial shows you how to do this.

Note: Liferay's Gradle plugin `com.liferay.plugin` automates several third party library configuration steps. The plugin is applied to Liferay Workspace Gradle module projects created in Liferay @ide@ or using Liferay Blade CLI automatically.

To leverage the `com.liferay.plugin` plugin outside of Liferay Workspace, add code like the listing below to your Gradle project:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins", version: "3.2.29"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.plugin"
```

If you use Gradle without the `com.liferay.plugin` plugin, you'll have to embed the third party libraries wholesale.

The recommended package resolution workflow is next.

Library Package Resolution Workflow

When you depend on a library JAR, much of the time you only need parts of it. Explicitly specifying only the Java packages you need makes your bundle more modular. This also insulates modules that depend on your module from unneeded packages.

Here's a configuration workflow that minimizes dependencies and Java package imports:

1. Add the library as a compile-only dependency (e.g., `compileOnly` in Gradle).

2. Copy only the library packages you need by specifying them in a conditional package instruction (`Conditional-Package`) in your `bnd.bnd` file. Here are some examples:

   `Conditional-Package: foo.common*` adds packages your module uses such as `foo.common`, `foo.common-messages`, `foo.common-web` to your module's class path.

   `Conditional-Package: foo.bar.*` adds packages your module uses such as `foo.bar` and all its sub-packages (e.g., `foo.bar.baz`, `foo.bar.biz`, etc.) to your module's class path.

   Deploy your module. If a class your module needs or class its dependencies need isn't found, go back to main workflow **Step 1 - Find an OSGi module version of the library** to resolve it.

   Important: Resolving packages by using compile-only dependencies and conditional package instructions assures you use only the packages you need and avoids unnecessary transitive dependencies. It's recommended to use the steps up to this point, as much as possible, to resolve required packages.

3. If a library package you depend on requires non-class files (e.g., DLLs, descriptors) from the library, then you might need to embed the library wholesale in your module. This adds the entire library to your module's classpath.

Next you'll learn how to embed libraries in your module.

Embedding Libraries in a Module

You can use Gradle, Maven, or Ivy to embed libraries in your module. Below are examples for adding Apache Shiro using all three build utilities.

Embedding a Library Using Gradle

Open your module's `build.gradle` file and add the library as a dependency in the `compileInclude` configuration:

```
dependencies {
    compileInclude group: 'org.apache.shiro', name: 'shiro-core', version: '1.1.0'
}
```

The `com.liferay.plugin` plugin's `compileInclude` configuration is transitive. The `compileInclude` configuration embeds the artifact and all its dependencies in a `lib` folder in the module's JAR. Also, it adds the artifact JARs to the module's `Bundle-ClassPath` manifest header.

Note: The `compileInclude` configuration does not download transitive optional dependencies. If your module requires such artifacts, add them as you would another third party library.

Note: If the library you've added as a dependency in your `build.gradle` file has transitive dependencies, you can reference them in an `-includeresource:` instruction by name without having to add them explicitly to the list of dependencies. See how it's used in the Maven section next.

Embedding a Library Using Maven or Ivy

Follow these steps:

1. Open your module's build file and add the library as a dependency in the `provided` scope:

   Maven:

   ```
   <dependency>
     <groupId>org.apache.shiro</groupId>
     <artifactId>shiro-core</artifactId>
     <version>1.1.0</version>
     <scope>provided</scope>
   </dependency>
   ```

   Ant/Ivy:

   ```
   <dependency conf="provided" name="shiro-core" org="org.apache.shiro" rev="1.1.0" />
   ```

2. Open your module's `bnd.bnd` file and add the library to an `-includeresource` instruction:

   ```
   -includeresource: META-INF/lib/shiro-core.jar=shiro-core-[0-9]*.jar;lib:=true
   ```

   This instruction adds the `shiro-core-[version].jar` file as an included resource in the module's `META-INF/lib` folder. The `META-INF/lib/shiro-core.jar` is your module's embedded library. The expression `[0-9]*` helps the build tool match the library version to make available on the module's classpath. The `lib:=true` directive adds the embedded JAR to the module's classpath via the `Bundle-Classpath` manifest header.

Lastly, if after embedding a library you get unresolved imports when trying to deploy to Liferay, you may need to blacklist some imports:

```
Import-Package:\
    !foo.bar.baz,\
    *
```

The * character represents all packages that the module refers to explicitly. Bnd detects the referenced packages.

Congratulations! Resolving all of your module's package dependencies, especially those from traditional Java libraries, is a quite an accomplishment.

115.4 Overriding Reluctant Service References

When there's an existing service that you want to customize or implement differently, you can override the existing one. To do this, you create and deploy a new, higher-ranked service implementation. But how do you replace a component's service that's bound by a static and reluctant reference? Reactivating the component would bind it to the new service but would render the component temporarily inactive. To replace the service and keep the component active, you can change the component's service reference to target your new service.

Here are the steps for overriding a component's service reference:

1. Find the component and service details.
2. Create a custom service.
3. Configure the component to use the custom service.

Throughout the tutorial, example modules `override-my-service-reference` and `overriding-service-reference` are used. You can download them and build them using Gradle (bundled with each module) or you can apply the tutorial steps to configure your own customization. Executing `gradlew jar` in each example module root generates the module JAR to the `build/libs` folder.

- `override-my-service-reference` (download): This module's portlet component `OverrideMyServiceReferencePortlet`'s field `_someService` references a service of type `SomeService`. The reference's policy is static and reluctant. By default, it binds to an implementation called `SomeServiceImpl`.

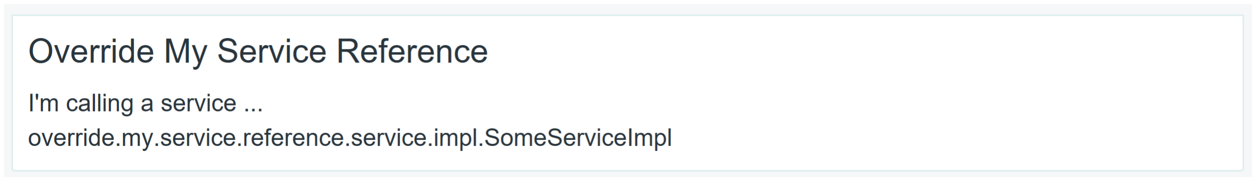
- `overriding-service-reference` (download): Provides a custom `SomeService` implementation called `CustomServiceImpl`. The module's configuration file overrides `OverrideMyServiceReferencePortlet`'s `SomeService` reference so that it binds to `CustomServiceImpl`.

The first step to overriding a service reference is finding the name of the component, service reference, and service interface. If you already have them, you can skip the next section.

Find the Component and Service Reference

You must have the following information to create a custom service and configure the component to use it.

- *Component name*: Name of the component whose service to replace.
- *Reference name*: Name of the component field that references the service.



Override My Service Reference

I'm calling a service ...
override.my.service.reference.service.impl.SomeServiceImpl

Figure 115.3: Prior to overriding the service reference in example portlet module `override-my-service-reference`, the portlet's message indicates it's calling the default service implementation `override.my.service.reference.service.impl.SomeServiceImpl`

- *Service interface*: Fully qualified name of the referenced service interface.

You can find the component using Liferay DXP's Application Manager and find the service reference information using Felix Gogo Shell.

Gogo Shell's Service Component Runtime (SCR) commands help you inspect components. The Gogo Shell command `scr:info [componentName]` lists the component's attributes, including the services it uses. Execute the command using Liferay Blade CLI or in Gogo Shell via telnet.

Here's an example of executing the `scr:info` command in a Gogo Shell telnet session:

```
scr:info override.my.service.reference.OverrideMyServiceReference
```

The resulting SCR information includes the component's service references.

For example, the following information describes the component's reference to service `SomeService`:

```
...
Component Description:
    Name: override.my.service.reference.portlet.OverrideMyServiceReferencePortlet
...
Reference: _someService
    Interface Name: override.my.service.reference.service.api.SomeService
    Cardinality: 1..1
    Policy: static
    Policy option: reluctant
    Reference Scope: bundle
...
```

Copy the following values from the command results. You'll use them in the custom service and service reference configuration you create later.

- *Component*: The component name you passed to the `scr:info` command.
- *Reference*: The *Reference* value.
- *Interface*: The *Interface Name* in the *Reference* section.

Note that the example result confirm's that the reference's policy and policy option are `static` and `reluctant`, respectively.

Here are the values for the example:

- *Component name*: `override.my.service.reference.portlet.OverrideMyServiceReferencePortlet`
- *Reference name*: `_someService`
- *Service interface*: `override.my.service.reference.service.api.SomeService`

The `scr:info` result's component configuration describes the service component implementation bound to the reference.

```
...
Component Configuration:
ComponentId: 2399
State: active
SatisfiedReference: _someService
  Target: null
  Bound to:        6840
      Properties:
        component.id = 2400
        component.name = override.my.service.reference.service.impl.SomeServiceImpl
        objectClass = [override.my.service.reference.service.api.SomeService]
        service.bundleid = 524
        service.id = 6840
        service.scope = bundle
...
```

The example's reference is bound to a component named `override.my.service.reference.service.impl.SomeServiceImpl`. By the end of this tutorial, the reference will be reconfigured to bind to a custom service implementation.

Note: OSGi Configuration Admin makes all Declarative Services components configurable, even if they don't explicitly declare anything about configuration. Each `@Reference` annotation in the source code has a name property, either *explicitly* set in the annotation or *implicitly* derived from the name of the member on which the annotation is used.

- If no reference name property is used and the `@Reference` is on a field, then the reference name is the field name.
- If the `@Reference` is on a method, then heuristics derive the reference name. Method name prefixes such as `set`, `add`, and `put` are ignored. If `@Reference` is on a method called`setSearchEngine(SearchEngine se)`, for example, then the reference name is `SearchEngine`.

Once you've found the referenced service component implementation, you can implement a replacement for it. If you've already created one, you can skip this section.

Create Your Service

It's time to create your own service implementation. Refer to the appropriate app, app suite, and Liferay DXP module Javadoc for service interface details.

Create a module and implement your service in it. Use the `@Component` annotation to make the service a Declarative Services component.

The example custom implementation for service `SomeService` looks like this:

```
@Component(
    immediate = true,
    service = SomeService.class
)
public class CustomServiceImpl implements SomeService {

    @Override
    public String doSomething() {

        StringBuilder sb = new StringBuilder();
        sb.append(this.getClass().getName());
        sb.append(", which delegates to ");
        sb.append(_defaultService.doSomething());

        return sb.toString();
    }
    @Reference  (
        unbind = "-",
        target = "(component.name=override.my.service.reference.service.impl.SomeServiceImpl)"
    )
    private SomeService _defaultService;
}
```

The service component above refers to the default service so that it can delegate work to it in its `doSomething` method. The reference targets the default service by its component name `override.my.service.reference.service.impl.SomeServiceImpl`.

To register your service with the Liferay DXP's OSGi runtime framework, deploy its module. To bind the component reference to your custom service, you must create and deploy instructions that configure the component reference to target your custom service.

Configure the Component to Use Your Service

You're ready to change the component's service reference to target your service. Liferay DXP's Configuration Admin lets you use configuration files to swap in service references on the fly.

1. Create a configuration file named after the referencing component. Here's the example component's configuration file name:

   ```
   override.my.service.reference.portlet.OverrideMyServiceReferencePortlet.config
   ```

```
**Note:** Liferay DXP DE 7.0 Fix Pack 8 and later, and Liferay CE Portal 7.0
GA4 and later support the Apache Felix ConfigAdmin implementation of OSGi
Configuration Admin files. Felix ConfigAdmin uses the file suffix `.config`
and supports additional types, such as arrays and vectors. The syntax for
`.config` and `.cfg` files can be found
[here](https://sling.apache.org/documentation/bundles/configuration-installer-factory.html).
```

---

2. In the configuration file, add a reference target entry that filters on your custom service. Follow this format for the entry:

   ```
   [reference].target=[filter]
   ```

   Replace `[reference]` with the name of the reference you're overriding. Replace `[filter]` with service properties that filter on your custom service.

```
**Tip**: You can use a `component.name` or `objectClass` reference to filter
on your custom implementation.
```

```
A `.config` file reference target entry for the example looks like this:

    _someService.target="(component.name\=overriding.service.reference.service.CustomServiceImpl)"

[The `.config` file syntax](https://sling.apache.org/documentation/bundles/configuration-installer-factory.html#configuration-files-
config)
requires surrounding the value in double quotes and escaping the value's
equals sign.

A `.cfg` file entry for the example looks like this:

    _someService.target=(component.name=overriding.service.reference.service.CustomServiceImpl)
```

3. Optionally, you can add a `cardinality.minimum` entry to specify the number of services the reference can use. Here's the format:

   ```
   [reference].cardinality.minimum=[int]
   ```

   Here's an example cardinality minimum:

   ```
   _someService.cardinality.minimum=1
   ```

4. Deploy the configuration by copying the configuration file into the folder `[Liferay_Home]/osgi/configs`.

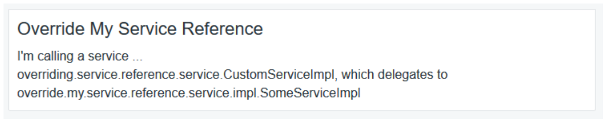
Executing `scr:info` on your component shows that the custom service implementation is now bound to the reference.

For example, executing `scr:info override.my.service.reference.portlet.OverrideMyServiceReferencePortlet` reports the following information:

```
...
Component Description:
  Name: override.my.service.reference.portlet.OverrideMyServiceReferencePortlet
  ...
  Reference: _someService
    Interface Name: override.my.service.reference.service.api.SomeService
    Cardinality: 1..1
    Policy: static
    Policy option: reluctant
    Reference Scope: bundle
    ...
  Component Configuration:
    ComponentId: 2399
    State: active
    SatisfiedReference: _someService
      Target: (component.name=overriding.service.reference.CustomServiceImpl)
      Bound to:        6841
          Properties:
            _defaultService.target = (component.name=overriding.service.reference.service.CustomServiceImpl)
            component.id = 2398
            component.name = overriding.service.reference.service.CustomServiceImpl
            objectClass = [override.my.service.reference.service.api.SomeService]
            service.bundleid = 525
            service.id = 6841
            service.scope = bundle
      Component Configuration Properties:
        _someService.target = (component.name=overriding.service.reference.service.CustomServiceImpl)
        ...
```

The example component's `_someService` reference targets custom service component `overriding.service.reference.servi`
`CustomServiceImpl` references default service `SomeServiceImpl` to delegates work to it.

Liferay DXP processed the configuration file and injected the service reference, which in turn bound the custom service to the referencing component!



Override My Service Reference

I'm calling a service ...
overriding.service.reference.service.CustomServiceImpl, which delegates to
override.my.service.reference.service.impl.SomeServiceImpl

Figure 115.4: Because the example component's service reference is overridden by the configuration file deployment, the portlet indicates it's calling the custom service.

115.5 Using the WAB Generator

Developers creating applications for 7.0 can choose to create them as Java EE-style Web Application ARchive (WAR) artifacts or as Java ARchive (JAR) OSGi bundle artifacts. Some plugin developers, however, don't have that flexibility. Portlets like Spring MVC and JSF must be packaged as WAR artifacts because their frameworks are designed for Java EE. Therefore, they expect a WAR layout and require Java EE resources such as the `WEB-INF/web.xml` descriptor.

Liferay provides a way for these WAR-styled plugins to be deployed and treated like OSGi modules by Liferay's OSGi runtime. They can be converted to *WABs*.

7.0 supports the OSGi Web Application Bundle (WAB) standard for deployment of Java EE style WARs. Simply put, a WAB is an archive that has a WAR layout and contains a `META-INF/MANIFEST.MF` file with the `Bundle-SymbolicName` OSGi directive. A WAB is an OSGi bundle. Although the source of the project has a WAR layout, the artifact filename may end with either the `.jar` or `.war` extension.

Liferay only supports the use of WABs that have been auto-generated by the WAB Generator. The WAB Generator transforms a general WAR-style plugin into a WAB during its deployment process. So what exactly does the WAB Generator do to a WAR file to transform it into a WAB?

The WAB Generator detects packages referenced in a plugin WAR's JSPs, descriptor files, and classes (in `WEB-INF/classes` and embedded JARs). The descriptor files include `web.xml`, `liferay-web.xml`, `portlet.xml`, `liferay-portlet.xml`, and `liferay-hook.xml`. The WAB Generator verifies whether the detected packages are in the plugin's `WEB-INF/classes` folder or in an embedded JAR in the `WEB-INF/lib` folder. Packages that aren't found in either location are added to an `Import-Package` header in the WAB's `META-INF/MANIFEST.MF` file.

To import a package that is only referenced in the following types of locations, you must add an `Import-Package` OSGi header to the plugin's `WEB-INF/liferay-plugin-package.properties` file and add the package to the header's list of values. - Unrecognized descriptor file - Custom or unrecognized descriptor element or attribute - Reflection code - Class loader code

---

Note: A known issue is preventing packages referenced in `web.xml` file `listener-class` elements from being detected and added to WAB `META-INF/MANIFEST.MF` file `Import-Package` headers. To import such packages, add them to an `Import-Package` header in the plugin's `WEB-INF/liferay-plugin-package.properties` file.

The WAB folder structure and WAR folder structure differ. Consider the following folder structure of a WAR-style portlet:

- my-war-portlet
    - src

        * main

            - java
            - webapp
            - WEB-INF
            - classes
            - lib
            - resources
            - views
            - faces-config.xml
            - liferay-display.xml
            - liferay-plugin-package.properties
            - liferay-portlet.xml
            - portlet.xml
            - web.xml

When a WAR-style portlet is deployed to Liferay DXP and processed by the WAB Generator, the portlet's folder structure is transformed to something like this

- my-war-portlet-that-is-now-a-wab

    - META-INF

        * MANIFEST.MF

    - WEB-INF

        * classes
        * lib
        * resources
        * views
        * faces-config.xml
        * liferay-display.xml
        * liferay-plugin-package.properties
        * liferay-portlet.xml
        * portlet.xml
        * web.xml

The major difference is the addition of the `META-INF/MANIFEST.MF` file. The WAB Generator automatically generates an OSGi-ready `MANIFEST.MF` file. If you want to affect the content of the manifest file, you can place BND directives and OSGi headers directly into the `liferay-plugin-package.properties` file. A `bnd.bnd` and/or a build-time plugin (e.g., `bnd-maven-plugin`) should not be provided for your WAR plugin, because the generated WAB cannot make use of them.

Do you want to try this out for yourself? Follow the steps below to see the WAB Generator in action.

1. Create a WAR-style plugin that follows a similar structure to the one outlined above. You can download an example WAR-style portlet here, for demonstration.

2. Open your Liferay DXP instance in a file explorer and add a `portal-ext.properties` file with the following properties:

```
module.framework.web.generator.generated.wabs.store=true
module.framework.web.generator.generated.wabs.store.dir=${module.framework.base.dir}/wabs
```

These properties store your generated WAB into your Liferay DXP instance's `osgi/wabs` folder. You can learn more about these properties in the Module Framework Web Application Bundles properties section. Restart Liferay DXP for these changes to be recognized.

3. Copy your WAR plugin in your Liferay DXP instance's `deploy` folder.

4. Navigate to your Liferay DXP instance's `osgi/wabs` folder and inspect the generated WAB.

Awesome! You've seen the WAB Generator in action!

115.6 Importing Packages

Your modules will often need to use Java classes from packages exported by other modules. When a module is set up to import, the OSGi framework finds other registered modules that export the needed packages and wires them to the importing module. At run time, the importing module gets the class from the wired module that exports the class's package.

For this to happen, a module must specify the `Import-Package` OSGi manifest header with a comma-separated list of the Java packages it needs. For example, if a module needs classes from the `javax.portlet` and `com.liferay.portal.kernel.util` packages, it must specify them like so:

```
Import-Package: javax.portlet,com.liferay.portal.kernel.util,*
```

The * character represents all packages that the module refers to explicitly. Bnd detects the referenced packages.

Import packages must sometimes be specified manually, but not always. Conveniently, Liferay DXP project templates and tools automatically detect the packages a module uses and add them to the package imports in the module JAR's manifest. Let's explore how package imports are specified in different scenarios.

Gradle and Maven module projects created using Blade CLI, Liferay's Maven archetypes, or Liferay @ide@ use bnd. On building such a project's module JAR, bnd detects the packages the module uses and generates a `META-INF/MANIFEST.MF` file whose `Import-Package` header specifies the packages.

Note: Liferay's Maven module archetypes use the `bnd-maven-plugin`. Liferay's Gradle module project templates use a third-party Gradle plugin to invoke bnd.

For example, suppose you're developing a Liferay module using Maven or Gradle. In most cases, you specify your module's dependencies in your `pom.xml` or `build.gradle` file. At build time, the Maven or Gradle bundle plugin reads your `pom.xml` or `build.gradle` file and bnd adds the required `Import-Package` headers to your module JAR's `META-INF/MANIFEST.MF`.

Here's an example dependencies section from a module's `build.gradle` file:

```
dependencies {
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.0.0"
    compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
    compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

And here's the `Import-Package` header that's generated in the module JAR's `META-INF/MANIFEST.MF` file:

```
Import-Package: com.liferay.portal.kernel.portlet.bridges.mvc;version=
"[1.0,2)",com.liferay.portal.kernel.util;version="[7.0,8)",javax.nami
ng,javax.portlet;version="[2.0,3)",javax.servlet,javax.servlet.http,j
avax.sql
```

Note that your build file need only specify JAR file dependencies. bnd examines your module's class path to determine which packages from those JAR files contain classes your application uses and imports the packages. The examination includes all classes found in the class path–even those from embedded third party library JARs.

Regarding classes used by a traditional Liferay plugin WAR, Liferay's WAB Generator detects their use in the WAR's JSPs, descriptor files, and classes (in `WEB-INF/classes` and embedded JARs). The WAB Generator searches the `web.xml`, `liferay-web.xml`, `portlet.xml`, `liferay-portlet.xml`, and `liferay-hook.xml` descriptor files. It adds package imports for classes that are neither found in the plugin's `WEB-INF/classes` folder nor in embedded JARs.

The WAB Generator and bnd don't add package imports for classes referenced in these places:

- Unrecognized descriptor file
- Custom or unrecognized descriptor element or attribute
- Reflection code
- Class loader code

In such cases, you must manually determine these packages and specify an `Import-Package` OSGi header that includes these packages and the packages that Bnd detects automatically. The `Import-Package` header belongs in the location appropriate to your project type:

Project type	`Import-Package` header location
Module (uses bnd)	`[project]/bnd.bnd`
Module (doesn't use bnd)	`[module JAR]/META-INF/MANIFEST.MF`
Traditional Liferay plugin WAR	`WEB-INF/liferay-plugin-package.properties`

Here's an example of adding a package called `com.liferay.docs.foo` to the list of referenced packages that Bnd detects automatically:

```
Import-Package:\
    com.liferay.docs.foo,\
    *
```

Note: The WAB Generator refrains from adding WAR project embedded third-party JARs to a WAB if Liferay DXP already exports the JAR's packages.

If your WAR requires a different version of a third-party package that Liferay DXP exports, specify that package in your `Import-Package:` list. Then if the package provider is an OSGi module, publish its exported packages by deploying the module. If the package provider is not an OSGi module, follow the instructions for adding third-party libraries.

Please see the `Import-Package` header documentation for more information.

Congratulations! Now you can import all kinds of packages for your modules and plugins to use.

Tooling

115.7 Exporting Packages

An OSGi module's Java packages are private by default. To expose a package, you must explicitly export it. This way you share only the classes you want to share. Exporting a package in your OSGi module JAR's manifest makes all the package's classes available for other modules to import.

To export a package, add it to your module's or plugin's `Export-Package` OSGi header. A header exporting `com.liferay.petra.io` and `com.liferay.petra.io.unsync` would look like this:

```
Export-Package:\
com.liferay.petra.io,\
com.liferay.petra.io.unsync
```

The correct location for the header depends on your project's type:

Project Type	`Export-Package` header location
Module (uses bnd)	`[project]/bnd.bnd`
Module (doesn't use bnd)	`[module JAR]/META-INF/MANIFEST.MF`
Traditional Liferay plugin WAR	`WEB-INF/liferay-plugin-package.properties`

Module projects created using Blade CLI, Liferay's Maven archetypes, or Liferay @ide@ use bnd. On building such a project's module JAR, bnd propagates the OSGi headers from the project's `bnd.bnd` file to the JAR's `META-INF/MANIFEST.MF`.

In module projects that don't use bnd, you must manually add package exports to an `Export-Package` header in the module JAR's `META-INF/MANIFEST.MF`.

In traditional Liferay plugin WAR projects, you must add package exports to an `Export-Package` header in the project's `liferay-plugin-package.properties`. On copying the WAR into the `[Liferay Home]/deploy` folder, the WAB Generator propagates the OSGi headers from the WAR's `liferay-plugin-package.properties` file to the `META-INF/MANIFEST.MF` file in the generated Web Application Bundle (WAB).

Note: bnd makes a module's exported packages *substitutable*. That is, the OSGi framework can substitute your module's exported package with a compatible package of the same name, but potentially different version, that's exported from a different module. bnd enables this for your module by automatically making your module import every package it exports. In this way, your module can work on its own, but can also work in conjunction with modules that provide a different (compatible) version, or even the same version, of the package. A package from another module might provide better "wiring" opportunities with other modules. Peter Kriens' blog post provides more details on how substitutable exports works.

Important: Don't export the same package from different JARs. Multiple exports of the same package leads to "split package" issues, whose side affects differ from case to case.

Now you can share your module's or plugin's terrific [EDITOR: or terrible!] packages with other modules!

115.8 Semantic Versioning

Semantic Versioning is a three tiered versioning system that increments version numbers based on the type of API change introduced to a releasable software component. It's a standard way of communicating programmatic compatibility of a package or module for dependent consumers and API implementations. If a package is programmatically (i.e., semantically) incompatible with a project, Bnd (used when building modules) fails that project's build immediately.

The semantic version format looks like this:

```
MAJOR.MINOR.MICRO
```

Certain events force each tier to be incremented:

- *MAJOR:* an incompatible, API-breaking change is made
- *MINOR:* a change that affects only providers of the API, or new backwards- compatible functionality is added
- *MICRO:* a backwards-compatible bug fix is made

For more details on semantic versioning, see the official Semantic Versioning site and OSGi Alliance's Semantic Versioning technical whitepaper.

All of Liferay DXP's modules use Semantic Versioning.

Following Semantic Versioning is especially important because Liferay DXP is a modular platform containing hundreds of independent OSGi modules. With many independent modules containing a slew of dependencies, releasing new package versions can quickly become terrifying. With this complex intertwined system of dependencies, you must meticulously manage your own project's API versions to ensure compatibility for those who leverage it. With Semantic Versioning's straightforward system and the help of Liferay tooling, managing your project's versions is easy.

Baselining Your Project

Following Semantic Versioning manually seems deceptively easy. There's a sad history of good-intentioned developers updating their projects' semantic versions manually, only to find out later they made a mistake. The truth is, it's hard to anticipate the ramifications of a simple update. To avoid this, you can *baseline* your project after it has been updated. Baselining verifies that the Semantic Versioning rules are obeyed by your project. This can catch many obvious API changes that are not so obvious to humans. Care must always be taken, however, when making any kind of code change because this tool is not smart enough to identify compatibility changes not represented in the signatures of Java classes or interfaces, or in API *use* changes (e.g., assumptions about method call order, or changes to input and/or output encoding). Baseline, as the name implies, does give you a certain measure of *baseline* comfort that a large class of compatibility issues won't sneak past you.

You can use Liferay's Baseline Gradle plugin to provide baselining capabilities. Add it to your Gradle build configuration and execute the following command:

```
./gradlew baseline
```

See the Baseline Gradle Plugin article for configuration details. This plugin is not provided in Liferay Workspace by default.

When you run the `baseline` command, the plugin baselines your new module against the latest released non-snapshot module (i.e., the baseline). That is, it compares the public exported API of your new module with the baseline. If there are any changes, it uses the OSGi Semantic Versioning rules to calculate the minimum new version. If your new module has a lower version, errors are thrown.

With baselining, your project's Semantic Versioning is as accurate as its API expresses.

Managing Artifact and Dependency Versions

There are two ways to track your project's artifact and dependency versions with Semantic Versioning:

- Range of versions
- Exact version (one-to-one)

You should track a range of versions if you intend to build your project for multiple versions of Liferay DXP and maintain maximum compatibility. In other words, if several versions of a package work for an app, you can configure the app to use any of them. What's more, Bnd automatically determines the semantically compatible range of each package a module depends on and records the range to the module's manifest.

For help with version range syntax, see the OSGi Specifications.

A version range for imported packages in an OSGi bundle's `bnd.bnd` looks like this:

```
Import-Package: com.liferay.docs.test; version="[1.0.0,2.0.0)"
```

Popular build tools also follow this syntax. In Gradle, a version range for a dependency looks like this:

```
compile group: "com.liferay.portal", name: "com.liferay.portal.test", version: "[1.0.0,2.0.0)"
```

In Maven, it looks like this:

```
<groupId>com.liferay.portal</groupId>
<artifactId>com.liferay.portal.test</artifactId>
<version>[1.0.0,2.0.0)</version>
```

Specifying the latest release version can also be considered a range of versions with no upper limit. For example, in Gradle, it's specified as `version: "latest.release"`. This can be done in Maven 2.x with the usage of the version marker `RELEASE`. This is not possible if you're using Maven 3.x. See Gradle and Maven's respective docs for more information.

Tracking a range of versions comes with a price. It's hard to reproduce old builds when you're debugging an issue. It also comes with the risk of differing behaviors depending on the version used. Also, relying on the latest release could break compatibility with your project if a major change is introduced. You should proceed with caution when specifying a range of versions and ensure your project is tested on all included versions.

Tracking a dependency's exact version is much safer, but is less flexible. This might limit you to a specific version of Liferay DXP. You would also be locked in to APIs that only exist for that specific version. This means your module is much easier to test and has less chance for unexpected failures.

Note: When specifying package versions in your `bnd.bnd` file, exact versions are typically specified like this: `version="1.1.2"`. However, this syntax is technically a range; it is interpreted as [1.1.2, ∞). Therefore, if a higher version of the package is available, it's used instead of the version you specified. For these cases, it may be better to specify a version range for compatible versions that have been tested. If you want to specify a true exact match, the syntax is like this: `[1.1.2]`. See the Version Range section in the OSGi specifications for more info.

Gradle and Maven use exact versions when only one version is specified.

You now know the pros and cons for tracking dependencies as a range and as an exact match.

115.9 Service Trackers

Now that Liferay is promoting more modular plugins deployed into an OSGi runtime, you have to consider how your own code, living in its own module, can rely on services in other modules for functionality. You must account for the possibility of service implementations being swapped out or removed entirely if your module is to survive and thrive in an OSGi environment. It's easy for 7.0 developers who need to call services from their `@Component` classes. They just use another Declarative Services (DS) annotation, `@Reference`, to get a service reference. The component activates when the referenced service is available.

If you're able to use DS and leverage the `@Component` and `@Reference` annotations, you should. DS handles much of the complexity of handling service dynamism for you transparently.

If you can't use DS to create a Component, keep reading to learn how to implement a Service Tracker to look up services in the service registry.

Note: When using Service Trackers in your WAR-style project, you must configure the required `org.osgi.core` dependency carefully in your build file (e.g., `build.gradle`, `pom.xml`, etc.) to avoid errors. Since it's included in Liferay DXP by default, it must be configured as `provided`. See the Third Party Packages Portal Exports tutorial for more information.

What scenarios might require using a service tracker? Keep in mind we're focusing on scenarios where DS *can't* be used. This typically involves a non-native (to OSGi) Dependency Injection framework.

- Calling OSGi services from a Spring MVC portlet
- Calling OSGi services from a JSF portlet
- Calling OSGi services from a WAR-packaged portlet that's been upgraded to run on 7.0, but not fully modularized and made into an OSGi module

---

Note: The static utility classes (e.g., `UserLocalServiceUtil`) that were useful in Liferay Portal 6.2 (and earlier) exist for compatibility but should not be called, if possible. Static utility classes cannot account for the OSGi runtime's dynamic environment. Using a static class, for example, you might attempt calling a service that has stopped or hasn't been deployed or started–this could cause unrecoverable runtime errors. Service Tracker, however, helps you make OSGi-friendly service calls.

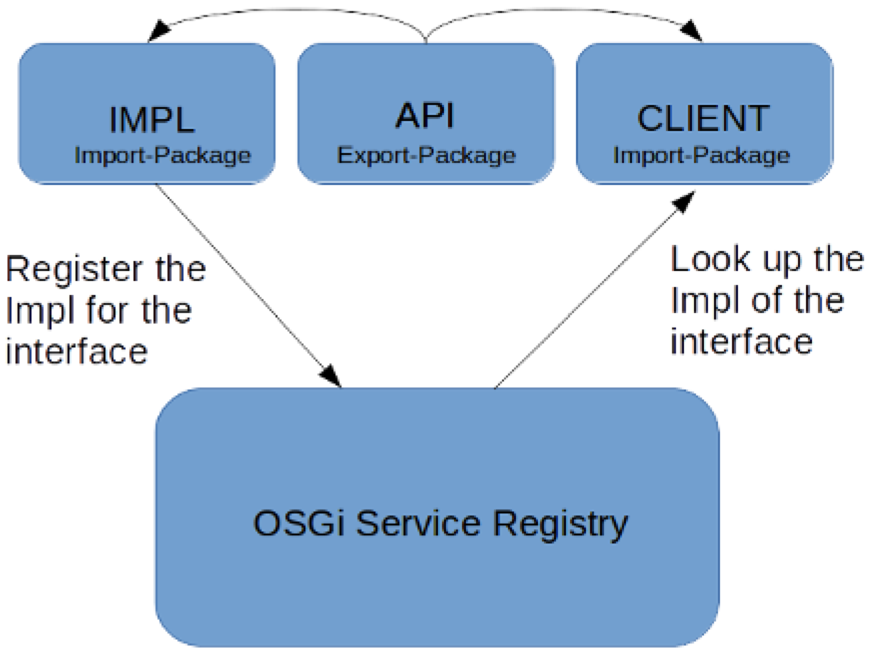

Figure 115.5: Service implementations that are registered in the OSGi service registry can be accessed using Service Trackers.

Using a Service Tracker, your non-OSGi application can access any service registered in the OSGi runtime, including your own Service Builder services and the services published by Liferay's modules (like the popular `UserLocalService`).

Implementing a Service Tracker

Although you don't have the luxury of using DS to manage your service dependencies, you can call services from the service registry with a little bit of code.

To implement a service tracker you can do this:

```
import org.osgi.framework.Bundle;
import org.osgi.framework.FrameworkUtil;
import org.osgi.util.tracker.ServiceTracker;

Bundle bundle = FrameworkUtil.getBundle(this.getClass());
BundleContext bundleContext = bundle.getBundleContext();
ServiceTracker<SomeService, SomeService> serviceTracker =
    new ServiceTracker(bundleContext, SomeService.class, null);
serviceTracker.open();
SomeService someService = serviceTracker.waitForService(500);
```

To simplify your code, you can create a class that extends `org.osgi.util.tracker.ServiceTracker`.

```
public class SomeServiceTracker
    extends ServiceTracker<SomeService, SomeService> {

    public SomeServiceTracker(Object host) {
        super(
            FrameworkUtil.getBundle(host.getClass()).getBundleContext(),
            SomeService.class, null);
    }
}
```

From the initialization part of your logic that uses the service, call your service tracker constructor. The Object host parameter is used to obtain your own bundle context and in order to give accurate results must be an object from your own bundle.

```
ServiceTracker<SomeService, SomeService> someServiceTracker =
    new SomeServiceTracker(this);
```

Remember to open the service tracker before using it, typically as early as you can.

```
someServiceTracker.open();
```

The most basic usage of a Service Tracker is to interrogate the service's state. In your program logic, for example, check whether the service is null before using it:

```
SomeService someService = someServiceTracker.getService();

if (someService == null) {
    _log.warn("The required service 'SomeService' is not available.");
}
else {
    someService.doSomethingCool();
}
```

Service Trackers have several other utility functions for introspecting tracked services.

Later when your application is being destroyed or undeployed, close the service tracker.

```
someServiceTracker.close();
```

Implementing a Callback Handler for Services

If there's a strong possibility the service might not be available, or if you need to track multiple services, the Service Tracker API provides a callback mechanism which operates on service *events*. To use this, override ServiceTracker's addingService and removedService methods. Their ServiceReference parameter references an active service object.

Here's an example ServiceTracker implementation from the OSGi Alliance's OSGi Core Release 7 specification:

```
new ServiceTracker<HttpService, MyServlet>(context, HttpService.class, null) {

    public MyServlet addingService(ServiceReference<HttpService> reference) {
        HttpService httpService = context.getService(reference);
        MyServlet myServlet = new MyServlet(httpService);
        return myServlet;
    }

    public void removedService(
        ServiceReference<HttpService> reference, MyServlet myServlet) {
        myServlet.close();
        context.ungetService(reference);
    }
}
```

When the HttpService is added to the OSGi registry, this ServiceTracker creates a new wrapper class, MyServlet, which uses the newly added service. When the service is removed from the registry, the removedService method cleans up related resources.

As an alternative to directly overloading ServiceTracker methods, create a org.osgi.util.tracker.ServiceTrackerCustomiz

```
class MyServiceTrackerCustomizer
    implements ServiceTrackerCustomizer<SomeService, MyWrapper> {

    private final BundleContext bundleContext;

    MyServiceTrackerCustomizer(BundleContext bundleContext) {
        this.bundleContext = bundleContext;
    }

    @Override
    public MyWrapper addedService(
        ServiceReference<SomeService> serviceReference) {

        // Determine if the service is one that's interesting to you.
        // The return type of this method is the `tracked` type. Its type
        // is what is returned from `getService*` methods; useful for wrapping
        // the service with your own type (e.g., MyWrapper).
        if (isInteresting(serviceReference)) {
            MyWrapper myWrapper = new MyWrapper(
                serviceReference, bundleContext.getService());

            // trigger the logic that requires the available service(s)
            triggerServiceAddedLogic(myWrapper);

            return myWrapper;
        }

        // If the return is null, the tracker is effectively ignoring any further
        // events for the service reference
        return null;
    }

    @Override
    public void modifiedService(
        ServiceReference<SomeService> serviceReference, MyWrapper myWrapper) {
        // handle the modified service
    }

    @Override
    public void removedService(
        ServiceReference<SomeService> serviceReference, MyWrapper myWrapper) {

        // finally, trigger logic when the service is going away
        triggerServiceRemovedLogic(myWrapper);
    }

}
```

Register the `ServiceTrackerCustomizer` by passing it as the `ServiceTracker` constructor's third parameter.

```
ServiceTrackerCustomizer<SomeService, MyWrapper> serviceTrackerCustomizer =
    new MyServiceTrackerCustomizer();

ServiceTracker<SomeService, MyWrapper> serviceTracker =
    new ServiceTracker<>(
        bundleContext, SomeService.class, serviceTrackerCustomizer);
```

There's a little boilerplate code you need to produce, but now you can look up services in the service registry, even if your plugins can't take advantage of the Declarative Services component model.

115.10 Waiting on Lifecycle Events

Liferay registers lifecycle events like portal and database initialization into the OSGi service registry. Your OSGi Component or non-component class can listen for these events by way of their service registrations.

The `ModuleServiceLifecycle` interface defines these names for the lifecycle event services:

- DATABASE_INITIALIZED
- PORTAL_INITIALIZED
- SPRING_INITIALIZED

Here you'll learn how to wait on lifecycle event services to act on them from within a component or non-component class.

Taking action from a component

Declarative Services (DS) facilitates waiting for OSGi services and acting on them once they're available.

Here's a component whose `doSomething` method is invoked once the `ModuleServiceLifecycle.PORTAL_INITIALIZED` lifecycle event service and other services are available.

```
@Component
public class MyXyz implements XyzApi {

    // Plain old OSGi service
    @Reference
    private SomeOsgiService _someOsgiService;

    // Service Builder generated service
    @Reference
    private DDMStructureLocalService _ddmStructureLocalService;

    // Liferay lifecycle service
    @Reference(target = ModuleServiceLifecycle.PORTAL_INITIALIZED)
    private ModuleServiceLifecycle _portalInitialized;

    @Activate
    public void doSomething() {
        // `@Activate` method is only executed once all of
        // `_someOsgiService`,
        // `_ddmStructureLocalService` and
        // `_portalInitialized`
        // are set.
    }
}
```

Here's how to act on services in your component:

1. For each lifecycle event service and OSGi service your component uses, add a field of that service type and add an `@Reference` annotation to that field. The OSGi framework binds the services to your fields. This field, for example, binds to a standard OSGi service.

   ```
   @Reference
   SomeOsgiService _someOsgiService;
   ```

2. To bind to a particular lifecycle event service, target its name as the `ModuleServiceLifecycle` interface defines. This field, for example, targets database initialization.

   ```
   @Reference(target = ModuleServiceLifecycle.DATABASE_INITIALIZED)
   ModuleServiceLifecycle _dataInitialized;
   ```

3. Create a method that's triggered on the event(s) and add the `@Activate` annotation to that method. It's invoked when all the service objects are bound to the component's fields.

Your component fires (via its `@Activate` method) after all its service dependencies resolve. DS components are the easiest way to act on lifecycle event services.

Taking action from a non-component class

Classes that aren't DS components can use a `org.osgi.util.tracker.ServiceTracker` or `org.osgi.util.tracker.ServiceTracker` as a service callback handler for the lifecycle event. If you depend on multiple services, add logic to your `ServiceTracker` or `ServiceTrackerCustomizer` to coordinate taking action when all the services are available.

To target a lifecycle event service, create a service tracker that filters on that service. Use `org.osgi.framework.FrameworkUtil` to create an `org.osgi.framework.Filter` that specifies the service. Then pass that filter as a parameter to the service tracker constructor. For example, this service tracker filters on the lifecycle service `ModuleServiceLifecycle.PORTAL_INITIALIZED`.

```
import org.osgi.framework.Filter;
import org.osgi.framework.FrameworkUtil;

Filter filter = FrameworkUtil.createFilter(
    String.format(
        "(&(objectClass=%s)%s)",
        ModuleServiceLifecycle.class.getName(),
        ModuleServiceLifecycle.PORTAL_INITIALIZED));

new ServiceTracker<>(bundleContext, filter, null);
```

Acting on lifecycle event services in this way requires service callback handling and some boilerplate code. Using DS components is easier and more elegant, but at least service trackers provide a way to work with lifecycle events outside of DS components.

Troubleshooting FAQ

When coding on any platform, you can sometimes run into issues that have no clear resolution. This can be particularly frustrating. If you have issues building, deploying, or running modules, you want to resolve them fast. These frequently asked questions and answers help you troubleshoot problems that arise based on the underlying OSGi platform, and then correct them.

Here are the troubleshooting sections:

- Modules
- Services and Components

Click a question to view the answer.

116.1 Modules

How can I configure dependencies on Liferay Portal artifacts?

```
<p>See <a href="/docs/7-0/tutorials/-/knowledge_base/t/configuring-dependencies">Configuring Dependencies</a>. </p>
```

What are optional package imports and how can I specify them?

```
<p>When developing Liferay Portal modules, you can declare <em>optional</em> package imports. An optional package import is one your module can use if it's

116.3 Resolving Bundle Requirements

If one of your bundles imports a package that no other bundle in the Liferay OSGi runtime exports, you get a bundle exception. Here's an example exception:

```
! could not resolve the bundles: [com.liferay.messaging.client.command-1.0.0.201707261701 org.osgi.framework.BundleException: Could not resolve module: com.
Unresolved requirement: Import-Package: com.liferay.messaging.client.api; version="[1.0.0,2.0.0)"
-> Export-Package: com.liferay.messaging.client.api; bundle-symbolic-name="com.liferay.messaging.client.provider"; bundle-version="1.0.0.201707261701"; vers
com.liferay.messaging.client.provider [2]
Unresolved requirement: Import-Package: com.liferay.messaging; version="[1.0.0,2.0.0)"
-> Export-Package: com.liferay.messaging; bundle-symbolic-name="com.liferay.messaging.api"; bundle-version="1.0.0"; version="1.0.0"; uses:="com.liferay.petr
com.liferay.messaging.api [12]
Unresolved requirement: Import-Package: com.liferay.petra.io; version="[1.0.0,2.0.0)"
-> Export-Package: com.liferay.petra.io; bundle-symbolic-name="com.liferay.petra.io"; bundle-version="1.0.0"; version="1.0.0"
com.liferay.petra.io [16]
Unresolved requirement: Require-Capability osgi.extender; filter:="(osgi.extender=osgi.serviceloader.processor)"
```

The first part of the message states *could not resolve the bundles*. The rest of the message shows a string of unresolved requirements. Liferay's OSGi Runtime could not resolve one of the bundle's transitive requirements.

The bundle exception message follows this general pattern:

- Module A has an unresolved requirement (package or capability) `aaa.bbb`.
- Module B provides `aaa.bbb` but has an unresolved requirement `ccc.ddd`.
- Module C provides `ccc.ddd` but has an unresolved requirement `eee.fff`.
- etc.
- Module Z provides `www.xxx` but has an unresolved requirement `yyy.zzz`.

The pattern stops at the final requirement no module provides. The last module's dependencies are key to resolving the bundle exception. There are two possible causes:

1. A dependency that satisfies the final requirement might be missing from the build file.

2. A dependency that satisfies the final requirement might not be deployed.

Both cases require deploying a bundle that provides the missing requirement.

The example bundle exception concludes that module `com.liferay.petra.io` requires capability `osgi.extender; filter:="(osgi.extender=osgi.serviceloader.processor)"`. To resolve the requirement, make sure all of `com.liferay.petra.io`'s dependencies are deployed.

First, note the module's dependencies. Here is the `dependencies` section of the `com.liferay.petra.io` module's `build.gradle` file.

```
dependencies {
    provided group: "com.liferay", name: "com.liferay.petra.concurrent", version: "1.0.0"
    provided group: "com.liferay", name: "com.liferay.petra.memory", version: "1.0.0"
    provided group: "org.apache.aries.spifly", name: "org.apache.aries.spifly.dynamic.bundle", version: "1.0.8"
    provided group: "org.slf4j", name: "slf4j-api", version: "1.7.2"
    testCompile group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "default"
}
```

Then use Felix Gogo Shell's `lb command` to verify the dependencies in Liferay's OSGi Runtime:

```
lb
START LEVEL 1
   ID|State      |Level|Name
    0|Active     |    0|OSGi System Bundle (3.10.100.v20150529-1857)|3.10.100.v20150529-1857
    1|Active     |    1|com.liferay.messaging.client.command (1.0.0.201707261923)|1.0.0.201707261923
    2|Active     |    1|com.liferay.messaging.client.provider (1.0.0.201707261927)|1.0.0.201707261927
    3|Active     |    1|Apache Felix Configuration Admin Service (1.8.8)|1.8.8
    4|Active     |    1|Apache Felix Log Service (1.0.1)|1.0.1
    5|Active     |    1|Apache Felix Declarative Services (2.0.2)|2.0.2
    6|Active     |    1|Meta Type (1.4.100.v20150408-1437)|1.4.100.v20150408-1437
    7|Active     |    1|org.osgi:org.osgi.service.metatype (1.3.0.201505202024)|1.3.0.201505202024
    8|Active     |    1|Apache Felix Gogo Command (0.16.0)|0.16.0
    9|Active     |    1|Apache Felix Gogo Runtime (0.16.2)|0.16.2
   10|Active     |    1|Apache Felix Gogo Runtime (1.0.0)|1.0.0
...
```

Notice the dependency module `org.apache.aries.spifly.dynamic.bundle` is missing from the runtime bundle list. Examining the module's `MANIFEST.MF` file shows it provides the requirement capability `osgi.extender; filter:="(osgi.extender=osgi.serviceloader.processor)"`.

```
Provide-Capability: osgi.extender;osgi.extender="osgi.serviceloader.regi
 strar";version:Version="1.0",osgi.extender;osgi.extender="osgi.servicel
 oader.processor";version:Version="1.0"
```

Deploying this missing bundle `org.apache.aries.spifly.dynamic.bundle` resolves the example's bundle exception.

You can follow these similar steps to resolve your bundle exceptions.

Note: Bndtools's *Resolve* button can resolve bundle dependencies automatically. You specify the bundles your application requires and Bndtools adds transitive dependencies from your configured artifact repository.

Resolving a Plugins's Dependencies

116.4 Resolving Bundle-SymbolicName Syntax Issues

An OSGi bundle's `Bundle-SymbolicName` and `Bundle-Version` manifest headers uniquely identify it. You can specify a bundle's `Bundle-SymbolicName` in these ways:

1. `Bundle-SymbolicName` header in a bundle's (module's) `bnd.bnd` file.

2. `Bundle-SymbolicName` header in a plugin WAR's `liferay-plugin-package.properties` file.

3. Plugin WAR file name, if the WAR's `liferay-plugin-package.properties` has no `Bundle-SymbolicName` header.

For plugin WARs, specifying the `Bundle-SymbolicName` in the `liferay-plugin-package.properties` file is preferred.

Important: `Bundle-SymbolicName` values must not contain spaces. On bundle deployment, Liferay's OSGi Runtime framework throws an `IllegalContextNameException` if its `Bundle-SymbolicName` has a space.

For example, if you deploy a plugin WAR that has no `Bundle-SymbolicName` header in its `liferay-plugin-package.properties`, the WAB Generator uses the WAR's name as the WAB's `Bundle-SymbolicName`. If the

WAR's name has a space in it (e.g., `space-program-theme v1.war`) an `IllegalContextNameException` occurs on deployment.

```
org.apache.catalina.core.ApplicationContext.log The context name 'space-program-theme v1' does not follow Bundle-SymbolicName syntax.
org.eclipse.equinox.http.servlet.internal.error.IllegalContextNameException: The context name 'space-program-theme v1' does not follow Bundle-
SymbolicName syntax.
```

To avoid using spaces and to follow naming best practices, you can use a reverse-domain name in your `Bundle-SymbolicName`.

Here's an example domain name and reverse domain name:

Module domain: `troubleshooting.liferay.com`

Module reverse-domain: `com.liferay.troubleshooting`

However you set your a `Bundle-SymbolicName`, refrain from using spaces.

116.5 Resolving ClassNotFoundException and NoClassDefFoundError in OSGi Bundles

Understanding a `ClassNotFoundException` or `NoClassDefFoundError` in non-OSGi environments is straightforward.

- `ClassNotFoundException`: thrown when looking up a class that isn't on the classpath or using an invalid name to look up a class that isn't on the runtime classpath.
- `NoClassDefFoundError`: occurs when a compiled class references another class that isn't on the runtime classpath.

In OSGi environments, however, there are additional cases where a `ClassNotFoundException` or `NoClassDefFoundError` can occur. Here are four:

1. The missing class belongs to a module dependency that's an OSGi module.
2. The missing class belongs to a module dependency that's *not* an OSGi module.
3. The missing class belongs to a global library, either at the Liferay DXP webapp scope or the application server scope.
4. The missing class belongs to a Java runtime package.

This tutorial explains how to handle each case.

Case 1: The Missing Class Belongs to an OSGi Module

In this case, there are two possible causes:

1. **The module doesn't import the class's package:** For a module (or WAB) to consume another module's exported class, the consuming module must import the exported package that contains the class. To do this, you add an `Import-Package` header in the consuming module's `bnd.bnd` file. If the consuming module tries to access the class without importing it, a `ClassNotFoundException` or `NoClassDefFoundError` occurs.

In the consuming module, make sure you import the correct package. First check the package name. If the package import is correct but you still get the exception or error, the class might no longer exist in the package.

2. **The class no longer exists in the imported package:** In OSGi runtime environments, modules can change and come and go. If you reference another module's class that its developer removed, a `NoClassDefFoundError` or `ClassNotFoundException` occurs. Semantic Versioning guards against this scenario: removing a class from an exported package constitutes a new major version for that package. Neglecting to increment the package's major version breaks dependent modules.

   For example, say a module that consumes the class `com.foo.Bar` specifies the package import `com.foo;version=[1.0.0, 2.0.0)`. The module uses `com.foo` versions from `1.0.0` up to (but not including) `2.0.0`. The first part of the version number (the `1` in `1.0.0`) represents the *major* version. The consuming module doesn't expect any *major* breaking changes, like a class removal. Removing `com.foo.Bar` from `com.foo` without incrementing the package to a new major version (e.g., `2.0.0`) causes a `ClassNotFoundException` or `NoClassDefFoundError` when other modules look up or reference that class.

   You have these options since the class no longer exists in the package:

   - Adapt to the new API. To learn how to do this, read the package's/module's Javadoc, release notes, and or formal documentation. You can also ask the author, or search forums.

   - Revert to the module version you used previously. Deployed module versions reside in `[Liferay_Home]/osgi/`. For details, see Backing up Liferay Installations.

   Do what you think is best to get your module working properly.

Now you know how to resolve common situations involving `ClassNotFoundException` or `NoClassDefFoundError`. For additional information on `NoClassDefFoundError`, see OSGi Enroute's article What is NoClassDef-FoundError?.

Case 2: The Missing Class Doesn't Belong to an OSGi Module

In this case, you have two options:

1. Convert the dependency into an OSGi module so it can export the missing class. Converting a non-OSGi `JAR` file dependency into an OSGi module that you can deploy alongside your application is the ideal solution, so it should be your first choice.

2. Embed the dependency in your module by embedding the dependency `JAR` file's packages as private packages in your module. If you want to embed a non-OSGi `JAR` file in your application, see the tutorial Adding Third Party Libraries to a Module.

Case 3: The Missing Class Belongs to a Global Library

In this case, you can configure Liferay DXP so the OSGi system module exports the missing class's package. Then your module can import it. You should **NOT**, however, undertake this lightly. If Liferay intended to make a global library available for use by developers, the system module would already export this library! Still, if you must access a global library that's not currently exported and can't think of **any** other solution, you can consider adding the required package for export by the system module. There are two ways to do this:

1. In your portal-ext.properties file, use the property module.framework.system.packages.extra to specify the packages to export.

2. If the package you need is from a Liferay DXP JAR, you might be able to add the module to the list of exported packages in [LIFERAY_HOME]/osgi/core/com.liferay.portal.bootstrap.jar's META-INF/system.packages.extra.bnd file. Try this option only if the first option doesn't work.

If the package you need is from a Liferay DXP module, (i.e., it's **NOT** from a global library), you can add the package to that module's bnd.bnd exports. You should **NOT**, however, undertake this lightly. The package would already be be exported if Liferay intended for it to be available.

Case 4: The Missing Class Belongs to a Java Runtime Package

rt.jar (the JRE library) has non-public packages. If your module imports one of them, configure Liferay DXP's system bundle to export the package to the module framework.

1. Add the current module.framework.system.packages.extra property setting to a [LIFERAY_HOME]/portal-ext.properties file. Your server's current setting is in the Liferay DXP web application's /WEB-INF/lib/portal-impl.jar/portal.properties file.

2. In your portal-ext.properties file, append the required Java runtime package to the end of the module.framework.system.packages.extra property's package list.

3. Restart your server.

The package requirement resolves.

116.6 Identifying Liferay Artifact Versions for Dependencies

When you're developing a Liferay DXP application, it's often necessary to use various Liferay DXP APIs or tools. For example, you might want to create a Service Builder application or use Liferay DXP's message bus or asset framework. How can you determine which versions of Liferay DXP artifacts (modules, apps, etc.) your application's modules need to specify as dependencies? To learn how to find and configure Liferay DXP dependencies, please refer to the following tutorial:

- Configuring Dependencies

Finding Extension Points

116.7 Connecting to JNDI Data Sources

Connecting to an application server's JNDI data sources from Liferay DXP's OSGi environment is almost the same as connecting to them from the Java EE environment. In an OSGi environment, the only difference is that you must use Liferay DXP's class loader to load the application server's JNDI classes. The following code demonstrates this.

```
Thread thread = Thread.currentThread();

// Get the thread's class loader. You'll reinstate it after using
// the data source you look up using JNDI

ClassLoader origLoader = thread.getContextClassLoader();

// Set Liferay's class loader on the thread

thread.setContextClassLoader(PortalClassLoaderUtil.getClassLoader());

try {

        // Look up the data source and connect to it

        InitialContext ctx = new InitialContext();
        DataSource datasource = (DataSource)
            ctx.lookup("java:comp/env/jdbc/TestDB");

        Connection connection = datasource.getConnection();
        Statement statement = connection.createStatement();

        // Execute SQL statements here ...

        connection.close();
}
catch (NamingException ne) {

    ne.printStackTrace();
}
catch (SQLException sqle) {

    sqle.printStackTrace();
}
finally {
       // Switch back to the original context class loader

       thread.setContextClassLoader(origLoader);
}
```

The example code sets Liferay DXP's classloader on the thread to access the JNDI API. After working with the data source, the code reinstates the thread's original classloader.

Here are the class imports for the code above:

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import javax.sql.DataSource;
import com.liferay.portal.kernel.util.PortalClassLoaderUtil;
```

Your applications can use similar code to access a data source. Make sure to substitute `jdbc/TestDB` with your data source name.

Note: An OSGi bundle's attempt to connect to a JNDI data source without using Liferay DXP's classloader results in a `java.lang.ClassNotFoundException`. For example, here's an exception from attempting to use Apache Tomcat's JNDI API without using Liferay DXP's classloader:

```
javax.naming.NoInitialContextException: Cannot instantiate class:
org.apache.naming.java.javaURLContextFactory [Root exception is
java.lang.ClassNotFoundException:
org.apache.naming.java.javaURLContextFactory]
```

An easier way to work with databases is to connect to them using Service Builder.

Connecting Service Builder to External Data Sources

116.8 Adjusting Module Logging

Liferay DXP uses Log4j logging services. Here are the ways to configure logging for module classes and class hierarchies.

- Liferay DXP's UI
- Configure Log4j for multiple modules in a `[anyModule]/src/main/resources/META-INF/module-log4j.xml` file.
- Configure Log4j for a specific module in a `[Liferay Home]/osgi/log4j/[symbolicNameOfBundle]-log4j-ext.xml` file.
- Configure Log4j for an OSGi fragment host module in a `/META-INF/module-log4j-ext.xml` file

Here's an example Log4j XML configuration:

```
<?xml version="1.0"?>
<!DOCTYPE log4j:configuration SYSTEM "log4j.dtd">
<log4j:configuration xmlns:log4j="http://jakarta.apache.org/log4j/">
    <category name="org.foo">
        <priority value="DEBUG" />
    </category>
</log4j:configuration>
```

Use `category` elements to specify each class or class hierarchy to log messages for. Set the `name` attribute to that class name or root package. The example category sets logging for the class hierarchy starting at package `org.foo`. Log messages at or above the `DEBUG` log level are printed for classes in `org.foo` and classes in packages starting with `org.foo`.

Set each category's `priority` element to the log level (priority) you want.

- ALL
- DEBUG
- ERROR
- FATAL
- INFO
- OFF
- TRACE
- WARN

The log messages are printed to Liferay log files in `[Liferay_Home]/logs`.

You can see examples of module logging in several Liferay sample projects. For example, the action-command-portlet, document-action, and service-builder/jdbc samples (among others) leverage module logging.

Note: If the log level configuration isn't appearing (e.g., you set the log level to `ERROR` but you're still getting `WARN` messages), make sure the log configuration file name prefix matches the module's symbolic name. If you have Bnd installed, output from command `bnd print [path-to-bundle]` includes the module's symbolic name (Here are instructions for installing Bnd for the command line).

Note: A Log4j configuration's appenders control log file location, naming, and rotation. To override advanced Log4j options such as Liferay DXP's log appenders, use an Ext plugin.

That's it for module log configuration. You're all set to print the information you want.

116.9 Implementing Logging

7.0 uses the Log4j logging framework, but a different one may eventually replace it. It's a best practice to use Simple Logging Facade for Java (SLF4J) to log messages in your modules and traditional plugins. SLF4J is already integrated into Liferay DXP, so you can focus on logging messages.

Here's how to use SLF4J to log messages in a class:

1. Add a private static SLF4J `Logger` field.

   ```
   private static Logger _logger;
   ```

2. Instantiate the logger.

   ```
   _logger = LoggerFactory.getLogger(this.getClass().getName());
   ```

3. Throughout your class, log messages where noteworthy things happen.

   For example,

   ```
   _logger.debug("...");
   _logger.warn("...");
   _logger.error("...");
   ...
   ```

   Use `Logger` methods appropriate for each message:

   - `debug`: Event and application information helpful for debugging.
   - `error`: Normal errors. This is the least verbose message level.
   - `info`: High level events.
   - `trace`: Provides more information than debug. This is the most verbose message level.
   - `warn`: Information that might, but does not necessarily, indicate a problem.

Log verbosity should correlate with the log level set for the class or package. Make sure you provide additional information at log levels expected to be more verbose, such as `info` and `debug`.

You're all set to add logging to your modules and traditional plugins.

116.10 Declaring Optional Import Package Requirements

When developing Liferay DXP modules, you can declare *optional* dependencies. An optional dependency is one your module can use if it's available, but can still function without it.

Important: Try to avoid optional dependencies. The best module designs rely on normal dependencies. If an optional dependency seems desirable, your module may be trying to provide distinct types of functionality. In such a situation, it's best to split it into multiple modules that provide smaller, more focused functionality.

If you decide that your module requires an optional dependency, follow these steps to add it:

1. Declare the package that your module optionally requires as an optional dependency in your module's `bnd.bnd` file:

   ```
   Import-Package: com.liferay.demo.foo;resolution:="optional"
   ```

   Note that you can use either an optional or dynamic import. The differences are explained in this blog post.

2. Create a component to use the optional package:

   ```
   import com.liferay.demo.foo.Foo; // A class from the optional package

   @Component(
       enabled = false // instruct declarative services to ignore this component by default
   )
   public class OptionalPackageConsumer implements Foo {...}
   ```

3. Create a second component to act as a controller of the first component. The second component checks the classloader for the optional class on the classpath. It handles both cases appropriately. If it's not there, this means you must catch any `ClassNotFoundException`. For example:

   ```
   @Component
   public class OptionalPackageConsumerStarter {
       @Activate
       void activate(ComponentContext componentContext) {
           try {
               Class.forName(com.liferay.demo.foo.Foo.class.getName());

               componentContext.enableComponent(OptionalPackageConsumer.class.getName());
           }
           catch (Throwable t) {
               _log.warn("Could not find {}", t.getMessage()); // Could use _log.info instead
           }
       }
   }
   ```

If the classloader check in the controller component is successful, the client component is enabled. This check is automatically performed whenever there are any wiring changes to the module containing these components (Declarative Services components are always restarted when there are wiring changes).

As above, if you install the module when the optional dependency is missing from Liferay DXP's OSGi runtime, your controller component catches a `ClassNotFoundException` and logs a warning or info message (or takes whatever other action you implement to handle this case). If you install the optional dependency, refreshing your module triggers the OSGi bundle lifecycle events that trigger your controller's `activate` method and the check for the optional dependency. Since the dependency exists, your client component uses it.

Note that you can refresh a bundle from Liferay DXP's Gogo shell with this command:

```
equinox:refresh [bundle ID]
```

For more information about optional dependencies, see OSGi Enroute's documentation.

Configuring Dependencies

116.11 Why Aren't my Module's JavaScript and CSS Changes Showing?

To determine why JavaScript and CSS updates to your module aren't having an effect in your browser, perform these checks:

1. If you're developing a portlet module, check that your portlet class has the correct properties specified in its `@Component` annotation:

    - Make sure the resources referred to by the properties of your portlet class's `@Component` annotation exist in the correct location in your module project.
    - Make sure that you're using a portlet CSS wrapper class to prevent potential CSS ID and class name conflicts with other applications on the page.

    For example, consider this sample portlet class:

    ```
    @Component(
        immediate = true,
        property = {
            "com.liferay.portlet.css-class-wrapper=example-portlet",
            "com.liferay.portlet.display-category=category.sample",
            "com.liferay.portlet.instanceable=true",
            "com.liferay.portlet.header-portlet-css=/css/main.css",
            "com.liferay.portlet.header-portlet-javascript=/css/main.js",
            "javax.portlet.display-name=Example Portlet",
            "javax.portlet.init-param.template-path=/",
            "javax.portlet.init-param.view-template=/view.jsp",
            "javax.portlet.name=" + ExamplePortletKeys.TicTacToe,
            "javax.portlet.resource-bundle=content.Language",
            "javax.portlet.security-role-ref=power-user,user"
        },
        service = Portlet.class
    )
    public class ExamplePortlet extends MVCPortlet {

    }
    ```

    As described in the first item above, the portlet's CSS file is specified by the property `com.liferay.portlet.header-portlet-css`. Paths specified as values of this property are relative to the module's `src/main/resources/META-INF/resources` folder. So if you specify a value of `css/main.css`, the actual path to the CSS file in the module is `src/main/resources/META-INF/resources/css/main.css`. The path to your portlet's JavaScript file is specified by the property `com.liferay.portlet.header-portlet-javascript`. Values for this property work the same as the values for the CSS property.

Also note that the property `com.liferay.portlet.css-class-wrapper` specifies the CSS class wrapper `example-portlet`. Thus, you should use subclasses of `example-portlet` in your portlet's actual CSS file. For example, in `main.css` you'd do this to change the background to green:

```
.example-portlet {
    .greenBackground {
        background-color: green;
    }

    ... (further properties)

}
```

In other words, to avoid CSS class and ID name conflicts, all the CSS properties you specify must be subclasses of the class specified via the `com.liferay.portlet.css-class-wrapper` property. Liferay DXP wraps your portlet's HTML content with a `<div>`. The class specified by `com.liferay.portlet.css-class-wrapper` (`example-portlet`, in this example) has been applied to this `<div>`.

2. Check that caching isn't preventing JS and CSS updates to your module from appearing in your browser:

    - Clear your browser's cache.
    - During development, enable developer mode to turn off Liferay DXP's resource caching. Click here to learn how to enable Liferay DXP's developer mode.

Using Developer Mode with Themes

116.12 Why Aren't JSP overrides I Made Using Fragments Showing?

The fragment module must specify the exact version of the host module. A Liferay DXP upgrade might have changed some JSPs in the host module, prompting a version update. If this occurs, check that your JSP customizations are compatible with the updated host JSPs and then update your fragment module's targeted version to match the host module.

For example, this `bnd.bnd` file from a fragment module uses `Fragment-Host` to specify the host module and host module version:

```
Bundle-Name: custom-login-jsp
Bundle-SymbolicName: custom.login.jsp
Bundle-Version: 1.0.0
Fragment-Host: com.liferay.login.web;bundle-version="1.1.18"
```

For information on finding the versions of your deployed modules, click here.
For more information on overriding JSPs, click here.

Configuring Dependencies

116.13 Detecting Unresolved OSGi Components

Liferay DXP includes Gogo shell commands that come in handy when trying to diagnose a problem due to an unresolved OSGi component. The specific tools to use depend on the component framework of the unresolved component. Most Liferay DXP components are developed using Declarative Services (DS), also known as SCR (Service Component Runtime). An exception to this is Liferay DXP's Service Builder services, which are provided as Dependency Manager (DM) components. Both Declarative Services and Dependency Manager are Apache Felix projects.

The troubleshooting instructions are divided into these sections:

- Declarative Services Components
  - Declarative Services Unsatisfied Component Scanner
  - ds:unsatisfied Command
- Service Builder Components
  - Unavailable Component Scanner
  - ServiceProxyFactory

Declarative Services Components

Start with DS, since most Liferay DXP components, apart from Service Builder components, are DS components. Suppose one of your bundle's components has an unsatisfied service reference. How can you detect this? Two ways:

- You can enable a Declarative Services Unsatisfied Component Scanner to report unsatisfied references automatically or
- You can use the Gogo shell command `ds:unsatisfied` to check for them manually.

Declarative Services Unsatisfied Component Scanner

Note: The Declarative Services Unsatisfied Component Scanner appears in DXP Digital Enterprise Fix 7.0 Pack 31 and Liferay CE Portal 7.0 GA5.

Here are the steps for enabling the unsatisfied component scanner:

1. Create a file `com.liferay.portal.osgi.debug.declarative.service.internal.configuration.UnsatisfiedComponentScann`
2. Add the following file content:

   ```
   unsatisfiedComponentScanningInterval=5
   ```

3. Copy the file into `[LIFERAY_HOME]/osgi/configs`.

The scanner detects and logs unsatisfied service component references. The log message includes the class that contains the reference, the bundle's ID, and the referenced component type.

Here's an example scanner message:

```
11:18:28,881 WARN  [Declarative Service Unsatisfied Component Scanner][UnsatisfiedComponentScanner:91]
Bundle {id: 631, name: com.liferay.blogs.web, version: 2.0.0}
    Declarative Service {id: 3333, name: com.liferay.blogs.web.internal.portlet.action.EditEntryMVCRenderCommand, unsatisfied references:
        {name: ItemSelectorHelper, target: null}
    }
```

The message above warns that service component `com.liferay.blogs.web.internal.portlet.action.EditEntryMVCRenderCo` has an unsatisfied reference to a component of type `ItemSelectorHelper`. The referencing component's ID (SCR ID) is 3333 and the component belongs to bundle 631.

ds:unsatisfied Command

Another way to detect unsatisfied component references is to invoke the Gogo shell command `ds:unsatisfied`.

- `ds:unsatisfied` shows all unsatisfied services
- `ds:unsatisfied [BUNDLE_ID]` shows the bundle's unsatisfied services

Note: The Gogo shell command `ds:unsatisfied` appears in DXP Digital Enterprise Fix 7.0 Pack 31 and Liferay CE Portal 7.0 GA5.

To view more detailed information about the component with the unsatisfied reference, use the command `scr:info [component ID]`. For example, the following command does this for the component ID `1701`:

```
g! scr:info 1701
*** Bundle: org.foo.bar.command (507)
Component Description:
    Name: org.foo.bar.command
    Implementation Class: org.foo.bar.command.FooBarCommand
    Default State: enabled
    Activation: delayed
    Configuration Policy: optional
    Activate Method: activate
    Deactivate Method: deactivate
    Modified Method: -
    Configuration Pid: [org.foo.bar.command]
    Services:
        org.foo.bar.command.DuckQuackCommand
    Service Scope: singleton
    Reference: Duck
        Interface Name: org.foo.bar.api.Foo
        Cardinality: 1..1
        Policy: static
        Policy option: reluctant
        Reference Scope: bundle
    Component Description Properties:
        osgi.command.function = foo
        osgi.command.scope = bar
    Component Configuration:
        ComponentId: 1701
        State: unsatisfied reference
        UnsatisfiedReference: Foo
        Target: null
        (no target services)
        Component Configuration Properties:
        component.id = 1701
        component.name = org.foo.bar.command
        osgi.command.function = foo
        osgi.command.scope = bar
```

In the `Component Configuration` section, `UnsatisfiedReference` lists the unsatisfied reference's type. This bundle's component isn't working because it's missing a `Foo` service. Now you can focus on why `Foo` is unavailable. The solution may be as simple as starting or deploying a bundle that provides the `Foo` service.

Service Builder Components

Liferay DXP's Service Builder modules are implemented using Spring. Liferay DXP uses the Apache Felix Dependency Manager to manage Service Builder modules' OSGi components via the Portal Spring Extender module.

When developing a Liferay Service Builder application, you might encounter a situation where your application has an unresolved Spring-related OSGi component. This could occur, for example, if you update your application's database schema but forget to trigger an upgrade (for information on creating database upgrade processes for your Liferay DXP applications, see the tutorial Creating an Upgrade Process for Your App).

These features detect unresolved Service Builder related components.

- Unavailable Component Scanner
- ServiceProxyFactory

Unavailable Component Scanner

The Liferay Foundation application suite's Unavailable Component Scanner reports missing components in modules that use Service Builder. Here are the steps for enabling the scanner:

1. Create configuration file `com.liferay.portal.osgi.debug.spring.extender.internal.configuration.UnavailableCompon`
2. In the configuration file, set the time interval (in seconds) between scans:

   ```
   unavailableComponentScanningInterval=5
   ```

3. Copy the file into folder `[LIFERAY_HOME]/osgi/configs`.

The scanner reports Spring extender dependency manager component status on the set interval. If all components are registered, the scanner sends a confirmation message.

```
11:10:53,817 INFO  [Spring Extender Unavailable Component Scanner][UnavailableComponentScanner:166] All Spring extender dependency manager components are re
```

If a component is unavailable, it reports an error like this one:

```
11:13:08,851 WARN  [Spring Extender Unavailable Component Scanner][UnavailableComponentScanner:173] Found unavailable component in bundle com.liferay.screen
Component ComponentImpl[null com.liferay.portal.spring.extender.internal.context.ModuleApplicationContextRegistrator@1541eee] is unavailable due to missing
```

Component unavailability, such as what's reported above, can occur when declarative services components and Service Builder components are published and used in the same module. We recommend you publish DS components and Service Builder components in separate modules.

Note: The Spring Extender Unavailable Component Scanner appears in DXP Digital Enterprise Fix 7.0 Pack 24 and Liferay CE Portal 7.0 GA5.

ServiceProxyFactory

Liferay DXP's logs report unresolved Service Builder components too. For example, Liferay DXP logs an error when a Service Proxy Factory can't create a new instance of a Service Builder based entity because a service is unresolved.

Note: The Service Proxy Factory timeout logs appear in DXP Digital Enterprise Fix 7.0 Pack 32 and Liferay CE Portal 7.0 GA5.

The following code demonstrates using a `ServiceProxyFactory` class to create a new entity instance:

```
private static volatile MessageBus _messageBus =
    ServiceProxyFactory.newServiceTrackedInstance(
        MessageBus.class, MessageBusUtil.class, "_messageBus", true);
```

This message alerts you to the unavailable service:

```
11:07:35,139 ERROR [localhost-startStop-1][ServiceProxyFactory:265] Service "com.liferay.portal.kernel.messaging.sender.SingleDestinationMessageSenderFactor
```

Based on the message above, there's no bundle providing the service `com.liferay.portal.kernel.messaging.sender.SingleI`

To check your Service Builder modules for unresolved Spring components, you can use the Dependency Manager's `dm` Gogo shell command, which is explained here:

- Dependency Manager - Leveraging the shell

For example, to get diagnostic information about Service Builder components, use the `dependencymanager:dm` command. This command lists all Service Builder components, their required services, and whether each required service is available.

Calling Non-OSGi Code that Uses OSGi Services

Felix Gogo Shell

OSGi Basics For Liferay Development

116.14 Using Files to Configure Module Components

Liferay DXP uses Felix File Install to monitor file system folders for new/updated configuration files, and the Felix OSGi implementation of Configuration Admin to let you use files to configure module service components.

To learn how to work with configuration files, first review Understanding System Configuration Files.

Configuration File Formats

There are two different configuration file formats:

- `.cfg`: An older, simple format that only supports string values as properties.
- `.config`: A format that supports strings, type information, and other non-string values in its properties.

Although Liferay DXP supports both formats, we recommend `.config` files for their flexibility. Since `.cfg` file lacks type information, if you want to store anything but a String, you'll need a properties utility class that casts the Strings to their proper types (and you must carefully document properties that aren't Strings). Since `.config` files can include type information, using them eliminates this need. The articles below provide a detailed explanation of these file formats, including their syntax:

- Understanding System Configuration Files
- Configuration file (`.config`) syntax
- Properties file(`.cfg`) syntax

Naming Configuration Files

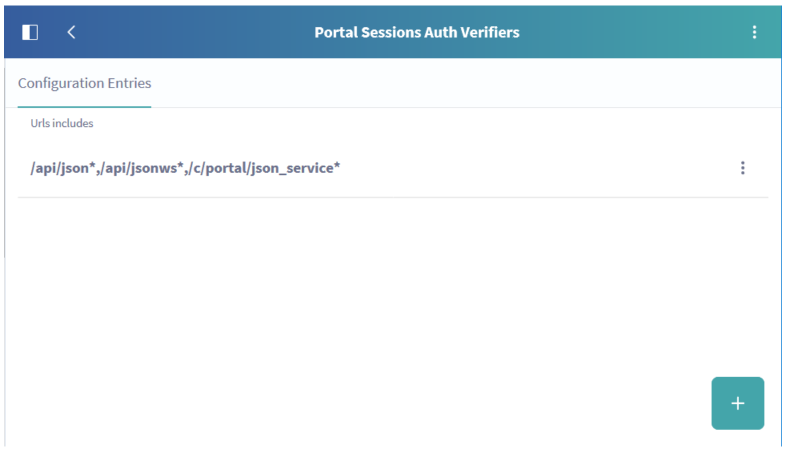
Before you create a configuration file, you should determine whether multiple instances of the component can be created, or if the component is intended to be a singleton. Follow these steps to make that determination:

1. Deploy the component's module if you haven't done so already.

2. In Liferay DXP's UI, go to *Control Panel* → *Configuration* → *System Settings*.

3. Find the component's settings by searching or browsing for the component.

4. If the component's settings page has a section called *Configuration Entries*, you can create multiple instances of the component configured however you like. Otherwise, you should treat the component as a singleton.



/api/json*,/api/jsonws*,/c/portal/json_service*

Figure 116.1: You can create multiple instances of components whose System Settings page has a *Configuration Entries* section.

All configuration file names must start with the component's PID (PID stands for *persistent identity*) and end with `.config` or `.cfg`.

For example, this class uses Declarative Services to define a component:

```
package com;
@Component
class Foo {}
```

The component's PID is `com.Foo`. All the component's configuration files must start with the PID `com.Foo`.

For each non-singleton component instance you want to create or update with a configuration, you must use a uniquely named configuration file that starts with the component's PID and ends with `.config` or `.cfg`. Creating configurations for multiple component instances requires that the configuration files use different *subnames*. A subname is the part of a configuration file name after the PID and before the suffix `.config` or `.cfg`. Here's the configuration file name pattern for non-singleton components:

- `[PID]-[subname1].config`
- `[PID]-[subname2].config`
- etc.

For example, you could configure two different instances of the component `com.Foo` by using configuration files with these names:

- `com.Foo-one.config`
- `com.Foo-two.config`

Each configuration file creates and/or updates an instance of the component that matches the PID. The subname is arbitrary–it doesn't have to match a specific component instance. This means you can use whatever subname you like. For example, these configuration files are just as valid as the two above:

- `com.Foo-puppies.config`
- `com.Foo-kitties.config`

Using the subname `default`, however, is Liferay DXP's convention for configuring a component's first instance. The file name pattern is therefore:

```
[PID]-default.config
```

A singleton component's configuration file must also start with `[PID]` and end with `.config` or `.cfg`. Here's the common pattern used for singleton component configuration file names:

```
[PID].config
```

When you're done creating a configuration file, you can deploy it.

Resolving Configuration File Deployment Failures

The following `IOException` hints that the configuration file has a syntax issue:

```
Failed to install artifact: [path to .config or .cfg file]
java.io.IOException: Unexpected token 78; expected: 61 (line=0, pos=107)
```

To resolve this, fix the configuration file's syntax.

Great! Now you know how to configure module components using configuration files.

Understanding System Configuration Files

116.15 Calling Non-OSGi Code that Uses OSGi Services

Liferay DXP's static utility functions (e.g., `UserServiceUtil`, `CompanyServiceUtil`, `GroupServiceUtil`, etc.) are examples of non-OSGi code that use OSGi services.

Note that it's safer to track and use Liferay DXP's OSGi services directly with Liferay DXP's Registry API than to invoke Liferay DXP's similar static utility functions. For example, you can't call an OSGi service unless all its dependencies are satisfied: the container won't enable the service. If you invoke Liferay DXP's static utility functions, you might invoke them prematurely (e.g., before OSGi bundle activation and application startup events). You could work around this by identifying all of the implied OSGi service dependencies and making sure they are satisfied before invocation, but then you're not only duplicating the container's more robust functionality for this, you're also creating a bigger surface for bugs. Avoid this mess by using Liferay DXP's Registry API to track the services you want. This way, you let OSGi make sure a service's dependencies are satisfied before invoking that service. For example, use Liferay DXP's OSGi service `UserService` instead of `UserServiceUtil`, which in turn uses the OSGi service `UserService`. Click here to see an example of this.

Remember that you can check the state of Liferay DXP's services in the Gogo shell. If you're running Liferay DXP locally, use the command `telnet localhost 11311` to connect to the Gogo shell. Once connected, the `scr:list` command shows all Declarative Services components, including inactive ones from unsatisfied dependencies. To find unsatisfied dependencies for Service Builder services, use the Dependency Manager's `dependencymanager:dm wtf` command. Note that these commands only show components that haven't been activated because of unsatisfied dependencies–they don't show pure service trackers that are waiting for a service because of unsatisfied dependencies.

OSGi Basics For Liferay Development

116.16 Patching DXP Source Code

Auto mechanics, enthusiasts, and prospective owners ask about cars, "What's under the hood?" Here are common reasons for asking that question:

- Concern about an issue
- Curiosity about the car's capability and inner-workings
- Desire to improve or customize the car

You might have similar reasons for asking "What's under the *DXP's* hood?" And since you get access to DXP Digital Enterprise (DXP)'s source code, you can attach a debugger see it in action! Setting up the code locally is your ticket to exploring DXP, investigating issues, and making improvements and customizations.

Here's how:

1. Download DXP, the DXP source code, and patches

2. Prepare DXP

3. Patch the DXP source code

Step 1: Download DXP, the DXP source code, and patches

1. Download a DXP bundle (or DXP JARs) and the DXP source code for the version you're using from the customer portal.

2. Download fix packs and their source code from here. Fix pack ZIP files that end in `-src.zip` contain a fix pack and source code.

Next you'll install and configure DXP. DXP's patching tool lets you install fix packs and fix pack source code. If you have a patched DXP installation already and want to use it, skip to the section *Patching the DXP Source Code*.

Step 2: Prepare DXP

Preparing DXP locally involves installing, configuring, and patching DXP.

Install and Configure DXP

Here's how to install and configure DXP:

1. Install and Deploy DXP locally.

2. Start DXP.

3. Configure DXP to use your database.

4. Stop DXP.

It's time apply the DXP patches you want.

Patch DXP

Here's how to patch DXP:

1. Copy all the patch ZIP files you want to `[LIFERAY_HOME]/patching-tool/patches`. The `-src.zip` fix pack files are best to use because they contain both the fix pack binaries and source code.

2. Open a terminal window to `[LIFERAY_HOME]/patching-tool`.

3. Run the command `patching-tool.sh auto-discovery` to generate the default patching profile called `default.properties`. Make sure the profile's properties refer to your DXP installation. See the patching tool documentation for more details.

   Here's an example profile:

   ```
   patching.mode=binary
   war.path=../tomcat-8.0.32/webapps/ROOT/
   global.lib.path=../tomcat-8.0.32/lib/ext/
   liferay.home=../
   ```

4. To list all the patch files available in `[LIFERAY_HOME]/patching-tool/patches`, execute the following command:

   ```
   patching-tool.sh info
   ```

5. Execute this command to install the patches:

   ```
   patching-tool.sh install
   ```

   The patching tool documentation describes additional steps that might apply to your situation, such as creating database indexes.

It's time to prepare the DXP source code and patch source code.

Step 3: Patch the DXP Source Code

Unzip the DXP source code to where you want to work with it.

Next you'll create a patching tool profile for your DXP source code.

Create a Patching Tool Profile for the Source Code

Here's how to create a profile that refers to your source code.

1. Execute the following command to create a profile. Replace `[profile]` with a name for your profile.

   ```
   patching-tool.sh auto-discovery [profile]
   ```

2. In the profile properties file generated in the previous step, set the `patching.mode` property to `source` and set the `source.path` property to your source code path:

   ```
       patching.mode=source
       source.path=[DXP source code path]
   ```

It's time to apply the DXP patches you downloaded earlier.

Patch the Source Code

DXP's patching tool is safe and easy to use. Beyond installing patches, it has these functions:

- List a patch's code changes
- List the issues (LPS/LPE tickets) a patch fixes
- Revert a patch

See the following patching tool documentation for more details:

- Comparing Patch Levels
- Removing or Reverting Patches

In addition to using the patching tool to manage DXP source code, you can optionally manage it in a version control system such as Git.

Here are commands for setting up the DXP source code in Git:

```
cd [path to source code root folder]
git init
git add .
git commit -a
```

Here's are the command descriptions:

- `init` creates a Git repository for the current folder (i.e., the root folder) and all its contents.
- `add` stages the root folder and its contents.
- `commit` checks in the staged files.

You can commit any code changes (e.g., DXP patches) to your Git repository.

The patching tool installs all patches and patch source code from the ZIP files it finds in `[LIFERAY_HOME]/patching-tool/patches`. All your patches must be in the `patches` folder for the patching tool to apply them.

1. Copy all the patch source ZIP files to `[LIFERAY_HOME]/patching-tool/patches` if you haven't already copied them there.

2. Execute the `info` command to make sure it lists your patches. If a patch isn't listed, copy its ZIP file into the `patches` folder. Replace `[profile]` with your DXP source code profile name:

```
patching-tool.sh [profile] info
```

3. Apply the patches by executing the `install` command on your profile:

```
patching-tool.sh [profile] install
```

Your DXP installation and source code is patched and ready to debug!

Attach your favorite debugger to your DXP instance and start the server. See your debugger's documentation for configuration details.

Congratulations! You're free to explore DXP inside and out!

Troubleshooting

Liferay @ide@

116.17 Liferay DXP Failed to Initialize Because the Database Wasn't Ready

If you start your database server and application server at the same time, Liferay DXP might try connecting to the data source before the database is ready. By default, Liferay DXP doesn't retry connecting to the database; it just fails. Now Liferay DXP provides a way to avoid this situation: database connection retries.

1. Create a `portal-ext.properties` file.

2. Set the property `retry.jdbc.on.startup.max.retries` equal to the number of times to retry connecting to the data source.

3. Set property `retry.jdbc.on.startup.delay` equal to the number of seconds to wait before retrying connection.

If at first the connection doesn't succeed, Liferay DXP uses the retry settings to try again.

116.18 Using OSGi Services from EXT Plugins

Using OSGi services from an Ext plugin is done the same way that Liferay DXP's core uses OSGi services: via the `com.liferay.registry` API provided by the `registry-api` bundle. All usages of this API in Liferay DXP's core can serve as examples. Here's a very simple example:

```
Registry registry = RegistryUtil.getRegistry();
UserService userService = registry.getService(UserService.class);
If (userService ≠ null) {
    User user = userService.getCurrentUser();
    System.out.println("Current user is " + user.getFirstName() + StringPool.BLANK +
        user.getLastName());
}
```

Remember that OSGi services can come and go at any time. Liferay DXP services, including `UserService`, aren't an exception to this rule. Although it's unlikely that `UserService` becomes unavailable, you must still account for that possibility. Liferay DXP's registry API provides `ServiceReference` and `ServiceTracker`, which you can use to simplify dealing with OSGi services. If you're familiar with OSGi development, you've heard of these classes because the OSGi framework provides them. Liferay DXP's versions of these classes wrap the OSGi ones, so you can use them the same way.

Here's a smarter version of the above example. Using service trackers takes away much of the pain of having to deal with services that can appear and disappear dynamically:

```
Registry registry = RegistryUtil.getRegistry();
ServiceTracker<UserService, UserService> tracker = registry.trackServices(UserService.class);
tracker.open();
UserService userService = tracker.getService();
if (userService ≠ null) {
    User user = userService.getCurrentUser();
    System.out.println("Current user is " + user.getFirstName() + StringPool.SPACE +
        user.getLastName());
}
tracker.close();
```

Remember to open your service trackers before use and close them after use. If you must use Liferay DXP's OSGi services in a servlet, for example, it's a good idea to open your service trackers in `Servlet.init()` and close them in `Servlet.destroy()`.

OSGi Basics For Liferay Development

116.19 Sort Order Changed with a Different Database

If you've been using Liferay DXP, but are switching it to use a different database type, consult your database vendor documentation to understand your old and new database's default query result order. The default order is either case-sensitive or case-insensitive. This affects entity sort order in Liferay DXP.

Here are some examples of ascending alphabetical sort order.

Case-sensitive:

```
111
222
AAA
BBB
aaa
bbb
```

Case-insensitive:

```
111
222
AAA
aaa
BBB
bbb
```

Your new database's default query result order might differ from your current database's order. Consult your vendor's documentation to configure the order the way you want.

CHAPTER 117

DATA UPGRADES

Your module goes through various stages of development, because you're constantly trying to improve it. You add new features, remove features, enhance features, reorganize the code, and do whatever you can to respond to what your users want and make your module the best it can be. To transition users to new and improved versions of your module, you need to take them through the process of upgrading.

Liferay provides a robust data upgrade framework for you to use. Here you'll learn how to create a data upgrade process.

117.1 Creating Data Upgrade Processes for Modules

Some changes you make to a module involve modifying the database. These changes bring with them the need for an upgrade process to move your module's database from one version to the next. Liferay has an upgrade framework you can use to make this easier to do. It's a feature-rich framework that makes upgrades safe: the system records the current state of the schema so that if the upgrade fails, the process can revert the module back to its previous version.

Note: Upgrade processes for traditional Liferay plugins (WAR files) work the same way they did for Liferay Portal 6.x.

Liferay DXP's upgrade framework executes your module's upgrades automatically when the new version starts for the first time. You implement concrete data schema changes in upgrade step classes and then register them with the upgrade framework using an upgrade step registrator. In this tutorial, you'll learn how to do all these things to create an upgrade process for your module.

Here's what's involved:

- **Specifying the schema version**
- **Declaring dependencies**
- **Writing upgrade steps**
- **Writing the registrator**
- **Waiting for upgrade completion**

It's time to get started.

Specifying the Schema Version

In your module's bnd.bnd file, specify a Liferay-Require-SchemaVersion header with the new schema version value. Here's an example schema version header for a module whose new schema is version 1.1.0:

```
    Liferay-Require-SchemaVersion: 1.1.0
```

Important: If no Liferay-Require-SchemaVersion header is specified, Liferay DXP considers the Bundle-Version header value to be the database schema version.

Next, you'll specify your upgrade's dependencies.

Declaring Dependencies

In your module's dependency management file (e.g., Maven POM, Gradle build file, or Ivy ivy.xml file), add a dependency on the com.liferay.portal.upgrade module.

In a build.gradle file, the dependency would look like this:

```
compile group: "com.liferay", name: "com.liferay.portal.upgrade", version: "2.0.0"
```

If there are other modules your upgrade process requires, specify them as dependencies.

You've configured your module project for the upgrade. It's time to create upgrade steps to update the database from the current schema version to the new one.

Writing Upgrade Steps

An upgrade step is a class that adapts module data to the module's target database schema. It can execute SQL commands and DDL files to upgrade the data. As a developer, you can encapsulate upgrade logic in multiple upgrade step classes per schema version.

The upgrade class extends the UpgradeProcess base class, which implements the UpgradeStep interface. Each upgrade step must override the UpgradeProcess class's method doUpgrade with instructions for modifying the database.

Since UpgradeProcess extends the BaseDBProcess class, you can use its runSQL and runSQLTemplate* methods to execute your SQL commands and SQL DDL, respectively.

If you want to create, modify, or drop tables or indexes by executing DDL sentences from an SQL file, make sure to use ANSI SQL only. Doing this assures the commands work on different databases.

If you need to use non-ANSI SQL, it's best to write it in the UpgradeProcess class's runSQL or alter methods, along with tokens that allow porting the sentences to different databases.

For example, consider the journal-service module's UpgradeSchema upgrade step class:

```
package com.liferay.journal.internal.upgrade.v0_0_4;

import com.liferay.journal.internal.upgrade.v0_0_4.util.JournalArticleTable;
import com.liferay.journal.internal.upgrade.v0_0_4.util.JournalFeedTable;
import com.liferay.portal.kernel.upgrade.UpgradeMVCCVersion;
import com.liferay.portal.kernel.upgrade.UpgradeProcess;
import com.liferay.portal.kernel.util.StringUtil;

/**
 * @author Eduardo Garcia
 */
public class UpgradeSchema extends UpgradeProcess {
    @Override
    protected void doUpgrade() throws Exception {
        String template = StringUtil.read(
            UpgradeSchema.class.getResourceAsStream("dependencies/update.sql"));

        runSQLTemplateString(template, false, false);

        upgrade(UpgradeMVCCVersion.class);

        alter(
            JournalArticleTable.class,
            new AlterColumnName(
                "structureId", "DDMStructureKey VARCHAR(75) null"),
            new AlterColumnName(
                "templateId", "DDMTemplateKey VARCHAR(75) null"),
            new AlterColumnType("description", "TEXT null"));

        alter(
            JournalFeedTable.class,
            new AlterColumnName("structureId", "DDMStructureKey TEXT null"),
            new AlterColumnName("templateId", "DDMTemplateKey TEXT null"),
            new AlterColumnName(
                "rendererTemplateId", "DDMRendererTemplateKey TEXT null"),
            new AlterColumnType("targetPortletId", "VARCHAR(200) null"));
    }

}
```

The above example class `UpgradeSchema` uses the `runSQLTemplateString` method to execute ANSI SQL DDL from an SQL file. To modify column names and column types, it uses the `alter` method and `UpgradeProcess`'s `UpgradeProcess.AlterColumnName` and `UpgradeProcess.AlterColumnType` inner classes as token classes.

Here's a simpler example upgrade step from the `com.liferay.calendar.service` module. It uses the `alter` method to modify a column type in the calendar booking table:

```
public class UpgradeCalendarBooking extends UpgradeProcess {

        @Override
        protected void doUpgrade() throws Exception {
                alter(
                        CalendarBookingTable.class,
                        new AlterColumnType("description", "TEXT null"));
        }

}
```

You can implement upgrade steps just like these for your module schemas.

How you name and organize upgrade steps is up to you. Liferay's upgrade classes are organized using a package structure similar to this one:

- *some.package.structure*
    - `upgrade`
        - `v1_1_0`
            - `UpgradeFoo.java` ← Upgrade Step
        - `v2_0_0`
            - `UpgradeFoo.java` ← Upgrade Step

- UpgradeBar.java ← Upgrade Step

* MyCustomModuleUpgrade.java ← Registrator

The example upgrade structure shown above is for a module that has two database schema versions: `1.1.0` and `2.0.0`. They're represented by packages `v1_1_0` and `v2_0_0`. Each version package contains upgrade step classes that update the database. The example upgrade steps focus on fictitious data elements `Foo` and `Bar`. The registrator class (`MyCustomModuleUpgrade`, in this example) is responsible for registering the applicable upgrade steps for each schema version.

Here are some organizational tips:

- Put all upgrade classes in a sub-package called `upgrade`.
- Group together similar database updates (ones that operate on a data element or related data elements) in the same upgrade step class.
- Create upgrade steps in sub-packages named after each data schema version.

Before continuing with upgrade step registrators, if your application was modularized from a former traditional Liferay plugin application (application WAR) and it uses Service Builder, it requires a Bundle Activator to register itself in Liferay DXP's `Release_` table. If this is the case for your application, create and register a Bundle Activator and then return here to write your upgrade step registrator.

Writing the Upgrade Step Registrator

A module's upgrade step registrator notifies Liferay's upgrade framework of all the upgrade steps to update the module data for each schema version. It specifies the module's entire upgrade process. The upgrade framework executes the upgrade steps to update the current module data to the latest schema.

For example, the upgrade step registrator class `MyCustomModuleUpgrade` (below) registers upgrade steps incrementally for each schema version (past and present):

```
package com.liferay.mycustommodule.upgrade;

import com.liferay.portal.upgrade.registry.UpgradeStepRegistrator;

import org.osgi.service.component.annotations.Component;

@Component(immediate = true, service = UpgradeStepRegistrator.class)
public class MyCustomModuleUpgrade implements UpgradeStepRegistrator {

    @Override
    public void register(Registry registry) {
        registry.register(
            "com.liferay.mycustommodule", "0.0.0", "2.0.0",
            new DummyUpgradeStep());

        registry.register(
            "com.liferay.mycustommodule", "1.0.0", "1.1.0",
            new com.liferay.mycustommodule.upgrade.v1_1_0.UpgradeFoo());

        registry.register(
            "com.liferay.mycustommodule", "1.1.0", "2.0.0",
            new com.liferay.mycustommodule.upgrade.v2_0_0.UpgradeFoo(),
            new com.liferay.mycustommodule.upgrade.v2_0_0.UpgradeBar());
    }

}
```

The registrator's `register` method informs the upgrade framework about each new schema and associated upgrade steps to adapt data to it. Each schema upgrade is represented by a registration. A registration is an abstraction for all the changes you need to apply to the database from one schema version to the next one.

The following diagram illustrates the relationship between the registrator and the upgrade steps.

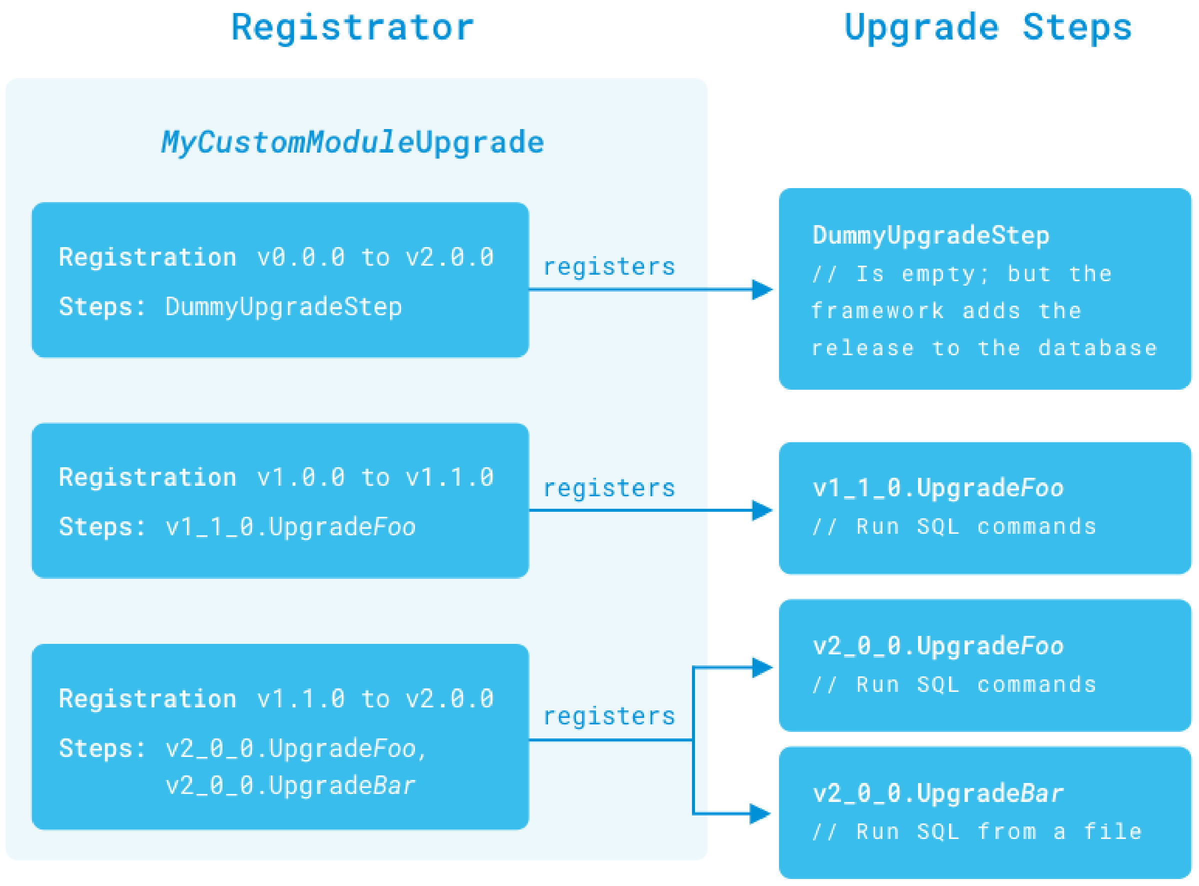

Figure 117.1: In a registrator class, the developer specifies a registration for each schema version upgrade. The upgrade steps handle the database updates.

The previous example `MyCustomModuleUpgrade` registrator class listing shows how this works.

The registrator class declares itself to be an OSGi Component of service type `UpgradeStepRegistrator.class`. The `@Component` annotation registers the class to the OSGi framework as the module's upgrade step registrator. The attribute `immediate = true` tells the OSGi framework to activate this module immediately after it's installed.

The registrator implements the `UpgradeStepRegistrator` interface, which is in the `com.liferay.portal.upgrade` module. The interface declares a `register` method that the registrator must override. In that method, the registrator implements all the module's upgrade registrations.

Upgrade registrations are defined by the following values:

- **Module's bundle symbolic name**
- **Schema version to upgrade from** (as a `String`)
- **Schema version to upgrade to** (as a `String`)

- **List of upgrade steps**

The example registrator `MyCustomModuleUpgrade` registers three upgrades:

- `0.0.0` to `2.0.0`
- `1.0.0` to `1.1.0`
- `1.1.0` to `2.0.0`

The `MyCustomModuleUpgrade` registrator's first registration is applied by the upgrade framework if the module has not been installed previously. Its list of upgrade steps contains only one: `new DummyUpgradeStep()`.

```
registry.register(
    "com.liferay.document.library.web", "0.0.0", "2.0.0",
    new DummyUpgradeStep());
```

The `DummyUpgradeStep` class provides an empty upgrade step. The `MyCustomModuleUpgrade` registrator defines this registration so that the upgrade framework records the module's latest schema version (i.e., `2.0.0`) in Liferay DXP's `Release_` table.

Important: Modules that use Service Builder *should not* define a registration for their initial database schema version, as Service Builder already records their schema versions to Liferay DXP's `Release_` table. Modules that don't use Service Builder, however, *should* define a registration for their initial schema.

The `MyCustomUpgrade` registrator's next registration (from schema version `1.0.0` to `1.1.0`) includes one upgrade step.

```
registry.register(
    "com.liferay.mycustommodule", "1.0.0", "1.1.0",
          new com.liferay.mycustommodule.upgrade.v1_1_0.UpgradeFoo());
```

The upgrade step's fully qualified class name is required because classes named `UpgradeFoo` are in package `com.liferay.mycustommodule.upgrade.v1_1_0`and `com.liferay.mycustommodule.upgrade.v2_0_0`.

The registrator's final registration (from schema version `1.1.0` to `2.0.0`) contains two upgrade steps.

```
registry.register(
    "com.liferay.mycustommodule", "1.1.0", "2.0.0",
    new com.liferay.mycustommodule.upgrade.v2_0_0.UpgradeFoo(),
    new UpgradeBar());
```

Both upgrade steps, `UpgradeFoo` and `UpgradeBar`, reside in the module's `com.liferay.mycustommodule.upgrade.v2_0_0` package. The fully qualified class name `com.liferay.mycustommodule.upgrade.v2_0_0.UpgradeFoo` is used for the `UpgradeFoo` class, while the simple class name `UpgradeBar` is fine for the second upgrade step.

A registration's upgrade step list can consist of as many upgrade steps as needed.

Important: If your upgrade step uses an OSGi service, your upgrade must wait for that service's availability. To specify that your upgrade is to be executed only after that service is available, add an OSGi reference to that service.

For example, the `WikiServiceUpgrade` registrator class references the `SettingsFactory` class. The upgrade step class `UpgradePortletSettings` upgrade step uses it. Here's the `WikiServiceUpgrade` class:

```
@Component(immediate = true, service = UpgradeStepRegistrator.class)
public class WikiServiceUpgrade implements UpgradeStepRegistrator {

    @Override
    public void register(Registry registry) {
        registry.register(
            "com.liferay.wiki.service", "0.0.1", "0.0.2", new UpgradeSchema());
        registry.register(
            "com.liferay.wiki.service", "0.0.2", "0.0.3",
            new UpgradeKernelPackage(), new UpgradePortletId());

        registry.register(
            "com.liferay.wiki.service", "0.0.3", "1.0.0",
            new UpgradeCompanyId(), new UpgradeLastPublishDate(),
            new UpgradePortletPreferences(),
            new UpgradePortletSettings(_settingsFactory),
            new UpgradeWikiPageResource());
    }

    @Reference(unbind = "-")
    protected void setSettingsFactory(SettingsFactory settingsFactory) {
        _settingsFactory = settingsFactory;
    }

    private SettingsFactory _settingsFactory;

}
```

In the third registration in the listing above, the `UpgradePortletSettings` upgrade step uses the `SettingsFactory` service. The `setSettingsFactory` method's `@Reference` annotation declares that the registrator class depends on and must wait for the `SettingsFactory` service to be available in the run time environment. The annotation's attribute setting `unbind = "-"` indicates that the registrator class has no method for unbinding the service.

Next, you must make sure the module's upgrade is executed before making its services available.

Waiting for Upgrade Completion

Before module services that access the database are used, the database should be upgraded to the latest database schema.

As a convenience, configuring the Bnd header `Liferay-Require-SchemaVersion` to the latest schema version is all that's required to assure the database is upgraded for Service Builder services.

For all other services, the developer can assure database upgrade by specifying an `@Reference` annotation that targets the containing module and its latest schema version.

Here are the target's required attributes:

- `release.bundle.symbolic.name`: module's bundle symbolic name
- `release.schema.version`: module's current schema version

For example, the `com.liferay.comment.page.comments.web` module's `PageCommentsPortlet` class assures upgrading to schema version `1.0.0` by defining the following reference:

```
@Reference(
    target = "(&(release.bundle.symbolic.name=com.liferay.comment.page.comments.web)(release.schema.version=1.0.0))",
    unbind = "-"
)
protected void setRelease(Release release) {
}
```

Dependencies between OSGi services can reduce the number of service classes in which upgrade reference annotations are needed. For example, there's no need to add an upgrade reference in a dependent service, if the dependency already refers to the upgrade.

Note: Data verifications using the class `VerifyProcess` are deprecated. Verifications should be tied schema versions. Upgrade processes are associated with schema versions but `VerifyProcess` instances are not.

Now you know how to create data upgrades for all your modules. You specify the new data schema version in the `bnd.bnd` file, add a reference to your module and to the schema version to assure upgrade execution if the module doesn't use Service Builder, and add a dependency on the `com.liferay.portal.upgrade` module. For the second part of the process, you create upgrade step classes to update the database schema and register the upgrade steps in a registrator class. That's all there is to it!

Upgrading Plugins to Liferay 7

Configuration

Migrating Data Upgrade Processes to the New Framework for Modules

117.2 Upgrade Processes for Former Service Builder Plugins

If you modularized a traditional Liferay plugin application that implements Service Builder services, your new modular application must register itself in the `Release_` table. This is required regardless of whether release records already exist for previous versions of the app. A Bundle Activator is the recommended way to add a release record for the first modular version of your converted application. Here you'll see an example Bundle Activator and learn how to create and activate a Bundle Activator for your application.

Important: This tutorial only applies to modular applications that use Service Builder and were modularized from traditional Liferay plugin applications. It does not apply to you if your application does not use Service Builder or has never been a traditional Liferay plugin application (a WAR application).

Bundle Activator class code is dense but straightforward. Referring to an example Bundle Activator can be helpful. Here's the Liferay Knowledge Base application's Bundle Activator:

```
public class KnowledgeBaseServiceBundleActivator implements BundleActivator {

    @Override
    public void start(BundleContext bundleContext) throws Exception {
        Filter filter = bundleContext.createFilter(
            StringBundler.concat(
                "(&(objectClass=", ModuleServiceLifecycle.class.getName(), ")",
                ModuleServiceLifecycle.DATABASE_INITIALIZED, ")"));

        _serviceTracker = new ServiceTracker<Object, Object>(
            bundleContext, filter, null) {

            @Override
            public Object addingService(
                ServiceReference<Object> serviceReference) {

                try {
                    BaseUpgradeServiceModuleRelease
                        upgradeServiceModuleRelease =
                            new BaseUpgradeServiceModuleRelease() {

                                @Override
                                protected String getNamespace() {
                                    return "KB";
                                }
                                @Override
                                protected String getNewBundleSymbolicName() {
                                    return "com.liferay.knowledge.base.service";
                                }

                                @Override
                                protected String getOldBundleSymbolicName() {
                                    return "knowledge-base-portlet";
                                }

                            };

                    upgradeServiceModuleRelease.upgrade();

                    return null;
                }
                catch (UpgradeException ue) {
                    throw new RuntimeException(ue);
                }
            }

        };

        _serviceTracker.open();
    }

    @Override
    public void stop(BundleContext bundleContext) throws Exception {
        _serviceTracker.close();
    }

    private ServiceTracker<Object, Object> _serviceTracker;

}
```

The following steps explain how to create a Bundle Activator, like the example above.

1. Create a class that implements the interface `org.osgi.framework.BundleActivator`.

2. Add a service tracker field:

   `private ServiceTracker<Object, Object> _serviceTracker;`

3. Override BundleActivator's `stop` method to close the service tracker:

   ```
   @Override
   public void stop(BundleContext bundleContext) throws Exception {
       _serviceTracker.close();
   }
   ```

4. Override BundleActivator's `start` method to instantiate a service tracker that creates a filter to listens for the app's database initialization event and initializes the service tracker to use that filter. You'll add the service tracker initialization code in the next steps. At the end of the `start` method, open the service tracker.

   ```
   @Override
   public void start(BundleContext bundleContext) throws Exception {
       Filter filter = bundleContext.createFilter(
           StringBundler.concat(
               "(&(objectClass=", ModuleServiceLifecycle.class.getName(), ")",
               ModuleServiceLifecycle.DATABASE_INITIALIZED, ")"));
   ```

```
    _serviceTracker = new ServiceTracker<Object, Object>(
        bundleContext, filter, null) {
        // See the next step for this code ...
    };

    _serviceTracker.open();
}
```

5. In the service tracker initialization block `{ // See the next step for this code ... }` from the previous step, add an `addingService` method that instantiates a `BaseUpgradeServiceModuleRelease` for describing your app. The example `BaseUpgradeServiceModuleRelease` instance below describes Liferay's Knowledge Base app:

```
@Override
public Object addingService(
    ServiceReference<Object> serviceReference) {

    try {
        BaseUpgradeServiceModuleRelease
                upgradeServiceModuleRelease =
            new BaseUpgradeServiceModuleRelease() {

                @Override
                protected String getNamespace() {
                    return "KB";
                }

                @Override
                protected String getNewBundleSymbolicName() {
                    return "com.liferay.knowledge.base.service";
                }

                @Override
                protected String getOldBundleSymbolicName() {
                    return "knowledge-base-portlet";
                }

            };

        upgradeServiceModuleRelease.upgrade();

        return null;
    }
    catch (UpgradeException ue) {
        throw new RuntimeException(ue);
    }
}
```

The `BaseUpgradeServiceModuleRelease` implements the following methods:

- `getNamespace`: Returns the namespace value as specified in the former plugin's `service.xml` file. This value is also in the `buildNamespace` field in the plugin's `ServiceComponent` table record.
- `getOldBundleSymbolicName`: Returns the former plugin's name.
- `getNewBundleSymbolicName`: Returns the module's symbolic name. In the module's `bnd.bnd` file, it's the `Bundle-SymbolicName` value.
- `upgrade`: Invokes the app's upgrade processes.

6. In the module's `bnd.bnd` file, reference the Bundle Activator class you created. Here's the example's Bundle Activator reference:

```
Bundle-Activator: com.liferay.knowledge.base.internal.activator.KnowledgeBaseServiceBundleActivator
```

The Bundle Activator uses one of the following values to initialize the `schemaVersion` field in the application's `Release_` table record:

- Current `buildNumber`: if there is an existing Release_ table record for the previous plugin.
- `0.0.1`: if there is no existing Release_ table record.

You've set your service module's data upgrade process.

Upgrading Plugins to Liferay 7

117.3 Upgrading Data Schemas in Development

As you develop modules, you might need to iterate through several database schema changes. Before you release new module versions with your finalized schema changes, you must create a formal data upgrade process. Until then, you can use the Build Auto Upgrade feature to test schema changes on the fly.

Note: In Liferay Portal 6.x Service Builder portlets, the `build.auto.upgrade` property in `service.properties` applies Liferay Service schema changes upon rebuilding services and redeploying the portlets. As of 7.0, this property is deprecated.

Liferay Digital Enterprise 7.0 Fix Pack 28, and Liferay CE Portal 7.0.4 GA5 reintroduce Build Auto Upgrade in a new global property `schema.module.build.auto.upgrade` in the file `[Liferay_Home]/portal-developer.properties`.

Setting the global property `schema.module.build.auto.upgrade` to `true` applies module schema changes for redeployed modules whose service build numbers have incremented. The `build.number` property in the module's `service.properties` file indicates the service build number. Build Auto Upgrade executes schema changes without massaging existing data. It leaves data empty for created columns, drops data from deleted and renamed columns, and orphans data from deleted and renamed tables.

Although Build Auto Upgrade updates databases quickly and automatically, it doesn't guarantee a proper data upgrade–you implement that via data upgrade processes. Build Auto Upgrade is for development purposes only.

WARNING: DO NOT USE the Build Auto Upgrade feature in production. Liferay DXP DOES NOT support Build Auto Upgrade in production. Build Auto Upgrade is for development purposes only. Enabling it in production can result in data loss and improper data upgrade. In production environments, leave the property `schema.module.build.auto.upgrade` in `portal-developer.properties` set to `false`.

By default, `schema.module.build.auto.upgrade` is set to `false`. On any module's first deployment, the module's tables are generated regardless of the `schema.module.build.auto.upgrade` value.

The following table summarizes Build Auto Upgrade's handling of schema changes:

Schema Change	Result
Add column	Create a new empty column.

Schema Change	Result
Rename column	Drop the existing column and delete all its data. Create a new empty column.
Delete column	Drop the existing column and delete all its data.
Create or rename a table in Liferay DXP's built-in data source.	Orphan the existing table and all its data. Create the new table.

Great! Now you know how to use the Build Auto Upgrade developer feature.

Chapter 118

Back-end Frameworks

What are back-end frameworks? Are they important? If so, why aren't they up-front and center in the docs? Good questions.

Back-end frameworks are analogous to supporting actors and actresses in show business. They fill out the stories in films we know and love. As actors bring richness and life to their films, Liferay's powerful back-end frameworks bring essential services and deliver terrific performances of their own. Here are some of the frameworks:

- Device Recognition
- Message Bus

These frameworks and more deliver smashing performances and are stars in their own right.

118.1 Device Recognition API

As you know, Internet traffic has risen exponentially over the past decade, and this trend shows no sign of stopping. In addition, the bulk of Internet traffic now comes from mobile devices. The mobile boom presents new obstacles and challenges for content management. How will content adapt to different devices with different capabilities? How can your grandma's gnarly tablet and your cousin's awesome new smart phone request the same information from your portal?

The Device API detects the capabilities of any device making a request to your portal. It can also determine what mobile device or operating system was used to make a request, and then follows rules to make Liferay DXP render pages based on the device. To use these features, you must first install a device detection database that can detect which mobile devices are accessing the portal. Liferay DXP provides such a database in the Liferay Mobile Device Detection (LMDD) app from the Liferay Marketplace. Click here for instructions on using Liferay Marketplace to find and install apps.

Important: On Windows, Liferay Mobile Device Detection Enterprise must be run on a 64-bit JVM. On all operating systems, Liferay Mobile Device Detection Enterprise requires a JVM minimum memory setting of at least 2 gb.

You can create your own plugin that makes use of the device database. This tutorial shows you some of the methods in the Device API that you can use to retrieve device attributes and capabilities. Now go ahead and get started!

Getting Started with the Device API

One important thing that you'll want to get using the Device API is the `Device` object. You can obtain it from the `themeDisplay` object like this:

```
Device device = themeDisplay.getDevice();
```

You can view the `Device` API. Using some of the methods from the Javadocs, here's an example that obtains a device's dimensions:

```
Dimensions dimensions = device.getScreenSize();
float height = dimensions.getHeight();
float width = dimensions.getWidth();
```

Now your code can get the `Device` object and the dimensions of a device. Of course, this is just a simple example. You can acquire many other device attributes that help you take care of the pesky problems that arise when sending content to different devices. Refer to the Device Javadocs mentioned above for assistance. Next, you'll learn about retrieving some other device capabilities.

Getting Device Properties

With the Device API, you can detect the *properties* of a device making a request to your portal and then render content accordingly. Properties refer to things that the requesting device can do. For example, you can determine the device's operating system, browser, form factor, and much more. Properties can be retrieved with the `getCapability` and `getCapabilities` methods of the Device API.

Most of the properties of the requesting device can be detected, depending on the device detection implementation you're using. For example, you can obtain the brand name of the device with this code:

```
String brand = device.getCapability("OEM");
```

You can grab many other device properties, including `HardwareModel`, `HardwareName`, `ReleaseYear`, and `ReleaseMonth`. You can also get boolean values like `IsMobile`, `IsTablet`, and many more.

Keep in mind the Device API is an API. The underlying implementation of the Device API may change. You can also implement your own. Thus, the device property names are specific and proprietary to the underlying Device API implementation.

Now that you know about the Device API, you can use it to make sure that your grandma's gnarly tablet and your cousin's awesome new smart phone can make requests to your portal and receive identical content. This will make everyone happy!

Chapter 119

Message Bus

If you ever need to do some data processing outside the scope of the web's request/response, look no further than the Message Bus. It's conceptually similar to Java Messaging Service (JMS) Topics, but sacrifices transactional, reliable delivery capabilities, making it much lighter-weight. Liferay DXP uses Message Bus all over the place:

- Auditing
- Search engine integration
- Email subscriptions
- Monitoring
- Document Library processing
- Background tasks
- Cluster-wide request execution
- Clustered cache replication

You can use it too! Here are some of Message Bus's most important features:

- publish/subscribe messaging
- request queuing and throttling
- flow control
- multi-thread message processing

There are also tools, such as the Java SE's JConsole, that can monitor Message Bus activities.

The Message Bus topics are covered in these tutorials:

- Messaging Destinations
- Message Listeners
- Sending Messages

Since all messages are sent to and received at destinations, messaging destinations is worth exploring first.

Figure 119.1: JConsole shows statistics on Message Bus messages sent, messages pending, and more.

119.1 Messaging Destinations

In Message Bus, you send messages to *destinations*. A destination is a named logical (not physical) location. Sender classes send messages to destinations, while listener classes wait to receive messages at the destinations. In this way, the sender and recipient don't need to know each other–they're loosely coupled. Here are the messaging destination topics this tutorial covers:

- Destination configuration
- Creating a destination
- Messaging event listeners

It's time to configure a destination.

Destination Configuration

Each destination has a name and type and can have several other attributes. The destination type determines whether there's a message queue, the kinds of threads involved with a destination, and the message delivery behavior to expect at the destination.

Here are the primary destination types:

- **Parallel Destination**

  - Messages sent here are queued.
  - Multiple worker threads from a thread pool deliver each message to a registered message listener. There's one worker thread per message per message listener.

- **Serial Destination**

  - Messages sent here are queued.
  - Worker threads from a thread pool deliver the messages to each registered message listener, one worker thread per message.

- **Synchronous Destination**

  - Messages sent here are directly delivered to message listeners.
  - The thread sending the message here delivers the message to all message listeners also.

Liferay has preconfigured destinations for various purposes. The `DestinationNames` class defines `String` constants for each of them. For example, `DestinationNames.HOT_DEPLOY` (value is `"liferay/hot_deploy"`) is for deployment event messages. Since destinations are tuned for specific purposes, don't modify them.

Destinations are based on `DestinationConfiguration` instances. The configuration specifies the destination type, name, and these destination- related attributes:

Maximum Queue Size: limits the number of queued messages for the destination.

Rejected Execution Handler: A `com.liferay.portal.kernel.concurrent.RejectedExecutionHandler` instance can take action (e.g., log warnings) regarding rejected messages when the destination queue is full.

Workers Core Size: initial number of worker threads for processing messages.

Workers Max Size: limits the number of worker threads for processing messages.

The `DestinationConfiguration` class provides these static methods for creating the various types of configurations.

- `createParallelDestinationConfiguration(String destinationName)`
- `createSerialDestinationConfiguration(String destinationName)`
- `createSynchronousDestinationConfiguration(String destinationName)`

You can also use the `DestinationConfiguration` constructor to create a configuration for any destination type, even your own.

Creating a Destination

Message Bus destinations are based on destination configurations and registered as OSGi services. Message Bus detects the destination services and manages their associated destinations.

Here are the general steps for creating a destination. The example configurator class that follows demonstrates these steps.

1. Create a destination configuration using one of `DestinationConfiguration`'s static `create*` methods or its constructor. Set any attributes that apply to the destinations you'll create with it.

2. Create a destination by invoking the `DestinationFactory` method `createDestination(DestinationConfiguration)`, passing in the destination configuration you created in the previous step.

3. Register the destination as an OSGi service by invoking the `BundleContext` method `registerService`, passing in the following parameters.

    - Destination class `Destination.class`
    - Your `Destination` object
    - A `Dictionary` of properties defining the destination, including the `destination.name`

4. Manage the destination object and service registration resources using a collection, such as a `Map<String, ServiceRegistration<Destination>>`. Keeping references to these resources is helpful for when you're ready to unregister and destroy them. The `deactivate` method in example below demonstrates this.

Here's an example messaging configurator component that creates and registers a parallel destination and manages its resources:

```
@Component (
    immediate = true,
    service = MyMessagingConfigurator .class
)
public class MyMessagingConfigurator {

    @Activate
    protected void activate(BundleContext bundleContext) {

        _bundleContext = bundleContext;

        // Create a DestinationConfiguration for parallel destinations.

        DestinationConfiguration destinationConfiguration =
            new DestinationConfiguration(
                DestinationConfiguration.DESTINATION_TYPE_PARALLEL,
                    "myDestinationName");

        // Set the DestinationConfiguration's max queue size and
        // rejected execution handler.

        destinationConfiguration.setMaximumQueueSize(_MAXIMUM_QUEUE_SIZE);

        RejectedExecutionHandler rejectedExecutionHandler =
            new CallerRunsPolicy() {

                @Override
                public void rejectedExecution(
                    Runnable runnable, ThreadPoolExecutor threadPoolExecutor) {
```

```
                if (_log.isWarnEnabled()) {
                    _log.warn(
                        "The current thread will handle the request " +
                            "because the graph walker's task queue is at " +
                                "its maximum capacity");
                }

                super.rejectedExecution(runnable, threadPoolExecutor);
            }

        };

     destinationConfiguration.setRejectedExecutionHandler(
          rejectedExecutionHandler);

     // Create the destination

     Destination destination = _destinationFactory.createDestination(
          kaleoGraphWalkerDestinationConfiguration);

      // Add the destination to the OSGi service registry

      Dictionary<String, Object> properties = new HashMapDictionary<>();

      properties.put("destination.name", destination.getName());

      ServiceRegistration<Destination> serviceRegistration =
          _bundleContext.registerService(
              Destination.class, destination, properties);

      // Track references to the destination service registrations

      _serviceRegistrations.put(destination.getName(),
          serviceRegistration);
    }

    @Deactivate
    protected void deactivate() {

        // Unregister and destroy destinations this component unregistered

        for (ServiceRegistration<Destination> serviceRegistration :
        _serviceRegistrations.values()) {

            Destination destination = _bundleContext.getService(
                serviceRegistration.getReference());

            serviceRegistration.unregister();

            destination.destroy();

        }

        _serviceRegistrations.clear();

     }

    @Reference
    private DestinationFactory _destinationFactory;

    private final Map<String, ServiceRegistration<Destination>>
        _serviceRegistrations = new HashMap<>();
}
```

On activation, the example configurator above does these things:

1. Creates a `DestinationConfiguration` for parallel destinations.

2. Sets the `DestinationConfiguration`'s max queue size and a rejected execution handler.

3. Uses the `DestinationFactory` (the one bound to the `_destinationFactory` field) to create the destination.

4. Adds the destination to the OSGi service registry

5. Adds the destination service registration to a map for managing them.

Once the destination is registered, Message Bus detects its service and manages the destination. On the example configurator's deactivation, its `deactivate` method unregisters the destination services and destroys the destinations.

As an added bonus to creating destinations, you can create classes that listen for new destinations and new message listeners. You might want to create such listeners to keep up to log the deployment of new message bus endpoints.

Messaging Event Listeners

There are Message Bus framework interfaces that let you listen for new destinations and message listeners.

Listening for new Destinations

The Message Bus notifies Message Bus Event Listeners when destinations are added and removed. To register these listeners, publish a `MessageBusEventListener` instance to the OSGi service registry (e.g., via an `@Component` annotation).

```
@Component(
    immediate = true,
    service = MessageBusEventListener.class
)
public class MyMessageBusEventListener implements MessageBusEventListener {

    void destinationAdded(Destination destination) {
        ...
    }

    void destinationDestroyed(Destination destination) {
        ...
    }
}
```

Listening for new message listeners is easy too.

Listening for new Message Listeners

The Message Bus notifies `DestinationEventListener` instances when message listeners are either registered or unregistered to destinations. To register a listener to a destination, publish a `DestinationEventListener` service to the OSGi service registry, making sure to specify the destination's `destination.name` property.

```
@Component(
    immediate = true,
    property = {"destination.name=myCustom/Destination"},
    service = DestinationEventListener.class
)
public class MyDestinationEventListener implements DestinationEventListener {

    void messageListenerRegistered(String destinationName,
                                   MessageListener messageListener) {
        ...
    }

    void messageListenerUnregistered(String destinationName,
                                MessageListener messageListener) {
        ...
    }
}
```

And that's how you listen for new destinations and message listeners.

Now you understand the different destination types, how to create and register destinations, and how to manage destination resources. Once you deploy your destination, registered message listeners receive messages sent to it.

Related Topics

Message Listeners

Sending Messages

119.2 Message Listeners

If you're interested in messages sent to a destination, you need to "listen" for them. That is, you must create and register a message listener for the destination.

To create a message listener, implement the `MessageListener` interface and override its `receive(Message)` method to process messages your way.

```
public void receive(Message message) {
    // Process messages your way
}
```

Here are the ways to register your listener with Message Bus:

- **Automatic Registration as a Component**: Publish the listener to the OSGi registry as a Declarative Services Component that specifies a destination. Message Bus automatically wires the listener to the destination.

- **Registering via MessageBus**: Obtain a reference to the Message Bus and use it directly to register the listener to a destination.

- **Registering directly to a Destination**: Obtain a reference to a specific destination and use it directly to register the listener with that destination.

Note: The `DestinationNames` class defines `String` constants for Liferay's preconfigured destinations.

The Declarative Services component module provides the easiest way to register a message listener.

Automatic Registration as a Component

You can specify a message listener in the Declarative Services (DS) `@Component` annotation:

```
@Component (
    immediate = true,
    property = {"destination.name=myCustom/Destination"},
    service = MessageListener.class
)
public class MyMessageListener implements MessageListener {
   ...

   public void receive(Message message) {
       // Handle the message
   }
}
```

The Message Bus listens for `MessageListener` service components like this one to publish themselves to the OSGi service registry. The attribute `immediate = true` tells the OSGi framework to activate the component as soon as its dependencies resolve. Message Bus wires each registered listener to the destination its `destination.name` property specifies. If the destination is not yet registered, Message Bus queues the listener until the destination registers.

Registration as a component is the preferred way to register message listeners to destinations.

Registering via MessageBus

You can use the `MessageBus` instance directly to register message listeners to destinations. You might want to do this if, for example, you want to create some special proxy wrappers. Here's a registrator that demonstrates registering a listener this way:

```
@Component (
    immediate = true,
    service = MyMessageListenerRegistrator.class
)
public class MyMessageListenerRegistrator {
    ...

    @Activate
    protected void activate() {

        _messageListener = new MessageListener() {

            public void receive(Message message) {
                // Handle the message
            }
        };

        _messageBus.registerMessageListener("myDestinationName",
            _messageListener);
    }

    @Deactivate
    protected void deactivate() {
        _messageBus.unregisterMessageListener("myDestinationName",
            _messageListener);
    }

    @Reference
    private MessageBus _messageBus;

    private MessageListener _messageListener;
}
```

The `_messageBus` field's `@Reference` annotation binds it to the `MessageBus` instance. The `activate` method creates the listener and uses the Message Bus to register the listener to a destination named `"myDestination"`. When this registrator component is destroyed, the `deactivate` method unregisters the listener.

Registering directly to the Destination

You can use a `Destination` instance to register a listener to that destination. You might want to do this if, for example, you want to create some special proxy wrappers. Here's a registrator that demonstrates registering a listener this way:

```
@Component (
    immediate = true,
    service = MyMessageListenerRegistrator.class
)
public class MyMessageListenerRegistrator {
   ...

    @Activate
    protected void activate() {

        _messageListener = new MessageListener() {

            public void receive(Message message) {
                // Handle the message
            }
        };

        _destination.register(_messageListener);
    }

    @Deactivate
    protected void deactivate() {

        _destination.unregister(_messageListener);
    }

    @Reference(target = "(destination.name=someDestination)")
    private Destination _destination;

    private MessageListener _messageListener;
}
```

The `_destination` field's `@Reference` annotation binds it to a destination named `"someDestination"`. The `activate` method creates the listener and registers it to the destination. When this registrator component is destroyed, the `deactivate` method unregisters the listener.

Now you know how to create and register message listeners for receiving messages sent to the destinations.

Sending Messages

119.3 Sending Messages

Message Bus lets you send messages to destinations that have any number of listening classes. As a message sender you don't need to know the message recipients. Instead, you focus on creating message content (payload) and sending messages to destinations.

You can also send messages in a synchronous or asynchronous manner. The synchronous option waits for a response that the message was received or that it timed out. The asynchronous option gives you the "fire and forget" behavior; send the message and continue processing without waiting for a response.

Here are the message sending topics:

- Creating a message
- Sending a message (the way you want)
- Sending messages across a cluster

Start by creating a message.

Creating a Message

Here's how to create a message:

1. Call the `Message` constructor.

   `Message message = new Message();`

2. Populate the message with a `String` or `Object` payload

   - String payload: `message.setPayload("Message Bus is great!")`

   - Object payload: `message.put("firstName", "Joe")`

3. To receive responses at a particular location, set both of these attributes

   - Response destination name: `setResponseDestinationName(String)`

   - Response ID: `setResponseId(String)`

Your new message is ready to send.

Sending a Message

Here are the ways to send a message:

- Directly using the `MessageBus`
- Asynchronously using a `SingleDestinationMessageSender`
- Using a `SynchronousMessageSender`

First, let's consider using Message Bus directly.

Directly Using the Message Bus

This method involves obtaining a `MessageBus` instance and invoking it to send messages. Here's an example of directly using Message Bus to send a message.

```
@Component(
    immediate = true,
    service = SomeServiceImpl.class
)
public class SomeServiceImpl {
    ...

    public void sendSomeMessage() {

        Message message = new Message();
        message.put("myId", 12345);
        message.put("someAttribute", "abcdef");
        _messageBus.sendMessage("myDestinationName", message);
    }

    @Reference
    private MessageBus _messageBus;
}
```

To send messages asynchronously, consider using `SingleDestinationMessageSender`.

Using SingleDestinationMessageSender

The `SingleDestinationMessageSender` class wraps the Message Bus to send messages asynchronously. This class demonstrates using a `SingleDestinationMessageSender`:

```
@Component(
    immediate = true,
    service = SomeServiceImpl.class
)
public class SomeServiceImpl {
    ...

    public void sendSomeMessage() {

        Message message = new Message();
        message.put("myId", 12345);
        message.put("someValue", "abcdef");

        SingleDestinationMessageSender messageSender =
           _messageSenderFactory.createSingleDestinationMessageSender("myDestinationName");

        messageSender.send(message);
    }

    @Reference
    private SingleDestinationMessageSenderFactory _messageSenderFactory;
}
```

The `_messageSenderFactory` field's `@Reference` wires it to a `SingleDestinationMessageSenderFactory` instance. The method `sendSomeMessage` creates a message, uses the `_messageSenderFactory` to create a `SingleDestinationMessageSender` for the specified destination, and sends the message through the sender.

Using a SynchronousMessageSender

A `SynchronousMessageSender` instance sends a message to the Message Bus and blocks until receiving a response or the response times out. A `SynchronousMessageSender` has these operating modes:

- `DEFAULT`: Delivers the message in a separate thread and also provides timeouts, in case the message is not delivered properly.
- `DIRECT`: Delivers the message in the same thread of execution and blocks until it receives a response.

Here's an example of using `SynchronousMessageSender` in `DEFAULT` mode.

```
@Component(
    immediate = true,
    service = SomeServiceImpl.class
)
public class SomeServiceImpl {
    ...
    public void sendSomeMessage() {

        Message message = new Message();
        message.put("myId", 12345);
        message.put("someAttribute", "abcdef");

        SingleDestinationSynchronousMessageSender messageSender =
            _messageSenderFactory.createSingleDestinationSynchronousMessageSender(
                "myDestinationName", SynchronousMessageSender.Mode.DEFAULT);

        messageSender.send(message);

    }

    @Reference
    private SingleDestinationMessageSenderFactory _messageSenderFactory;
}
```

And those are the ways to send messages. Next, if you're in a cluster and want messages sent to a destination across all nodes, you must register a bridge message listener to that destination.

Sending Messages Across the Cluster

To ensure a message sent to a destination is received by all cluster nodes, you must register a `ClusterBridgeMessageListener` at that destination. This bridges the local destination to the cluster.

Here's a message listener registrator that bridges a destination for distributing messages to all the cluster nodes.

```
@Component(
    immediate = true,
    service = MyMessageListenerRegistrator.class
)
public class MyMessageListenerRegistrator {
    ...

    @Activate
    protected void activate() {

        _clusterBridgeMessageListener = new ClusterBridgeMessageListener();
        _clusterBridgeMessageListener.setPriority(Priority.LEVEL_5)
        _destination.register(_clusterBridgeMessageListener);
    }

    @Deactivate
    protected void deactivate() {

        _destination.unregister(_clusterBridgeMessageListener );
    }

    @Reference(target = "(destination.name=liferay/live_users)")
    private Destination _destination;

    private MessageListener _clusterBridgeMessageListener;
}
```

The destination named `"liferay/live_users"` is bound to the `_destination` field. The `activate` method creates a `ClusterBridgeMessageListener`, sets its priority queue, and registers it to the destination. Messages sent to the destination are distributed across the cluster's JVMs.

The `com.liferay.portal.kernel.cluster.Priority` class has ten levels (`Level_1` through `Level_10`, with `Level 10` being the most important). Each level is a priority queue for sending messages through the cluster. This is similar in concept to thread priorities: `Thread.MIN_PRIORITY`, `Thread.MAX_PRIORITY`, and `Thread.NORM_PRIORITY`.

That concludes the tour on sending messages. You've learned how to create messages, send messages synchronously and asynchronously, and send messages to a destination in a clustered environment.

Chapter 120

Audience Targeting

Liferay's Audience Targeting application lets you monitor your users. You can organize them into user segments, target specific content to those user segments, and create campaigns to expose user segments to a certain set of assets. Visit the Targeting Content to your Audience section for more information on Audience Targeting and how to use it.

Although the Audience Targeting app can be configured to monitor your audience out of the box, it is also designed as a framework to be extended by developers.

There are a set of extensions that can be easily hooked by creating other hot-deployable plugins.

These extension points include

- Rule Types
- Report Types
- Report Metrics

Audience Targeting extensions are created using OSGi modules. There are convenient Blade CLI templates for creating these projects, but you can create the modules any way you want. To use the templates, see the Blade CLI tutorials.

In this section's tutorials, you'll learn how to create these extension points for your Audience Targeting application.

120.1 Accessing the Content Targeting API

The Audience Targeting application can be used to show relevant content to users based on profiles. You might want to take the next step and use the Content Targeting API. For instance, you could list user segments in your own application or update a campaign when someone creates a calendar event. Using the Content Targeting API, you can unleash the power of Audience Targeting to the realms outside of Liferay's default applications.

In this tutorial, you'll learn how to give your application access to the Content Targeting API. Then you can view some examples of how to use the Java and JSON APIs that are available.

Exposing the Content Targeting API

Configuring your app to have access to the Content Targeting API requires only one line of code. This line of code is a dependency that should be added to your Gradle project. Follow the instructions below to add the Content Targeting API dependency.

1. Open the `build.gradle` file in your app's project folder.
2. Find the `dependencies` declaration and add the following line within that declaration:

   ```
   provided group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.api", version: "4.0.0"
   ```

   The complete declaration should look like this:

   ```
   dependencies {
       ...
       provided group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.api", version: "4.0.0"
   }
   ```

Your app now has access to the Content Targeting API and can take advantage of everything Audience Targeting has to offer. In the next section, you'll learn how to use the Content Targeting API by studying a few examples.

Using the Content Targeting Java API

There are two ways to call the Content Targeting API: through the Java API or through the JSON API.

Suppose you'd like to display a list of existing user segments in your portlet. First you need to obtain an implementation of the `UserSegmentLocalService` provided by Audience Targeting. You can do this by adding the following code to your Portlet class (e.g., the class that extends the `MVCPortlet` class):

```
@Reference(unbind = "-")
protected void setUserSegmentLocalService(
    UserSegmentLocalService userSegmentLocalService) {

    _userSegmentLocalService = userSegmentLocalService;
}

private UserSegmentLocalService _userSegmentLocalService;
```

When an implementation of the `UserSegmentLocalService` is available (i.e., the Audience Targeting app has been installed) the `_userSegmentLocalService` field is populated. Otherwise, the portlet won't be available till this dependency is resolved.

It's a good practice to access Audience Targeting services this way instead of using util classes (e.g., `UserSegmentLocalServiceUtil.java`). You can take advantage of dependency management, and you also won't be tied to a specific implementation of the service.

The next step is to use the service to obtain a list of existing user segments and make it available to your view layer as a request attribute. To do this, add logic to your portlet class that obtains user segments and exposes them as a request attribute, like this:

```
ThemeDisplay themeDisplay = (ThemeDisplay)renderRequest.getAttribute(
    WebKeys.THEME_DISPLAY);

List<UserSegment> userSegments = null;

try {
```

```
    userSegments = _userSegmentLocalService.getUserSegments(
        themeDisplay.getScopeGroupId());
}
catch (Exception e) {
    _log.error(e, e);
}

renderRequest.setAttribute("userSegments", userSegments);

private static final Log _log = LogFactoryUtil.getLog(MyPortlet.class)
```

Notice that the `userSegments` list is populated by calling `UserSegmentLocalService`'s `getUserSegments` method. This service is part of the Content Targeting API.

To finish off this example, some logic needs to be added to your portlet's `view.jsp`:

```
<h2>User Segments</h2>

<ul>

<%
List<UserSegment> userSegments = (List<UserSegment>)request.getAttribute("userSegments");

for (UserSegment userSegment : userSegments) {
%>

    <li><%= userSegment.getName(locale) %></li>

<%
}
%>

</ul>
```

This logic uses the `UserSegment` object to list the existing user segments. That's it! By importing the `UserSegment` and `UserSegmentLocalService` classes into your files, you have direct access to your portal's user segments through the Content Targeting Java API.

Using the Content Targeting JSON API

Suppose you'd like to show a list of existing campaigns in your portlet using the JSON API. You could do this by opening your portlet's `view.jsp` file and using the following code:

```
<h2>Campaigns</h2>

<ul id="<portlet:namespace/>campaigns">
</ul>

<aui:script use="aui-base">
    var campaignsList = A.one('#<portlet:namespace/>campaigns');

    Liferay.Service(
        '/ct.campaign/get-campaigns',
        {
        groupId: '<%= scopeGroupId %>'
        },
        function(response) {
            if (response.length) {
                A.Array.each(response, function(item) {
                    campaignsList.append('<li>' + item.name + '</li>');
                });
            }
        }
    );
</aui:script>
```

Notice that the Content Targeting API is called to retrieve the existing campaigns:

```
...
Liferay.Service(
    '/ct.campaign/get-campaigns',
    {
...
```

Then, each campaign is listed in the `campaignsList` and displayed in your portlet for users to see.

If you'd like to view all the available methods (with examples) exposed in the JSON API by Audience Targeting, you can visit the `/api/jsonws` URL (e.g., `localhost:8080/api/jsonws`). As you can see, accessing the Content Targeting JSON API is just as easy as accessing the related Java API.

You've learned how easy it is to expose the Content Targeting API and use it in your application to unleash its power!

Targeting Content to Your Audience

Running Service Builder and Understanding the Generated Code

120.2 Creating New Audience Targeting Rule Types

In the Audience Targeting application, a User Segment is defined as a group of users that match a set of rules. Out of the box, Liferay provides several types of rules that are based on characteristics such as age range, gender, location, and so on. You combine these rules to create User Segments. For example, if you want to target probable buyers of a shoe that has a particular style, you might create a User Segment composed of Females over 40 who live in urban areas.

The Audience Targeting app ships with many rules you can use make up User Segments, but it's also extensible. This means that if there isn't a rule that already fits your case, you can create it yourself!

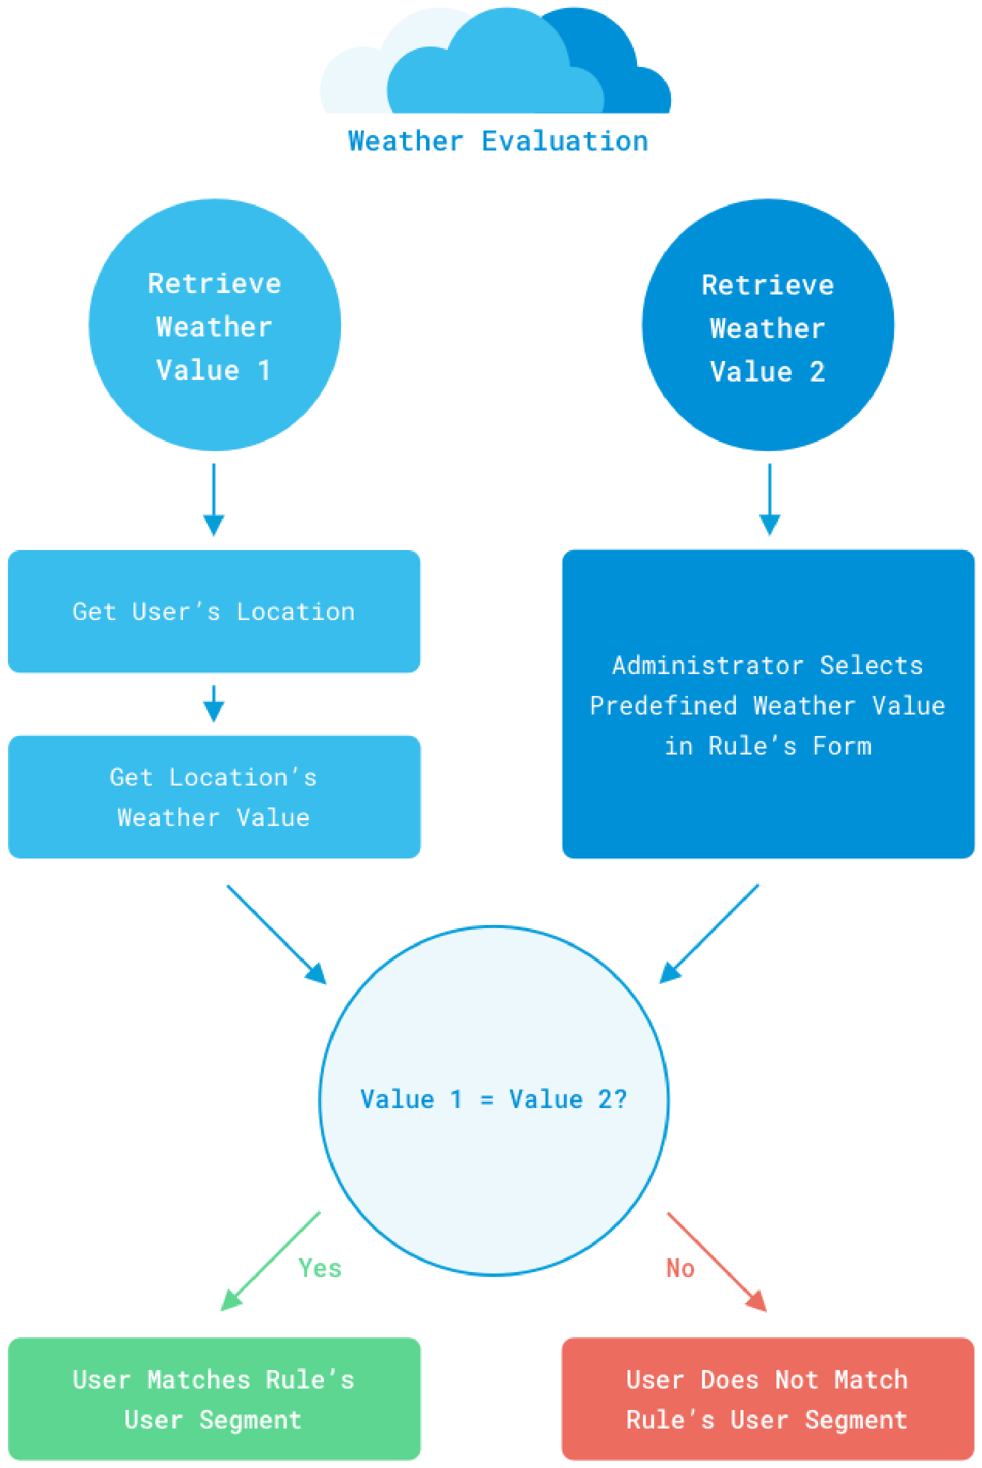
Creating a rule type involves targeting what you want to evaluate. Suppose you own an Outdoor Sporting Goods store. On your website, you'd like to promote goods that are appropriate for the current weather. If a user is from Los Angeles and it's raining the day he or she visits your website, you could show that user new umbrellas. If it's sunny, however, you could show the user sunglasses instead. For this example, your evaluation entity would be weather based on the user's location. To make this work, you'll need to do two things:

1. Retrieve the user's location so you can obtain that location's weather.

2. Let administrators set the value that should be compared with the user's current weather, using a UI component like a selection list of weather options.

With this design, an administrator can set *rainy* as the value for the rule, and the rule could be added to a user segment targeted for rain-related goods. When users visit your site, their user segment assignments come from matching the weather in their current locations with the rule's preset weather value (rainy). On a match, you show rain-related content; otherwise, the user is part of a different User Segment and sees that segment's content, like a promotion for sunglasses.

Now that you have an idea of how to plan your custom rule's development, you'll begin creating one yourself!



Weather Evaluation
Retrieve Weather Value 1
Retrieve Weather Value 2
Get User’s Location
Get Location’s Weather Value
Administrator Selects Predefined Weather Value in Rule’s Form
Value 1 = Value 2?
Yes
No
User Matches Rule’s User Segment
User Does Not Match Rule’s User Segment

Figure 120.1: This diagram breaks down the evaluation process for the weather rule.

Creating a Custom Rule Type

Adding a new type of rule to the Audience Targeting application is easy. First, you must create a module and ensure it has the necessary Content Targeting API dependencies.

1. Create a module project for deploying a rule. A Blade CLI content-targeting-rule template is available to help you get started quickly. It sets the default configuration for you, and it contains boilerplate code so you can skip the file creation steps and get started right away.

2. Make sure your module specifies the dependencies necessary for an Audience Targeting rule. For example, you should specify the Content Targeting API and necessary Liferay packages. For example, this is the example `build.gradle` file used from a Gradle based rule:

```
dependencies {
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.analytics.api", version: "3.0.0"
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.anonymous.users.api", version: "2.0.2"
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.api", version: "4.0.0"
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.3.0"
    compileOnly group: "com.liferay.portal", name: "com.liferay.util.taglib", version: "2.0.0"
    compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
    compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
    compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

   You can learn more about exposing the Content Targeting API in the Accessing the Content Targeting API tutorial. Once you've created your module and specified its dependencies, you'll need to define your rule's behavior. How your rule behaves is controlled by a Java class file that you create.

3. Create a unique package name in the module's `src` directory, and create a new Java class in that package. To follow naming conventions, your class name should begin with the rule name you're creating, and end with *Rule* (e.g., `WeatherRule.java`). Your Java class should implement the `com.liferay.content.targeting.api.model.Rule` interface.

   It is required to implement the Rule interface, but there are `Rule` extension classes that provide helpful utilities that you can extend. For example, your rule can extend the BaseJSPRule class to support generating your rule's UI using JSPs. This tutorial demonstrates implementing the UI using a JSP, and assumes the `Rule` interface is implemented by extending the `BaseJSPRule` class. For more information on choosing a UI for your rule, see the Selecting a UI Technology section.

4. Directly above the class's declaration, insert the following code:

```
@Component(immediate = true, service = Rule.class)
```

   This annotation declares the implementation class of the Component and specifies to immediately start the module once deployed to Liferay DXP.

Now that your Java class is set up, you'll need to define how your rule works by implementing the Rule interface's methods. You'll begin implementing these methods next.

Note: If you're planning on developing a social rule type that classifies users based on their social network profile, it's important to remember that the specific social network's SSO (Single Sign On) must be enabled and configured properly. Visit the Social Rules section for more details.

The first thing you'll define in your weather rule is the view/save lifecycle.

Defining a Rule's View/Save Lifecycle

This section covers how to define a rule's view/save lifecycle. This is when a user applies a rule to a user segment using the User Segment Editor.

In this section, you'll begin defining the weather rule's Java class. This assumes that you followed the instructions above, creating the `WeatherRule` class and extending BaseJSPRule. If you used the `content-targeting-rule` Blade CLI template, your project is already extending `BaseJSPRule` and has a default `view.jsp` file already created.

1. Add the activation and deactivation methods to your class.

   ```
   @Activate
   @Override
   public void activate() {
       super.activate();
   }

   @Deactivate
   @Override
   public void deActivate() {
       super.deActivate();
   }
   ```

   These methods call the super class BaseRule to implement necessary logging and processing for when your rule starts and stops. Make sure to include the @Activate and @Deactivate annotations, which are required.

2. Define the category for the Rule when displayed in the User Segment Editor.

   ```
   @Override
   public String getRuleCategoryKey() {
       return SessionAttributesRuleCategory.KEY;
   }
   ```

   This code puts the weather rule in the Session Attributes category. To put your rule into the appropriate category, use the `getRuleCategoryKey` method to return the category class's key. Available category classes include BehaviourRuleCategory, SessionAttributesRuleCategory, SocialRuleCategory, and UserAttributesRoleCategory.

3. Add the following method:

   ```
   @Override
   protected void populateContext(
       RuleInstance ruleInstance, Map<String, Object> context,
       Map<String, String> values) {

       String weather = "";

       if (!values.isEmpty()) {
           weather = GetterUtil.getString(values.get("weather"));
       }
       else if (ruleInstance != null) {
           weather = ruleInstance.getTypeSettings();
       }

       context.put("weather", weather);
   }
   ```

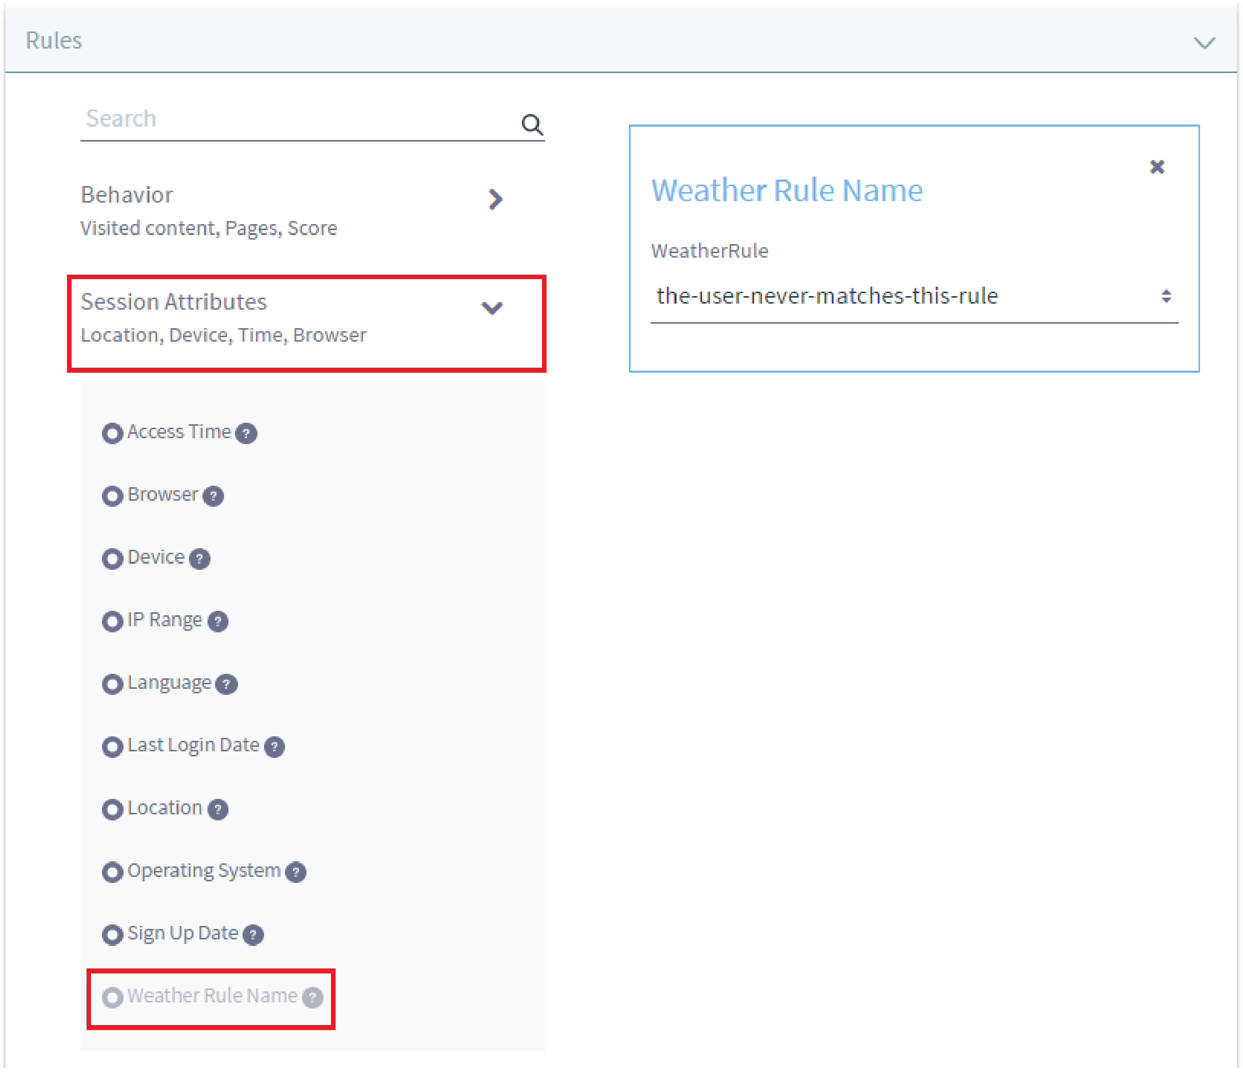


Figure 120.2: This example Weather rule was modified to reside in the Session Attributes category.

To understand what this method accomplishes, you'll need to examine the rule's configuration lifecycle.

When the user opens the User Segment Editor, the render phase begins for the rule. The `getFormHTML(...)` method retrieves the HTML to display. You don't have to worry about implementing this method because it's already implemented in the BaseJSPRule class you're extending. The `getFormHTML` method calls the `populateContext(...)` method.

You'll notice the `populateContext` method is not available in the Rule interface. This is because it's not needed in all cases. It's available by extending the BaseJSPRule class, and you'll need to add more logic to it for the weather rule.

The goal of the `populateContext` method is to generate a map with all the parameters your JSP view needs to render the rule's HTML. This map is stored in the `context` variable, which is pre-populated with basic values in the Portlet logic, and then each rule contributes its specific parameters to it. The `populateContext` method above populates a `weather` context variable with the `weather` values from the `values` map parameter, which is then passed to the JSP.

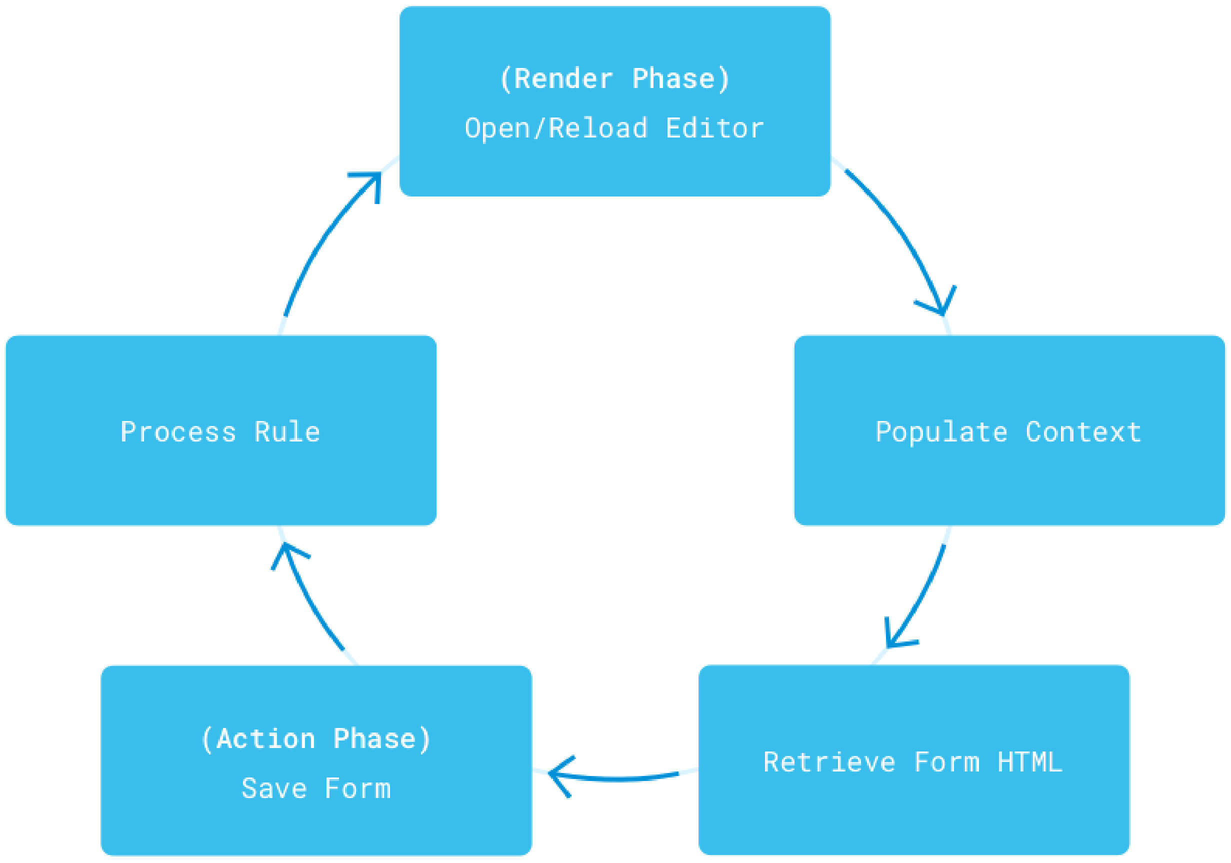

Figure 120.3: An Audience Targeting rule must be configured by the user and processed before it can become part of a User Segment.

For the weather rule, the `populateContext` method accounts for three use cases:

a. The rule was added but has no set values yet. In this case, the default values defined by the developer are injected (e.g., `weather=""`).

b. The rule was added and a value is set, but the request failed to complete (e.g., due to an error). In this case, the `values` parameter of the `populateContext` method contains the values that were intended to be saved, and they are injected so that they are displayed in the rule's view together with the error message.

c. The rule was added and a value was successfully set. In this case, the `values` parameter is empty, and you have to obtain the values from storage that the form should display and inject them in the context so they're displayed in the rule's HTML. The weather rule uses the `typeSettings` field of the rule instance, but complex rules could use services to store values.

You can think of the `populateContext` method as the intermediary between your JSP and your backend code. You can see how to create the weather rule's UI using a JSP by seeing the Defining the Rule's UI section. Once the HTML is successfully retrieved and the user has set the weather value and clicked *Save*, the action phase begins.

4. Add the following method:

   ```
   @Override
   public String processRule(
       PortletRequest portletRequest, PortletResponse portletResponse,
       String id, Map<String, String> values) {

       return values.get("weather");
   }
   ```

   The `processRule(...)` method is invoked when the action phase is initiated. The `values` parameter only contains the value(s) the user added in the form. The logic you could add to a `processRule` method is outlined below.

   a. Obtain the value(s) from the `values` parameter.

   b. (Optional) Validate the data consistency and possible errors. If anything is wrong, throw an InvalidRuleException and prohibit the values from being stored. In the weather rule scenario, when the rule is reloaded after an exception is thrown in the form, case 3b from the previous step occurs.

   c. Return the value to be stored in the rule instance's `typeSettings` field. The `typeSettings` field is managed by the framework in the Rule Instance table. If your rule has its own storage mechanism, then you should call your services in the `processRule` method.

   Once the rule processing ends, the form is reloaded and the lifecycle restarts again. The value(s) selected in the rule are stored and are ready to be accessed once user segment evaluation begins. There are a couple more methods you'll need to add to the `WeatherRule` class before defining the rule's evaluation.

5. Define a way to retrieve the rule's localized summary. In many instances, you can do this by combining keys in the rule's resource bundle with the information stored for the rule. For the weather rule, you can return the rule's type settings, which contains the selected weather condition.

   ```
   @Override
   public String getSummary(RuleInstance ruleInstance, Locale locale) {
       return ruleInstance.getTypeSettings();
   }
   ```

6. Set the servlet context for your rule.

   ```
   @Override
   @Reference(
       target = "(osgi.web.symbolicname=weather)",
       unbind = "-"
   )
   public void setServletContext(ServletContext servletContext) {
       super.setServletContext(servletContext);
   }
   ```

   This is only required for rules extending the BaseJSPRule class. The servlet context must be set for the rule to render its own JSP files. The `setServletContext` method is invoked automatically when the rule module is installed and resolved in Liferay. Make sure the `osgi.web.symbolicname` in the `target` property of the `@Reference` annotation is set to the same value as the `Bundle-SymbolicName` defined in the `bnd.bnd` file of the module.

Next, you'll learn how to evaluate a rule that is configured and saved to a user segment.

Evaluating a Rule

Imagine an administrator has successfully configured and saved your custom rule to his or her user segment. Now what? Your rule needs to fulfill its purpose, which is to evaluate the preset weather value compared to a user's weather value visiting the site. If the user's value matches the preset value (along with the segment's other rules), that user is added to the user segment.

1. You must implement the `evaluate(...)` rule to begin the evaluation process. This method is part of the user segmentation lifecycle. When a page is loaded, Liferay invokes the `evaluate` method of the rule to determine if the current user belongs to the user segment. For the weather rule, add this `evaluate` method:

   ```
   @Override
   public boolean evaluate(
           HttpServletRequest request, RuleInstance ruleInstance,
           AnonymousUser anonymousUser)
       throws Exception {

       String userWeather = getUserWeather(anonymousUser);

       String weather = ruleInstance.getTypeSettings();

       if (Validator.equals(userWeather, weather)) {
           return true;
       }

       return false;
   }
   ```

   You acquire the user's weather by calling the `getUserWeather` method, which you'll define later. Then you get the preset weather value by accessing the rule instance's `typeSettings` parameter. Finally, you compare the two values. If they match, return `true`; otherwise return `false`. Remember that users are only added to User Segments when all the Rules in the User Segment return true.

2. Next, you need to retrieve the user's weather. As you learned earlier, you must access the user's location first. Add the logic below to do this.

   ```
   protected String getCityFromUserProfile(long contactId, long companyId)
       throws PortalException, SystemException {

       List<Address> addresses = AddressLocalServiceUtil.getAddresses(companyId, Contact.class.getName(), contactId);

       if (addresses.isEmpty()) {
           return null;
       }

       Address address = addresses.get(0);

       return address.getCity() + StringPool.COMMA + address.getCountry().getA2();
   }
   ```

   This method retrieves the location by accessing the user's profile information. You could also have used a geo-location service to find this by the user's IP address. Once you have the user's location, you can find the current weather for that location.

3. Add the following method to retrieve a user's weather forecast.

```
protected String getUserWeather(AnonymousUser anonymousUser)
    throws PortalException, SystemException {

    User user = anonymousUser.getUser();

    String city = getCityFromUserProfile(user.getContactId(), user.getCompanyId());

    Http.Options options = new Http.Options();

    String location = HttpUtil.addParameter(API_URL, "q", city);
    location = HttpUtil.addParameter(location, "format", "json");

    options.setLocation(location);

    int weatherCode = 0;

    try {
        String text = HttpUtil.URLtoString(options);

        JSONObject jsonObject = JSONFactoryUtil.createJSONObject(text);

        weatherCode = jsonObject.getJSONArray("weather").getJSONObject(0).getInt("id");
    }
    catch (Exception e) {
        _log.error(e);
    }

    return getWeatherFromCode(weatherCode);
}

private static Log _log = LogFactoryUtil.getLog(WeatherRule.class);
```

This method calls the `getCityFromUserProfile` method to acquire the user's location. Then it retrieves the weather code for that location from a weather service.

4. Set the `API_URL` field to the Open Weather Map's API URL:

```
private static final String API_URL = "http://api.openweathermap.org/data/2.5/weather";
```

   For the weather rule, you can access Open Weather Map's APIs to retrieve the weather code.

5. The last thing is to convert the weather code to a string you can evaluate (e.g., sunny). Add the following method to convert Open Weather Map's weather codes:

```
protected String getWeatherFromCode(int code) {
    if (code == 800 || code == 801) {
        return "sunny";
    }
    else if (code > 801 && code < 805) {
        return "clouds";
    }
    else if (code >= 600 && code < 622) {
        return "snow";
    }
    else if (code >= 500 && code < 532) {
        return "rain";
    }

    return null;
}
```

   All possible weather codes are here.

Excellent! You've implemented the evaluate method and added the necessary logic in your -Rule class to acquire a user's local weather. The weather rule's behavior is defined and complete. The last thing you need to do is create a JSP template.

Defining the Rule's UI

The Java code you've added to this point has assumed that a preset weather value is available for comparing during the evaluation process. To let administrators set that value, you must define a UI so your rule can be configured during the view/save lifecycle. Create a `view.jsp` file in your rule's module (e.g., `/src/main/resources/META-INF/resources/view.jsp`) and add the following logic:

```
<%
Map<String, Object> context = (Map<String, Object>)request.getAttribute("context");

String weather = (String)context.get("weather");
%>

<aui:fieldset>
    <aui:select name="weather" value="<%= weather %>">
        <aui:option label="sunny" value="sunny" />
        <aui:option label="clouds" value="clouds" />
        <aui:option label="snow" value="snow" />
        <aui:option label="rain" value="rain" />
    </aui:select>
</aui:fieldset>
```

The `weather` variable in the `context` map should be set for the weather rule. When the user selects an option, it's passed from the view template to the `populateContext` method.

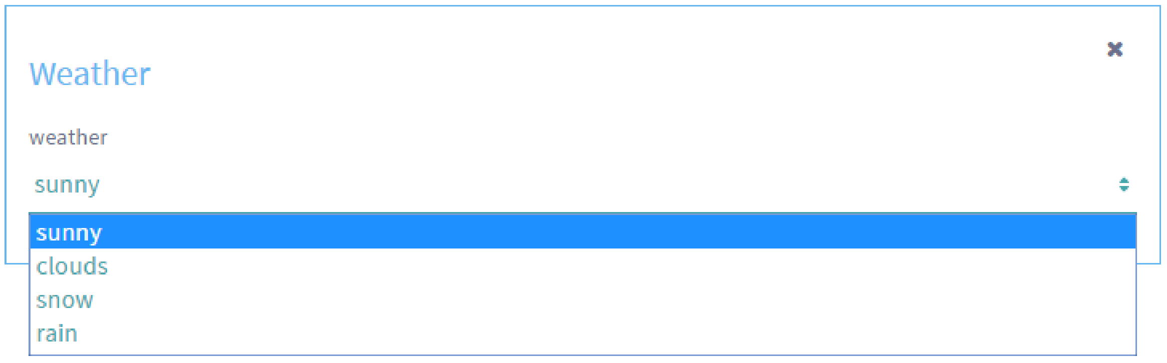

Figure 120.4: The weather rule uses a select drop-down box to set the weather value.

The weather rule uses JSP templates to display the rule's view. Audience Targeting, however, is compatible with any UI technology. Visit the Selecting a UI Technology section for details on how to use other UI technologies like FreeMarker.

Congratulations! You've created the weather rule and can now target users based on their weather conditions. You can view the finished version of the weather rule by downloading its ZIP file.

Now you've created and examined a fully functional rule and have the knowledge to create your own.

120.3 Tracking User Actions with Audience Targeting

In the Audience Targeting (AT) application, a campaign defines a set of content targeted to specific user segments during a time period. Campaign custom reports allow campaign administrators to learn how users behave in the context of a campaign by monitoring their interaction over different elements of the site. Out of the box, Liferay provides several metrics that are based on entity types that you can track, such as content, forms, links, pages, etc. You can use these metrics to create custom reports. For example, if you want track how many users watch a YouTube video that is published on your site, you might create a custom report with the YouTube Videos metric.

The AT app ships with many metrics you can apply to custom reports, but it's also extensible. This means that if the default metrics available do not fulfill your needs, you can create one yourself!

A metric's development strategy comes down to four choices:

- Entity to Track
- Tracking Mechanism
- Tracking Events
- Differentiation Method

Creating a metric involves targeting what you want to track in a custom report. Suppose you're the owner of a hardware store and you'd like to send emails to your customers notifying them of the store's weekly newsletter. You send the email every week, but you're in the dark about how many customers actually open and read the newsletter. For this example, your entity to track is a newsletter.

To track how many customers view the newsletter, you'll need to create a tracking mechanism. You can provide a custom tracking mechanism (e.g., a servlet) or you can use the ones provided by Audience Targeting. For a newsletter, you could use a transparent image as the tracking mechanism, which would have the *View* tracking event capability. Whenever the image is viewed, the Audience Targeting app computes and stores the information.

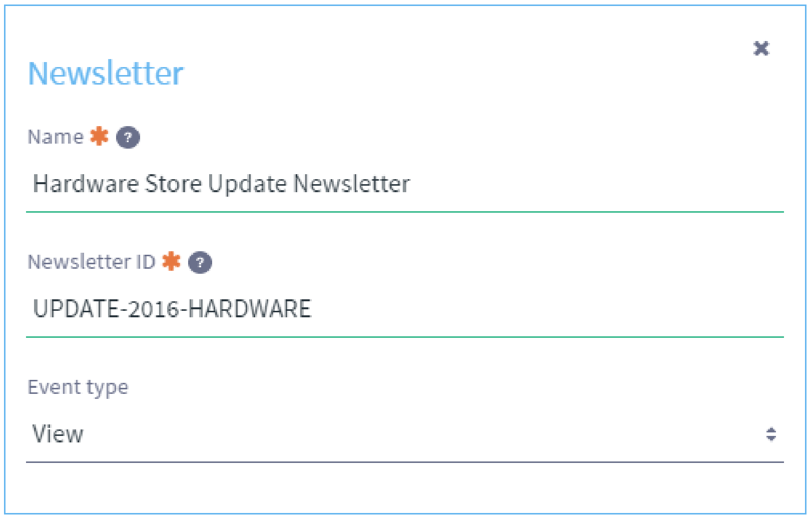
In many cases, a metric can have multiple tracking event options. For example, the YouTube Videos metric provides tracking event options like Buffering, Playing, Paused, Ended, etc. This lets you track different kinds of actions on an entity, providing a more accurate report on user interactions.

Finally, you must assign the metric to an entity. For a newsletter, you could provide a Newsletter ID field that the user could fill in to differentiate newsletters, if there's more than one.

To learn more about how metrics are used in the Audience Targeting application, visit the Defining Metrics section.

For this tutorial, you'll create a newsletter that can track who views it. This process involves defining the view/save lifecycle, which is when a user applies a metric to a report using the Report Editor. Then you'll define its tracking mechanism, tracking event(s), and differentiation method, similar to what was described above.

Now that you have an idea of how to plan your new metric, you'll begin creating one next!



Newsletter

Name *

Hardware Store Update Newsletter

Newsletter ID *

UPDATE-2016-HARDWARE

Event type

View

Figure 120.5: The sample Newsletter metric requires the newsletter name, ID, and event type.

Creating a Metric

Adding a new metric to the Audience Targeting application is easy. First, you must create a module and ensure it has the necessary Content Targeting API dependencies.

1. Create a module project for deploying a metric. A Blade CLI content-targeting-tracking-action template is available to help you get started quickly. It sets the default configuration for you, and it contains boilerplate code so you can skip the file creation steps and get started right away.

2. Make sure your module specifies the dependencies necessary for an Audience Targeting metric. For example, you should specify the Content Targeting API and necessary Liferay packages. For example, this is the example `build.gradle` file used from a Gradle based metric:

```
dependencies {
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.analytics.api", version: "3.0.0"
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.anonymous.users.api", version: "2.0.2"
    compileOnly group: "com.liferay.content-targeting", name: "com.liferay.content.targeting.api", version: "4.0.0"
    compileOnly group: "com.liferay.portal", name: "com.liferay.portal.kernel", version: "2.3.0"
    compileOnly group: "com.liferay.portal", name: "com.liferay.util.taglib", version: "2.0.0"
    compileOnly group: "javax.portlet", name: "portlet-api", version: "2.0"
    compileOnly group: "javax.servlet", name: "javax.servlet-api", version: "3.0.1"
    compileOnly group: "org.osgi", name: "org.osgi.service.component.annotations", version: "1.3.0"
}
```

   You can learn more about exposing the Content Targeting API in the Accessing the Content Targeting API tutorial. Once you've created your module and specified its dependencies, you'll need to define your metric's behavior. How your metric behaves is controlled by a Java class file that you create.

3. Create a unique package name in the module's src directory, and create a new Java class in that package. To follow naming conventions, your class name should begin with the metric's name you're creating and end with *TrackingAction* (e.g., `NewsletterTrackingAction.java`). Your Java class should implement the com.liferay.content.targeting.api.model.TrackingAction‘ interface.

   You must implement the TrackingAction interface, but there are `TrackingAction` extension classes that provide helpful utilities that you can extend. For example, your metric can extend the BaseJSP-TrackingAction class to support generating your metric's UI using JSPs. This tutorial demonstrates implementing the UI using a JSP and assumes the TrackingAction interface is implemented by extending the `BaseJSPTrackingAction` class. For more information on choosing a UI for your metric, see the Selecting a UI Technology section.

4. Directly above the class's declaration, insert the following annotation:

   ```
   @Component(immediate = true, service = TrackingAction.class)
   ```

   This declares the Component's implementation class and configures it to start immediately once deployed to Liferay DXP.

Now that your Java class is set up, you'll need to define how your metric works by implementing the TrackingAction interface's methods. You'll begin implementing these methods next.

The first thing you'll define in your newsletter metric is the view/save lifecycle.

Defining a Metric's View/Save Lifecycle

This section covers how to define a metric's view/save lifecycle. This is when a user applies a metric to a report using the Report Editor.

In this section, you'll begin defining the newsletter metric's Java class. This assumes that you followed the instructions above, creating the `NewsletterTrackingAction` class and extending BaseJSPTrackingAction. If you used the `content-targeting-tracking-action` Blade CLI template, your project is already extending `BaseJSPTrackingAction` and a default `view.jsp` file is already created.

1. Add the activation and deactivation methods to your class.

   ```
   @Activate
   @Override
   public void activate() {
       super.activate();
   }

   @Deactivate
   @Override
   public void deActivate() {
       super.deActivate();
   }
   ```

   These methods call the super class BaseTrackingAction to implement necessary logging and processing for when your metric starts and stops. Make sure to include the @Activate and @Deactivate annotations, which are required.

2. Add the following method:

   ```
    @Override
    protected void populateContext(
        TrackingActionInstance trackingActionInstance,
        Map<String, Object> context, Map<String, String> values) {

        String alias = StringPool.BLANK;
        String elementId = StringPool.BLANK;
        String eventType = StringPool.BLANK;

        if (!values.isEmpty()) {
            alias = values.get("alias");
            elementId = values.get("elementId");
   ```

```
        eventType = values.get("eventType");
    }
    else if (trackingActionInstance != null) {
        alias = trackingActionInstance.getAlias();
        elementId = trackingActionInstance.getElementId();
        eventType = trackingActionInstance.getEventType();
    }

    context.put("alias", alias);
    context.put("elementId", elementId);
    context.put("eventType", eventType);
    context.put("eventTypes", getEventTypes());
}
```

To understand what this method accomplishes, you should understand the metric's configuration lifecycle.

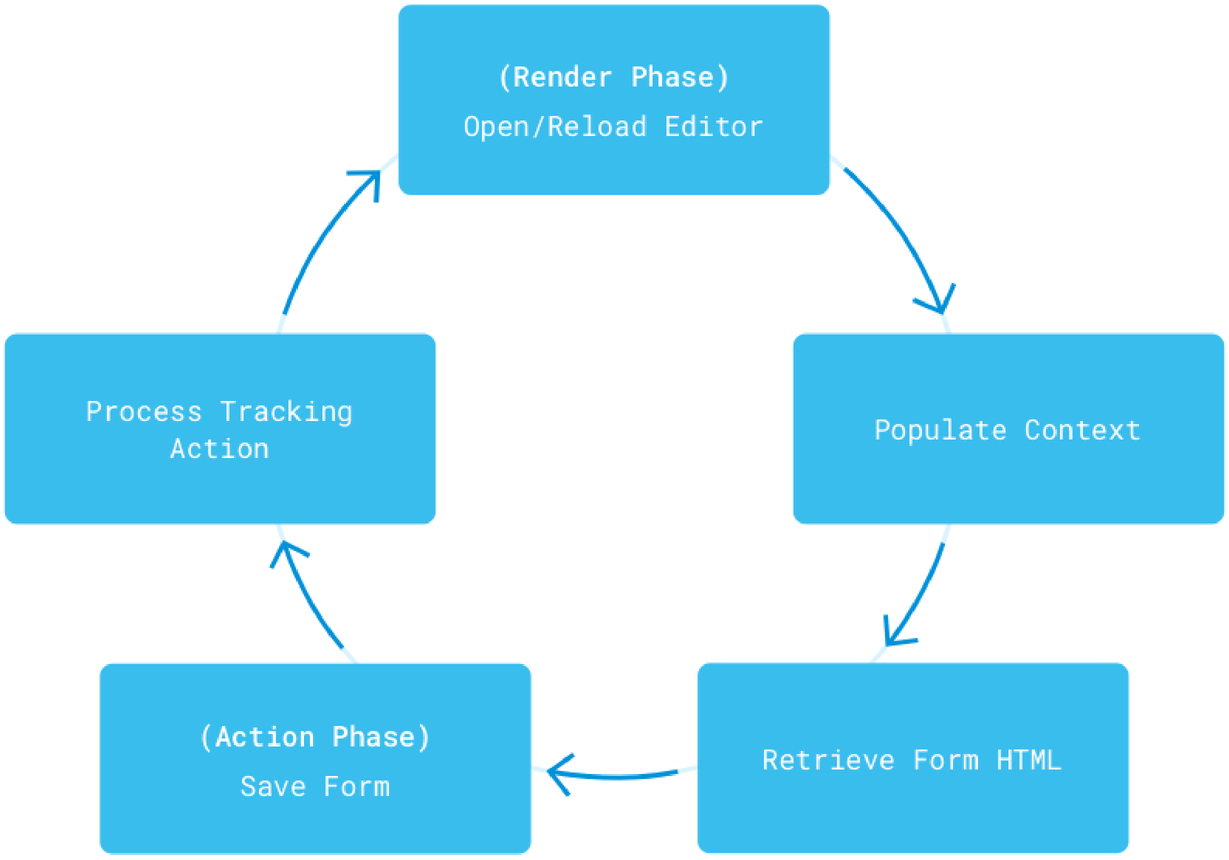


Figure 120.6: An Audience Targeting metric must be configured by the user and processed before it can become part of a Report.

When the user opens the Report Editor, the render phase begins for the metric. The `getFormHTML(...)` method retrieves the HTML to display. You don't have to worry about implementing this method because it's already implemented in the BaseJSPTrackingAction class you're extending. The `getFormHTML` method calls the `populateContext(...)` method.

You'll notice the `populateContext` method is not available in the TrackingAction interface. This is because it's not needed in all cases. It's available by extending the `BaseJSPTrackingAction` class, and you'll need to add more logic to it for the newsletter metric.

The goal of the `populateContext` method is to generate a map with all the parameters your JSP view needs to render the metric's HTML. This map is stored in the `context` variable, which is pre-populated with basic values in the Portlet logic, and then each metric contributes its specific parameters to it. The `populateContext` method above populates the `alias`, `elementId`, `eventType`, and `eventTypes` context variables with the adjacent values from the `values` map parameter, which is then passed to the JSP.

For the newsletter metric, the `populateContext` method accounts for three use cases:

a. The metric was added but has no set values yet. In this case, the default values defined by the developer are injected (e.g., `alias=""`).

b. The metric was added and a value is set, but the request failed to complete (e.g., due to an error). In this case, the `values` parameter of the `populateContext` method contains the values that were intended to be saved, and they are injected so that they are displayed in the metric's view together with the error message.

c. The metric was added and a value was successfully set. In this case, the `values` parameter is empty, and you have to obtain the values from storage that the form should display and inject them in the context so they're displayed in the metric's HTML. The newsletter metric stores values in the metric's instance, but complex metrics could use services to store values.

You can think of the `populateContext` method as the intermediary between your JSP and your backend code. You can see how to create the newsletter metric's UI using a JSP by skipping to the Defining the Metric's UI section. Once the HTML is successfully retrieved and the user has set the newsletter's values and clicked *Save*, the action phase begins.

3. Once the action phase begins, AT processes the tracking action (metric). The `processTrackingAction(...)` method takes the values from the metric's UI form and stores them in the corresponding fields of the `trackingActionInstance`. Since the BaseTrackingAction class provides a default implementation of this method that returns `null`, the `NewsletterTrackingAction` class does not need to implement it.

   If you need to process any custom fields in your metric, you should override this method. If you want your custom values to be stored in the `typeSettings` field of the `trackingActionInstance`, return their value instead of `null`.

```
**Note:** For more complex cases, you can create your own services to store
your metric's information to a database. You should invoke your services'
update logic within the `processTrackingAction` method. For more information
on creating services, see the
[Service Builder](/docs/7-0/tutorials/-/knowledge_base/t/service-builder)
tutorials.
```

```
Once the metric processing ends, the form is reloaded and the lifecycle
restarts again. The value(s) specified in the metric are stored and are
ready to be accessed once the report generation begins. Next, you must set
the event types that the newsletter metric should evaluate.
```

4. Add the following method and private field:

   ```
   @Override
   public List<String> getEventTypes() {
       return ListUtil.fromArray(_EVENT_TYPES);
   }

   private static final String[] _EVENT_TYPES = {"view"};
   ```

   This specifies that your newsletter metric only tracks who views the newsletter.

5. Define a way to retrieve the metric's localized summary. In many instances, you can do this by combining keys in the metric's resource bundle with the information stored for the metric. For the newsletter metric, you can provide information about the ID of the newsletter being tracked, which is stored in the `alias` field of the `trackingActionInstance` object.

   ```
   @Override
   public String getSummary(
       String summary = LanguageUtil.format(
           locale, "tracking-newsletter-x",
           new Object[] {trackingActionInstance.getAlias()});

       return summary;
   }
   ```

6. Set the servlet context for your metric.

   ```
   @Override
   @Reference(
       target = "(osgi.web.symbolicname=newsletter)",
       unbind = "-"
   )
   public void setServletContext(ServletContext servletContext) {
       super.setServletContext(servletContext);
   }
   ```

   This is only required for metrics extending the `BaseJSPTrackingAction` class. The servlet context must be set for the metric to render its own JSP files. The `setServletContext` method is invoked automatically when the metric module is installed and resolved in Liferay. Make sure the `osgi.web.symbolicname` in the `target` property of the `@Reference` annotation is set to the same value as the `Bundle-SymbolicName` defined in the `bnd.bnd` file of the module.

Next, you'll define a tracking mechanism for your metric to use.

Using a Tracking Mechanism

Imagine an administrator has successfully configured and saved your custom metric to his or her report. Now what? Your metric needs to fulfill its purpose, which is to track the `view` event type for the defined newsletter. To do this, you must define a tracking mechanism. For your newsletter, you'll use a transparent image as the tracking mechanism, which would have the *View* tracking event capability. Whenever the image is viewed, the newsletter metric computes and stores the information.

For the newsletter metric, you'll use a tracking mechanism provided by the Audience Targeting app.

1. You must set the analytics processor that the Content Targeting API provides for tracking events. Add the following method and private field:

```
@Reference
protected void setAnalyticsProcessor(AnalyticsProcessor analyticsProcessor) {
    _analyticsProcessor = analyticsProcessor;
}

private AnalyticsProcessor _analyticsProcessor;
```

The analytics processor is a module of the Audience Targeting Analytics system. It contains a servlet to track analytics from Liferay pages (views, clicks, etc.) and an API to leverage this tracking mechanism. In the `setAnalyticsProcesoor(...)` method, you're obtaining a reference of the current analytics processor to build the URL used to generate a transparent image. All you have to do is insert the generated URL into your newsletter's HTML, and the transparent image tracks who reads it. Everything is processed by the default Audience Targeting Analytics system automatically.

Now that you've obtained a reference of the analytics processor, you need to add logic for generating the appropriate tracking URL.

2. Replace the `populateContext` method with the updated method:

```
@Override
protected void populateContext(
    TrackingActionInstance trackingActionInstance,
    Map<String, Object> context, Map<String, String> values) {

    String alias = StringPool.BLANK;
    String elementId = StringPool.BLANK;
    String eventType = StringPool.BLANK;
    String trackImageHTML = StringPool.BLANK;

    if (!values.isEmpty()) {
        alias = values.get("alias");
        elementId = values.get("elementId");
        eventType = values.get("eventType");
    }
    else if (trackingActionInstance ≠ null) {
        alias = trackingActionInstance.getAlias();
        elementId = trackingActionInstance.getElementId();
        eventType = trackingActionInstance.getEventType();

        String trackImageURL = _analyticsProcessor.getTrackingURL(
            trackingActionInstance.getCompanyId(), 0, 0, "", 0,
            Campaign.class.getName(),
            new long[] {trackingActionInstance.getCampaignId()},
            trackingActionInstance.getElementId(), "view", "");

        trackImageHTML = "<img alt=\"\" src=\"" + trackImageURL + "\" />";
    }

    context.put("alias", alias);
    context.put("elementId", elementId);
    context.put("eventType", eventType);
    context.put("eventTypes", getEventTypes());
    context.put("trackImageHTML", trackImageHTML);
}
```

This updated method creates a new variable named `trackImageHTML`, retrieves a tracking URL using the analytics processor, and then populates the `trackImageHTML` context variable. When creating a new metric, the transparent image's URL field is not present in the metric's form. When the metric is initially saved, however, the URL is generated using the analytics processor and is available for copying.

Excellent! You've obtained the analytics processor and can create the transparent image tracking mechanism. The newsletter metric's behavior is defined and complete. The last thing you need to do is create a JSP template.

Defining the Metric's UI

The Java code you've added to this point has assumed that there are three configurable fields for your newsletter metric:

- *Name:* used in reports that count the number of times a metric has been triggered. This is also known as the newsletter's alias.
- *Newsletter ID:* used to differentiate between newsletters.
- *Event Type:* used to differentiate several actions on the same newsletter, such as opening the newsletter or clicking on a link.

To let administrators set these values, you must define a UI so your metric can be configured during the view/save lifecycle. Remember that you must also define a field to display the generated transparent image's URL. Create a `view.jsp` file in your metric's module (e.g., `/src/main/resources/META-INF/resources/view.jsp`) and add the following logic:

```
<%
Map<String, Object> context = (Map<String, Object>)request.getAttribute("context");

String alias = (String)context.get("alias");
String elementId = (String)context.get("elementId");
String eventType = (String)context.get("eventType");
List<String> eventTypes = (List<String>)context.get("eventTypes");
String trackImageHTML = (String)context.get("trackImageHTML");
%>

<aui:input helpMessage="name-help" label="name" name='<%= ContentTargetingUtil.GUID_REPLACEMENT + "alias" %>' type="text" value="<%= alias %>">
    <aui:validator name="required" />
</aui:input>

<aui:input helpMessage="enter-the-id-of-the-newsletter-to-be-tracked" label="newsletter-id" name='<%= ContentTargetingUtil.GUID_REPLACEMENT + "elementId" %>
    <aui:validator name="required" />
</aui:input>

<c:if test="<%= ListUtil.isNotEmpty(eventTypes) %>">
    <aui:select label="event-type" name='<%= ContentTargetingUtil.GUID_REPLACEMENT + "eventType" %>'>

        <%
        for (String curEventType : eventTypes) {
        %>

            <aui:option label="<%= curEventType %>" selected="<%= curEventType.equals(eventType) %>" value="<%= curEventType %>" />

        <%
        }
        %>

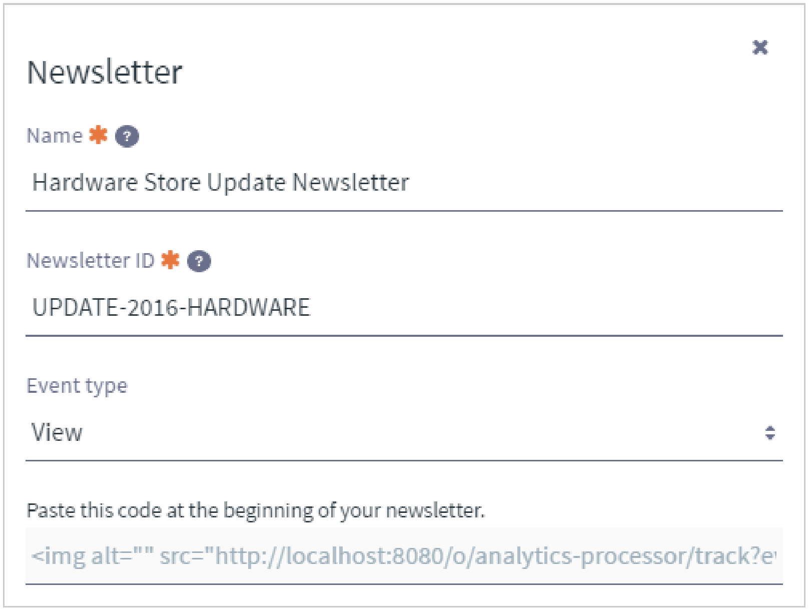
    </aui:select>
</c:if>

<c:if test="<%= !Validator.isBlank(trackImageHTML) %>">
    <span class="h5">
        <liferay-ui:message key="paste-this-code-at-the-beginning-of-your-newsletter" />
    </span>
    <label for='<%= renderResponse.getNamespace() + ContentTargetingUtil.GUID_REPLACEMENT + "trackImageHTML" %>' key="paste-this-code-
at-the-beginning-of-your-newsletter" /></label>
```

```
    <liferay-ui:input-resource id='<%= renderResponse.getNamespace() + ContentTargetingUtil.GUID_REPLACEMENT + "trackImageHTML" %>' url="<%= trackImageHTML
</c:if>
```

First you instantiate the context variable and its attributes you configured in your Java class's `populateContext` method. Then you specify the appropriate fields Name, Newsletter ID, and Event Type. Finally, you present the generated transparent image URL.

Notice that the input field names in the JSP are prefixed with `ContentTargetingUtil.GUID_REPLACEMENT`. This prefix is required for multi-instantiable metrics, which are metrics that return true in the `isInstantiable` method of their `-TrackingAction` class and can be added more than once to the Metrics form.



Newsletter

Name: Hardware Store Update Newsletter

Newsletter ID: UPDATE-2016-HARDWARE

Event type: View

Paste this code at the beginning of your newsletter.

<img alt="" src="http://localhost:8080/o/analytics-processor/track?e

Figure 120.7: Once you've saved the metric, you can copy the generated transparent image URL into your newsletter's HTML to track who views it.

Congratulations! You've created the newsletter metric and can now track whether users viewed a newsletter. You can test if the metric is working by copying the generated tracking image HTML into an email HTML editor, sending it, and opening it as if it were an actual newsletter. Then open the custom report containing the newsletter metric and select *Update Report*. A chart and table with the newsletter's view count is shown.

You can view the finished version of the newsletter metric by downloading its ZIP file.

Now you've created and examined a fully functional metric and have the knowledge to create your own.

Defining Metrics

Audience Targeting Metrics

120.4 Best Practices for Metrics

In this tutorial, you'll learn about best practices to keep in mind when creating Audience Targeting Metrics. Before going through some best practices, you should understand the four components you can specify for a metric:

- *Metric Behavior*
- *Tracking Mechanism*
- *UI for Configuration (optional)*
- *Language Keys (optional)*

You discuss metric behavior and its UI configuration in great detail in the Tracking User Actions with Audience Targeting tutorial. To learn more about language keys and how to create, use, and generate them, visit the Internationalization tutorials.

Audience Targeting gives you the option to choose whatever frontend technology you like. In the next section, you'll learn how to use your preferred technology for displaying content in Audience Targeting metrics.

Selecting a UI Technology

Since 7.0, JSP is the preferred technology for Audience Targeting extension views. FreeMarker views, however, are still supported through their respective base classes (e.g., `BaseFreemarkerTrackingAction`). If you're interested in using a technology besides JSP or FreeMarker to implement your UI, you can add a method `getFormHTML` to your `-TrackingAction` class. Here's an example of implementing the `getFormHTML` method:

```
@Override
public String getFormHTML(
    TrackingActionInstance trackingActionInstance,
    Map<String, Object> context, Map<String, String> values) {

    String content = "";

    try {
        populateContext(trackingActionInstance, context, values);

        content = ContentTargetingContextUtil.includeJSP(
            _servletContext, getFormTemplatePath(), context);
    }
    catch (Exception e) {
        _log.error(
            "Error while processing form template " +
                getFormTemplatePath(),
            e);
    }

    return content;
}
```

The `getFormHTML` is used to retrieve the HTML created by the technology you choose, and to return it as a string that is viewable from your metric's form. If you plan, therefore, on using an alternative to JSP or FreeMarker, you must override this method by creating and modifying it in your `-TrackingAction` class.

120.5 Best Practices for Rules

In this tutorial, you'll learn about best practices to keep in mind when creating Audience Targeting Rules. Before going through some best practices, you should understand the three components you can specify for a rule:

- *Rule Behavior*
- *UI for Configuration (optional)*
- *Language Keys (optional)*

You discuss rule behavior and its UI configuration in great detail in the Creating New Audience Targeting Rule Types tutorial. To learn more about language keys and how to create, use, and generate them, visit the Internationalization tutorials.

Audience Targeting gives you the option to choose whatever frontend technology you like. In the next section, you'll learn how to use your preferred technology for displaying content in Audience Targeting rules.

Selecting a UI Technology

Since 7.0, JSP is the preferred technology for Audience Targeting extension views. FreeMarker views, however, are still supported through their respective base classes (e.g., `BaseFreemarkerRule`). If you're interested in using a technology besides JSP or FreeMarker to implement your UI, you can add a method `getFormHTML` to your `-Rule` class. Here's an example of implementing the `getFormHTML` method:

```
@Override
public String getFormHTML(
    RuleInstance ruleInstance, Map<String, Object> context,
    Map<String, String> values) {

    String content = "";

    try {
        populateContext(ruleInstance, context, values);

        content = ContentTargetingContextUtil.parseTemplate(
            getClass(), getFormTemplatePath(), context);
    }
    catch (Exception e) {
        _log.error(
            "Error while processing template " + getFormTemplatePath(), e);
    }

    return content;
}
```

The `getFormHTML` is used to retrieve the HTML created by the technology you choose, and to return it as a string that is viewable from your rule's form. If you plan, therefore, on using an alternative to JSP or FreeMarker, you must override this method by creating and modifying it in your `-Rule` class.

Other Best Practices

Here are some things to consider as you implement and deploy Audience Targeting rules:

- As an alternative to storing complex information in the `typeSettings` field, which is managed by the framework in the Rule Instance table, you may want to consider persisting to a database by using Service Builder, which is supported for Rule plugins.

- If you deploy your rule into a production environment, you may want to consider adding your values to the cache (e.g., weather in different locations), since obtaining the same value on every request is very inefficient and could result in slowing down your portal. For example, when the `evaluate` method is called, you could obtain the current user ID, current user's weather forecast, and the time at which the user first visited the page. Then you could evaluate the rule only when the cached time is over three hours old. This would prevent the rule from evaluating every time the user visited the page. This is best done using services.

- You can override the `BaseJSPRule.deleteData` method in your `-Rule`, so that it deletes any data associated with the rule that is currently being deleted.

- If your rule handles data or references to data that can be staged (e.g., a reference to a page or web content article), you may need to override the `BaseRule.exportData` and `BaseRule.importData` methods, to manage the content properly.

Chapter 121

Customizable Web Applications

One of the great strengths of Liferay DXP is the sheer number of out of the box applications. This gives it great flexibility in what it can do, which is why Liferay DXP is used to run many different kinds of websites around the world. For example, if you want users to add Blog posts, you can configure the Blogs portlet to handle those requests.

But really, that's technology from the last decade. What if you could define a particular function that users might want to perform and let Liferay DXP choose an available installed app to perform that function? That way, if users want to Blog, and you've installed your own custom-developed app for blogging instead of Liferay's, the Liferay DXP instance can just use yours instead?

With Liferay DXP 7, you can do just that. You can request an app based on an entity and action type. Processing the entity type and action, Liferay uses an available portlet that can handle the request. This increases the flexibility and modularity of using portlets in Liferay DXP.

121.1 Providing Portlets to Manage Requests

In this tutorial, you'll learn how to declare an entity type and action for a desired function, and you'll create a module that finds the correct application (portlet) to use based on those given parameters.

Specifying a Desired Portlet Behavior

To find the portlet you need for your particular request, you'll use the *Portlet Providers* framework. The first thing you'll need to do is call the PortletProviderUtil class and request the framework find a portlet suitable for the current task. You can request the portlet ID or portlet URL, depending on what you prefer. Here's an example declaration:

```
String portletId = PortletProviderUtil.getPortletId(
    "com.liferay.portlet.trash.model.TrashEntry", PortletProvider.Action.VIEW);
```

This declaration expects two parameters: the class name of the entity type you want the portlet to handle and the type of action. The above code requests a portlet ID for a portlet that can view Recycle Bin entries.

There are five different kinds of actions supported by the Portlet Providers framework: `ADD`, `BROWSE`, `EDIT`, `PREVIEW`, and `VIEW`. Find the portlet ID or portlet URL (depending on your needs), and specify the entity type and action you want the portlet to handle.

Note: The `getPortletURL` methods require an additional `HttpServletRequest` or `PortletRequest` parameter, depending on which you use. Make sure to account for this additional parameter when using the `getPortletURL` method.

You've successfully requested the portlet ID/portlet URL of a portlet that matches your entity and action type. The portal, however, is not yet configured to handle this request. You'll need to create a module that can find the correct portlet to handle the request.

1. Create an OSGi module.

2. Create a unique package name in the module's `src` directory and create a new Java class in that package. To follow naming conventions, name the class based on the element type and action type, followed by *PortletProvider* (e.g., `LanguageEntryViewPortletProvider`). The class should extend the `BasePortletProvider` class and implement the appropriate portlet provider interface based on the action type you chose your portlet to handle (e.g., ViewPortletProvider, BrowsePortletProvider, etc.).

3. Directly above the class's declaration, insert the following annotation:

   ```
   @Component(
       immediate = true,
       property = {"model.class.name=CLASS_NAME"},
       service = INTERFACE.class
   )
   ```

   The `property` element should match the element type you specified in your `getPortletID`/`getPortletURL` declaration (e.g., `com.liferay.portal.kernel.servlet.taglib.ui.LanguageEntry`). Also, your `service` element should match the interface you're implementing (e.g., `ViewPortletProvider.class`). You can view an example of a similar `@Component` annotation in the RolesSelectorEditPortletProvider class:

   ```
   @Component(
       immediate = true,
       property = {"model.class.name=com.liferay.portal.kernel.model.UserGroupRole"},
       service = EditPortletProvider.class
   )
   ```

4. In some cases, a default portlet is already in place to handle the entity and action type requested. To override the default portlet with a custom portlet, you can assign your portlet a higher service ranking. You can do this by setting the following property in your `@Component` declaration:

   ```
   property= {"service.ranking:Integer=10"}
   ```

   Make sure to replace the integer with a number that is ranked higher than the portlet being used by default.

5. Specify the methods you'd like to implement. Make sure to retrieve the portlet ID/portlet URL that should be provided when this service is called.

Lastly, generate the module's JAR file and deploy it to your portal instance. Now a portlet that can handle the entity and action type you specified is used when requesting a portlet ID/URL. You can now specify portlet usage without hardcoding a specific portlet!

Developer Reference

Chapter 122

Development Reference

Here you'll find reference documentation for Liferay DXP, Liferay Screens, Liferay Faces, and technologies related to you as a third-party developer.

The different types of reference docs you'll find in this section of the Liferay Developer Network are as follows:

- Descriptions of Java and JavaScript APIs, CSS, tags and tag libraries, and XML DTDs
- Write ups on the latest Screenlets for Liferay Screens
- Breaking changes
- Cheat sheets and tips on
  - Plugin anatomy
  - Design patterns
  - Tools
  - Adapting to new APIs

Liferay's reference docs are at your fingertips.

122.1 Java APIs

Here you'll find Javadoc for Liferay DXP and Liferay DXP apps.

7.0 Java APIs

This table links you to the 7.0 API modules. Their root location is here. (Opens New Window) The reference doc JAR is available here. (Opens New Window)

Core:

com.liferay.portal.kernel (portal-kernel): (Opens New Window) for developing applications on Liferay DXP

com.liferay.util.bridges (util-bridges): (Opens New Window) for using various non-proprietary computing languages, frameworks, and utilities on Liferay DXP

com.liferay.util.java (util-java): (Opens New Window) for using various Java-related frameworks and utilities on Liferay DXP com.liferay.util.slf4j (util-slf4j): (Opens New Window) for using the Simple Logging Facade for Java (SLF4J)

com.liferay.portal.impl (portal-impl): (Opens New Window) refer to this only if you are an advanced Liferay developer that needs a deeper understanding of 7.0's implementation in order to contribute to it

Faces Taglibs

Faces 3.2 Taglibs: the latest version of Liferay Faces JSF tag docs in View Declaration Language (VDL) format. VDL docs for all versions of Liferay Faces are available here.

JavaScript and CSS

Lexicon: The web implementation of Liferay's Lexicon Experience Language. Lexicon is a system for building applications in and outside of Liferay DXP, designed to be fluid and extensible, as well as provide a consistent and documented API.

Bootstrap: The base CSS library onto which Lexicon is built. Liferay DXP uses Bootstrap natively and all of its CSS classes and JavaScript features are available within portlets, templates, and themes.

AlloyUI: Liferay includes AlloyUI and all of its JavaScript APIs are available within portlets, templates and themes.

Descriptor Definitions

DTDs: Describes the XML files used in configuring Liferay DXP apps, 7.0 plugins, and @product-ver@.

Chapter 123

Liferay API Modules

The following table maps commonly used Liferay DXP components to their API modules and key classes. You configure dependencies on the component API modules to use them.

Chapter 124

Portlet Descriptor to OSGi Service Property Map

This section describes the mapping of portlet XML descriptor values to OSGi service properties that can be used when publishing OSGi Portlets.

OSGi services can contain properties in their definitions. Using OSGi service properties makes dealing with configuration concerns simple and cohesive. These properties are typically represented as key-value pairs or, more generally, as a Map-like object.

Portlet spec property keys are prefixed by:

```
javax.portlet.
```

Liferay property keys are prefixed by:

```
com.liferay.portlet.
```

The mappings essentially flatten what is found in the XML descriptor, sticking relatively closely to the original naming in order to have a memorable relationship with those definitions.

JSR-168 & JSR-286 Descriptor Mappings

Note: XPath notation derived from the **Portlet XSD** 4 is used in this document for simplicity.

- [1] Portlets are registered as concrete objects.

- [2] Multiples of these properties may be used. This results in an array of values.
- [3] This type is registered as an OSGi service.
- [4] http://java.sun.com/xml/ns/portlet/portlet-app_2_0.xsd
- [5] http://www.liferay.com/dtd/liferay-portlet-app_7_0_0.dtd
- [6] Liferay DXP creates each portlet's ID based on the portlet's name (i.e., the `portlet-name` descriptor in `liferay-portlet.xml` or the `javax.portlet.name` OSGi service property). Dashes, periods, and spaces are allowed in the portlet name, but they and all other JavaScript unsafe characters are stripped from the name value that's used for the portlet ID. Therefore, make your portlet name unique in light of the characters that are removed. Otherwise, if you try to deploy a portlet whose ID is the same as a portlet that's already deployed, your portlet deployment fails and Liferay DXP logs a message like this:

  ```
  Portlet id [portletId] is already in use
  ```

Chapter 125

Classes Moved from portal-service.jar

To leverage the benefits of modularization in 7.0, many classes from former Liferay Portal 6 JAR file portal-service.jar have been moved into application and framework API modules. The table below provides details about these classes and the modules they've moved to. Package changes and each module's symbolic name (artifact ID) are listed, to facilitate configuring dependencies.

Classes Moved from portal-service to modules

This information was generated based on comparing classes in liferay-portal-src-6.2-ce-ga6 to classes in liferay-portal-src-7.0-ce-ga1.

Class

Package

Module Symbolic Name (Artifact ID)

ActionHandler

Theme Gulp Tasks

Theme projects that use the liferay JS Theme Toolkit, such as those created with the Liferay Theme Generator have access to several gulp tasks that you can execute to manage and deploy your theme.

Note: Gulp is included as a local dependency in generated themes, so you are not required to install it. It can be accessed by running `node_modules\.bin\gulp` followed by the Gulp task from a generated theme's root folder.

Here are the gulp tasks you can execute:

- `build`: generates the base theme files, compiles Sass into CSS, and zips all theme files into a WAR file that you can deploy to a Liferay server.
- `deploy`: runs the `build` task and deploys the WAR file to the configured local app server.

```
**Note:** If you're running the [Felix Gogo shell](/docs/7-0/reference/-/knowledge_base/r/using-the-felix-gogo-shell),
you can also deploy your theme using the `gulp deploy:gogo` command. **This
task will NOT work for 6.2 themes.**
```

- `extend`: allows you to specify a base theme or themelet to extend. By default, themes created with the Liferay Theme Generator are based off of the styled theme.

  You first are prompted if you want to extend a Base theme or Themelet, then you're prompted for where you would like to search for modules. Selecting *Globally installed npm modules* searches globally accessible npm modules on your computer. Selecting *npm registry* searches for published modules on npm. If you have v8.x.x of the Liferay JS Theme Toolkit installed, you can also *Specify a package URL* to locate a themelet.

```
**Note:** You can retrieve the URL for a package by running
`npm show package-name dist.tarball`.
```

```
After you've selected modules from the options it provides, the modules are
added to your `package.json` file as dependencies. Run `npm install` to
install them.
```

```
 **Note:** The Classic theme is an implementation of an existing base theme
 and is therefore not meant to be extended. Extending Liferay's Classic
 theme is strongly discouraged.
```

- `kickstart`: allows you to copy the CSS, images, JS, and templates from another theme into the `src` directory of your own. While this is similar to the `extend` task, kickstarting from another theme is a one time inheritance, whereas extending from another theme is a dynamic inheritance that applies your src files on top of the base theme on every build.
- `init`: prompts you for local and remote app server information to use in theme deployment.
- `status`: displays the name of the base theme/themelets your theme extends.
- `watch`: allows you to preview the changes you make to your theme without requiring a full redeploy. After invoking the `watch` task, every time you save any changes to a file in your theme, applicable changes are compiled and they're copied directly to a proxy port (e.g. `9080`) for you to preview live. **Note:** you must have Developer Mode enabled to use the `watch` task. Once you're happy with the live preview, deploy your theme to apply the changes.

CHAPTER 127

THEME REFERENCE GUIDE

A theme is made up of several files. Although most of the files are named after their matching components, their function may be unclear.

This document explains each file's usage to make clear which files to modify and which files to leave untouched.

Theme Anatomy

There are two main approaches to theme development for 7.0: themes built using the Node.js build tools with the theme generator and themes built using @ide@.

Themes developed with the theme generator have the anatomy shown below. Although themes developed with @ide@ have a slightly different anatomy built with the theme project template, the core theme files are the same. Note that the `build` folder is shown for reference, and is generated when the theme is compiled.

- `theme-name/`
  - `build/`(generated when the theme is compiled)
    - `css/`
      - `_application.scss`
      - `_aui_custom.scss`
      - `_aui_variables.scss`
      - `_base.scss`
      - `_custom.scss`
      - `_extras.scss`
      - `_imports.scss`
      - `_layout.scss`
      - `_liferay_custom.scss`
      - `_liferay_variables_custom.scss`
      - `_liferay_variables.scss`
      - `_navigation.scss`
      - `_portal.scss`
      - `_portlet.scss`

        - _taglib.scss
        - application/
        - aui/
        - aui.scss
        - base/
        - font-awesome.scss
        - layout/
        - main.scss
        - navigation/
        - portal/
        - portlet/
        - taglib/

    * templates/

        - init_custom.ftl
        - init.ftl
        - navigation.ftl
        - portal_normal.ftl
        - portal_pop_up.ftl
        - portlet.ftl
        - (other directories that have been copied from src)

- `dist/` (generated when the theme is compiled. This is where the theme's war file is placed after a build/deploy.)
- `gulpfile.js`
- `liferay-theme.json`
- `node_modules/` (generated when an `npm install` command is run from the root of the theme, and can be deleted at anytime and re-generated by running `npm install`.)

    * (many directories)

- `package.json`
- `src/`

    * `css/`

        - (modified CSS files)

    * `images/`

        - (many directories)

    * `js/`

        - `main.js`

    * `templates/`

        - (Modified theme templates)

* WEB-INF/ - lib/

  - liferay-look-and-feel.xml
  - liferay-plugin-package.properties
  - src/
  - resources-importer/
  - (Many directories)

Regarding CSS files, it is recommended that you only modify `_custom.scss`, `_aui_custom.scss`, `_aui_variables.scss`, and `_liferay_variables_custom.scss`.

You can of course overwrite any CSS file that you wish, but if you modify any other files, you will most likely be removing styling that 7.0 needs to work properly.

127.1 Theme Files

_application.scss

Contains imports for application styles. Generally these files style components that aren't Liferay specific, i.e. Alloy or Bootstrap components.

_aui_custom.scss

Used for AUI custom styles, i.e. styles for a third party Bootstrap theme. Anything written in this file is compiled in the same scope as Bootstrap/Lexicon, so you can use their variables, mixins, etc. You can also implement any of the variables you define in `_aui_variables.scss`.

_aui_variables.scss

Used to store custom Sass variables. This file get's injected into the Bootstrap/Lexicon build, so you can overwrite variables and change how those libraries are compiled.

_base.scss

Contains imports for the base styles for Liferay.

_custom.scss

Used for custom CSS styles. It is recommended that you place all of your custom CSS modfications in this file.

_extras.scss

Contains styling that is considered non-essential and potentially dated in the near future i.e. box-shadows, rounded corners, etc. This allows for easy maintenance.

_imports.scss

Contains imports for third-party libraries required for the theme e.g. Bourbon, Liferay Mixins, Lexicon Base Variables, and Bootstrap Mixins.

_layout.scss

Contains imports for layout styles and variables.

_liferay_custom.scss

Contains Liferay DXP styles that are compiled in the same scope as Bootstrap/Lexicon.

It's recommended that you NOT overwrite this file.

_liferay_variables_custom.scss

Used for overwriting variables defined in `_liferay_variables.scss` without wiping out the whole file.

_liferay_variables.scss

Contains variables that are used in `_liferay_custom.scss`.

It's recommended that you NOT overwrite this file.

_navigation.scss

Contains imports for navigation styles.

_portal.scss

Contains imports for Portal components.

_portlet.scss

Contains imports for portlet components.

_taglib.scss

Contains imports for taglib styles.

aui.scss

Contains the Lexicon base CSS import. If you want to just use Bootstrap, or use Atlas, you can do so by adding one of the following imports:

```
@import "aui/lexicon/bootstrap";
```

or

```
@import "aui/lexicon/atlas";
```

font-awesome.scss

Contains the Font Awesome icon imports for Liferay.

main.scss

Contains imports for the core CSS files.

init_custom.ftl

Used for custom FreeMarker variables i.e. theme setting variables.

init.ftl

Contains common FreeMarker variables that are available to use in your theme templates. Useful for reference if you need access to theme objects.

It's recommended that you NOT overwrite this file.

navigation.ftl

The theme template for the theme's navigation.

portal_normal.ftl

Similar to the `index.html` of a website, this file acts as a hub for all of the theme templates.

portal_pop_up.ftl

The theme template for pop up dialogs for the theme's portlets.

portlet.ftl

The theme template for the theme's portlets. If your theme uses Application Decorators, you can modify this file to create application decorator specific theme settings. See the Portlet Decorators tutorial for more info.

gulpfile.js

Defines the required gulp tasks for Node.js tool developed themes.

It's recommended that you NOT overwrite this file.

liferay-theme.json

Contains the configuration settings for your app server, in Node.js tool based themes. You can change this file manually at any time to update your server settings. The file can also be updated via the `gulp init` task.

package.json

contains theme setting information such as the theme template langauge, version, and base theme, for Node.js tool developed themes. This file can be updated manually. The `gulp extend` task can also be used to change the base theme.

main.js

Used for custom JavaScript.

liferay-look-and-feel.xml

Contains basic information for the theme. If your theme has theme settings , they are defined in this file. For a full explanation of this file please see the Definitions docs.

liferay-plugin-package.properties

Contains general properties for the theme. [Resources Importer]{/docs/7-0/tutorials/-/knowledge_base/t/importing-resources-with-a-theme} configuration settings are also placed in this file. For a full explanation of the properties available for this file please see the 7.0 Propertiesdoc.

Chapter 128

Screenlets in Liferay Screens for Android

Liferay Screens for Android contains several Screenlets that you can use in your Android apps. This section contains the reference documentation for each. If you're looking for instructions on using Screens, see the Screens tutorials. The Screens tutorials contain instructions on using Screenlets and using views in Screenlets. Each Screenlet reference document here lists the Screenlet's features, compatibility, its module (if any), available Views, attributes, listener methods, and more. The available Screenlets are listed here with links to their reference documents:

- **Login Screenlet:** Signs users in to a Liferay DXP instance.
- **Sign Up Screenlet:** Registers new users in a Liferay DXP instance.
- **Forgot Password Screenlet:** Sends emails containing a new password or password reset link to users.
- **User Portrait Screenlet:** Show the user's portrait picture.
- **DDL Form Screenlet:** Presents dynamic forms to be filled out by users and submitted back to the server.
- **DDL List Screenlet:** Shows a list of records based on a pre-existing DDL in a Liferay instance.
- **Asset List Screenlet:** Shows a list of assets managed by Liferay's Asset Framework. This includes web content, blog entries, documents, users, and more.
- **Web Content Display Screenlet:** Shows the web content's HTML or structured content. This Screenlet uses the features available in Web Content Management.
- **Web Content List Screenlet:** Shows a list of web contents from a folder, usually based on a pre-existing `DDMStructure`.
- **Image Gallery Screenlet:** Shows a list of images from a folder. This Screenlet also lets users upload and delete images.
- **Rating Screenlet:** Shows the rating for an asset. This Screenlet also lets the user update or delete the rating.
- **Comment List Screenlet:** Shows a list of comments for an asset.

- **Comment Display Screenlet:** Shows a single comment for an asset.
- **Comment Add Screenlet:** Lets the user comment on an asset.
- **Asset Display Screenlet:** Displays an asset. Currently, this Screenlet can display Documents and Media Library files (`DLFileEntry` entities), blog articles (`BlogsEntry` entities), and web content articles (`WebContent` entities). You can also use it to display custom assets.
- **Blogs Entry Display Screenlet:** Shows a single blog entry.
- **Image Display Screenlet:** Shows a single image file from a Liferay DXP instance's Documents and Media Library.
- **Video Display Screenlet:** Shows a single video file from a Liferay DXP instance's Documents and Media Library.
- **Audio Display Screenlet:** Shows a single audio file from a Liferay DXP instance's Documents and Media Library.
- **PDF Display Screenlet:** Shows a single PDF file from a Liferay DXP instance's Documents and Media Library.
- **Web Screenlet:** Displays any web page. You can also customize the web page through injection of local and remote JavaScript and CSS files.

128.1 Login Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Login Screenlet lets you authenticate portal users in your Android app. The following types of authentication are supported:

- **Basic:** uses user login and password according to HTTP Basic Access Authentication specification. Depending on the authentication method used by your Liferay instance, you need to provide the user's email address, screen name, or user ID. You also need to provide the user's password.
- **OAuth:** implements the OAuth 1.0a specification.

- **Cookie:** uses a cookie to log in. This lets you access documents and images in the portal's document library without the guest view permission in the portal. The other authentication types require this permission to access such files.

Note: Cookie authentication with Login Screenlet is broken in fix packs 14 through 18 of Liferay Digital Enterprise 7.0. This issue is fixed in newer fix packs for Liferay Digital Enterprise 7.0.

For instructions on configuring the Screenlet to use these authentication types, see the below Portal Configuration and Screenlet Attributes sections.

When a user successfully authenticates, their user attributes are retrieved for use in the app. You can use the `SessionContext` class to get the current user's attributes.

Note that user credentials and attributes can be stored in an app's data store (see the `saveCredentials` attribute). Android's `SharedPreferences` is currently the only data store implemented. However, new and more secure data stores will be added in the future. Stored user credentials can be used to automatically log the user in to subsequent sessions. To do this, you can use the method `SessionContext.loadStoredCredentials()`.

JSON Services Used

Screenlets in Liferay Screens call the portal's JSON web services. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`getUserByEmailAddress`	Basic login
`UserService`	`getUserByScreenName`	Basic login
`UserService`	`getUserById`	Basic login
`UserService`	`getCurrentUser`	Cookie and OAuth login

Module

- Auth

Views

- Default
- Material

For instructions on using these Views, see the `layoutId` attribute in the Attributes section below.

Portal Configuration

Basic Authentication

Before using Login Screenlet, you should make sure your portal is configured with the authentication option you want to use. You can choose email address, screen name, or user ID. You can set this in the Control Panel by selecting *Configuration → Instance Settings*, and then selecting the *Authentication* section. The authentication options are in the *How do users authenticate?* selector menu.

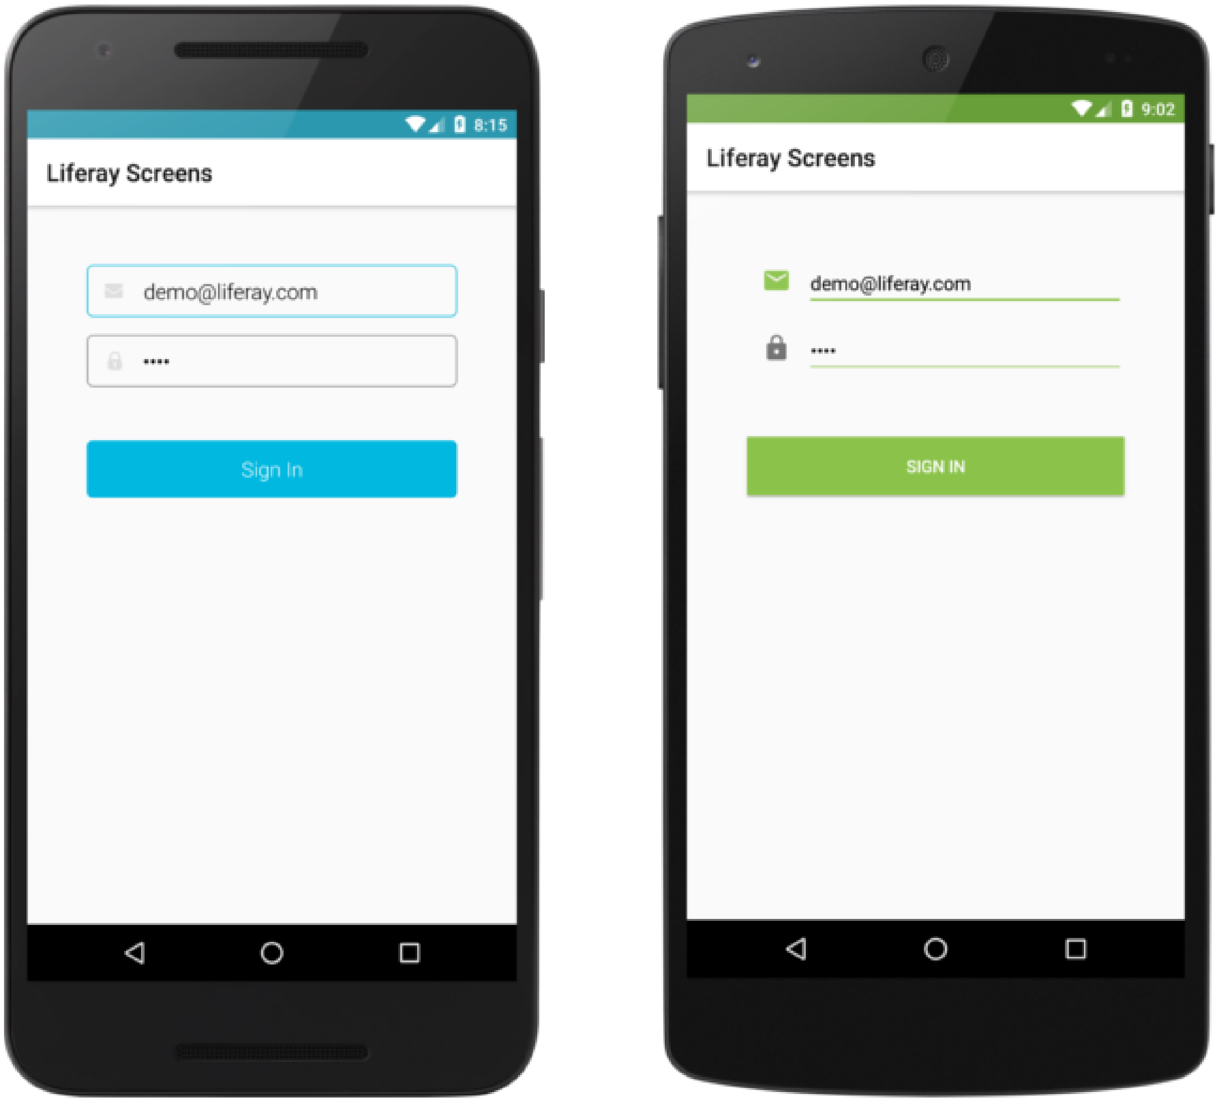

Figure 128.1: The Login Screenlet using the Default (left) and Material (right) Viewsets.

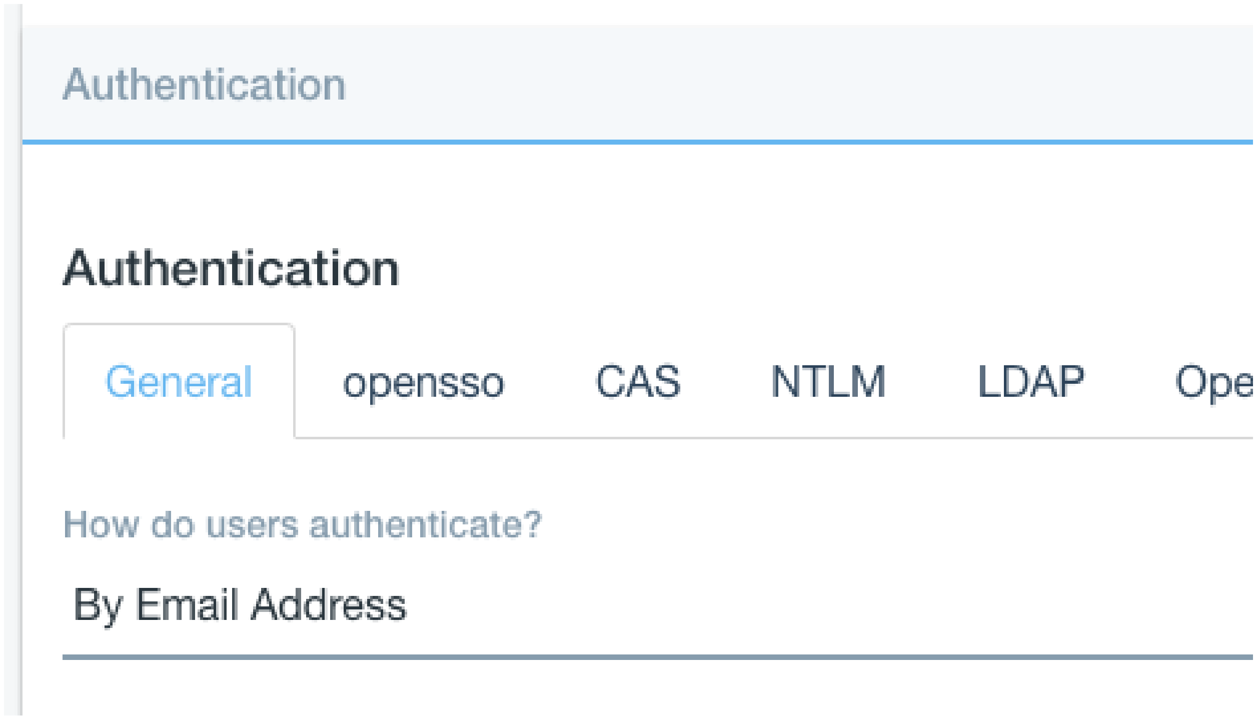

Authentication

Authentication

How do users authenticate?

By Email Address

Figure 128.2: Setting the authentication method in your Liferay instance.

For more details, see the Setting up a Liferay Instance section of the User Guide.

OAuth Authentication

Note: OAuth authentication is only available in Liferay DXP instances.

To use OAuth authentication, first install the OAuth provider app from the Liferay Marketplace. Click here to get this app. Once it's installed, go to *Control Panel* → *Users* → *OAuth Admin*, and add a new application to be used from Liferay Screens. Once the application exists, copy the *Consumer Key* and *Consumer Secret* values for later use in Login Screenlet.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity. If you need to log in users automatically, even when there's no network connection, you can use the `credentialsStorage` attribute together with the `SessionContext.loadStoredCredentials` method.

Required Attributes

- None

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The ID of the View's layout. You can set this attribute to `@layout/login_default` (Default View) or `@layout/login_material` (Material View). To use the Material View, you must first install the Material View Set. Click here for instructions on installing and using Views and View Sets, including the Material View Set. | `companyId` | `number` | The ID of the portal instance to authenticate to. If you don't set this attribute or set it to `0`, the Screenlet uses the `companyId` setting in `LiferayServerContext`. | `loginMode` | `enum` | The Screenlet's authentication type. You can set this attribute to `basic`, `oauth`, or `cookie`. If you don't set this attribute, the Screenlet defaults to basic authentication. | `basicAuthMethod` | `string` | Specifies the authentication option to use with basic or cookie authentication. You can set this attribute to `email`, `screenName` or `userId`. This must match the server's authentication option. If you don't set this attribute, and don't set the `loginMode` attribute to `oauth`, the Screenlet defaults to basic authentication with the `email` option. | `OAuthConsumerKey` | `string` | Specifies the *Consumer Key* to use in OAuth authentication. | `OAuthConsumerSecret` | `string` | Specifies the *Consumer Secret* to use in OAuth authentication. | `credentialsStorage` | `enum` | Sets the mode for storing user credentials. The possible values are `none`, `auto`, and `shared_preferences`. If set to `shared_preferences`, the user credentials and attributes are stored using Android's `SharedPreferences` class. If set to `none`, user credentials and attributes aren't saved at all. If set to `auto`, the best of the available storage modes is used. Currently, this is equivalent to `shared_preferences`. The default value is `none`. | `shouldHandleCookieExpiration` | `bool` | Whether to refresh the cookie automatically when using cookie login. When set to `true` (the default value), the cookie refreshes as it's about to expire. | `cookieExpirationTime` | `int` | How long the cookie lasts, in seconds. This value depends on your portal instance's configuration. The default value is `900`. | `authenticator` | `Authenticator` | An instance of a class that implements the `Authenticator` interface. The *Challenge-Response Authentication* section below discusses this further. |

Listener

The Login Screenlet delegates some events to an object that implements the `LoginListener` interface. This interface let you implement the following methods:

- `onLoginSuccess(User user)`: Called when login successfully completes. The `user` parameter contains a set of the logged in user's attributes. The supported keys are the same as those in the portal's User entity.

- `onLoginFailure(Exception e)`: Called when an error occurs in the process.

Challenge-Response Authentication

To support challenge-response authentication when using a cookie to log in to the portal, Login Screenlet has an `authenticator` attribute. As mentioned in the above *Attributes* table, this attribute's value is a class that implements the `Authenticator` interface.

Here's an example of such a class. It sends a basic authorization in response to an authentication challenge:

```
public class BasicAuthAutenticator extends BasicAuthentication implements Authenticator {

    public BasicAuthAutenticator(String username, String password) {
        super(username, password);
    }

    @Override
    public Request authenticate(Proxy proxy, Response response) throws IOException {
        String credential = Credentials.basic(username, password);
        return response.request().newBuilder().header(Headers.AUTHORIZATION, credential).build();
    }

    @Override
    public Request authenticateProxy(Proxy proxy, Response response) throws IOException {
        return null;
    }
}
```

128.2 Sign Up Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Sign Up Screenlet creates a new user in your Liferay instance: a new user of your app can become a new user in your portal. You can also use this Screenlet to save new users' credentials on their devices. This enables auto login for future sessions. The Screenlet also supports navigation of form fields from the device's keyboard.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`addUser`	

Module

- Auth

Views

- Default
- Material

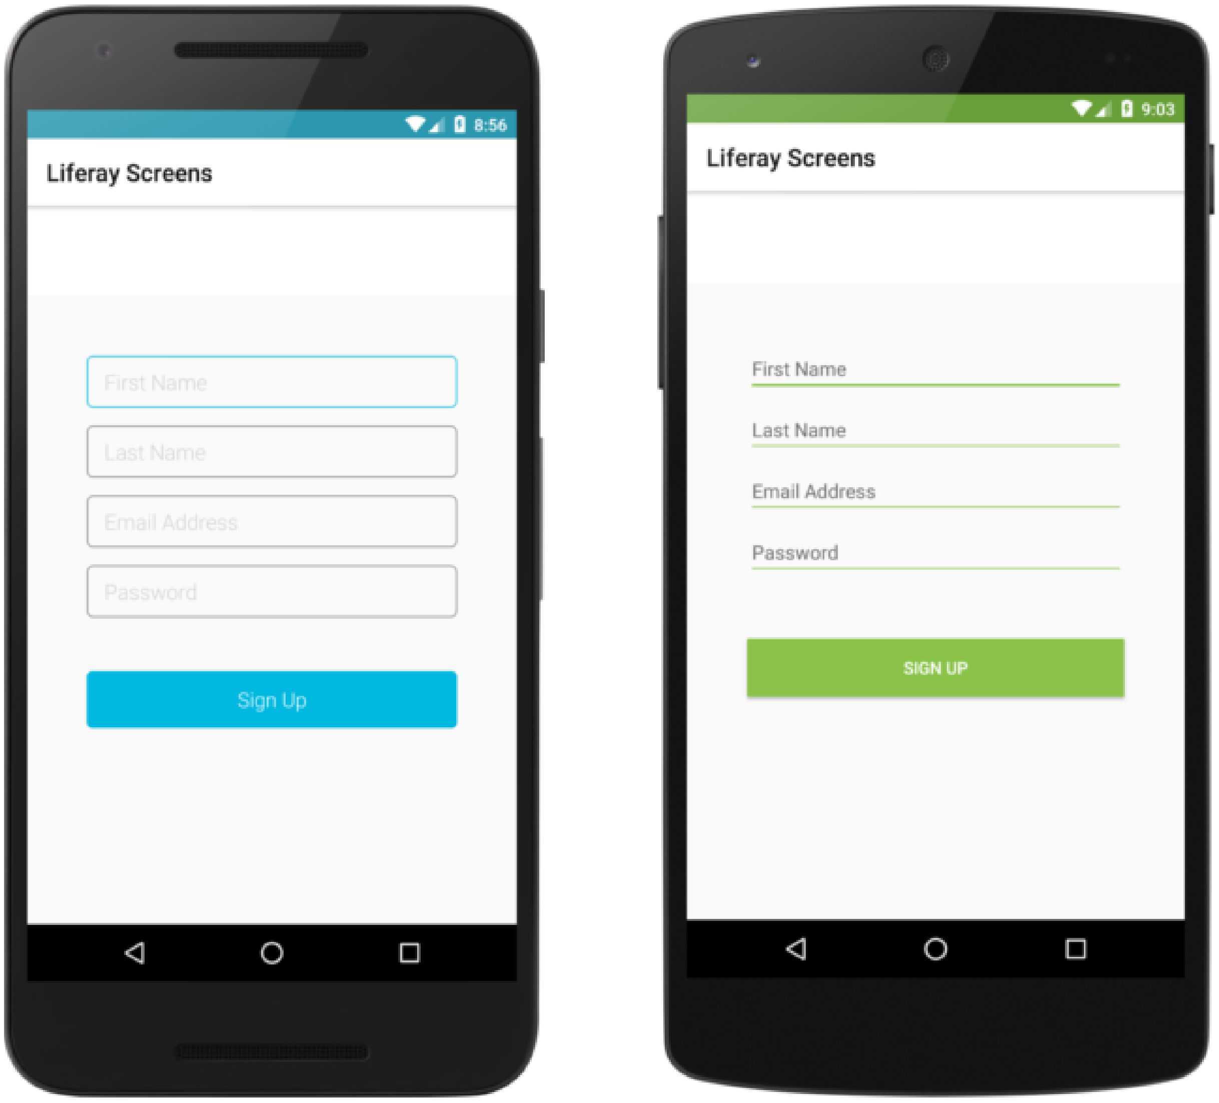

Figure 128.3: The Sign Up Screenlet with the Default (left) and Material (right) Viewsets.

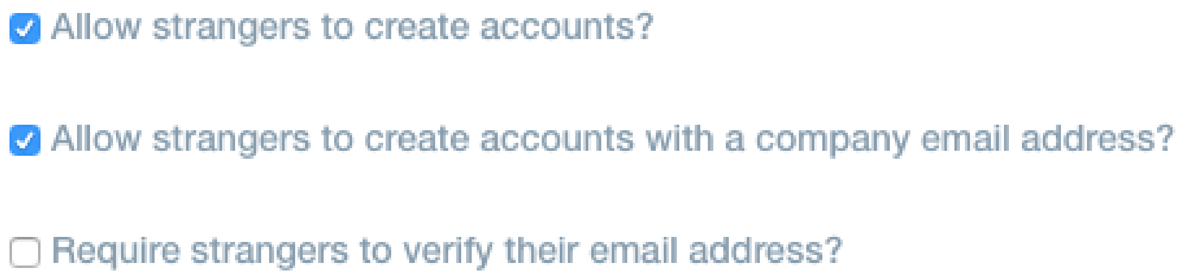
Portal Configuration

Sign Up Screenlet's corresponding configuration in the Liferay instance can be set in the Control Panel by selecting *Configuration* → *Instance Settings*, and then selecting the *Authentication* section.



- [✓] Allow strangers to create accounts?
- [✓] Allow strangers to create accounts with a company email address?
- [ ] Require strangers to verify their email address?

Figure 128.4: The Liferay instance's authentication settings.

For more details, refer to the Setting up a Liferay Instance section of the User Guide.

Anonymous Requests

Anonymous requests are unauthenticated requests. Authentication is still required, however, to call the API. To allow this operation, the portal administrator should create a user with minimal permissions. To use Sign Up Screenlet, you need to use that user in your layout. You should add that user's credentials to `server_context.xml`.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity.

Required Attributes

- `anonymousApiUserName`
- `anonymousApiPassword`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout used to show the View.| `anonymousApiUserName` | `string` | The user's name, email address, or ID to use for authenticating the request. The portal's authentication method defines which of these is used. | `anoymousApiPassword` | `string` | The password used to authenticate the request. | `companyId` | `number` | When set, a user in the specified company is authenticated. If not set, the company specified in `LiferayServerContext` is used. | `autoLogin` | `boolean` | Sets whether the user is logged in automatically after a successful sign up. | `credentialsStorage` | `enum` | Sets the mode for storing user credentials. The possible values are `none`, `auto`, and `shared_preferences`. If set to `shared_preferences`, the user credentials and attributes are stored using Android's `SharedPreferences` class. If set to `none`, user credentials and attributes aren't saved at all. If set to `auto`, the best of the available storage modes is used. Currently, this is equivalent to `shared_preferences`. The default value is `none`. |

`basicAuthMethod`|`enum`| Specifies the authentication method to use after a successful sign up. This must match the authentication method configured on the server. You can set this attribute to `email`, `screenName` or `userId`. The default value is `email`. |

Listener

The Sign Up Screenlet delegates some events to an object that implements the `SignUpListener` interface. This interface lets you implement the following methods:

- `onSignUpSuccess(User user)`: Called when sign up successfully completes. The `user` parameter contains a set of the created user's attributes. The supported keys are the same as those in the portal's User entity.
- `onSignUpFailure(Exception e)`: Called when an error occurs in the process.

128.3 Forgot Password Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Forgot Password Screenlet sends an email to registered users with their new passwords or password reset links, depending on the server configuration. The available authentication methods are

- Email address
- Screen name
- User id

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`sendPasswordByEmailAddress`	
`UserService`	`sendPasswordByUserId`	
`UserService`	`sendPasswordByScreenName`	

Module

- Auth

Views

- Default
- Material

Portal Configuration

To use Forgot Password Screenlet, the portal must be configured to allow users to request new passwords. The below sections show you how to do this. Also, Liferay Screens' Compatibility Plugin must be installed.

Authentication Method

The authentication method configured in the portal can be different from the one used by this Screenlet. For example, it's *perfectly fine* to use `screenName` for sign in authentication, but allow users to recover their password using the `email` authentication method.

Password Reset

You can set the Liferay instance's corresponding password reset options in the Control Panel by selecting *Configuration → Instance Settings*, and then selecting the *Authentication* section. The Screenlet's password functionality depends on the authentication settings in the portal:

If these options are both unchecked, password recovery is disabled. If both options are checked, an email containing a password reset link is sent when a user requests it. If only the first option is checked, an email containing a new password is sent when a user requests it.

For more details on authentication in Liferay Portal, please refer to the Setting up a Liferay Instance section of the User Guide.

Anonymous Request

An anonymous request can be made without the user being logged in. However, authentication is needed to call the API. To allow this operation, the portal administrator should create a specific user with minimal permissions.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity.

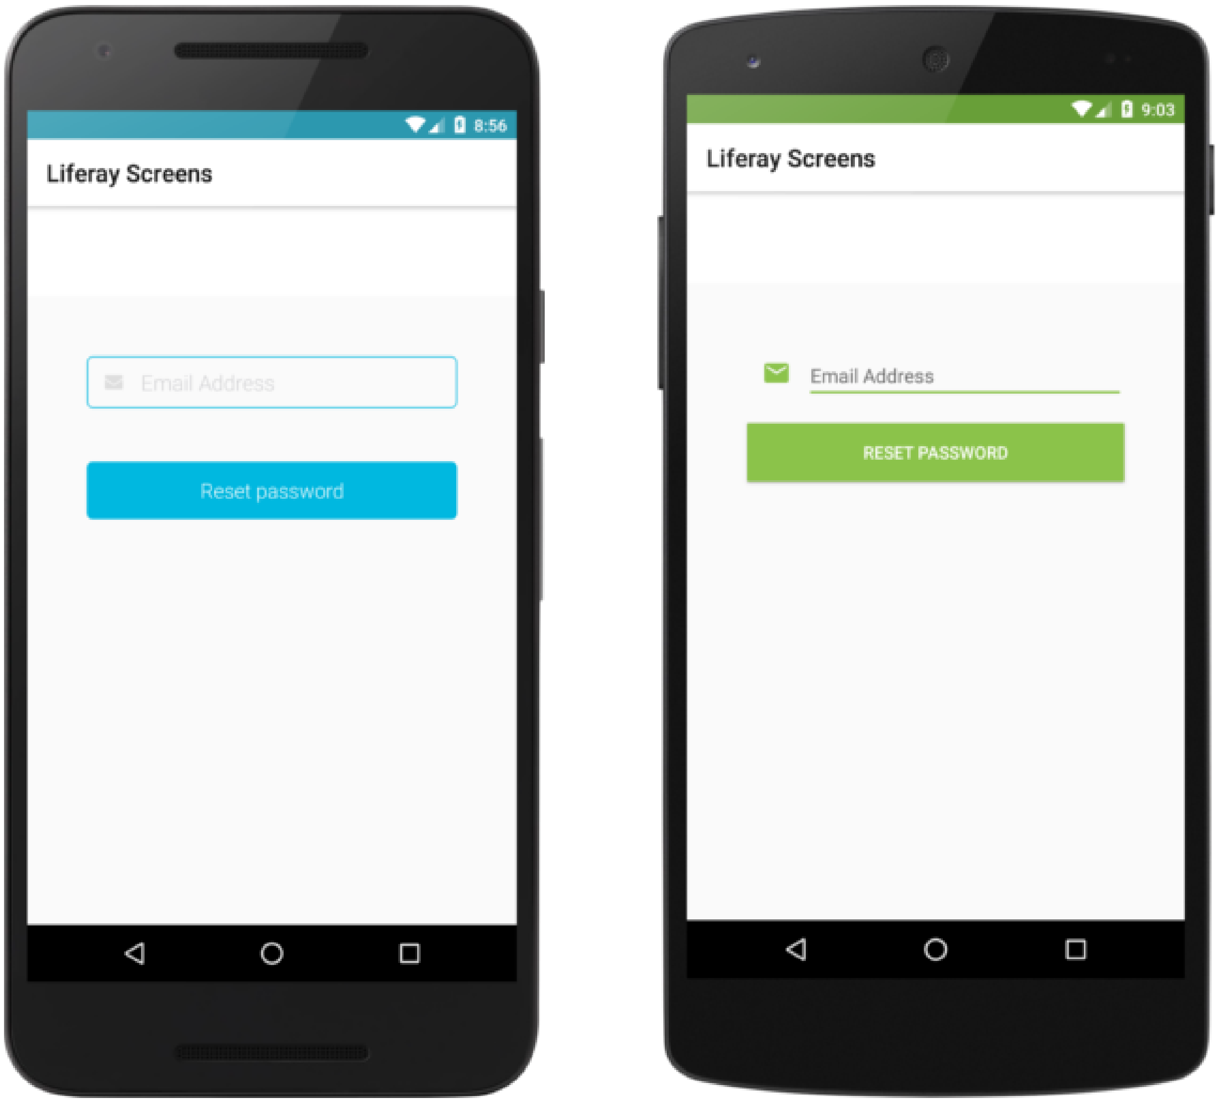


Figure 128.5: The Forgot Password Screenlet with the Default (left) and Material (right) Viewsets.

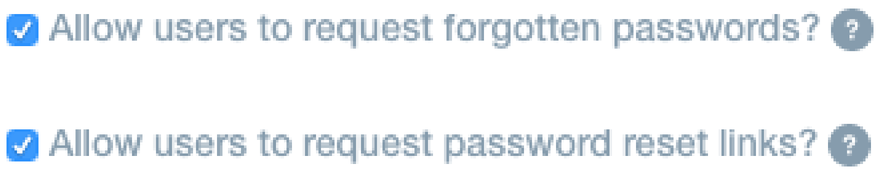

☑ Allow users to request forgotten passwords?

☑ Allow users to request password reset links?

Figure 128.6: Checkboxes for the password recovery features in your Liferay instance.

Required Attributes

- `anonymousApiUserName`
- `anonymousApiPassword`

Attributes

Attribute	Data type	Explanation
`layoutId`	`@layout`	The layout used to show the View.
`anonymousApiUserName`	`string`	The user name, email address, or `userId` to use for authenticating the request. This depends on the portal's authentication settings.
`anonymousApiPassword`	`string`	The password to use to authenticate the request.
`companyId`	`number`	When set, a user within the specified company is authenticated. If the value is set to `0`, the company specified in `LiferayServerContext` is used.
`basicAuthMethod`	`string`	The authentication method presented to the user. This can be `email`, `screenName`, or `userId`. The default value is `email`.

Listener

The Forgot Password Screenlet delegates some events to an object that implements the `ForgotPasswordListener` interface. This interface lets you implement the following methods:

- `onForgotPasswordRequestSuccess(boolean passwordSent)`: Called when a password reset email is successfully sent. The boolean parameter determines whether the email contains the new password or a password reset link.

- `onForgotPasswordRequestFailure(Exception e)`: Called when an error occurs in the process.

128.4 User Portrait Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Picasso library

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The User Portrait Screenlet shows the users' profile pictures. If a user doesn't have a profile picture, a placeholder image is shown. The Screenlet allows the profile picture to be edited via the `editable` property.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`getUserById`	

Module

- None

Views

- Default
- Material

Portal Configuration

No additional steps required.

Activity Configuration

The User Portrait Screenlet needs the following user permissions:

```
<uses-permission android:name="android.permission.CAMERA"/>
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>
```

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

When loading the portrait, the Screenlet supports the following offline mode policies:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the user portrait from the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet loads the portrait, it stores the received image in the local cache for later use. | Use this policy when you always need to show updated portraits, and show the default placeholder when there's no connection. | `CACHE_ONLY` | The Screenlet loads the user portrait from the local cache. If the portrait isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show local portraits, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the user portrait from the portal. The Screenlet displays the portrait to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the portrait from the local cache. If the portrait doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent portrait when connected, but show a potentially outdated version when there's no connection. | `CACHE_FIRST` | If the portrait exists in the local cache, the Screenlet loads it from there. If it doesn't exist

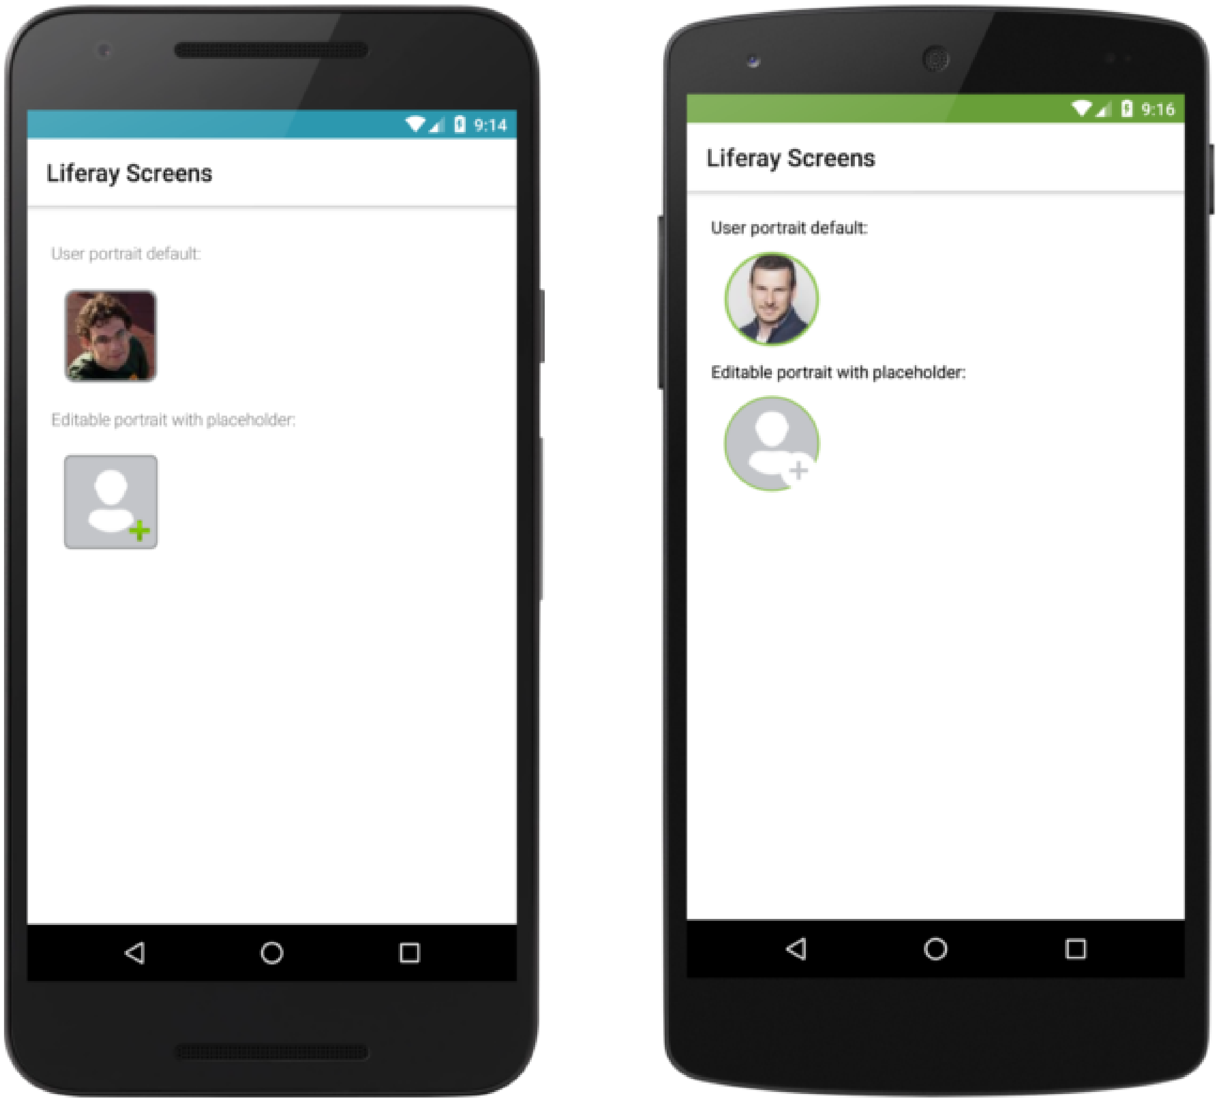

Figure 128.7: The User Portrait Screenlet using the Default (left) and Material (right) Views.

there, the Screenlet requests the portrait from the portal and uses the listener to notify the developer about any connection errors. | Use this policy to save bandwidth and loading time in the event a local (but probably outdated) portrait exists. |

When editing the portrait, the Screenlet supports the following offline mode policies:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet sends the user portrait to the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error, but it also discards the new portrait. | Use this policy when you need to make sure portal always has the most recent version of the portrait. | `CACHE_ONLY` | The Screenlet stores the user portrait in the local cache. | Use this policy when you need to save the portrait locally, but don't want to change the portrait in the portal. | `REMOTE_FIRST` | The Screenlet sends the user portrait to the portal. If this succeeds, the Screenlet also stores the portrait in the local cache for later usage. If a connection issue occurs, the Screenlet stores the portrait in the local cache with the *dirty flag* enabled. This causes the portrait to be sent to the portal when the synchronization process runs. | Use this policy when you need to make sure the Screenlet sends the new portrait to the portal as soon as the connection is restored. | `CACHE_FIRST` | The Screenlet stores the user portrait in the local cache and then sends it to the portal. If a connection issue occurs, the Screenlet stores the portrait in the local cache with the *dirty flag* enabled. This causes the portrait to be sent to the portal when the synchronization process runs. | Use this policy when you need to make sure the Screenlet sends the new portrait to the portal as soon as the connection is restored. Compared to `REMOTE_FIRST`, this policy always stores the portrait in the cache. The `REMOTE_FIRST` policy only stores the new image in the cache in the event of a network error or a successful upload. |

Required Attributes

- None

Note that if you don't set any attributes, the Screenlet loads the logged-in user's portrait.

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout used to show the View. | `autoLoad` | `boolean` | Whether the portrait should load when the Screenlet is attached to the window. | `userId` | `number` | The ID of the user whose portrait is being requested. If this attribute is set, the `male`, `portraitId`, and `uuid` attributes are ignored. | `male` | `boolean` | Whether the default portrait placeholder shows a male or female outline. This attribute is used if `userId` isn't specified. | `portraitId` | `number` | The ID of the portrait to load. This attribute is used if `userId` isn't specified. | `uuid` | `string` | The `uuid` of the user whose portrait is being requested. This attribute is used if `userId` isn't specified. | `editable` | `boolean` | Lets the user change the portrait image by taking a photo or selecting a gallery picture. | `offlinePolicy` | `enum` | Configure the loading and saving behavior in case of connectivity issues. For more details, read the "Offline" section below. |

Methods

Method | Return | Explanation | `load()` | `void` | Starts the request to load the user specified in the `userId` property, or the portrait specified in the `portraitIdand` `uuid` properties. | `upload(int requestCode,Intent` `onActivityResultData)` | `void` | Starts the request to upload a profile picture from the source specified in the `requestCode` property (gallery or camera), and with the path stored in the `onActivityResultData` variable. |

Listener

The User Portrait Screenlet delegates some events to an object that implements the `UserPortraitListener` interface. This interface lets you implement the following methods:

- `onUserPortraitLoadReceived(Bitmap bitmap)`: Called when an image is received from the server. You can then apply image filters (grayscale, for example) and return the new image. You can return `null` or the original image supplied as the argument if you don't want to modify it.
- `onUserPortraitUploaded()`: Called when the user portrait upload service finishes.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. For example, an error can occur when receiving or uploading a user portrait. The `userAction` argument distinguishes the specific action in which the error occurred.

128.5 DDL Form Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

DDL Form Screenlet shows a set of fields that can be filled in by the user. Initial or existing values can be shown in the fields. Fields of the following data types are supported:

- *Boolean*: A two state value typically represented by a checkbox.
- *Date*: A formatted date value. The format depends on the device's current locale.
- *Decimal, Integer, and Number*: A numeric value.
- *Documents & Media*: A file stored on the device. It can be uploaded to a specific portal repository.
- *Radio*: A set of options to choose from. A single option must be chosen.
- *Select*: A selection box of options to choose from. A single option must be chosen.
- *Text*: A single line of text.
- *Text Area*: Multiple lines of text.

The DDL Form Screenlet also supports the following features:

- Stored records can support a specific workflow.
- A Submit button can be shown at the end of the form.
- Required values and validation for fields can be used.
- Users can traverse the form fields from the keyboard.
- Supports i18n in record values and labels.

There are also a few limitations that you should be aware of when using DDL Form Screenlet. They are listed here:

- Nested fields in the data definition aren't supported.
- Selection of multiple items in the Radio and Select data types isn't supported.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensddlrecordService` (Screens compatibility plugin)	`getDDMStructureVersion`	Load form
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecord`	Load record
`DLAppService`	`addFileEntry`	Upload document
`DDLRecordService`	`addRecord`	Submit form
`DDLRecordService`	`updateRecord`	Update form

Module

- DDL

Views

- Default
- Material

The Default View uses a standard vertical `ScrollView` to show a scrollable list of fields. Other Views may use different components, such as `ViewPager` or others, to show the fields. You can find a sample of this implementation in the `DDLFormScreenletPagerView` class.

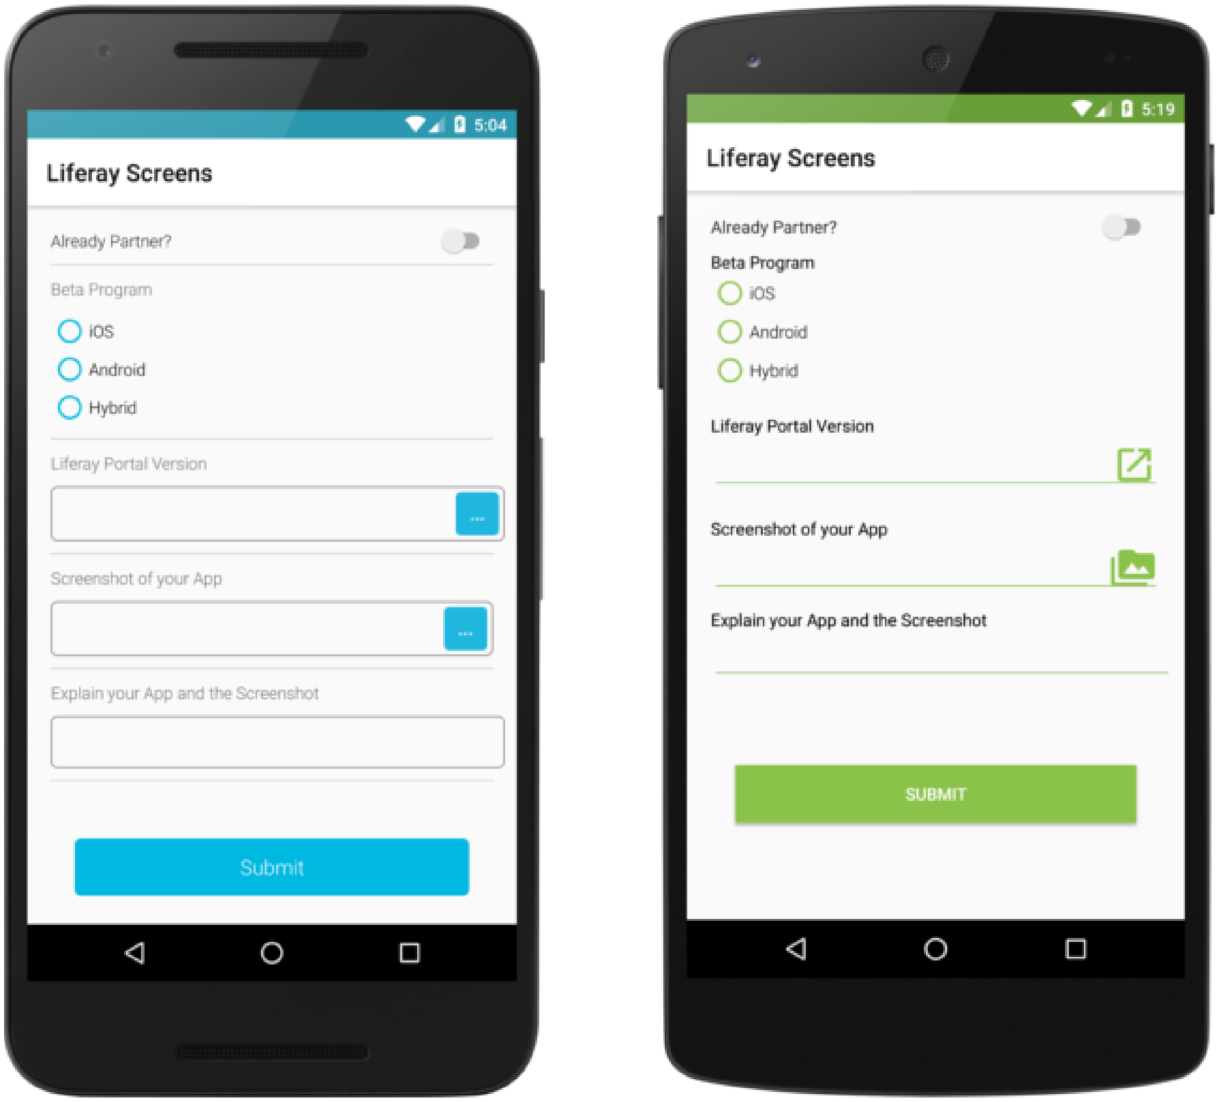

Figure 128.8: DDL Form Screenlet's Default (left) and Material (right) Views.

Editor Types

Each field defines an editor type. You must define each editor type's layout by using the following attributes:

- `checkboxFieldLayoutId`: The layout to use for Boolean fields.
- `dateFieldLayoutId`: The layout to use for Date fields.
- `numberFieldLayoutId`: The layout to use for Number, Decimal, or Integer fields.
- `radioFieldLayoutId`: The layout to use for Radio fields.
- `selectFieldLayoutId`: The layout to use for Select fields.
- `textFieldLayoutId`: The layout to use for Text fields.
- `textAreaFieldLayoutId`: The layout to use for Text Box fields.
- `textDocumentFieldLayoutId`: The layout to use for Documents & Media fields.

If you don't define the editor type's layout in DDL Form Screenlet's attributes, the default layout `ddlfield_xxx_default` is used, where `xxx` is the name of the editor type. It's important to note that you can change the layout used with any editor type at any point.

Custom Editors

If you want to have a unique appearance for one specific field, you can customize your field's editor View by calling the Screenlet's `setCustomFieldLayoutId(fieldName, layoutId)` method, where the first parameter is the name of the field to customize and the second parameter is the layout to use. You can also create custom editor Views. For examples of this, see the files `ddlfield_custom_rating_number.xml` and `CustomRatingNumberView.java`.

Activity Configuration

DDL Form Screenlet needs the following user permissions:

```
<uses-permission android:name="android.permission.CAMERA"/>
<uses-permission android:name="android.permission.WRITE_EXTERNAL_STORAGE"/>
```

Both are used by the Documents and Media fields to take a picture/video and store it locally before uploading it to the portal. The Documents and Media fields also need to override the `onActivityResult` method to receive the picture/video information. Here's an example implementation:

```
@Override
protected void onActivityResult(int requestCode, int resultCode, Intent data) {
    super.onActivityResult(requestCode, resultCode, data);

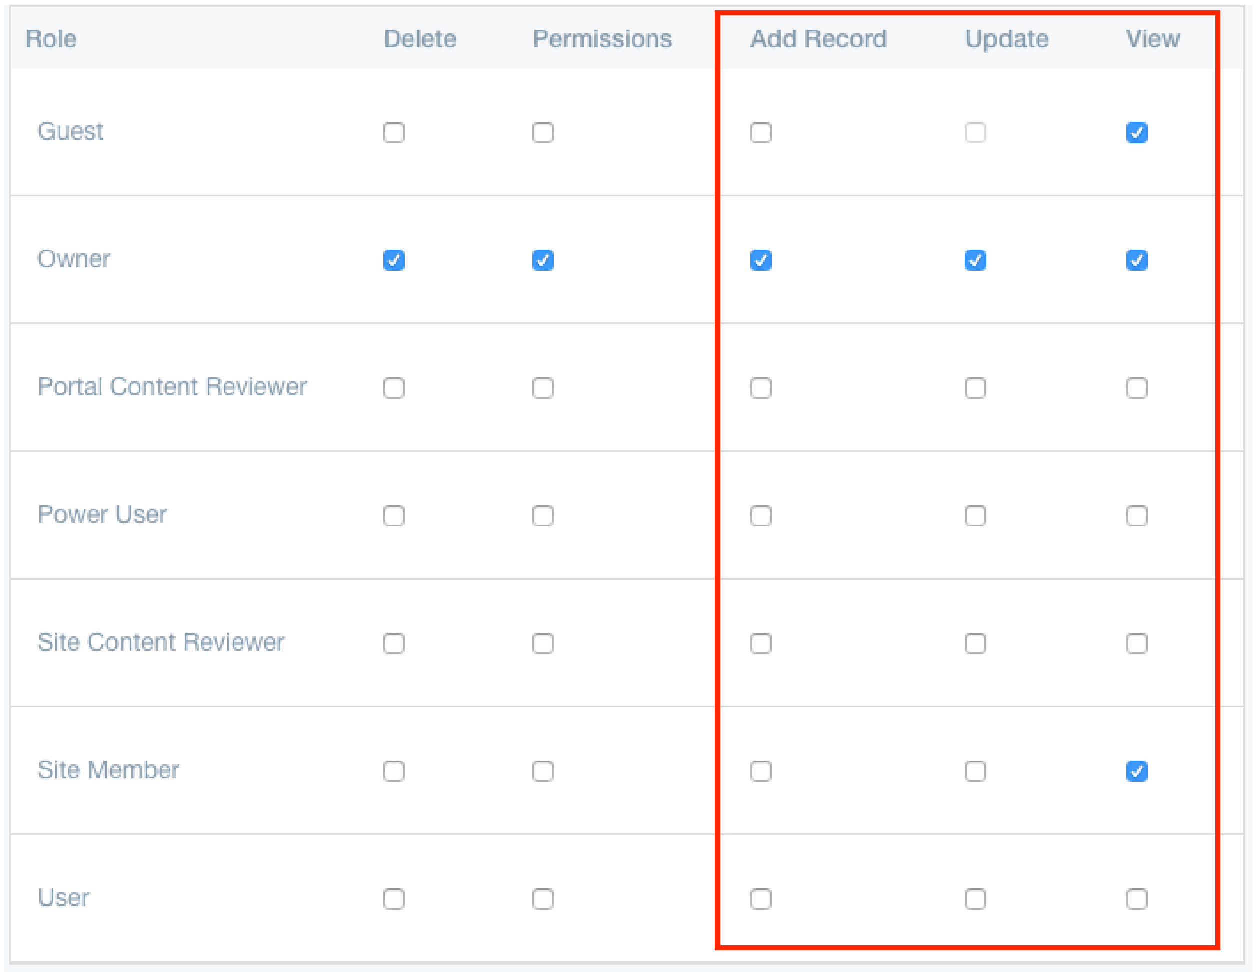
    screenlet.startUploadByPosition(requestCode);
}
```

Portal Configuration

Before using DDL Form Screenlet, you should make sure that Dynamic Data Lists and Data Types are configured properly in the portal. Refer to the Creating Data Definitions and Creating Data Lists sections of the User Guide for more details. If Workflow is required, it must also be configured. See the Using Workflow section of the User Guide for details.

Permissions

To use DDL Form Screenlet to add new records, you must grant the Add Record permission in the Dynamic Data List in the portal. If you want to use DDL Form Screenlet to view or edit record values, you must also grant the View and Update permissions, respectively. The Add Record, View, and Update permissions are highlighted by the red boxes in the following screenshot:



Role	Delete	Permissions	Add Record	Update	View
Guest	☐	☐	☐	☐	☑
Owner	☑	☑	☑	☑	☑

Figure 128.9: The permissions for adding, viewing, and editing DDL records.

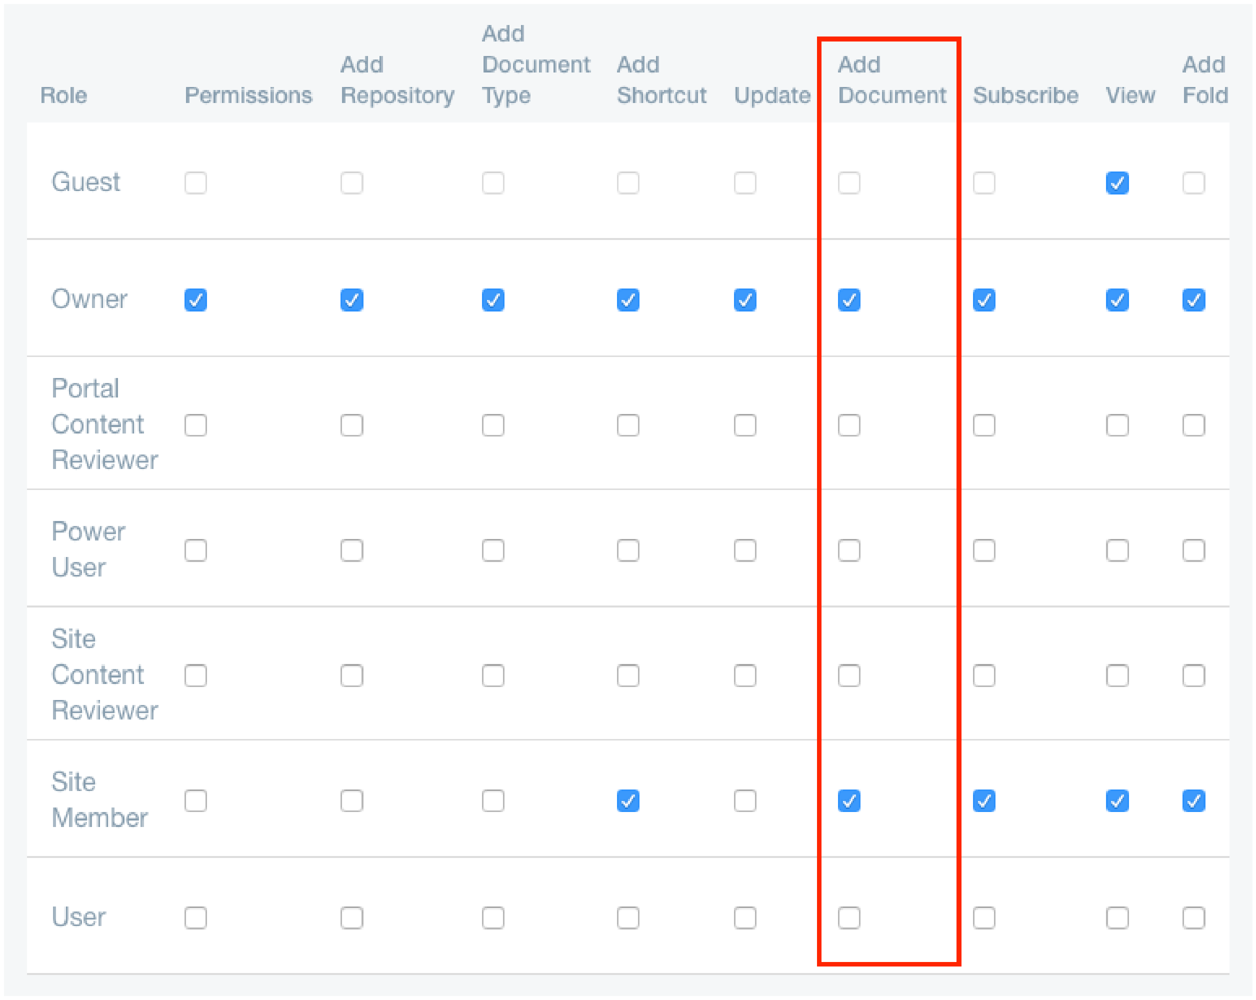
Also, if your form includes at least one Documents and Media field, you must grant permissions in the target repository and folder. For more details, see the `repositoryId` and `folderId` attributes below.

For more details, see the User Guide sections Creating Data Definitions, Creating Data Lists, and Using Workflow.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

When loading the form or record, the Screenlet supports the following offline mode policies:



Role	Permissions	Add Repository	Add Document Type	Add Shortcut	Update	Add Document	Subscribe	View	Add Fold
Guest	☐	☐	☐	☐	☐	☐	☐	✓	☐
Owner	✓	✓	✓	✓	✓	✓	✓	✓	✓

Site Member	☐	☐	☐	✓	☐	✓	✓	✓	✓
User	☐	☐	☐	☐	☐	☐	☐	☐	☐

Figure 128.10: The permission for adding a document to a Documents and Media folder.

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the form or record from the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet loads the form or record, it stores the received data (record structure and data) in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the form or record from the local cache. If the form or record isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet requests the form or record from the portal. The Screenlet shows the record or form to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the form or record from the local cache. If the form or record doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | If the form or record exists in the local cache, the Screenlet loads it from there. If it doesn't exist there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

When editing the record, the Screenlet supports the following offline mode policies:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet sends the record to the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error, but it also discards the record. | Use this policy to make sure the portal always has the most recent version of the record. | `CACHE_ONLY` | The Screenlet stores the record in the local cache. | Use this policy when you need to save the data locally, but don't want to update the data in the portal (update or add record). | `REMOTE_FIRST` | The Screenlet sends the record to the portal. If this succeeds, it also stores the record in the local cache for later usage. If a connection issue occurs, then Screenlet stores the record in the local cache with the *dirty flag* enabled. This causes the synchronization process to send the record to the portal when it runs. | Use this policy when you need to make sure the Screenlet sends the record to the portal as soon as the connection is restored. | `CACHE_FIRST` | The Screenlet stores the record in the local cache and then sends it to the remote portal. If a connection issue occurs, then Screenlet stores the record in the local cache with the *dirty flag* enabled. This causes the the synchronization process to send the record to the portal when it runs. | Use this policy when you need to make sure the Screenlet sends the record to the portal as soon as the connection is restored. Compared to `REMOTE_FIRST`, this policy always stores the record in the cache. The `REMOTE_FIRST` policy only stores the record in the event of a network error. |

Required Attributes

- `structureId`
- `recordSetId`

Attributes

Attribute | Data Type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `checkboxFieldLayoutId` | `@layout` | The layout to use to show the view for Boolean fields. | `dateFieldLayoutId` | `@layout` | The layout to use to show the view for Date fields. | `numberFieldLayoutId` | `@layout` | The layout to use to show the view for Number, Decimal, and Integer fields. | `radioFieldLayoutId` | `@layout` | The layout to use to show the view for Radio fields. | `selectFieldLayoutId` | `@layout` | The layout to use to show the view for Select fields. | `textFieldLayoutId` | `@layout` | The layout to use to show the view for Text fields. | `textAreaFieldLayoutId` | `@layout` | The layout to use to show the view for Text Box fields. | `documentFieldLayoutId` | `@layout` | The layout to use to show the view for Documents & Media fields. | `structureId` | `number` | The ID of a data definition in your Liferay site. To find the IDs for your data definitions, click *Admin → Content* from the Dockbar. Then click *Dynamic Data Lists* on the left and click the *Manage Data Definitions* button. The ID of each data definition is in the ID column of the table. | `groupId` | `number` | The ID of the site (group) where the record is stored. If this value is `0`, the `groupId` specified in `LiferayServerContext` is used. | `recordSetId` | `number` | A dynamic data list's ID. To find your dynamic data lists' IDs, click *Admin → Content* from the Dockbar. Then click *Dynamic Data Lists* on the left. Each dynamic data list's ID is in the ID column of the table. | `recordId` | `number` | The ID of the record you want to show. You can also allow the record's values to be edited. This ID can be obtained from other methods or listeners. | `repositoryId` | `number` | The ID of the Documents and Media repository to upload to. If this value is `0`, the default repository for the site specified by `groupId` is used. | `folderId` | `number` | The ID of the folder where Documents and Media files are uploaded. If this value is `0`, the root is used. | `filePrefix` | `string` | The prefix to attach to the names of files uploaded to a Documents and Media repository. The upload date followed by the original file name is appended following the prefix. | `autoLoad` | `boolean` | Sets whether the form loads when the Screenlet is shown. If `recordId` is set, the record value is loaded together with the form definition. The default value is `false`. | `autoScrollOnValidation` | `boolean` | Sets whether the form automatically scrolls to the first failed field when validation is used. The default value is `true`. | `showSubmitButton` | `boolean` | Sets whether the form shows a submit button at the bottom. If this is set to `false`, you should call the `submitForm()` method. The default value is `true`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Methods

Method | Return Type | Explanation | `loadForm()` | `void` | Starts the request to load the form definition. The form fields are shown when the response is received. | `loadRecord()` | `void` | Starts the request to load the record specified by `recordId`. If needed, the form definition also loads. When the response is received, the form fields are shown filled with record values. | `load()` | `void` | Starts the request to load the record if `recordId` is specified. Otherwise, the form definition is loaded. | `submitForm()` | `void` | Starts the request to submit form values to the dynamic data list specified by `recordSetId`. If the record is new, a new record is added. If `loadRecord` is used to retrieve the record, or the record already exists, its values are updated. Fields are validated prior to the request. If validation fails, the validation errors are shown and the request is terminated. |

Listener

DDL Form Screenlet delegates some events to an object that implements to the `DDLFormListener` interface. This interface lets you implement the following methods:

- `onDDLFormLoaded(Record record)`: Called when the form definition successfully loads.
- `onDDLFormRecordLoaded(Record record, Map<String, Object> valuesAndAttributes)`: Called when the form record data successfully loads.
- `onDDLFormRecordAdded(Record record)`: Called when the form record is successfully added.
- `onDDLFormRecordUpdated(Record record)`: Called when the form record data successfully updates.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. For example, this method is called when an error occurs while loading a form definition or record, or adding or updating a record. The `userAction` variable distinguishes these events.
- `onDDLFormDocumentUploaded(DocumentField field)`: Called when a specified document field's upload completes.
- `onDDLFormDocumentUploadFailed(DocumentField field, Exception e)`: Called when a specified document field's upload fails.

128.6 DDL List Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above

- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The DDL List Screenlet has the following features:

- Shows a scrollable collection of Dynamic Data List (DDL) records.
- Implements fluent pagination with configurable page size.
- Allows record filtering by creator.
- Supports i18n in record values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecords`	With `ddlRecordSetId`, or `ddlRecordSetId` and `userId`
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecordsCount`	

Module

- DDL

Views

- Default
- Material

The Default View uses a standard `RecyclerView` to show the scrollable list. Other Views may use a different component, such as `ViewPager` or others, to show the items.

Figure 128.11: The DDL List Screenlet using the Default and Material Views.

Portal Configuration

DDLs and Data Types should be configured in the portal before using DDL List Screenlet. For more details, see the Liferay User Guide sections Creating Data Definitions and Creating Data Lists .

Also, to allow remote calls without the `userId`, the Liferay Screens Compatibility app must be installed in your Liferay instance. You can find this app on Liferay Marketplace.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the list from the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the list from the portal. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `recordSetId`
- `labelFields`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Defines whether the list should be loaded when it's presented on the screen. The default value is `true`. | `recordSetId` | `number` | The ID of the DDL being called. To find your DDLs' IDs, click *Admin* → *Content* from the Dockbar. Then click *Dynamic Data Lists* on the left. Each DDL's ID is in the ID column of the table. | `userId` | `number` | The ID of the user to filter records on. Records aren't filtered if the `userId` is `0`. The default value is `0`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `firstPageSize` | `number` | The number of items to retrieve from the server for display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items to retrieve from the server for display on the second and subsequent pages. The default value is `25`. | `labelFields` | `string` | The comma-separated names of the DDL fields to show. Refer to the list's data definition to find the field names. For more information on this, see Creating Data Definitions. Note that the appearance of these values in your app depends on the `layoutId` set. | `obcClassName` | `string` | The name of the `OrderByComparator` class to use to sort the results. Omit this property if you don't want to sort the results. Click here to see some comparator classes. Note, however, that not all of these classes can be used with `obcClassName`. You can only use comparator classes that extend `OrderByComparator<DDLRecord>`. You can also create your own comparator classes that extend `OrderByComparator<DDLRecord>`. |

Methods

Method | Return | Explanation | `loadPage(pageNumber)` | `void` | Starts the request to load the specified page of records. The page is shown when the response is received. |

Listener

DDL List Screenlet delegates some events to an object or a class that implements the `BaseListListener` interface. This interface lets you implement the following methods:

- `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call fails.

- `onListPageReceived(int startRow, int endRow, List<Record> records, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method may be called more than once; once for each page received. Because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first item on the first page.

- `onListItemSelected(Record records, View view)`: Called when an item is selected in the list. This method's arguments include the selected list item (`Record`).

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.7 Asset List Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Asset List Screenlet can be used to show asset lists from a Liferay instance. For example, you can use the Screenlet to show a scrollable list of assets. It also implements fluent pagination with configurable page size. The Asset List Screenlet can show assets belonging to the following classes:

- `BlogsEntry`
- `BookmarksEntry`
- `BookmarksFolder`
- `CalendarEvent`
- `DLFileEntry`
- `DDLRecord`
- `DDLRecordSet`
- `Group`
- `JournalArticle` (Web Content)
- `JournalFolder`
- `Layout`
- `LayoutRevision`
- `MBThread`
- `MBCategory`
- `MBDiscussion`
- `MBMailingList`
- `Organization`
- `User`
- `WikiPage`
- `WikiPageResource`
- `WikiNode`

The Asset List Screenlet also supports i18n in asset values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensddlrecordService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensddlrecordService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`
`AssetEntryService`	`getEntriesCount`	

Module

- None

Views

- Default
- Material

The Default Views use a standard `RecyclerView` to show the scrollable list. Other Views may use a different component, such as `ViewPager` or others, to show the items.

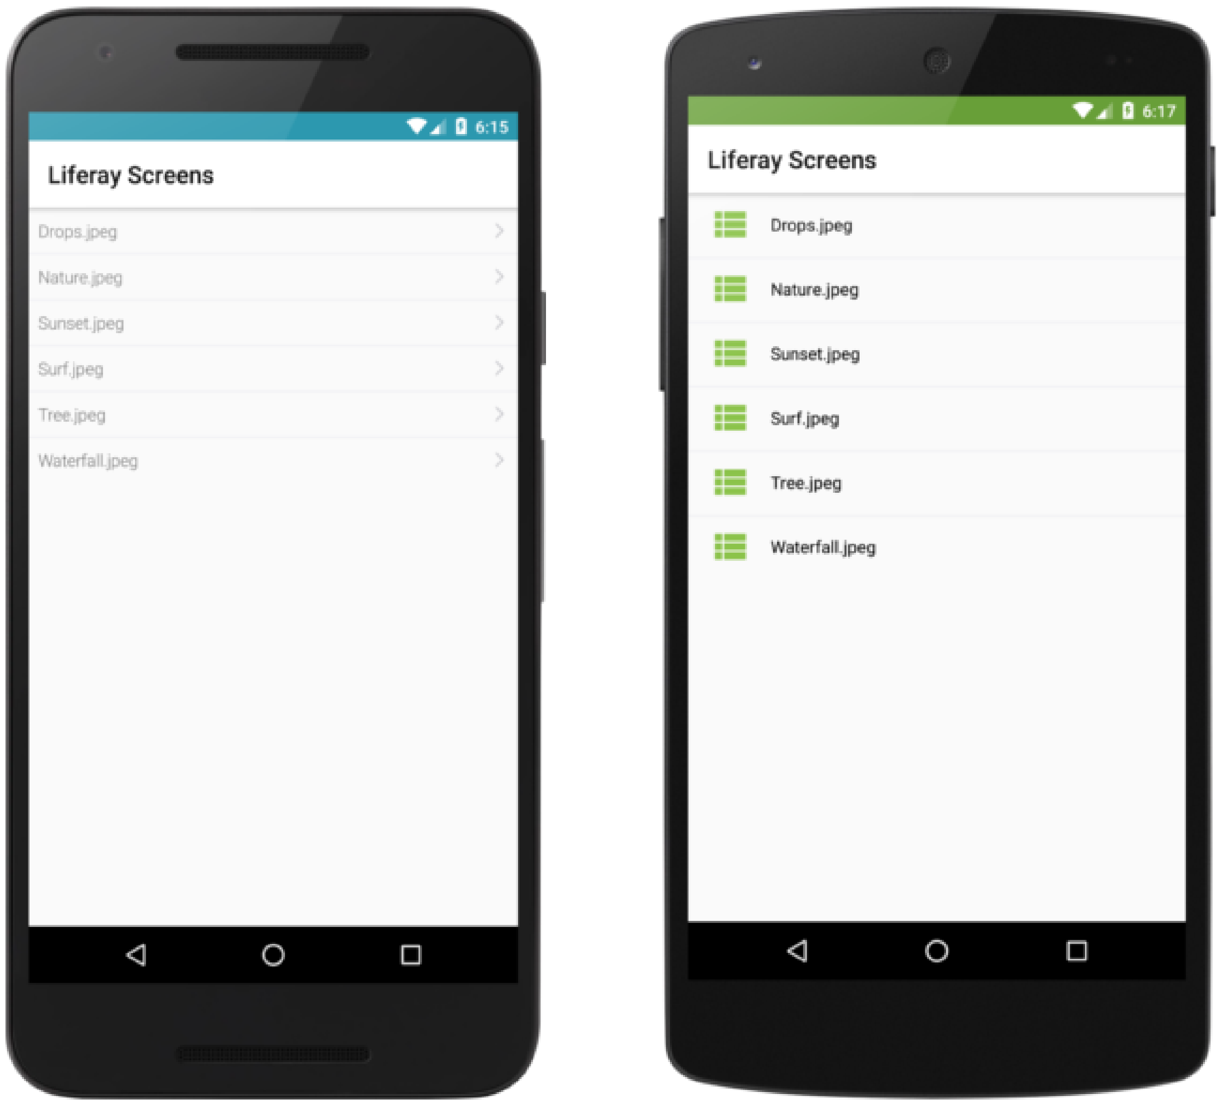

Figure 128.12: Asset List Screenlet using the Default (left) and Material (right) Views.

Portal Configuration

Dynamic Data Lists (DDL) and Data Types should be configured properly in the portal. Refer to the Creating Data Definitions
and Creating Data Lists sections of the User Guide for more details.

Also, to allow remote calls without the `userId`, the Liferay Screens Compatibility app must be installed in your Liferay instance. You can find this app on Liferay Marketplace.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the list from the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the list from the portal. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `classNameId`

If you don't set `classNameId`, you must set this attribute instead:

- `portletItemName`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View.| `autoLoad` | `boolean` | Whether the list should be loaded when it's presented on the screen. The default value is `true`. | `groupId` | `number` | The asset's group (site) ID. If this value is `0`, the `groupId` specified in `LiferayServerContext` is used. The default value is `0`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `portletItemName` | `string` | The name of the configuration template you used in the Asset Publisher. To use this feature, add an Asset Publisher to one of your site's pages (it may be a hidden page), configure the Asset Publisher's filter (in *Configuration → Setup → Asset Selection*), and then use the Asset Publisher's *Configuration Templates* option to save this configuration with a name. Use this name in this attribute. | `classNameId` | `number` | The asset class name's ID. Use values from the portal's `classname_` database table. | `firstPageSize` | `number` | The number of items to retrieve from the server for display on the list's first page. The default value is `50`. | `pageSize` | `number` | The number of items to retrieve from the server for display on the second and subsequent pages. The default value is `25`. | `labelFields` | `string` | The comma-separated names of the DDL fields to show. Refer to the list's data definition to find the field names. For more information on this, see Creating Data Definitions. Note that the appearance of these values in your app depends on the layoutId set. | customEntryQuery | HashMap | The set of keys (string) and values (string or number) to be used in the AssetEntryQuery object. These values filter the assets returned by the Liferay instance. |

Methods

Method | Return | Explanation | loadPage(pageNumber) | void | Starts the request to load the specified page of assets. The page is shown when the response is received. |

Listener

Asset List Screenlet delegates some events to an object or a class that implements the BaseListListener interface. This interface lets you implement the following methods:

- `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call fails.

- `onListPageReceived(int startRow, int endRow, List<Model> entries, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method may be called more than once; once for each page received. Because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first item on the first page.

- `onListItemSelected(Model entries, View view)`: Called when an item is selected in the list. This method's arguments include the selected list item (`Model`).

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.8 Web Content Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Web Content Display Screenlet shows web content elements in your app, rendering the web content's inner HTML. The Screenlet also supports i18n, rendering contents differently depending on the device's locale.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`DDMStructureService`	`getStructure`	
`JournalArticleService`	`getArticle`	
`JournalArticleService`	`getArticleContent`	
`ScreensddlrecordService` (Screens compatibility plugin)	`getJournalArticleContent`	With `entryQuery`

Module

- None

Views

- Default

  The Default View uses a standard `WebView` to render the HTML.

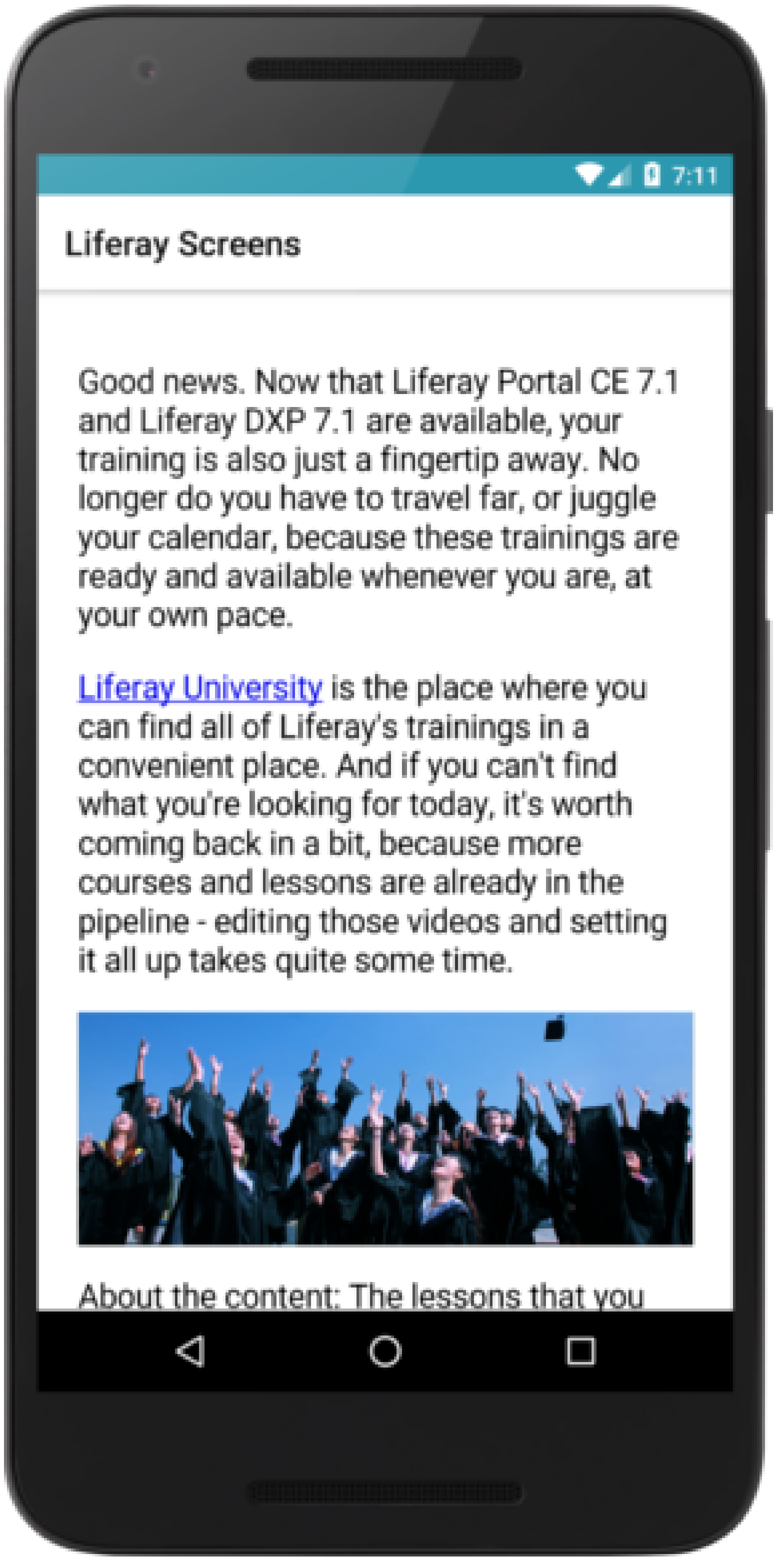
Portal Configuration

For the Web Content Display Screenlet to function properly, there should be web content in the Liferay instance your app connects to. For more details on web content, see the Creating Web Content section of the Liferay User Guide.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the content from the portal. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the content, it stores the data in the local cache for later use. | Use this policy when you always need to show updated content, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the content from the local cache. If the content isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local content, without



Good news. Now that Liferay Portal CE 7.1 and Liferay DXP 7.1 are available, your training is also just a fingertip away. No longer do you have to travel far, or juggle your calendar, because these trainings are ready and available whenever you are, at your own pace.

Liferay University is the place where you can find all of Liferay's trainings in a convenient place. And if you can't find what you're looking for today, it's worth coming back in a bit, because more courses and lessons are already in the pipeline - editing those videos and setting it all up takes quite some time.

About the content: The lessons that you

Figure 128.13: Web Content Display Screenlet using the Default View.

retrieving remote content under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the content from the portal. If this succeeds, the Screenlet shows the content to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the content from the local cache. If the content doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the content when connected, but show a possibly outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the content from the local cache. If the content isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) content. |

Required Attributes

- `articleId`

Note that if your web content uses structures and templates, you can use `templateId` or `structureId` in conjunction with `articleId`.

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout used to show the View. | `groupId` | `number` | The site (group) identifier where the asset is stored. If this value is `0`, the `groupId` specified in `LiferayServerContext` is used. | `articleId` | `string` | The identifier of the web content to display. You can find the identifier by clicking *Edit* on the web content in the portal. | `classPK` | `number` | The corresponding asset's class primary key. If the web content is an asset (from Asset List Screenlet, for example), this is the asset's identifier. This attribute is used only if `articleId` is empty. | `templateId` | `number` | The identifier of the template used to render the web content. This only applies to structured web content. | `structureId` | `number` | The identifier of the `DDMStructure` used to model the web content. This parameter lets the Screenlet retrieve and parse the structure. | `labelFields` | `string` | A comma-delimited list of `DDMStructure` fields to display in the Screenlet. | `autoLoad` | `boolean` | Whether the content should be retrieved from the portal as soon as the screenlet appears. Default value is `true`. | `javascriptEnabled` | `boolean` | Enables support for JavaScript. This is disabled by default. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Methods

Method | Return | Explanation | `load()` | `void` | Starts the request to load the web content. The HTML is rendered when the response is received. | `getLocalized(String name)` | `String` | Returns the value, according to the device locale, of a field of the `DDMStructure` used to render the web content.

Listener

The Web Content Display Screenlet delegates some events to an object that implements the `WebContentDisplayListener` interface. This interface lets you implement the following methods:

- `onWebContentReceived(WebContent webContent)`: Called when the web content's HTML or `DDMStructure` is received. The HTML is available by calling the `getHtml` method. To make some adaptations, the listener may return a modified version of the HTML. The original HTML is rendered if the listener returns `null`.
- `onUrlClicked(String url)`: Called when a URL is clicked. Return `true` to replace the default behavior, or `false` to load the url.
- `onWebContentTouched(View view, MotionEvent event)`: Called when something is touched in the web content. Return `true` to replace the default behavior, or `false` to keep processing the event.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.9 Web Content List Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Web Content List Screenlet has the following features:

- Shows a scrollable collection of web content articles.
- Implements fluent pagination with configurable page size.
- Supports i18n in web content values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`JournalArticleService`	`getJournalArticles`	
`JournalArticleService`	`getJournalArticlesCount`	

Module

- None

Views

- Default

The Default View uses a standard `RecyclerView` to show the scrollable list. Other Views may use a different component, such as `ViewPager` or others, to show the items.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the list from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the list from the Liferay instance. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show a possibly outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but possibly outdated) data. |

Required Attributes

- `folderId`
- `labelFields`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The ID of the layout to use to show the View. | `autoLoad` | `boolean` | Whether the list loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `folderId` | `number` | The ID of the web content folder to retrieve content from. | `groupId` | `number` | The ID of the site (group) where the asset is stored. If set to `0`, the `groupId` specified in `LiferayServerContext` is used. The default value is `0`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `firstPageSize` | `number` | The number of items to retrieve from the server for display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items to retrieve from the server for display on the second and subsequent pages. The default value is `25`. | `labelFields` |

Figure 128.14: The Web Content List Screenlet using the Default View.

`string` | The comma-separated names of the DDM fields to show. Refer to the list's data definition to find the field names. For more information on this, see the article on structured web content. Note that the appearance of data from a structure's fields depends on the `layoutId`. | `obcClassName` | `string` | The name of the `OrderByComparator` class to use to sort the results. Omit this property if you don't want to sort the results. Click here to see some comparator classes. Note, however, that not all of these classes can be used with `obcClassName`. You can only use comparator classes that extend `OrderByComparator<JournalArticle>`. You can also create your own comparator classes that extend `OrderByComparator<JournalArticle>`. |

Methods

Method | Return | Explanation | `loadPage(pageNumber)` | `void` | Starts the request to load the specified page of records. The page is shown when the response is received. |

Listener

Web Content List Screenlet delegates some events to an object or a class that implements the `BaseListListener` interface. This interface lets you implement the following methods:

- `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call fails.

- `onListPageReceived(int startRow, int endRow, List<Record> records, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method may be called more than once; once for each page received. Because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first item on the first page.

- `onListItemSelected(Record records, View view)`: Called when an item is selected in the list. This method's arguments include the selected list item (`Record`).

128.10 Image Gallery Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Image Gallery Screenlet shows a list of images from a Documents and Media folder in a Liferay instance. You can also use Image Gallery Screenlet to upload images to and delete images from the same folder. The Screenlet implements fluent pagination with configurable page size, and supports i18n in asset values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`DLAppService`	`getFileEntries`	Load
`DLAppService`	`getFileEntriesCount`	
`DLAppService`	`addFileEntry`	Upload
`DLAppService`	`deleteFileEntry`	Delete

Module

- None

Views

The included Views use a standard Android `RecyclerView` to show the scrollable list. Other custom Views may use a different component, such as `ViewPager` or others, to show the items.

This Screenlet has three different Views:

1. Grid (default)
2. Slideshow
3. List

Offline

This Screenlet supports offline mode so it can function without a network connection when loading or uploading images (deleting images while offline is unsupported). For more information on how offline mode works, see the tutorial on its architecture. This Screenlet supports the `REMOTE_ONLY`, `CACHE_ONLY`, `REMOTE_FIRST`, and `CACHE_FIRST` offline mode policies.

These policies take the following actions when loading images from a Liferay instance:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the list from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving

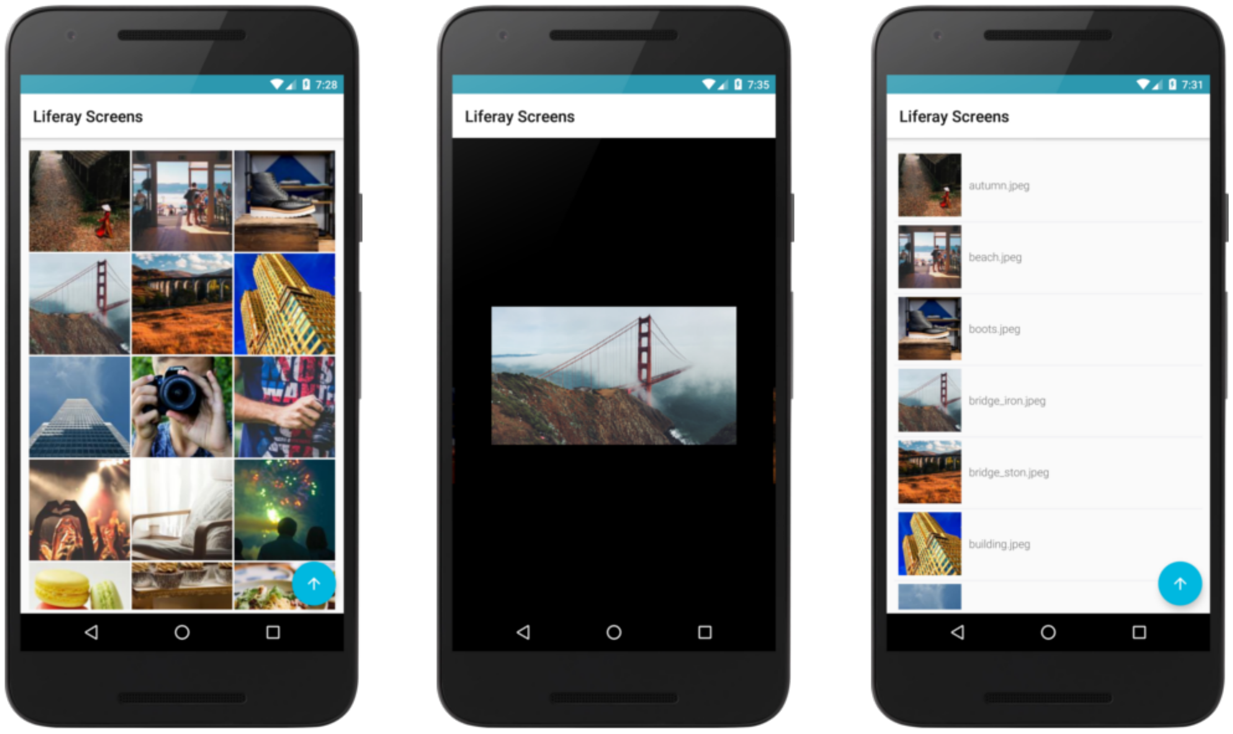

Figure 128.15: Image Gallery Screenlet using the Grid, Slideshow, and List Views.

remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the list from the Liferay instance. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

These policies take the following actions when uploading an image to a Liferay instance:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet sends the image to the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error, but it also discards the image. | Use this policy to make sure the Liferay instance always has the most recent version of the image. | `CACHE_ONLY` | The Screenlet stores the image in the local cache. | Use this policy when you need to save the image locally, but don't want to update the image in the Liferay instance (delete or add image). | `REMOTE_FIRST` | The Screenlet sends the image to the Liferay instance. If this succeeds, it also stores the image in the local cache for later use. If a connection issue occurs, the Screenlet stores the image in the local cache and sends it to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the image to the Liferay instance as soon as the connection is restored. | `CACHE_FIRST` | The Screenlet stores the image in the local cache and then attempts to send it to the Liferay instance. If a connection issue occurs, the Screenlet sends the image to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the image to the Liferay instance as soon as the connection is restored. Compared to `REMOTE_FIRST`, this policy always stores the image in the cache. The `REMOTE_FIRST` policy only stores the image in the event of a network error. |

Required Attributes

- `folderId`
- `repositoryId`

Attributes

Attribute | Data type | Explanation | `repositoryId` | `number` | The ID of the Liferay instance's Documents and Media repository that contains the image gallery. If you're using a site's default Documents and Media repository, then the `repositoryId` matches the site ID (`groupId`). | `folderId` | `number` | The ID of the Documents and Media repository folder that contains the image gallery. When accessing the folder in your browser, the `folderId` is at the end of the URL. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `firstPageSize` | `number` | The number of items to display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items to display on second and subsequent pages. The default value is `25`. | `mimeTypes` | `string` | The comma-separated list of MIME types for the Screenlet to support. | `autoLoad` | `boolean` | Whether the list automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `layoutId` | `@layout` | The layout to use to show the View. | `obcClassName` | `string` | The name of the `OrderByComparator` class to use to sort the results. Omit this property if you don't want to sort the results. Note that you can only use comparator classes that extend `OrderByComparator<DLFileEntry>`. Liferay contains no such comparator classes. You must therefore create your own by extending `OrderByComparator<DLFileEntry>`. To see examples of some comparator classes that extend other Document Library classes, click here. |

Methods

Method | Return | Explanation | `loadPage(pageNumber)` | `void` | Starts the request to load the specified page of images. The page is shown when the response is received. |

Listener

Image Gallery Screenlet delegates some events to an object or class that implements its `ImageGalleryListener` interface. This interface extends the `BaseListListener` interface. Therefore, Image Gallery Screenlet's listener methods are as follows:

- `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call fails.

- `onListPageReceived(int startRow, int endRow, List<Record> records, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method may be called more than once; once for each page received. Because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first item on the first page.

- `onListItemSelected(Record records, View view)`: Called when an item is selected in the list. This method's arguments include the selected list item (`Record`).
- `onImageEntryDeleted(long imageEntryId)`: Called when an item in the list is deleted.
- `onImageUploadStarted(String picturePath, String title, String description, String changelog)`: Called when an item is prepared for upload.
- `onImageUploadProgress(int totalBytes, int totalBytesSent)`: Called when an item is uploading.
- `onImageUploadEnd(ImageEntry entry)`: Called when an item finishes uploading.
- `showUploadImageView(String actionName, String picturePath, int screenletId)`: Called when the View for uploading an image is instantiated. The default behavior is to show the default View in a dialog. To retain this behavior, all this method needs to do is return `false`. To change the default behavior, use the `initializeUploadView` method to initialize a custom View that extends `BaseDetailUploadView`. Then return `true` to prevent the Screenlet from executing the default behavior. For example, the following sample implementation uses `initializeUploadView` to initialize the custom View instance `uploadDetailView`. It then performs a custom UI action (`uploadImageCard.goRight()`) and returns `true`:

  ```
  @Override
  public boolean showUploadImageView(String actionName, String picturePath, int screenletId) {
      uploadDetailView.initializeUploadView(actionName, picturePath, screenletId);
      uploadImageCard.goRight();

      return true;
  }
  ```

- `provideImageUploadDetailView()`: Called when the Screenlet provides the image upload View. To inflate the default View, return `0` in this method. Alternatively, display this View with a custom layout by returning its layout ID. Such a layout must have `DefaultUploadDetailView` as its root class.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.11 Rating Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Rating Screenlet shows an asset's rating. It also lets users update or delete the rating. This Screenlet comes with different Views that display ratings as thumbs, stars, and emojis.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensratingsentryService` (Screens compatibility plugin)	`getRatingsEntries`	With `entryId`
`ScreensratingsentryService` (Screens compatibility plugin)	`getRatingsEntries`	With `classPK` and `className`
`ScreensratingsentryService` (Screens compatibility plugin)	`updateRatingsEntry`	
`ScreensratingsentryService` (Screens compatibility plugin)	`deleteRatingsEntry`	

Module

- None

Views

The default View uses an Android `RatingBar` to show an asset's rating. Other custom Views may show the rating with a different Android component such as `Button`, `ImageButton`, or others.

This Screenlet has five different Views:

1. Like
2. Thumbs (default)
3. Stars
4. Reactions
5. Emojis

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when

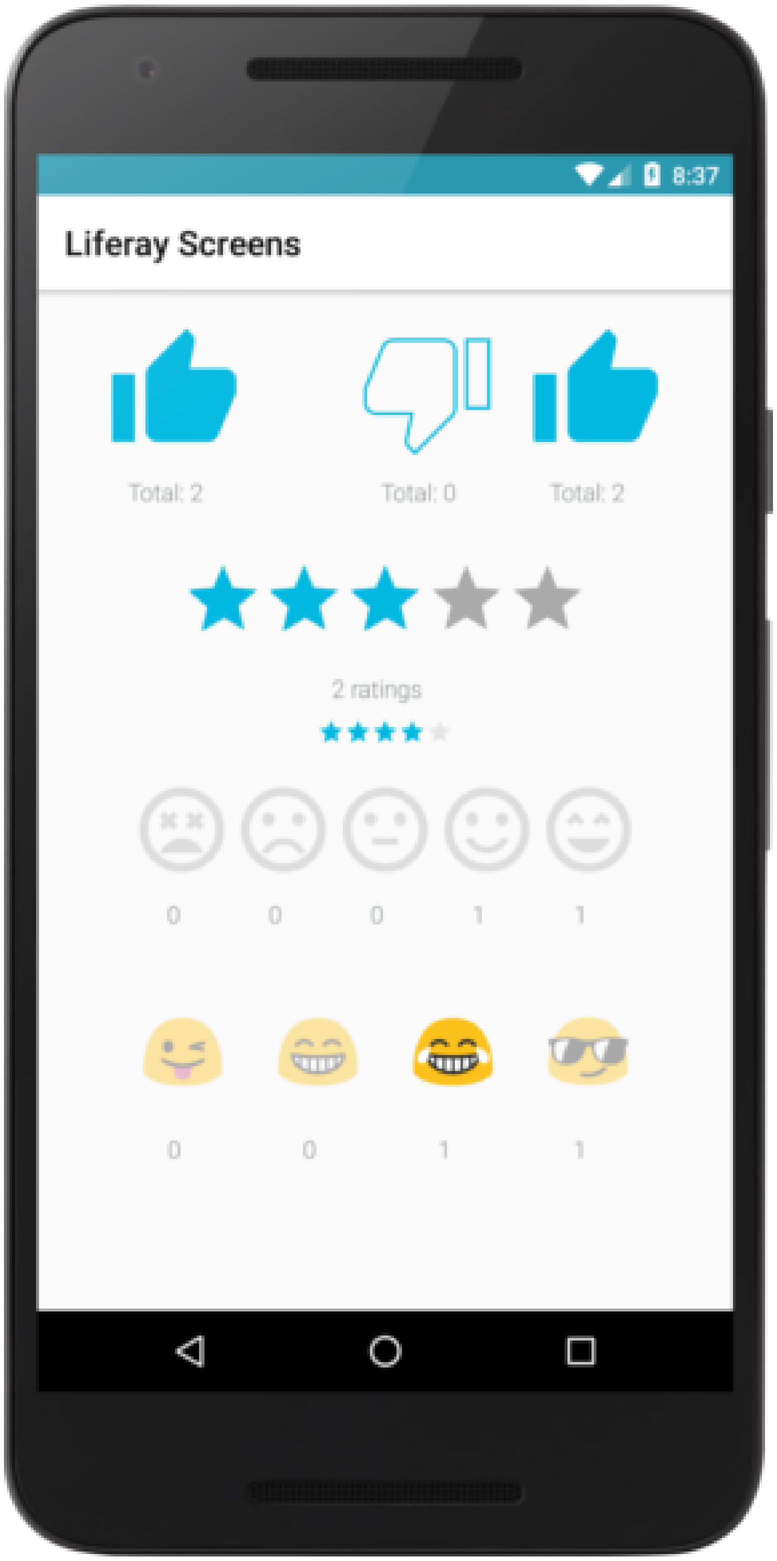

Figure 128.16: Rating Screenlet's different Views.

you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId`

If you don't use `entryId`, you must use both of the following attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The ID of the layout to use to show the View. | `autoLoad` | `boolean` | Whether the rating loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `editable` | `boolean` | Whether the user can change the rating. | `entryId` | `number` | The primary key of the asset with the rating to display. | `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` attribute is required when using it with `classPK` to instantiate the Screenlet. | `classPK` | `number` | The asset's unique identifier. Only use this attribute when also using `className` to instantiate the Screenlet. | `groupId` | `number` | The ID of the site (group) containing the asset. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Methods

Method | Return | Explanation | `load()` | `void` | Starts the request to load the asset's ratings. |

Listener

Rating Screenlet delegates some events to an object or class that implements its `RatingListener` interface. Therefore, Rating Screenlet's listener methods are as follows:

- `onRatingOperationSuccess(AssetRating assetRating)`: Called when the operation finishes successfully and the rating is loaded.

128.12 Comment List Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment List Screenlet can list all the comments of an asset in a Liferay instance. It also lets the user update or delete comments.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`getComments`	
`ScreenscommentService` (Screens compatibility plugin)	`getCommentsCount`	

Module

- None

Views

- Default

The Default View uses an Android `RecyclerView` to show an asset's comments. Other Views may use a different component, such as `TableView` or others, to show the items.

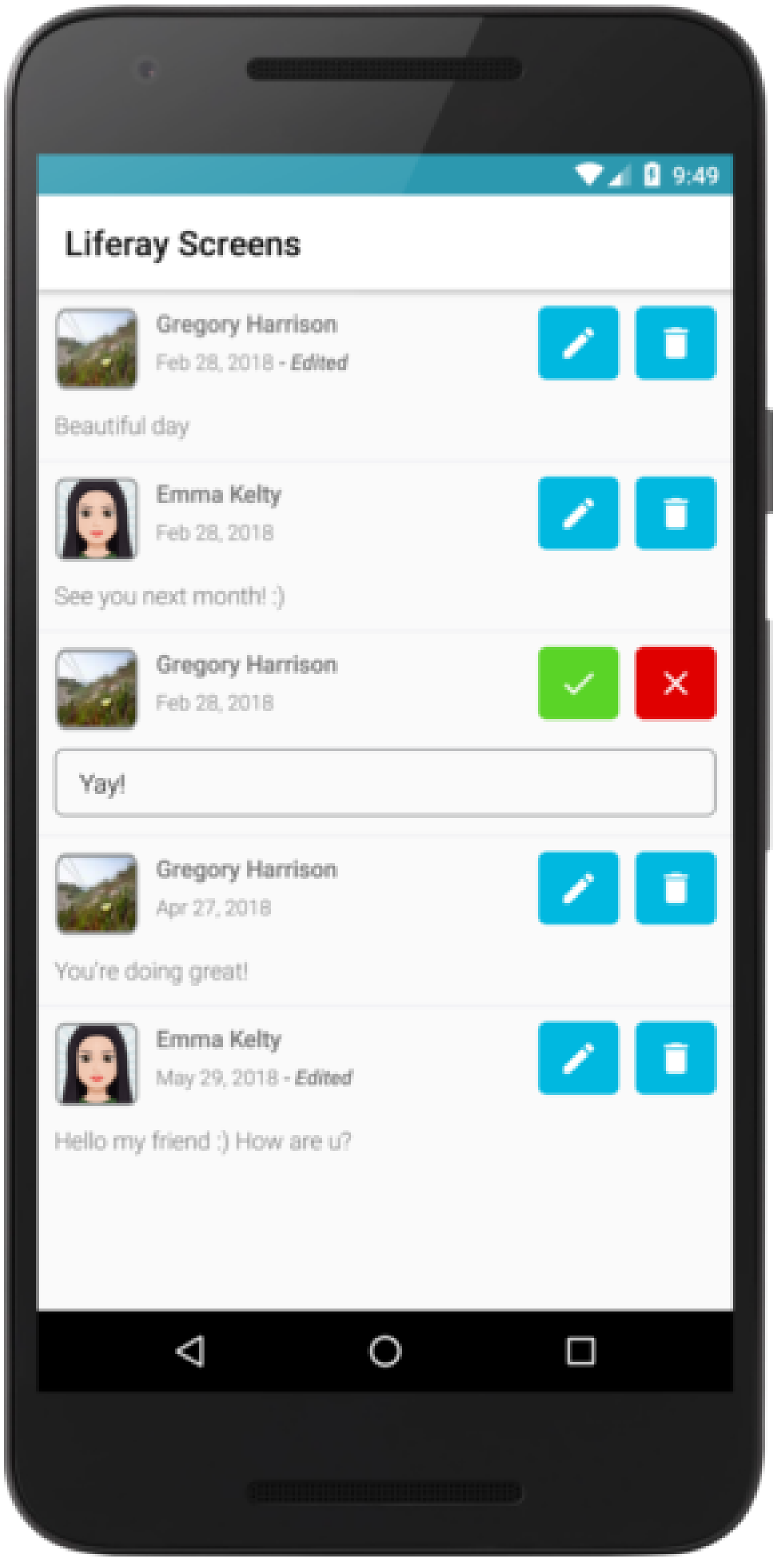

Figure 128.17: Comment List Screenlet using the Default View.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the comments from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the comments, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the comments from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the comments from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the comments from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Whether the list should automatically load when the Screenlet appears in the app's UI. The default value is `true`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `firstPageSize` | `number` | The number of items to retrieve from the server for display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items to retrieve from the server for display on the second and subsequent pages. The default value is `25`. | `labelFields` | `string` | The comma-separated names of the DDL fields to show. Refer to the list's data definition to find the field names. For more information on this, see the article on structured web content. Note that the appearance of data from a structure's fields depends on the `layoutId`. | `editable` | `boolean` | Whether the user can edit the comment. |

Methods

Method | Return | Explanation | `loadPage(pageNumber)` | `void` | Starts the request to load the specified page of records. The page is shown when the response is received. |

Listener

Comment List Screenlet delegates some events to a class that implements `CommentListListener`. This interface lets you implement the following methods:

- `onDeleteCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully deletes the comment.
- `onUpdateCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully updates the comment.
- `onListPageFailed(int startRow, Exception e)`: Called when the server call to retrieve a page of items fails. This method's arguments include the `Exception` generated when the server call fails.
- `onListPageReceived(int startRow, int endRow, List<CommentEntry> entries, int rowCount)`: Called when the server call to retrieve a page of items succeeds. Note that this method may be called more than once; once for each page received. Because `startRow` and `endRow` change for each page, a `startRow` of `0` corresponds to the first item on the first page.
- `onListItemSelected(CommentEntry element, View view)`: Called when an item is selected in the list. This method's arguments include the selected list item (`CommentEntry`).
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.13 Comment Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment Display Screenlet can show one comment of an asset in a Liferay instance. It also lets the user update or delete the comment.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`getComment`	
`ScreenscommentService` (Screens compatibility plugin)	`updateComment`	
`CommentmanagerjsonwsService`	`deleteComment`	

Module

- None

Views

- Default

The Default View uses User Portrait Screenlet, and `TextView` and `ImageButton` elements to show an asset's comment. Other Views may different components to show the comment.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

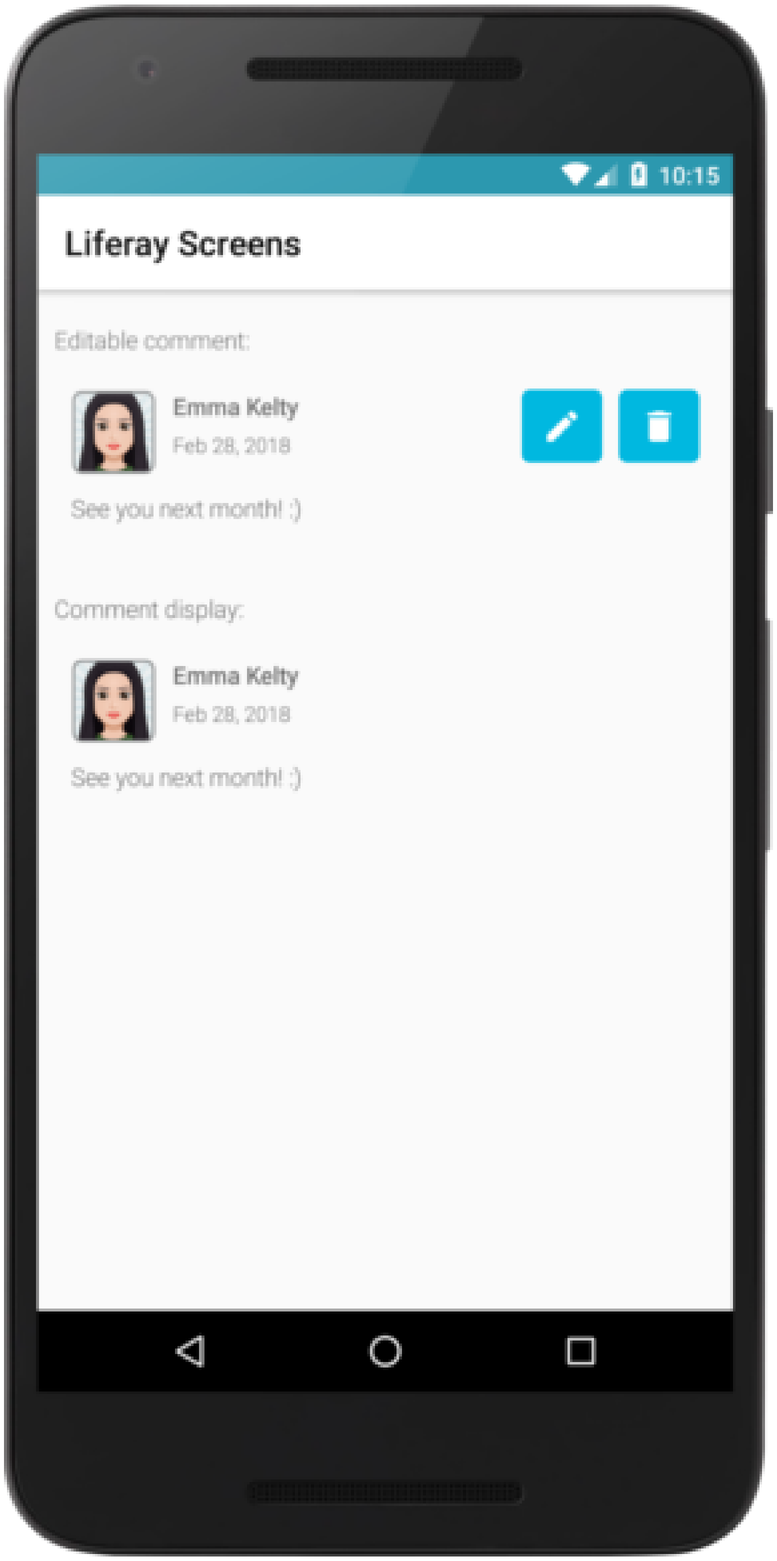

Figure 128.18: Comment Display Screenlet using the Default View.

Required Attributes

- `commentId`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View.| `autoLoad` | `boolean` | Whether the list should automatically load when the Screenlet appears in the app's UI. The default value is `true`. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `commentId` | `number` | The primary key of the comment to display. | `editable` | `boolean` | Whether the user can edit the comment. |

Methods

Method | Return | Explanation | `load()` | `void` | Starts the request to load the comment. |

Listener

Comment Display Screenlet delegates some events to a class that implements `CommentDisplayListener`. This interface lets you implement the following methods:

- `onLoadCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully loads the comment.

- `onDeleteCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully deletes the comment.

- `onUpdateCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully updates the comment.

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.14 Comment Add Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment Add Screenlet can add a comment to an asset in a Liferay instance.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`addComment`	

Module

- None

Views

- Default

The Default View uses Android's `EditText` and `Button` elements to show an add comment dialog. Other Views may use different components to show this dialog.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet sends the data to the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully sends the data, it also stores it in the local cache. | Use this policy when you always need to send updated data, and send nothing when there's no connection. | `CACHE_ONLY` | The Screenlet sends the data to the local cache. If an error occurs, the Screenlet uses the listener to notify the developer. | Use this policy when you always need to store local data without sending remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet sends the data to the Liferay instance. If this succeeds, the Screenlet also stores the data in the local cache. If a connection issue occurs, the Screenlet stores the data to the local cache and sends it to the Liferay instance when the connection is restored. If an error occurs, the Screenlet uses the listener to notify the developer. | Use this policy to send the most recent version of the data when connected, and store the data for later synchronization when there's no connection. | `CACHE_FIRST` | The Screenlet sends

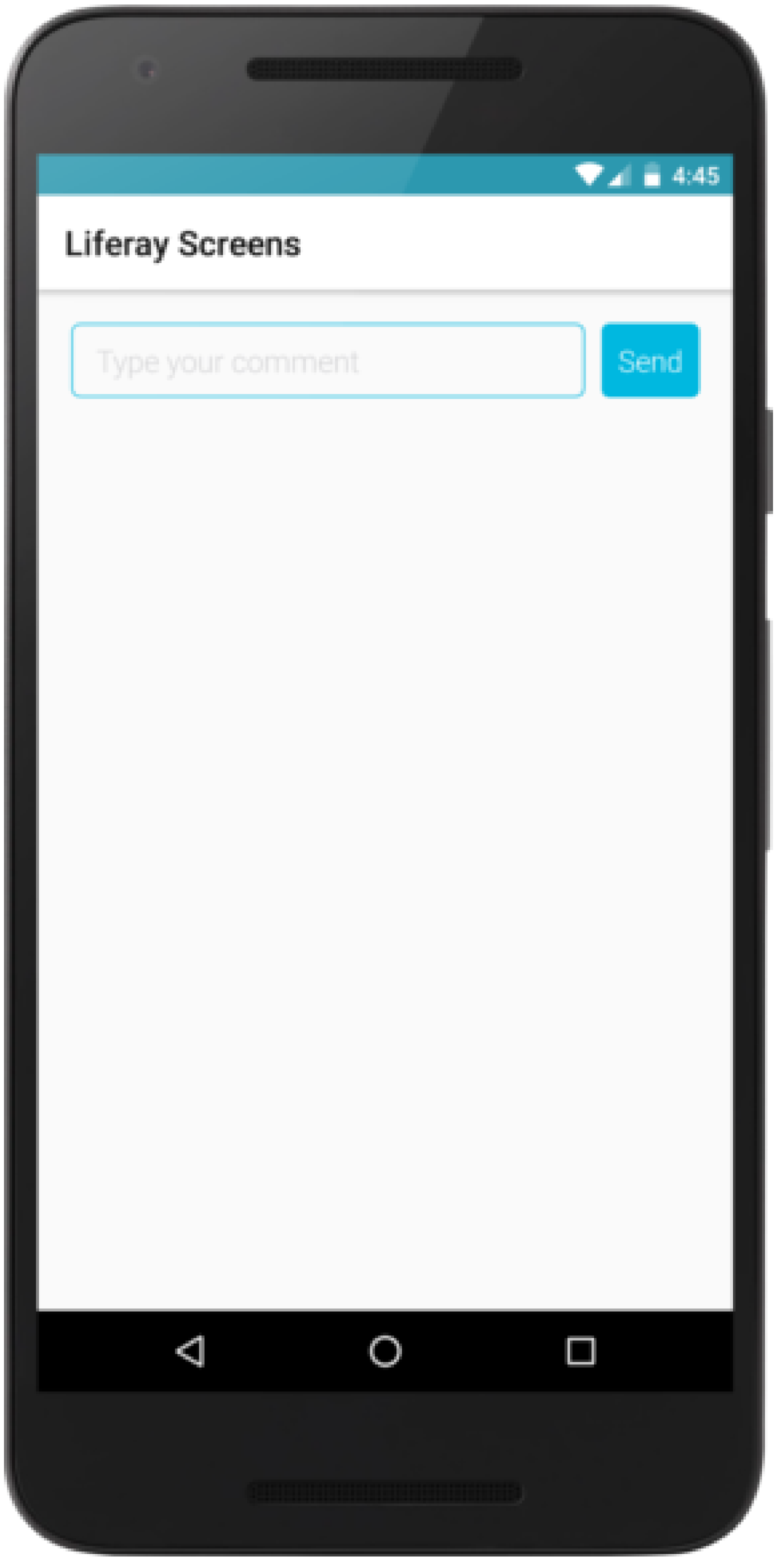

Figure 128.19: Comment Add Screenlet using the Default View.

the data to the local cache, then sends it to the Liferay instance. If sending the data to the Liferay instance fails, the Screenlet still stores the data locally and then notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and store local (but possibly outdated) data. |

Required Attributes

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View.| `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Listener

Comment Add Screenlet delegates some events to a class that implements `CommentAddListener`. This interface lets you implement the following methods:

- `onAddCommentSuccess(CommentEntry commentEntry)`: Called when the Screenlet successfully adds a comment to the asset.

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.15 Asset Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Asset Display Screenlet can display an asset from a Liferay instance. The Screenlet can currently display Documents and Media files (`DLFileEntry` images, videos, audio files, and PDFs), blogs entries (`BlogsEntry`) and web content articles (`WebContent`).

Asset Display Screenlet can also display your custom asset types. See the Listener section of this document for details.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses different UI elements to show each asset type. For example, it displays images with `ImageView` and blogs with `TextView`. Note that other Views may use different UI elements.

This Screenlet can also render other Screenlets as inner Screenlets:

- Images: Image Display Screenlet
- Videos: Video Display Screenlet
- Audio: Audio Display Screenlet
- PDFs: PDF Display Screenlet
- Blog entries: Blogs Entry Display Screenlet
- Web content: Web Content Display Screenlet

These Screenlets can also be used alone without Asset Display Screenlet.

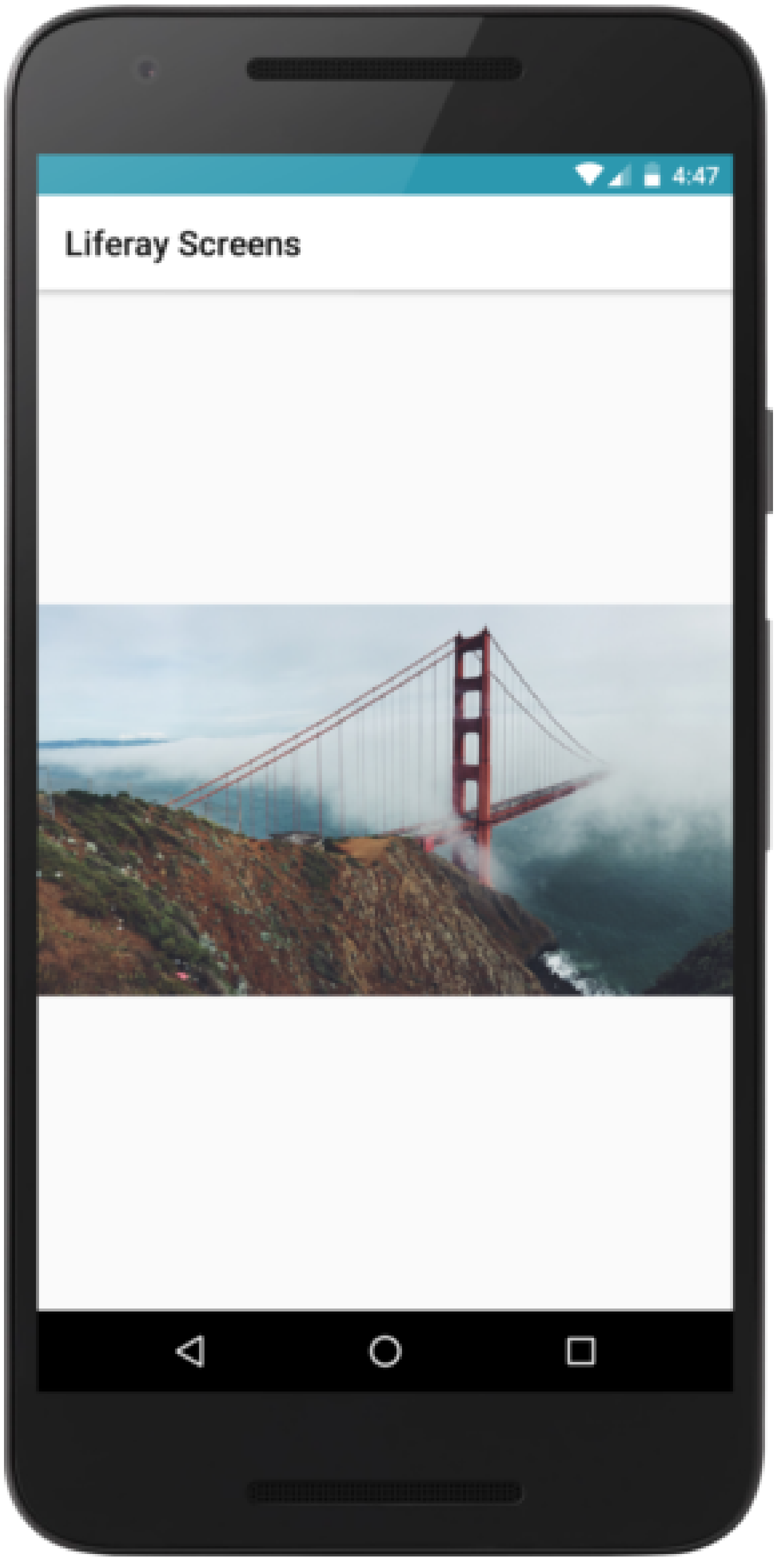

Figure 128.20: Asset Display Screenlet using the Default View.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId`

Instead of `entryId`, you can use both of the following attributes:

- `className`
- `classPK`

If you don't use `entryId`, `className`, or `classPK`, you must use this attribute:

- `portletItemName`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Whether the asset automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `entryId` | `number` | The primary key of the asset. | `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `portletItemName` | `string` | The name of the configuration template you used in the Asset Publisher. To use this feature, add an Asset Publisher to one of your site's pages (it may be a hidden page), configure the Asset Publisher's filter (in *Configuration → Setup → Asset Selection*), and then use the Asset Publisher's *Configuration Templates* option to save this configuration with a name. Use this name in this attribute. If there is more than one asset in the configuration, the Screenlet displays only the first one. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `imageLayoutId` | `@layout` | The layout to use to show an image (`DLFileEntry`). | `videoLayoutId` | `@layout` | The layout to use to show a video (`DLFileEntry`). | `audioLayoutId` | `@layout` | The layout to use to show an audio file (`DLFileEntry`). | `pdfLayoutId` | `@layout` | The layout to use to show a PDF (`DLFileEntry`). | `blogsLayoutId` | `@layout` | The layout to use to show a blog entry (`BlogsEntry`). | `webDisplayLayoutId` | `@layout` | The layout to use to show a web content article (`WebContent`). |

Methods

Method | Return | Explanation | `load(AssetEntry assetEntry)` | `void` | Loads the given `AssetEntry` in the Screenlet. If no inner Screenlet is instantiated, the method tries to load the asset with a custom asset listener method. If this returns `null`, a new `Intent` is called to display the asset. | `loadAsset()` | `void` | Searches for the `AssetEntry` defined by the required attributes and loads it in the Screenlet. |

Listener

Asset Display Screenlet delegates some events to a class that implements `AssetDisplayListener`. This interface contains the following methods:

- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the asset.

A second listener, `AssetDisplayInnerScreenletListener`, also exists for configuring a child Screenlet (the Screenlet rendered inside Asset Display Screenlet) or rendering a custom asset.

- `onConfigureChildScreenlet(AssetDisplayScreenlet screenlet, BaseScreenlet innerScreenlet, AssetEntry assetEntry)`: Called when the child Screenlet has been successfully initialized. Use this method to configure or customize the child Screenlet. The example implementation here sets the child Screenlet's background color to light gray if the asset is a blog entry entity (`BlogsEntry`):

```
@Override
public void onConfigureChildScreenlet(AssetDisplayScreenlet screenlet,
    BaseScreenlet innerScreenlet, AssetEntry assetEntry) {
        if ("blogsEntry".equals(assetEntry.getObjectType())) {
            innerScreenlet.setBackgroundColor(ContextCompat.getColor(this,
            R.color.light_gray));
        }
}
```

- `onRenderCustomAsset(AssetEntry assetEntry)`: Called to render a custom asset. The following example implementation inflates and returns the custom View necessary to render a user from a Liferay instance (`User`):

```
@Override
public View onRenderCustomAsset(AssetEntry assetEntry) {
    if (assetEntry instanceof User) {
        View view = getLayoutInflater().inflate(R.layout.user_display, null);
        User user = (User) assetEntry;

        TextView username = (TextView) view.findViewById(R.id.liferay_username);

        username(user.getUsername());
```

```
            return view;
        }
        return null;
    }
```

128.16 Blogs Entry Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Blogs Entry Display Screenlet displays a single blog entry. Image Display Screenlet renders any header image the blogs entry may have.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses different components to show a blogs entry (`BlogsEntry`). For example, it uses an Android `TextView` to show the blog's text, and User Portrait Screenlet to show the profile picture of the Liferay user who posted it. Note that other custom Views may use different components.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote data under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId`

If you don't use `entryId`, you must use both of the following attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View.| `autoLoad` | `boolean` | Whether the blog entry automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `entryId` | `number` | The primary key of the blog entry (`BlogsEntry`). | `className` | `string` | The `BlogsEntry` object's fully qualified class name. This is `com.liferay.blogs.kernel.model.BlogsEntry`. If you don't use `entryId`, the `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The `BlogsEntry` object's unique identifier. If you don't use `entryId`, the `className` and `classPK`

Designing animations for a multicultural product

The world is big and diverse. Right now there are around 7.6 billion people in the world, 4 billion with an internet access. When you're improving a Design System for a product used worldwide, like Lexicon for Liferay, you should take this simple statement into account. Cultural, religious and regional concerns need to be considered. It may sound obvious, but the true fact is that we sometimes forget about it.

I'm going to explain how we redesigned and tested empty states illustrations for Liferay products.

1. The past

Let's put a bit of context around this story. As you may know, an empty state illustration is shown when there is not any other info to display and capture the user's attention. A friendly face looking around, smiling, or winking was the animation family for empty states in Lexicon 1 by Marcos

Figure 128.21: Blogs Entry Display Screenlet using the Default View.

attributes are required to instantiate the Screenlet. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Listener

Because a blog entry is an asset, Blogs Entry Display Screenlet delegates its events to a class that implements `AssetDisplayListener`. This interface lets you implement the following method:

- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the blog entry.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.17 Image Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Image Display Screenlet displays an image file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses an Android `ImageView` to display the image.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId` or `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Whether the image automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `entryId` | `number` | The primary key of the image. | `classPK` | `number` | The image's unique identifier. |

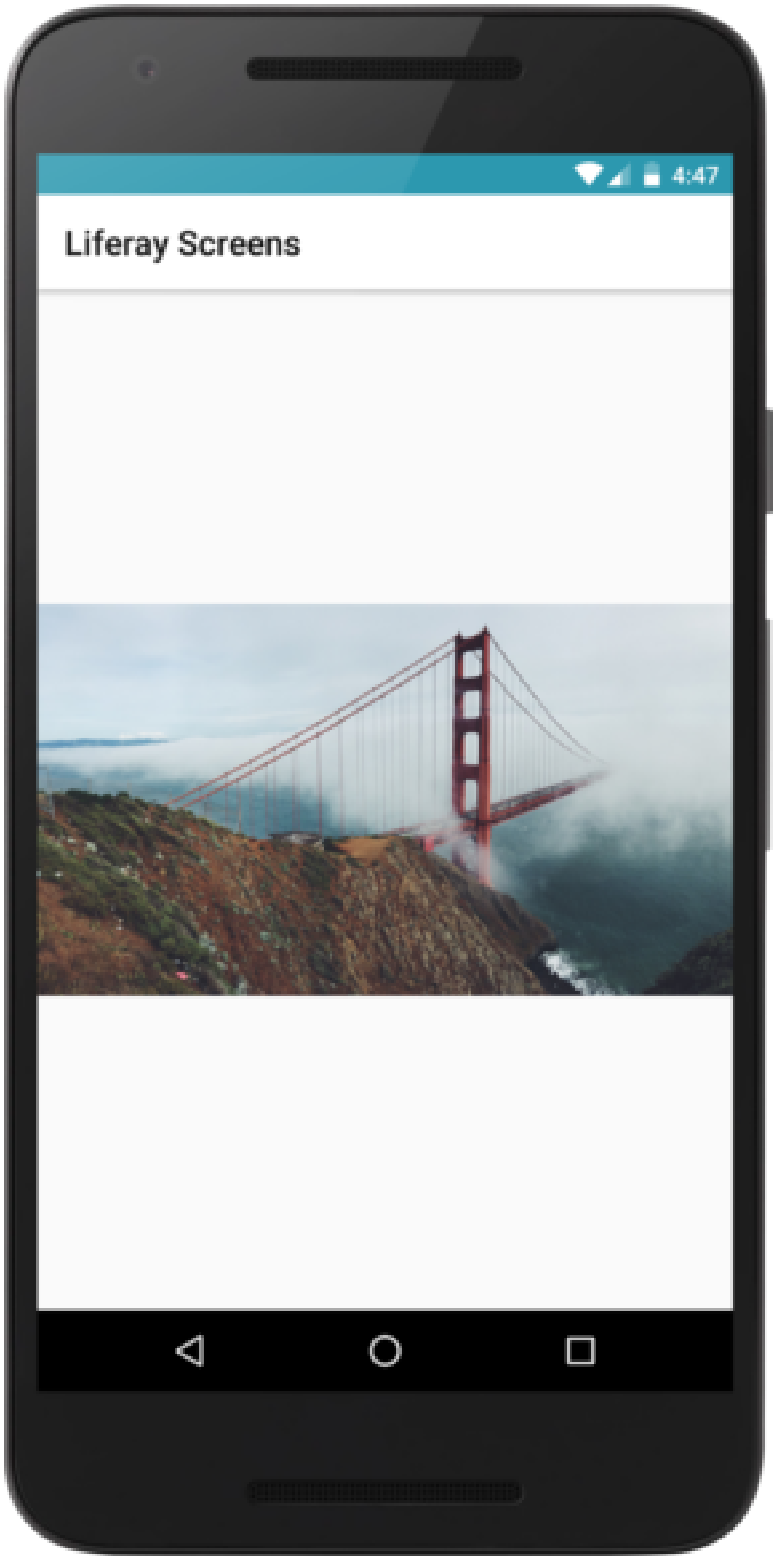

Figure 128.22: Image Display Screenlet using the Default View.

`cachePolicy` | `string` | The offline mode setting. See the Offline section for details. | `imageScaleType` | `number` | Lets you set a scale image type like `CENTER`, `CENTER_CROP`, `CENTER_INSIDE`, `FIT_CENTER`, `FIT_END`, `FIT_START`, `FIT_XY`, `MATRIX`. | `placeHolder` | `@resource` | Image to load until the final image loads. | `placeHolderScaleType` | `number` | Lets you set a scale image type for the placeholder like `CENTER`, `CENTER_CROP`, `CENTER_INSIDE`, `FIT_CENTER`, `FIT_END`, `FIT_START`, `FIT_XY`, `MATRIX`. |

Note that the values for `imageScaleType` and `placeHolderScaleType` match those described in Android's `ImageView.ScaleType`.

Listener

Because images are assets, Image Display Screenlet delegates its events to a class that implements `AssetDisplayListener`. This interface lets you implement the following methods:

- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the image.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.18 Video Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Video Display Screenlet displays a video file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses an Android `VideoView` to display the video.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId` or `classPK`

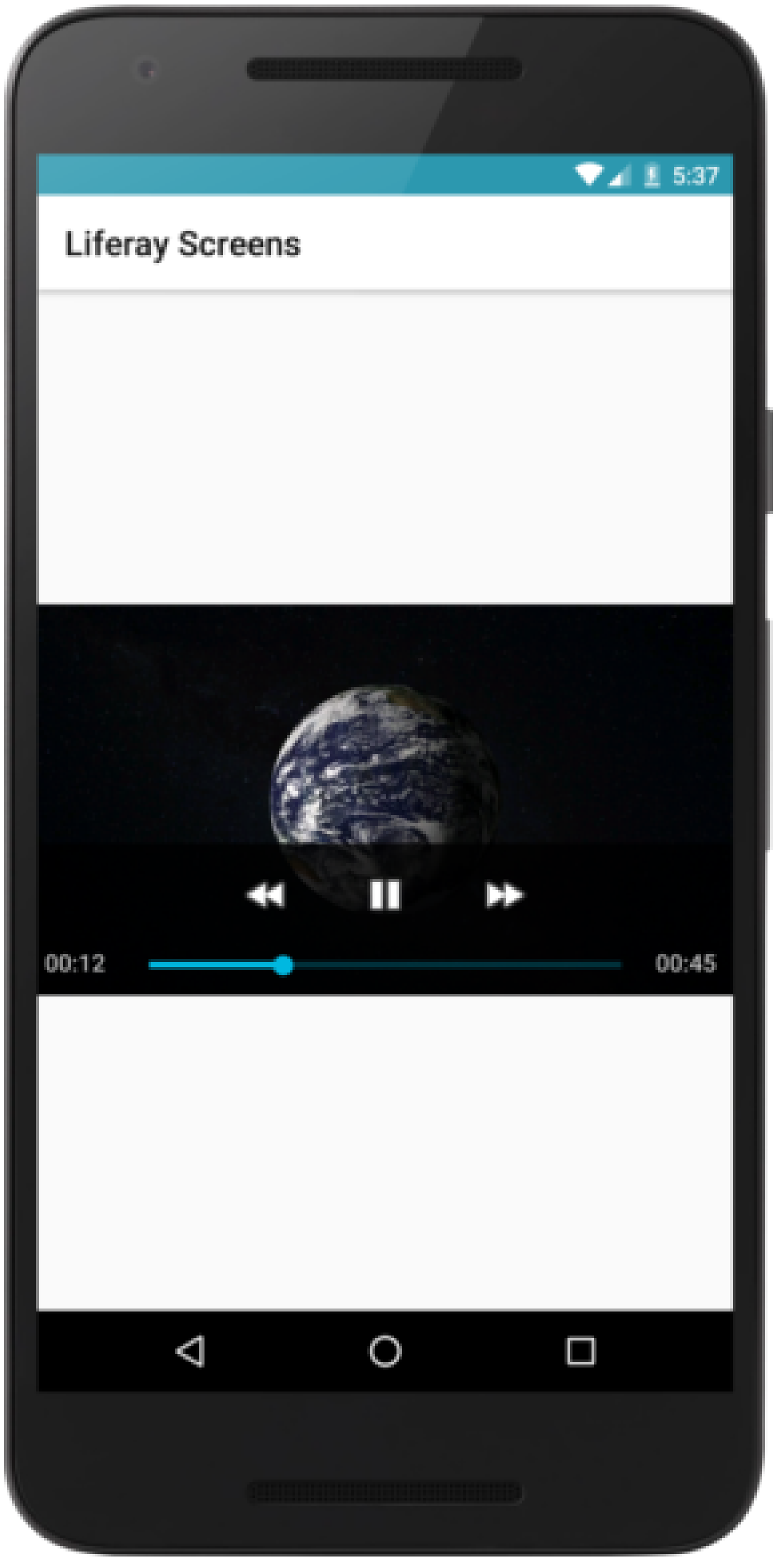

Figure 128.23: Video Display Screenlet using the Default View.

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Whether the video automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `entryId` | `number` | The primary key of the video file. | `classPK` | `number` | The video file's unique identifier. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Listener

Video Display Screenlet delegates its events to a class that implements `VideoDisplayListener`. This interface lets you implement these methods:

- `onVideoPrepared()`: Called when the video is ready for display.
- `onVideoCompleted()`: Called when the video is completed.
- `onVideoError(Exception e)`: Called when an error occurs displaying the video.
- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the video.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.19 Audio Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Audio Display Screenlet displays an audio file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses an Android `VideoView` to display the audio file.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

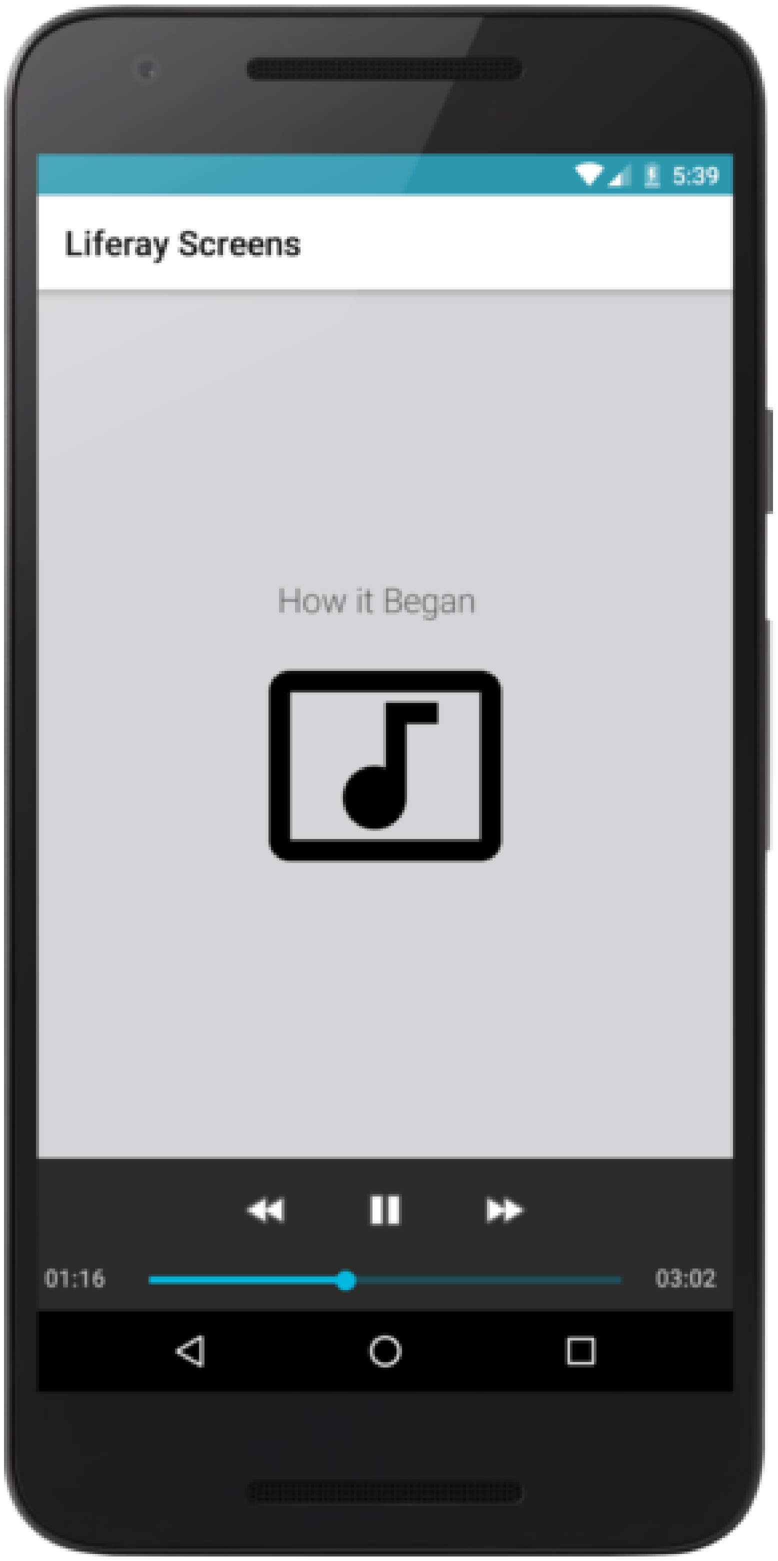

Figure 128.24: Audio Display Screenlet using the Default View.

Required Attributes

- `entryId` or `classPK`

Attributes

Attribute	Data type	Explanation
`layoutId`	`@layout`	The layout to use to show the View.
`autoLoad`	`boolean`	Whether the audio file automatically loads when the Screenlet appears in the app's UI. The default value is `true`.
`entryId`	`number`	The primary key of the audio file.
`classPK`	`number`	The audio file's unique identifier.
`cachePolicy`	`string`	The offline mode setting. See the Offline section for details.

Listener

Because audio files are assets, Audio Display Screenlet delegates its events to a class that implements `AssetDisplayListener`. This interface lets you implement the following methods:

- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the audio file.

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.20 PDF Display Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

PDF Display Screenlet displays a PDF file from a Liferay Instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Views

- Default

The Default View uses Android's `PdfRenderer` to display the PDF. Note that `PdfRenderer` requires an Android API level of 21 or higher.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `REMOTE_ONLY` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `CACHE_ONLY` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `REMOTE_FIRST` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `CACHE_FIRST` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity

errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `entryId` or `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The layout to use to show the View. | `autoLoad` | `boolean` | Whether the PDF automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `entryId` | `number` | The primary key of the PDF file. | `classPK` | `number` | The PDF file's unique identifier. | `cachePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Listener

Because PDF files are assets, PDF Display Screenlet delegates its events to a class that implements `AssetDisplayListener`. This interface lets you implement the following methods:

- `onRetrieveAssetSuccess(AssetEntry assetEntry)`: Called when the Screenlet successfully loads the PDF file.

- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.21 Web Screenlet for Android

Requirements

- Android SDK 4.1 (API Level 16) or above
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- Android SDK 4.1 (API Level 16) or above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Web Screenlet lets you display any web page. It also lets you customize the web page through injection of local and remote JavaScript and CSS files. If you're using Liferay DXP as backend, you can use Application Display Templates in your page to customize its content from the server side.

Module

- None

Views

- Default

Configuration

To learn how to use Web Screenlet, follow the steps in the tutorial Rendering Web Pages in Your Android App. That tutorial gives detailed instructions for using the configuration items described here.

Web Screenlet has `WebScreenletConfiguration` and `WebScreenletConfiguration.Builder` classes that you can use together to supply the parameters that the Screenlet needs to work. `WebScreenletConfiguration.Builder` has the following methods, which let you supply the described configuration parameters:

Method	Return	Explanation
`addLocalJs(fileName)`	`WebScreenletConfiguration.Builder`	Adds a local JavaScript file with the supplied filename. The JavaScript files must be in the first level of your app's `assets` folder. Create this folder at the same level of the `res` folder.
`addLocalCss(fileName)`	`WebScreenletConfiguration.Builder`	Adds a local CSS file with the supplied filename. The CSS files must be in the first level of your app's `assets` folder. Create this folder at the same level of the `res` folder.
`addRawJs(rawJs, name)`	`WebScreenletConfiguration.Builder`	Adds a JavaScript file from your app's `res/raw` folder. Create this folder if it doesn't exist. Reference the file using `R.raw.yourfilename`. This method also takes a second parameter called `name`, which is only for debugging purposes. If there's an error, the console displays it with this `name` value.
`addRawCss(rawCss, name)`	`WebScreenletConfiguration.Builder`	Adds a CSS file from your app's `res/raw` folder. Create this folder if it doesn't exist. Reference the file using `R.raw.yourfilename`. This method also takes a second parameter called `name`, which is only for debugging purposes. If there's an error, the console displays it with this `name` value.
`addRemoteJs(url)`	`WebScreenletConfiguration.Builder`	Adds a JavaScript file from the supplied URL.
`addRemoteCss(url)`	`WebScreenletConfiguration.Builder`	Adds a CSS file from the supplied URL.
`setWebType(webType)`	`WebScreenletConfiguration.Builder`	Sets the `WebType`.
`enableCordova(observer)`	`WebScreenletConfiguration.Builder`	Enables Cordova inside the Web Screenlet.
`load()`	`WebScreenletConfiguration`	Returns the `WebScreenletConfiguration` object that you can set to the Screenlet instance.

Note: If you want to add comments in the scripts, use the `/**/` notation.

WebType

- **WebType.LIFERAY_AUTHENTICATED** (default): Displays a Liferay DXP page that requires authentication. The user must therefore be logged in with Screens via Login Screenlet or a `SessionContext` method. For this `WebType`, the URL you must pass to the `WebScreenletConfiguration.Builder` constructor is a relative URL. For example, if the full URL is `http://screens.liferay.org.es/web/guest/blog`, then the URL you must supply to the constructor is `/web/guest/blog`.

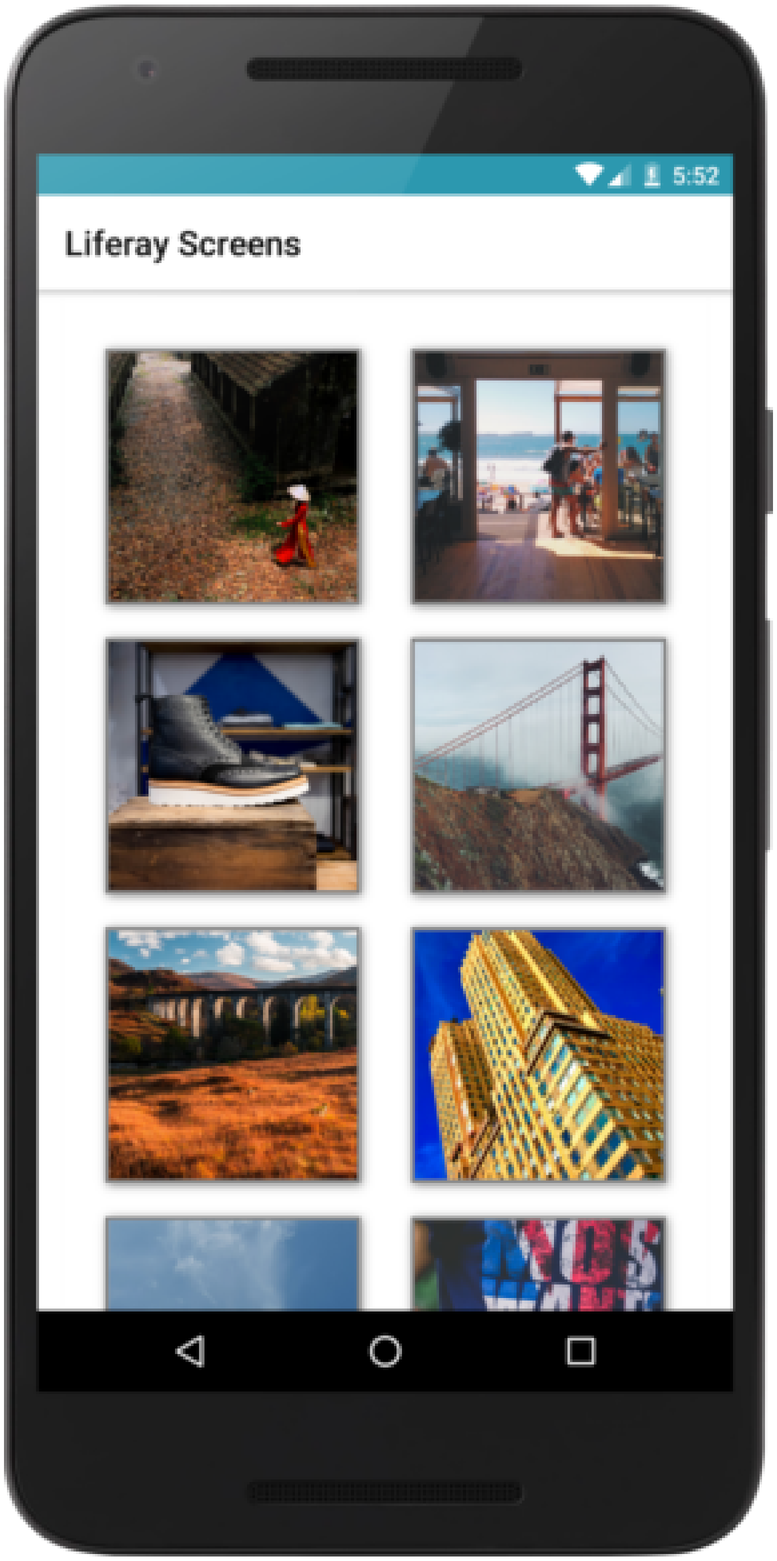

Figure 128.26: The Web Screenlet with the Default View Set.

- **WebType.OTHER**: Displays any other page. For this `WebType`, the URL you must pass to the `WebScreenletConfiguration.Builder` constructor is a full URL. For example, if the full URL is `http://screens.liferay.org.es/web/guest/blog`, then you must supply that URL to the constructor.

Attributes

Attribute | Data type | Explanation | `autoLoad` | `boolean` | Whether to load the page automatically when the Screenlet appears in the app's UI. The default value is true. | `layoutId` | `@layout` | The layout to use to show the View. | `isLoggingEnabled` | `boolean` | Whether logging is enabled. | `isScrollEnabled` | `boolean` | Whether to enable scrolling on the page inside the Screenlet. |

Methods

Method | Return | Explanation | `load()` | `void` | Checks if the page's URL is valid, and then loads it. The operation fails if the URL is invalid. | `clearCache()` | `void` | Clears the Web Screenlet's cache. | `injectScript(script)` | `void` | Injects a script when the page is already loaded. |

Listener

Web Screenlet delegates some events to an object or class that implements its `WebListener` interface. This interface extends the `BaseCacheListener` interface. Therefore, Web Screenlet's listener methods are as follows:

- `onPageLoaded(String url)`: Called when the Screenlet loads the page correctly.
- `onScriptMessageHandler(String namespace, String body)`: Called when the `WebView` in the Screenlet sends a message. The `namespace` parameter is the source namespace key, and `body` is the source namespace body.
- `error(Exception e, String userAction)`: Called when an error occurs in the process. The `userAction` argument distinguishes the specific action in which the error occurred.

128.22 Android Breaking Changes

This document presents a list of changes in Liferay Screens for Android 2.0 that break preceding functionality. We try our best to minimize these disruptions, but sometimes they are unavoidable.

Breaking Changes List

Interactors Now Run in a Background Process

What changed? Interactors now run in a background process, so you don't need to create or set callback classes manually. This means you can write what appear to be synchronous server calls, and Liferay Screens handles the background threading for you. The Interactor's `execute` method makes the server call. Invoking the `start` method in your Screenlet class causes `execute` to run in a background thread.

Note that you no longer have to handle the exception when making the server call. The Screenlet framework does this for you and propagates any error via the listeners. Also note that the `screenletId` is no longer required. The Screenlet framework automatically decorates the event with a `screenletId` that it generates.

Who is affected? This affects all Screenlet Interactors.

How should I update my code? You must rewrite your Interactors. See the tutorial Creating Android Screenlets for the most recent instructions on creating an Interactor.

Why was this change made? Asynchronous calls can be difficult to develop and work with. By handling them for you, Liferay Screens removes this potential source of error and frees you to focus on other parts of your Screenlet.

Changes to View Set Inheritance

What changed? To use a View Set, your app or activity's theme must also inherit that View Set's styles. For example, to use the Default View Set, your app or activity's theme must inherit `default_theme`.

Who is affected? This affects any apps or activities that use a View Set without inheriting that View Set's styles. For example, if you use the Default View for a Screenlet by setting the Screenlet XML's `layoutId` attribute, your app or activity's theme must now inherit `default_theme` as well. Likewise, your app or activity's theme must inherit `westeros_theme` or `material_theme` to use the Westeros or Material View Set, respectively.

How should I update my code? Change your app or activity's theme to inherit the styles of the View Set you want to use.

Example

This code snippet from an app's `res/values/styles.xml` tells `AppTheme.NoActionBar` to inherit the Default View Set's styles:

```
<resources>

    <style name="AppTheme.NoActionBar" parent="default_theme">
        <item name="colorPrimary">@color/colorPrimary</item>
        <item name="colorPrimaryDark">@color/colorPrimaryDark</item>
        <item name="colorAccent">@color/colorAccent</item>

        <item name="windowActionBar">false</item>
        <item name="windowNoTitle">true</item>
    </style>
    ...
</resources>
```

Why was this change made? This lets you change an Android theme's colors and styles according to Android conventions. Before, the Android themes were hardcoded inside the Screenlets.

The Screenlet Attribute offlinePolicy is now cachePolicy

What changed? The Screenlet attribute `offlinePolicy` is now `cachePolicy`.

Who is affected? This affects any Screenlets that used the `offlinePolicy` attribute to set that Screenlet's offline mode policy.

How should I update my code? In the app layouts that contain the Screenlet, change the `offlinePolicy` attribute to `cachePolicy`.

Example

Old way:

```
<com.liferay.mobile.screens.assetlist.AssetListScreenlet
    android:id="@+id/asset_list_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    liferay:autoLoad="false"
    liferay:offlinePolicy="REMOTE_FIRST" />
```

New way:

```
<com.liferay.mobile.screens.asset.list.AssetListScreenlet
    android:id="@+id/asset_list_screenlet"
    android:layout_width="match_parent"
    android:layout_height="match_parent"
    liferay:autoLoad="false"
    liferay:cachePolicy="REMOTE_FIRST"
    />
```

Why was this change made? This change was made for consistency throughout Liferay Screens. The method and class names in the offline mode APIs contain *cache*, as do the offline policies `CACHE_ONLY` and `CACHE_FIRST`.

Some Listener Methods in DDL Form Screenlet Have Changed

What changed? The following error listener methods in DDL Form Screenlet's `DDLFormListener` have been removed:

- `void onDDLFormLoadFailed(Exception e)`: Called when an error occurs in the load form definition request.
- `void onDDLFormRecordLoadFailed(Exception e)`: Called when an error occurs in the load form record request.
- `void onDDLFormRecordAddFailed(Exception e)`: Called when an error occurs in the request to add a new record.
- `void onDDLFormUpdateRecordFailed(Exception e)`: Called when an error occurs in the request to update an existing record.

Also in `DDLFormListener`, the method `onDDLFormRecordLoaded` now takes an additional parameter for the attribute map received from the server.

Who is affected? This affects any classes that implement `DDLFormListener`.

How should I update my code? In place of the removed error listeners, use `BaseCacheListener`'s generic error listener:

```
void error(Exception e, String userAction)
```

You must also change any `onDDLFormRecordLoaded` implementations to account for the method's new signature:

```
public void onDDLFormRecordLoaded(Record record, Map<String, Object> valuesAndAttributes)
```

Why was this change made? The old error listener methods were usually implemented the same way: by logging the exception. Multiple error listener methods aren't needed for this. You can use the new error listener method to log the exception and take any other action that depends on the user action.

Cache Listener Methods Moved into Their Own Listener

What changed? The cache listener methods `loadingFromCache`, `retrievingOnline`, and `storingToCache` have been moved to their own listener, `CacheListener`. Note, this change was introduced in Liferay Screens 1.4.0.

Who is affected? All activity classes that implement a listener.

How should I update my code? If you don't have special behavior in your old cache listener method implementations, you can remove them. Otherwise, you must implement the new `CacheListener`. When implementing `CacheListener` (in an activity or fragment, for example), you should also register a Screenlet instance as the cache listener:

```
    screenlet.setCacheListener(this);
```

Example
In the Liferay Screens test app, the activity `UserPortraitActivity` implements `CacheListener`:

```
public class UserPortraitActivity extends ThemeActivity implements UserPortraitListener,
    CacheListener {

    private UserPortraitScreenlet screenlet;

    @Override
    protected void onCreate(Bundle savedInstanceState) {
            super.onCreate(savedInstanceState);

            setContentView(R.layout.user_portrait);

            screenlet = (UserPortraitScreenlet) findViewById(R.id.user_portrait_screenlet);
            screenlet.setListener(this);
            screenlet.setCacheListener(this);
    }

    …

    @Override
    public void loadingFromCache(boolean success) {
        View content = findViewById(android.R.id.content);
        Snackbar.make(content, "Trying to load from cache: " + success,
            Snackbar.LENGTH_SHORT).show();
    }

    @Override
    public void retrievingOnline(boolean triedInCache, Exception e) {

    }

    @Override
    public void storingToCache(Object object) {
        View content = findViewById(android.R.id.content);
        Snackbar.make(content, "Storing to cache...", Snackbar.LENGTH_SHORT).show();
    }

    …

}
```

Why was this change made? Reacting to cache errors via the cache listener methods is a niche use case. Because the old cache listener methods were part of the normal listener, developers were forced to implement them whether they needed them or not. Putting them in their own listener makes their implementation optional.

Changed BaseListListener Methods

What changed? The `BaseListListener` methods `onListPageFailed` and `onListPageReceived` no longer have the `BaseListScreenlet` argument `source`. These methods also now account for a page's start and end row instead of the page number.

Who is affected? This affects any classes or interfaces that extend or implement `BaseListListener`.

How should I update my code? Remove the `BaseListScreenlet` argument from your `onListPageFailed` and `onListPageReceived` implementations. You must also replace the `int page` argument in `onListPageFailed` with an `int` argument representing the page's start row. Likewise, replace the `int page` argument in `onListPageReceived` with two `int` arguments that represent the page's start row and end row, respectively.

Example

Old signatures:

```
void onListPageFailed(BaseListScreenlet source, int page, Exception e)
void onListPageReceived(BaseListScreenlet source, int page, List<E> entries, int rowCount)
```

New signatures:

```
void onListPageFailed(int startRow, Exception e)
void onListPageReceived(int startRow, int endRow, List<E> entries, int rowCount)
```

Why was this change made? The `BaseListScreenlet` argument served to disambiguate two instances of the same Screenlet in a single activity. This is a very rare use case. Therefore, forcing the argument on all `BaseListListener` implementations was unnecessary. If you still need this use case, create a Screenlet instance and listener for each Screenlet instead of relying on the `BaseListScreenlet` argument in a single listener. The start row and end row change was made for consistency with other listeners that also use start row and end row arguments.

Changed Asset List Screenlet Package

What changed? Asset List Screenlet's package is now `com.liferay.mobile.screens.asset.list` instead of `com.liferay.mobile.screens.assetlist`.

Who is affected? This affects any activities or fragments that use Asset List Screenlet.

How should I update my code? Change your `com.liferay.mobile.screens.assetlist` imports to `com.liferay.mobile.screens.asset.list`.

Why was this change made? This allows for other Screenlets that work with assets, like Asset Display Screenlet. For example, the package `com.liferay.mobile.screens.asset` now contains Asset List Screenlet, Asset Display Screenlet, and classes common to both.

Changed Return Type for a DDL Record Method

What changed? The `getModelValues()` method for DDL records now returns a `Map` instead of a `HashMap`.

Who is affected? This affects any code that expects `getModelValues()` to return a `HashMap`.

How should I update my code? Change any code that uses `getModelValues()` to expect a `Map` instead of a `HashMap`.

Why was this change made? This follows general Java conventions.

Changed Code Conventions for Private and Protected Fields

What changed? Private and protected fields in Screenlets are no longer prefixed by `_`.

Who is affected? This affects any code that directly accesses protected fields.

How should I update my code? Change your code to use the new variable name. For example, if your code directly accesses a protected Screenlet variable named `_fields`, change it to use `fields` instead.

Why was this change made? This follows general Java naming conventions.

Changes to Using a Screenlet without a View

What changed? If you're using a Screenlet without View (like you might be if you need to log a user in programmatically), you no longer have to call `LiferayScreensContext.init(this)` to initialise the library. This is now called automatically.

Who is affected? This affects any apps that use a Screenlet without a View.

How should I update my code? Remove your manual call to `LiferayScreensContext.init(this)`.

Why was this change made? This removes the possibility of an error if you forget to call `LiferayScreensContext.init(this)` when using a Screenlet without a View.

Chapter 129

Screenlets in Liferay Screens for iOS

Liferay Screens for iOS contains several Screenlets that you can use in your iOS apps. This section contains the reference documentation for each. If you're looking for instructions on using Screens, see the Screens tutorials. The Screens tutorials contain instructions on using Screenlets and using Themes in Screenlets. Each Screenlet reference document here lists the Screenlet's features, compatibility, its module (if any), available Themes, attributes, delegate methods, and more. The available Screenlets are listed here with links to their reference documents:

- **Login Screenlet:** Signs users in to a Liferay DXP instance.
- **Sign Up Screenlet:** Registers new users in a Liferay DXP instance.
- **Forgot Password Screenlet:** Sends emails containing a new password or password reset link to users.
- **User Portrait Screenlet:** Shows the user's portrait picture.
- **DDL Form Screenlet:** Presents dynamic forms to be filled out by users and submitted back to the server.
- **DDL List Screenlet:** Shows a list of records based on a pre-existing DDL in a Liferay DXP instance.
- **Asset List Screenlet:** Shows a list of assets managed by Liferay DXP's Asset Framework. This includes web content, blog entries, documents, and more.
- **Web Content Display Screenlet:** Shows the web content's HTML or structured content. This Screenlet uses the features available in Web Content Management.
- **Web Content List Screenlet:** Shows a list of web contents from a folder, usually based on a pre-existing `DDMStructure`.
- **Image Gallery Screenlet:** Shows a list of images from a folder. This Screenlet also lets users upload and delete images.
- **Rating Screenlet:** Shows the rating for an asset. This Screenlet also lets the user update or delete the rating.
- **Comment List Screenlet:** Shows a list of comments for an asset.

- **Comment Display Screenlet:** Shows a single comment for an asset.
- **Comment Add Screenlet:** Lets the user comment on an asset.
- **Asset Display Screenlet:** Displays an asset. Currently, this Screenlet can display Documents and Media Library files (`DLFileEntry` entities), blog articles (`BlogsEntry` entities), and web content articles (`WebContent` entities). You can also use it to display custom assets.
- **Blogs Entry Display Screenlet:** Shows a single blogs entry.
- **Image Display Screenlet:** Shows a single image file from a Liferay DXP instance's Documents and Media Library.
- **Video Display Screenlet:** Shows a single video file from a Liferay DXP instance's Documents and Media Library.
- **Audio Display Screenlet:** Shows a single audio file from a Liferay DXP instance's Documents and Media Library.
- **PDF Display Screenlet:** Shows a single PDF file from a Liferay DXP instance's Documents and Media Library.
- **File Display Screenlet:** Shows a single file from a Liferay DXP instance's Documents and Media Library. Use this Screenlet to display file types not covered by the other display Screenlets (e.g., DOC, PPT, XLS).
- **Web Screenlet:** Displays any web page. You can also customize the web page through injection of local and remote JavaScript and CSS files.

129.1 Login Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Login Screenlet authenticates portal users in your iOS app. The following authentication methods are supported:

- **Basic:** uses user login and password according to HTTP Basic Access Authentication specification. Depending on the authentication method used by your Liferay instance, you need to provide the user's email address, screen name, or user ID. You also need to provide the user's password.
- **OAuth:** implements the OAuth 1.0a specification.
- **Cookie:** uses a cookie to log in. This lets you access documents and images in the portal's document library without the guest view permission in the portal. The other authentication types require this permission to access such files.

Note: Cookie authentication with Login Screenlet is broken in fix packs 14 through 18 of Liferay Digital Enterprise 7.0. This issue is fixed in newer fix packs for Liferay Digital Enterprise 7.0.

For instructions on configuring the Screenlet to use these authentication types, see the below Portal Configuration and Screenlet Attributes sections.

When a user successfully authenticates, their attributes are retrieved for use in the app. You can use the `SessionContext` class to get the current user's attributes.

Note that user credentials and attributes can be stored securely in the keychain (see the `saveCredentials` attribute). Stored user credentials can be used to automatically log the user in to subsequent sessions. To do this, you can use the method `SessionContext.loadStoredCredentials()` method.

JSON Services Used

Screenlets in Liferay Screens call the portal's JSON web services. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`getUserByEmailAddress`	Basic login
`UserService`	`getUserByScreenName`	Basic login
`UserService`	`getUserById`	Basic login
`UserService`	`getCurrentUser`	Cookie and OAuth login

Module

- Auth

Themes

- Default (`default`)
- Flat7 (`flat7`)

For instructions on using Themes, click here.

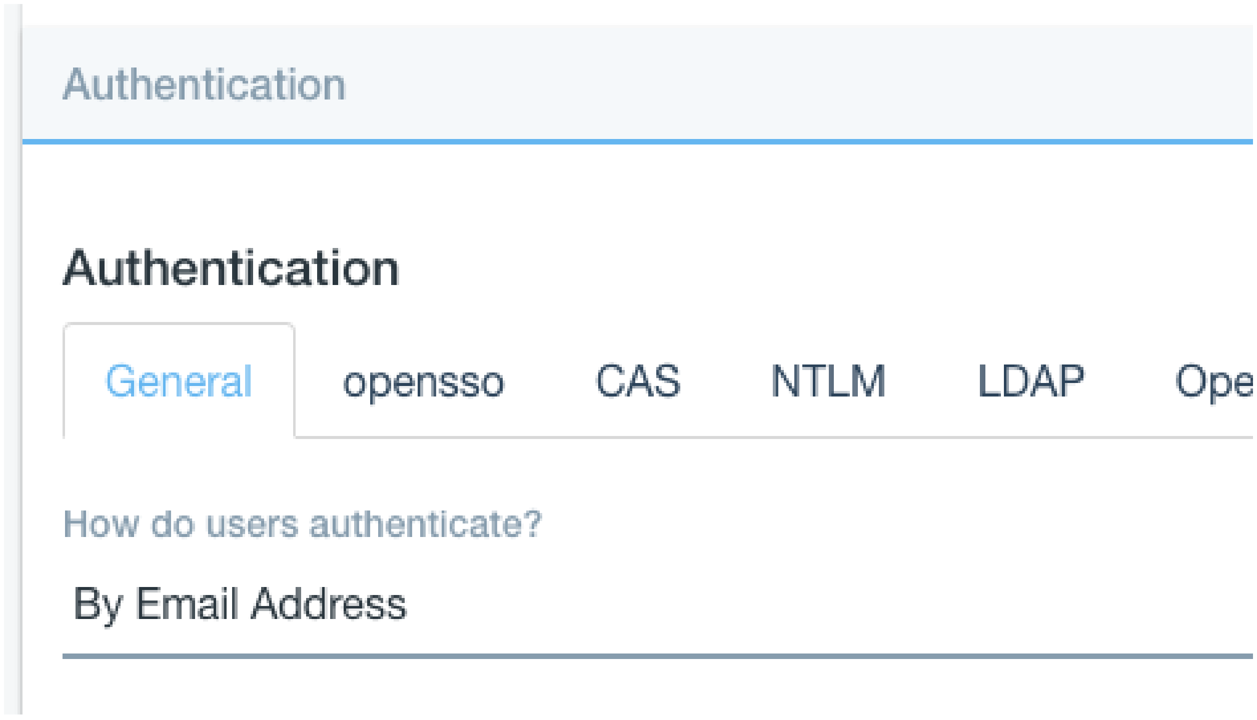
Login

Figure 129.1: The Login Screenlet using the Default and Flat7 Themes.

Portal Configuration

Basic Authentication

Before using Login Screenlet, you should make sure your portal is configured with the authentication option you want to use. You can choose email address, screen name, or user ID. You can set this in the Control Panel by selecting *Configuration* → *Instance Settings*, and then selecting the *Authentication* section. The authentication options are in the *How do users authenticate?* selector menu.



How do users authenticate?
By Email Address

Figure 129.2: Setting the authentication method in your Liferay instance.

For more details, please refer to the Setting up a Liferay Instance section of the User Guide.

OAuth

Note: OAuth authentication is only available in Liferay DXP instances.

To use OAuth authentication, first install the OAuth provider app from the Liferay Marketplace. Click here to get this app. Once it's installed, go to *Control Panel* → *Users* → *OAuth Admin*, and add a new application to be used from Liferay Screens. Once the application exists, copy the *Consumer Key* and *Consumer Secret* values for later use in Login Screenlet.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity. If you need to log in users automatically, even when there's no network connection, you can use the `saveCredentials` attribute together with the `SessionContext.loadStoredCredentials()` method.

Attributes

Attribute | Data type | Explanation | `companyId` | `number` | The ID of the portal instance to authenticate to. If you don't set this attribute or set it to `0`, the Screenlet uses the `companyId` setting in `LiferayServerContext`. | `loginMode` | `string` | The Screenlet's authentication type. You can set this attribute to `basic`, `oauth`, or `cookie`. If you don't set this attribute, the Screenlet defaults to basic authentication. | `basicAuthMethod` | `string` | Specifies the basic authentication option to use. You can set this attribute to `email`, `screenName` or `userId`. This must match the server's authentication option. If you don't set this attribute, and don't set the `loginMode` attribute to `oauth` or `cookie`, the Screenlet defaults to basic authentication with the `email` option. | `OAuthConsumerKey` | `string` | Specifies the *Consumer Key* to use in OAuth authentication. | `OAuthConsumerSecret` | `string` | Specifies the *Consumer Secret* to use in OAuth authentication. | `saveCredentials` | `boolean` | When set, the user credentials and attributes are stored securely in the keychain. This information can then be loaded in subsequent sessions by calling the `SessionContext.loadStoredCredentials()` method. | `shouldHandleCookieExpiration` | `bool` | Whether to refresh the cookie automatically when using cookie login. When set to `true` (the default value), the cookie refreshes as it's about to expire. | `cookieExpirationTime` | `int` | How long the cookie lasts, in seconds. This value depends on your portal instance's configuration. The default value is `900`. |

Delegate

The Login Screenlet delegates some events to an object that conforms to the `LoginScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onLoginResponseUserAttributes:`: Called when login successfully completes. The user attributes are passed as a dictionary of keys (`String` or `NSStrings`) and values (`AnyObject` or `NSObject`). The supported keys are the same as the portal's User entity.

- `- screenlet:onLoginError:`: Called when an error occurs during login. The `NSError` object describes the error.

- `- screenlet:onCredentialsSavedUserAttributes:`: Called when the user credentials are stored after a successful login.

- `- screenlet:onCredentialsLoadedUserAttributes:`: Called when the user credentials are retrieved. Note that this only occurs when the Screenlet is used and stored credentials are available.

Challenge-Response Authentication

To support challenge-response authentication when using a cookie to log in to the portal, the `SessionContext` class has a `challengeResolver` attribute. For more information about how iOS handles challenge-response authentication, see the article Authentication Challenges and TLS Chain Validation.

The challenge resolver type is a closure or block that receives two parameters:

1. `URLAuthenticationChallenge`
2. Another closure or block. You must call this to resolve the challenge (e.g., by passing credentials, canceling the challenge, etc.). You can do this by passing a `URLSession.AuthChallengeDisposition`.

Here's an example that sends a basic authorization in response to an authentication challenge:

```
SessionContext.challengeResolver = resolver

func resolver(challenge: URLAuthenticationChallenge,
    decisionCallback: (URLSession.AuthChallengeDisposition, URLCredential) -> Void) {

    // Use the challenge variable to get information about the challenge itself
    if challenge.previousFailureCount == 0 {
        // To solve the challenge, call the decision callback with your decision
        // Pass the credentials to the server
        decisionCallback(.useCredential, URLCredential(user: "user", password: "password",
            persistence: .forSession))
    }
    else {
        // Something went wrong, so let the system handle the challenge
        decisionCallback(.performDefaultHandling, URLCredential(user: "these credentials",
            password: "are ignored", persistence: .none))
    }

}
```

129.2 Sign Up Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Sign Up Screenlet creates a new user in your Liferay instance: a new user of your app can become a new user in your portal. You can also use this Screenlet to save the credentials of the new user in their keychain. This enables auto login for future sessions. The Screenlet also supports navigation of form fields from the keyboard of the user's device.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`addUser`	

Module

- Auth

Themes

- Default (`default`)
- Flat7 (`flat7`)

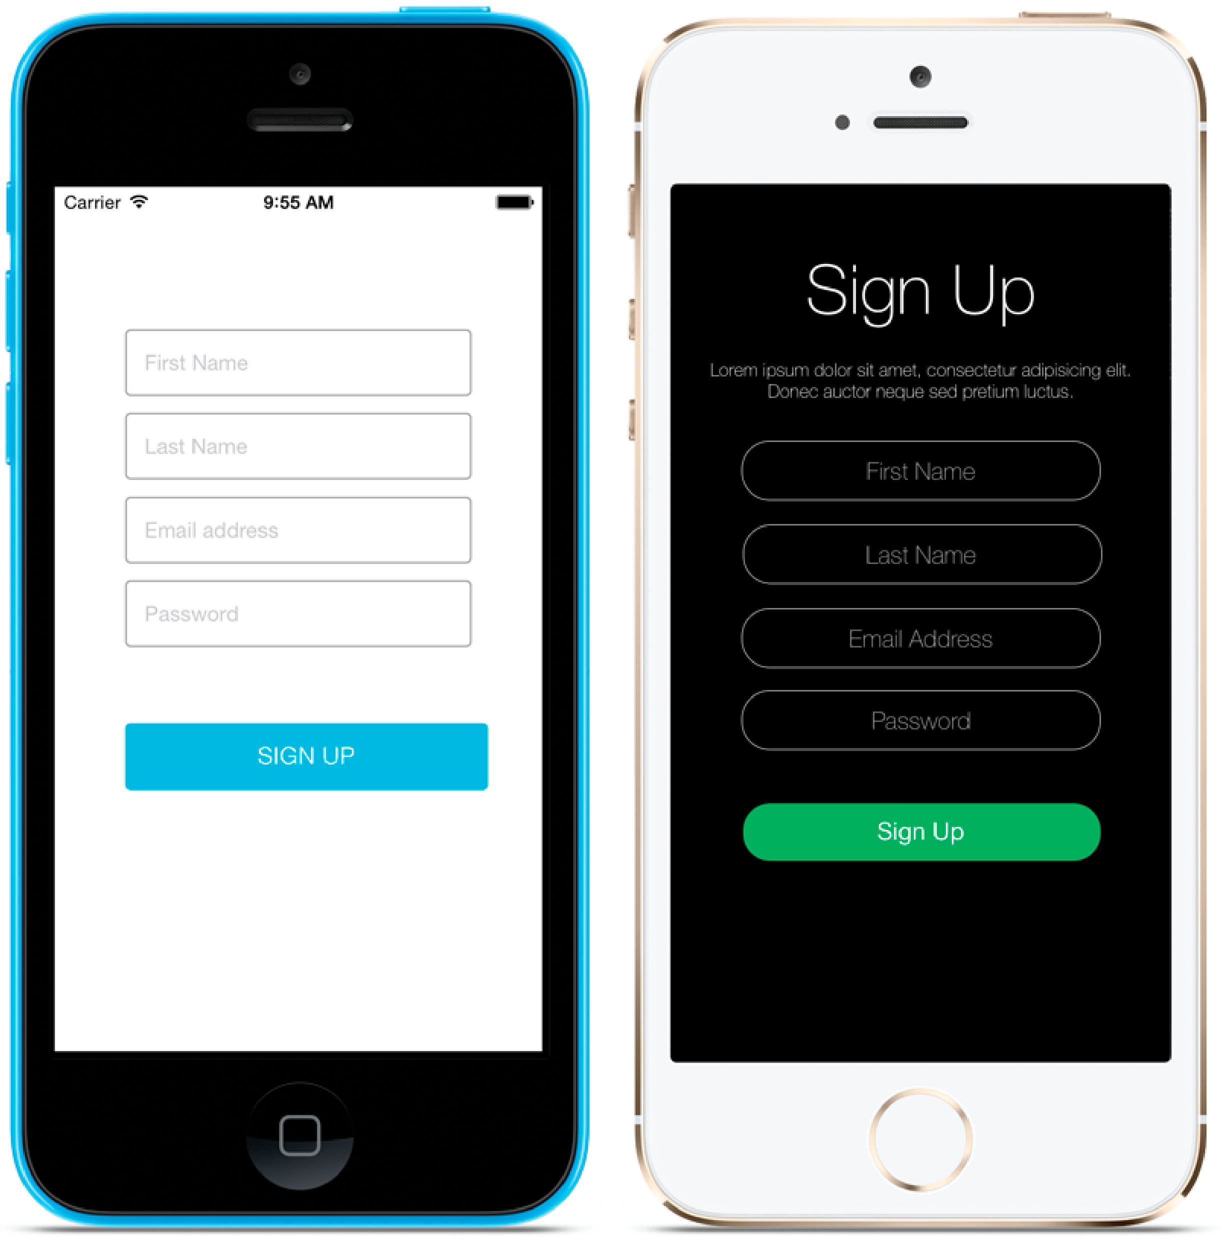


Figure 129.3: The Sign Up Screenlet with the Default and Flat7 Themes.

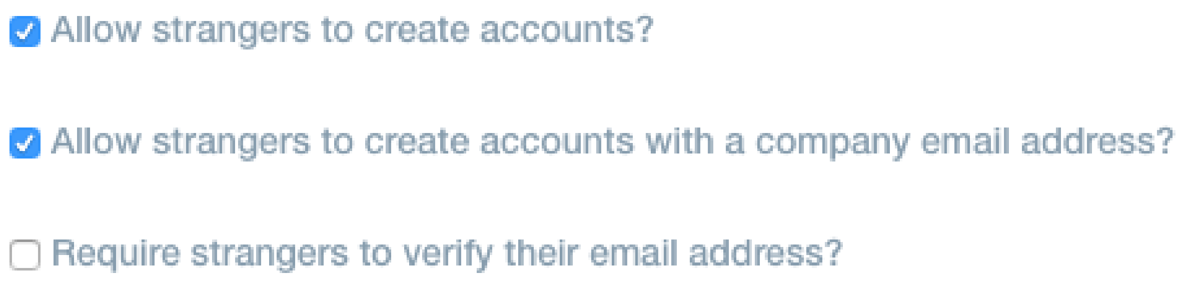
Portal Configuration

Sign Up Screenlet's corresponding configuration in the Liferay instance can be set in the Control Panel by selecting *Configuration* → *Instance Settings*, and then selecting the *Authentication* section.



☑ Allow strangers to create accounts?

☑ Allow strangers to create accounts with a company email address?

☐ Require strangers to verify their email address?

Figure 129.4: The Liferay instance's authentication settings.

For more details, please refer to the Setting up a Liferay Instance section of the User Guide.

Anonymous Request

Anonymous requests are unauthenticated requests. Authentication is needed, however, to call the API. To allow this operation, the portal administrator should create a specific user with minimal permissions.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity.

Attributes

Attribute | Data type | Explanation | `anonymousApiUserName` | `string` | The user name, email address, or user ID (depending on the portal's authentication method) to use for authenticating the request. | `anoymousApiPassword` | `string` | The password for use in authenticating the request. | `companyId` | `number` | When set, authentication is done for a user in the specified company. If the value is `0`, the company specified in `LiferayServerContext` is used. | `autoLogin` | `boolean` | Whether the user is logged in automatically after a successful sign up. | `saveCredentials` | `boolean` | Sets whether or not the user's credentials and attributes are stored in the keychain after a successful log in. This attribute is ignored if `autologin` is disabled. |

Delegate

The Sign Up Screenlet delegates some events to an object that conforms to the `SignUpScreenletDelegate` protocol. If the `autologin` attribute is enabled, login events are delegated to an object conforming to the `LoginScreenletDelegate` protocol. Refer to the `LoginScreenlet` documentation for more details.

The `SignUpScreenletDelegate` protocol lets you implement the following methods:

- `- screenlet:onSignUpResponseUserAttributes::` Called when sign up successfully completes. The user attributes are passed as a dictionary of keys (`String` or `NSStrings`) and values (`AnyObject` or `NSObject`). The supported keys are the same as Liferay Portal's User entity.
- `- screenlet:onSignUpError::` Called when an error occurs in the process. The `NSError` object describes the error.

129.3 Forgot Password Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Forgot Password Screenlet sends emails to registered users with their new passwords or password reset links, depending on the server configuration. The available authentication methods are:

- Email address
- Screen name
- User id

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

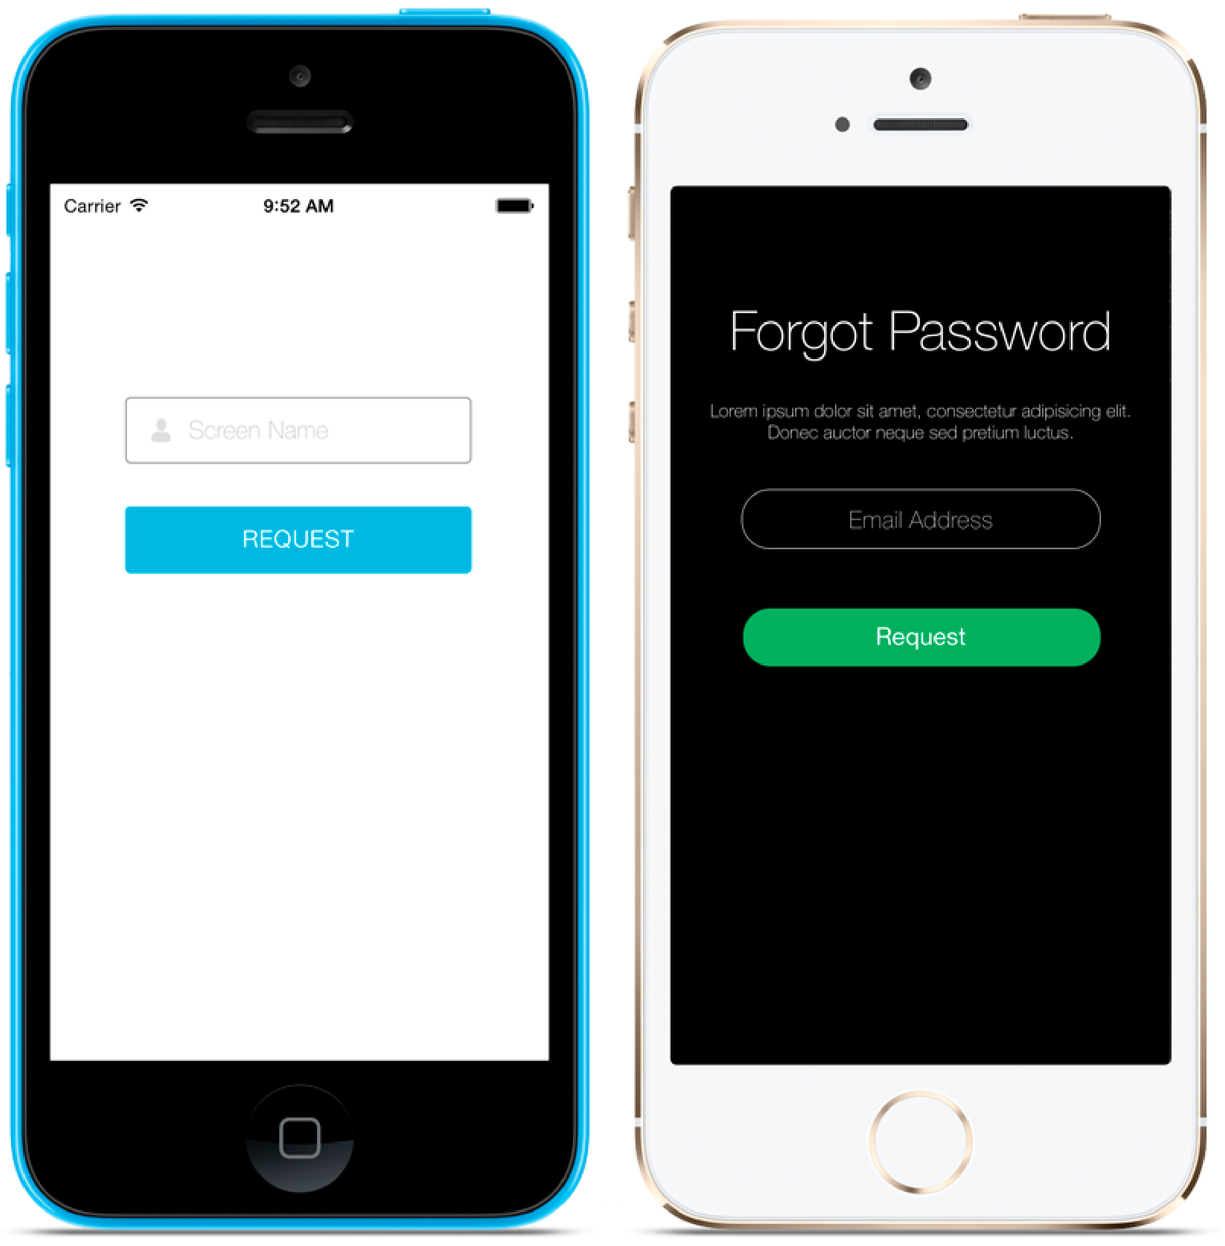
Service	Method	Notes
`UserService`	`sendPasswordByEmailAddress`	
`UserService`	`sendPasswordByUserId`	
`UserService`	`sendPasswordByScreenName`	

Module

- Auth

Themes

- Default (`default`)
- Flat7 (`flat7`)



Carrier
9:52 AM
Screen Name
REQUEST
Forgot Password
Lorem ipsum dolor sit amet, consectetur adipisicing elit.
Donec auctor neque sed pretium luctus.
Email Address
Request

Figure 129.5: The Forgot Password Screenlet with the Default and Flat7 Themes.

Portal Configuration

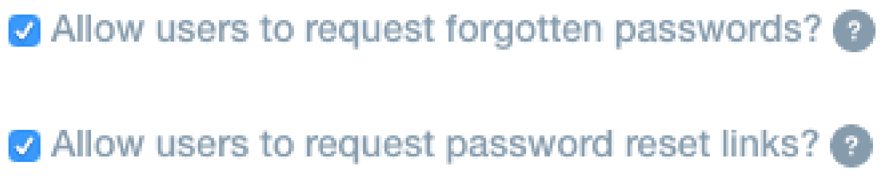
To use the Forgot Password Screenlet, you must allow users to request new passwords in the portal. The next sections show you how to do this.

Authentication Method

Note that the authentication method configured in the portal can be different from the one used by this Screenlet. For example, it's *perfectly fine* to use `screenName` for sign in authentication, but allow users to recover their password using the `email` authentication method.

Password Reset

You can set the Liferay instance's corresponding password reset options in the Control Panel by selecting *Configuration* → *Instance Settings*, and then selecting the *Authentication* section. The Screenlet's password functionality depends on the authentication settings in the portal:



✓ Allow users to request forgotten passwords?

✓ Allow users to request password reset links?

Figure 129.6: Checkboxes for the password recovery features in Liferay Portal.

If both of these options are unchecked, password recovery is disabled. If both options are checked, an email containing a password reset link is sent when a user requests it. If only the first option is checked, an email containing a new password is sent when a user requests it.

For more details on authentication in Liferay Portal, please refer to the Setting up a Liferay Instance section of the User Guide.

Anonymous Request

An anonymous request can be made without the user being logged in. However, authentication is needed to call the API. To allow this operation, the portal administrator should create a specific user with minimal permissions.

Offline

This Screenlet doesn't support offline mode. It requires network connectivity.

Attributes

Attribute | Data type | Explanation | `anonymousApiUserName` | `string` | The user name, email address, or userId (depending on the portal's authentication method) to use for authenticating the request. | `anonymousApiPassword` | `string` | The password to use to authenticate the request. | `companyId` | `number` | When set, the authentication is done for a user within the specified company. If the value is `0`, the company specified in `LiferayServerContext` is used. | `basicAuthMethod` | `string` | The authentication method that is presented to the user. This can be `email`, `screenName`, or `userId`. |

Delegate

The Forgot Password Screenlet delegates some events to an object that conforms to the `ForgotPasswordScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onForgotPasswordSent:`: Called when a password reset email is successfully sent. The Boolean parameter indicates whether the email contains the new password or a password reset link.
- `- screenlet:onForgotPasswordError:`: Called when an error occurs in the process. The `NSError` object describes the error.

129.4 User Portrait Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The User Portrait Screenlet shows the user's portrait from Liferay Portal. If the user doesn't have a portrait configured, a placeholder image is shown.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`UserService`	`getUserById`	
`UserService`	`getUserByEmailAddress`	
`UserService`	`getUserByScreenName`	

Module

- None

Themes

- Default (`default`)
- Flat7 (`flat7`)

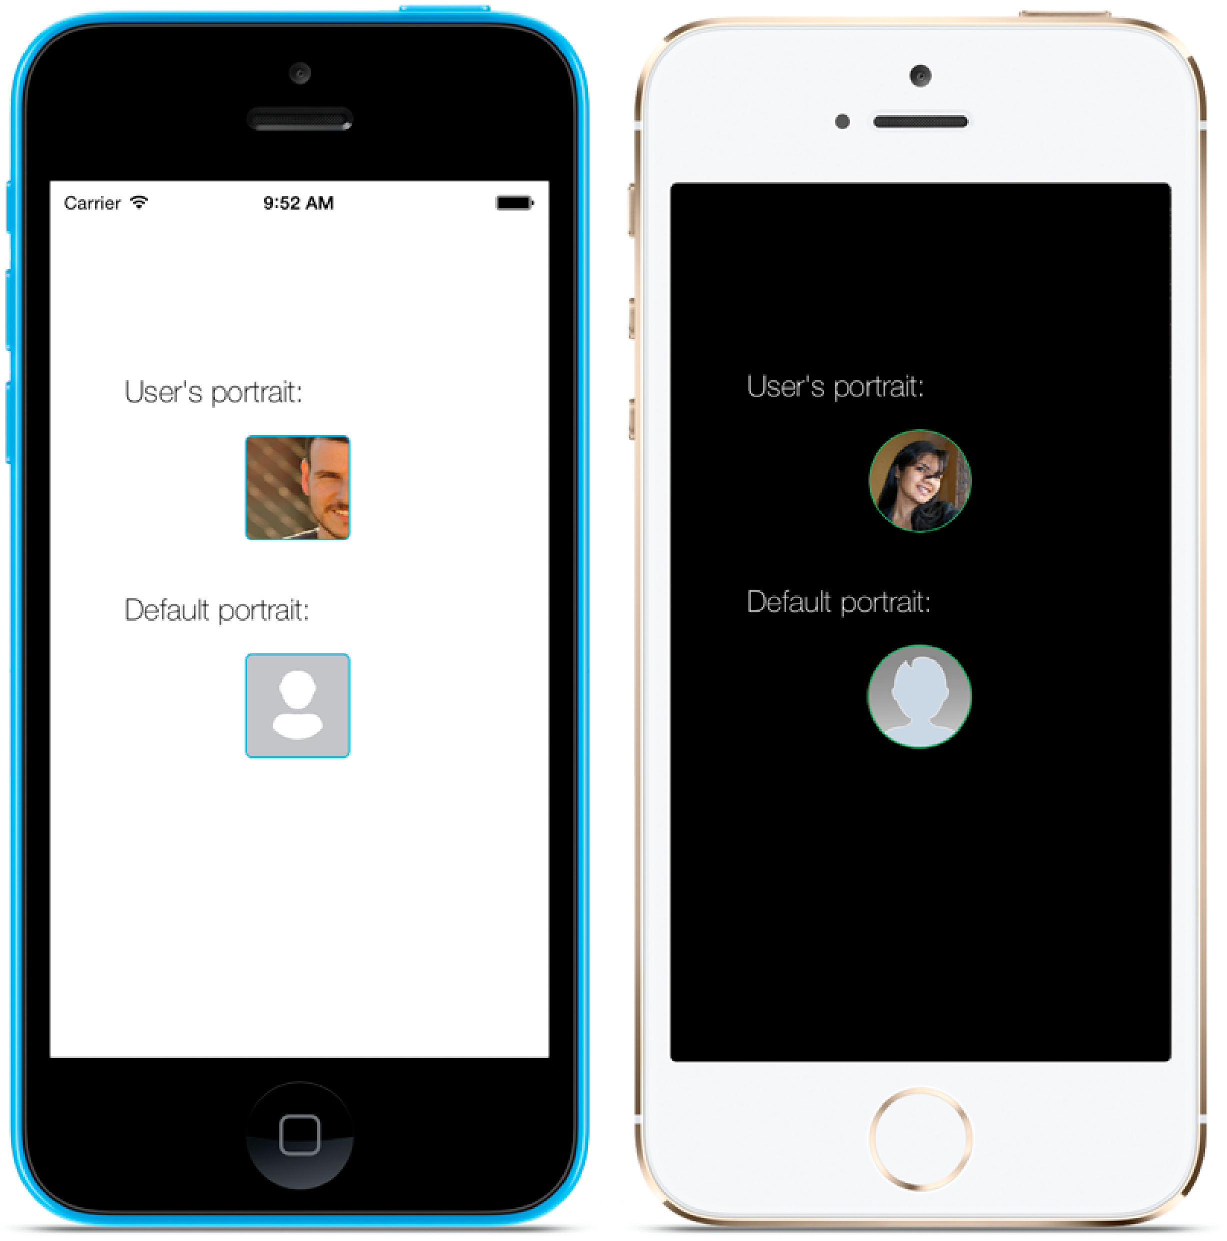


Figure 129.7: The User Portrait Screenlet using the Default and Flat7 Themes.

Portal Configuration

None

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

When loading the portrait, the Screenlet supports the following offline mode policies:

Policy	What happens	When to use
`remote-only`	The Screenlet loads the user portrait from the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet loads the portrait, it stores the received image in the local cache for later use.	Use this policy when you always need to show updated portraits, and show the default placeholder when there's no connection.
`cache-only`	The Screenlet loads the user portrait from the local cache. If the portrait isn't there, the Screenlet uses the delegate to notify the developer about the error.	Use this policy to show local portraits, without retrieving remote information under any circumstance.
`remote-first`	The Screenlet loads the user portrait from the portal. The Screenlet displays the portrait to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the portrait from the local cache. If the portrait doesn't exist there, the Screenlet uses the delegate to notify the developer about the error.	Use this policy to show the most recent portrait when connected, but show a potentially outdated version when there's no connection.
`cache-first`	If the portrait exists in the local cache, the Screenlet loads it from there. If it doesn't exist there, the Screenlet requests the portrait from the portal and uses the delegate to notify the developer about any connection errors.	Use this policy to save bandwidth and loading time in the event a local (but probably outdated) portrait exists.

When editing the portrait, the Screenlet supports the following offline mode policies:

Policy	What happens	When to use
`remote-only`	The Screenlet sends the user portrait to the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error, but it also discards the new portrait.	Use this policy when you need to make sure portal always has the most recent version of the portrait.
`cache-only`	The Screenlet stores the user portrait in the local cache.	Use this policy when you need to save the portrait locally, but don't want to change the portrait in the portal.
`remote-first`	The Screenlet sends the user portrait to the portal. If this succeeds, the Screenlet also stores the portrait in the local cache for later usage. If a connection issue occurs, the Screenlet stores the portrait in the local cache with the *dirty flag* enabled. This causes the portrait to be sent to the portal when the synchronization process runs.	Use this policy when you need to make sure the Screenlet sends the new portrait to the portal as soon as the connection is restored.
`cache-first`	The Screenlet stores the user portrait in the local cache and then sends it to the portal. If a connection issue occurs, the Screenlet stores the portrait in the local cache with the *dirty flag* enabled. This causes the portrait to be sent to the portal when the synchronization process runs.	Use this policy when you need to make sure the Screenlet sends the new portrait to the portal as soon as the connection is restored. Compared to `remote-first`, this policy always stores the portrait in the cache. The `remote-first` policy only stores the new image in the event of a network error.

Attributes

Attribute | Data type | Explanation | `borderWidth` | `number` | The size in pixels for the portrait's border. The default value is 1. Set this to `0` if you want to hide the border.| `borderColor` | `UIColor` | The border's color. Use the system's transparent color to hide the border. | `editable` | `boolean` | Lets the user change the portrait image by taking a photo or selecting a gallery picture. The default value is `false`. Portraits loaded with the `load(portraitId, uuid, male)` method aren't editable. | `offlinePolicy` | `string` | Configure the loading and saving behavior in case of connectivity issues. For more details, read the "Offline" section below. |

Methods

Method | Return | Explanation | `loadLoggedUserPortrait()` | `boolean` | Starts the request to load the currently logged in user's portrait image (see the `SessionContext` class). | `load(userId)` | `boolean` | Starts the request to load the specified user's portrait image. | `load(portraitId, uuid, male)` | `boolean` | Starts the request to load the portrait image using the specified user's data. The parameters `portraitId` and `uuid` can be retrieved by using the `SessionContext.userAttributes()` method. | `load(companyId, emailAddress)` | `boolean` | Starts the request to load the portrait image using the user's email address. | `load(companyId, screenName)` | `boolean` | Starts the request to load the portrait image using the user's screen name. |

Delegate

The User Portrait Screenlet delegates some events to an object that conforms to the `UserPortraitScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onUserPortraitResponseImage:`: Called when an image is received from the server. You can then apply image filters (grayscale, for example) and return the new image. You can return the original image supplied as the argument if you don't want to modify it.
- `- screenlet:onUserPortraitError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onUserPortraitUploaded:`: Called when a new portrait is uploaded to the server. You receive the user attributes as a parameter.
- `- screenlet:onUserPortraitUploadError:`: Called when an error occurs in the upload process. The `NSError` object describes the error.

129.5 DDL Form Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

DDL Form Screenlet can be used to show a collection of fields so that a user can fill in their values. Initial or existing values may be shown in the fields. Fields of the following data types are supported:

- *Boolean*: A two state value typically shown using a checkbox.
- *Date*: A formatted date value. The format depends on the device's locale.
- *Decimal, Integer, and Number*: A numeric value.
- *Document and Media*: A file stored on the current device. It can be uploaded to a specific portal repository.
- *Radio*: A set of options to choose from. A single option must be chosen.
- *Select*: A selection box of options to choose from. A single option must be chosen.
- *Text*: A single line of text.
- *Text Box*: Supports multiple lines of text.

DDL Form Screenlet also supports the following features:

- Stored records can support a specific workflow.
- A Submit button can be shown at the end of the form.
- Required values and validation for fields can be used.
- Users can traverse the form fields from the keyboard.
- Supports i18n in record values and labels.

There are also a few limitations you should be aware of when using DDL Form Screenlet. They are listed here:

- Nested fields in the data definition aren't supported.
- Selection of multiple items in the Radio and Select data types isn't supported yet.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`DDMStructureService`	`getStructureWithStructureId`	Load form
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecord`	Load record
`DLAppService`	`addFileEntry`	Upload document
`DDLRecordService`	`addRecord`	Submit form

Service	Method	Notes
`DDLRecordService`	`updateRecord`	Update form

Module

- DDL

Themes

- Default

The Default Theme uses a standard `UITableView` to show a scrollable list of fields. Other Themes may use a different component, such as `UICollectionView` or others, to show the fields.

Custom Cells

A Theme needs to define a cell view for each field type. For instance, the `xib` file `DDLFieldDateTableCell_default` is used to render `Date` fields in the Default Theme.

If you want a specific field to have a unique appearance, you can customize your field's display by using the following filename pattern, where `XXX` is your field's name: `DDLCustomFieldXXXTableCell_default`. For example, the "Are you a subscriber?" field in screenshot above shows how text fields appear in the Default Theme. If you want to customize this, you don't need to create an entire Theme. You just need to create an `xib` file for the field `subscriberName`. The filename is therefore `DDLCustomFieldSubscriberNameTableCell_default`. Be careful to keep the same components and `IBOutlet` defined in the custom file.

Portal Configuration

Before using DDL Form Screenlet, you should make sure that Dynamic Data Lists and Data Types are configured properly in the portal. Refer to the Creating Data Definitions and Creating Data Lists sections of the User Guide for more details. If Workflow is required, it must also be configured. See the Using Workflow section of the User Guide for details.

Permissions

To use DDL Form Screenlet to add new records, you must grant the Add Record permission in the Dynamic Data List in the portal. If you want to use DDL Form Screenlet to view or edit record values, you must also grant the View and Update permissions, respectively. The Add Record, View, and Update permissions are highlighted by the red boxes in the following screenshot:

Also, if your form includes at least one Documents and Media field, you must grant permissions in the target repository and folder. For more details, see the `repositoryId` and `folderId` attributes below.

For more details, please see the User Guide sections Creating Data Definitions, Creating Data Lists, and Using Workflow.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture.

When loading the form or record, the Screenlet supports the following offline mode policies:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the form or record from the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet loads the form or record, it stores the received data (record structure and data) in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection.| `cache-only` | The Screenlet loads the form or record from the local cache. If the form or record isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance.| `remote-first` | The Screenlet requests the form or record from the portal. The Screenlet shows the record or form to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the form or record from the local cache. If the form or record doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the

data when connected, but show an outdated version when there's no connection. | `cache-first` | If the form or record exists in the local cache, the Screenlet loads it from there. If it doesn't exist there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

When editing the record, the Screenlet supports the following offline mode policies:

Policy | What happens | When to use | `remote-only` | The Screenlet sends the record to the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error, but it also discards the record. | Use this policy to make sure the portal always has the most recent version of the record. | `cache-only` | The Screenlet stores the record in the local cache. | Use this policy when you need to save the data locally, but don't want to update the data in the portal (update or add record). | `remote-first` | The Screenlet sends the record to the portal. If this succeeds, it also stores the record in the local cache for later usage. If a connection issue occurs, then Screenlet stores the record in the local cache with the *dirty flag* enabled. This causes the synchronization process to send the record to the portal when it runs. | Use this policy when you need to make sure the Screenlet sends the record to the portal as soon as the connection is restored. | `cache-first` | The Screenlet stores the record in the local cache and then sends it to the remote portal. If a connection issue occurs, then Screenlet stores the record in the local cache with the *dirty flag* enabled. This causes the the synchronization process to send the record to the portal when it runs. | Use this policy when you need to make sure the Screenlet sends the record to the portal as soon as the connection is restored. Compared to `remote-first`, this policy always stores the record in the cache. The `remote-first` policy only stores the record in the event of a network error. |

Required Attributes

- `structureId`
- `recordSetId`

Attributes

Attribute | Data Type | Explanation | `structureId` | `number` | This is the identifier of a data definition for your site in Liferay. To find the identifiers for your data definitions, click *Admin* from the Dockbar and select *Content*. Then click *Dynamic Data Lists* and click the *Manage Data Definitions* button. The identifier of each data definition is in the ID column of the table that appears. | `groupId` | `number` | The site (group) identifier where the record is stored. If this value is `0`, the `groupId` specified in `LiferayServerContext` is used. | `recordSetId` | `number` | The identifier of a dynamic data list. To find the identifiers for your dynamic data lists, click *Admin* from the Dockbar and select *Content*. Then click *Dynamic Data Lists*. The identifier of each dynamic data list is in the ID column of the table that appears. | `recordId` | `number` | The identifier of the record you want to show. Setting the `editable` attribute to `true` allows editing of the record's values. The `recordId` can be obtained from other methods or delegates. | `repositoryId` | `number` | The identifier of the Documents and Media repository to upload to. If this value is `0`, the default repository for the site specified in `groupId` is used. | `folderId` | `number` | The identifier of the folder where Documents and Media files are uploaded. If this value is `0`, the root folder is used. | `filePrefix` | `string` | The prefix to attach to the names of files uploaded to a Documents and Media repository. A random GUID string is appended following the prefix. | `autoLoad` | `boolean` | Sets whether or not the form is loaded when the Screenlet is shown. If `recordId` is set, the record value is loaded together with the form definition. | `autoscrollOnValidation` | `boolean` | Sets whether or not the form automatically scrolls to the first failed field when validation is used. | `showSubmitButton` | `boolean` | Sets whether or not the form shows a submit button at the bottom. If this is set to `false`, you should call the `submitForm()` method. | `editable` | `boolean` | Sets whether the values can be changed by the user. The default is `true`. |

Methods

Method | Return Type | Explanation | `loadForm()` | `boolean` | Starts the request to load the form definition. The form fields are shown when the response is received. This method returns `true` if the request is sent. | `loadRecord()` | `boolean` | Starts the request to load the record specified in `recordId`. If needed, the form definition is also loaded. The form fields are shown filled with record values when the response is received. This method returns `true` if the request is sent. | `submitForm()` | `boolean` | Starts the request to submit form values to the dynamic data list specified in `recordSetId`. All fields are validated prior to submission. Validation errors stop the submit process. |

Delegate

DDL Form Screenlet delegates some events to an object that conforms with the `DDLFormScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFormLoaded:`: Called when the form is loaded. The second parameter (`record`) contains only field definitions.
- `- screenlet:onFormLoadError:`: Called when an error occurs while loading the form. The `NSError` object describes the error.
- `- screenlet:onRecordLoaded:`: Called when a form with values loads. The second parameter (`record`) contains field definitions and values. The method `onFormLoadResult` is called before `onRecordLoaded`.
- `- screenlet:onRecordLoadError:`: Called when an error occurs while loading a record. The `NSError` object describes the error.
- `- screenlet:onFormSubmitted:`: Called when the form values are successfully submitted to the server.
- `- screenlet:onFormSubmitError:`: Called when an error occurs while submitting the form. The `NSError` object describes the error.
- `- screenlet:onDocumentFieldUploadStarted:`: Called when the upload of a Documents and Media field begins.
- `- screenlet:onDocumentField:uploadedBytes:totalBytes:`: Called when a block of bytes in a Documents and Media field is uploaded. This method is intended to track progress of the uploads.
- `- screenlet:onDocumentField:uploadResult:`: Called when a Documents and Media field upload is completed.
- `- screenlet:onDocumentField:uploadError:`: Called when an error occurs in the Documents and Media upload process. The `NSError` object describes the error.

129.6 DDL List Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The DDL List Screenlet enables the following features:

- Shows a scrollable collection of DDL records.
- Implements fluent pagination with configurable page size.
- Allows filtering of records by creator.
- Supports i18n in record values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecords`	With `ddlRecordSetId`, or `ddlRecordSetId` and `userId`
`ScreensddlrecordService` (Screens compatibility plugin)	`getDdlRecordsCount`	

Module

- DDL

Themes

- The Default Theme uses a standard `UITableView` to show the scrollable list. Other Themes may use a different component, such as `UICollectionView` or others, to show the items.

Portal Configuration

Dynamic Data Lists (DDL) and Data Types should be configured in the portal. For more details, please refer to the Liferay User Guide sections Creating Data Definitions and Creating Data Lists.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

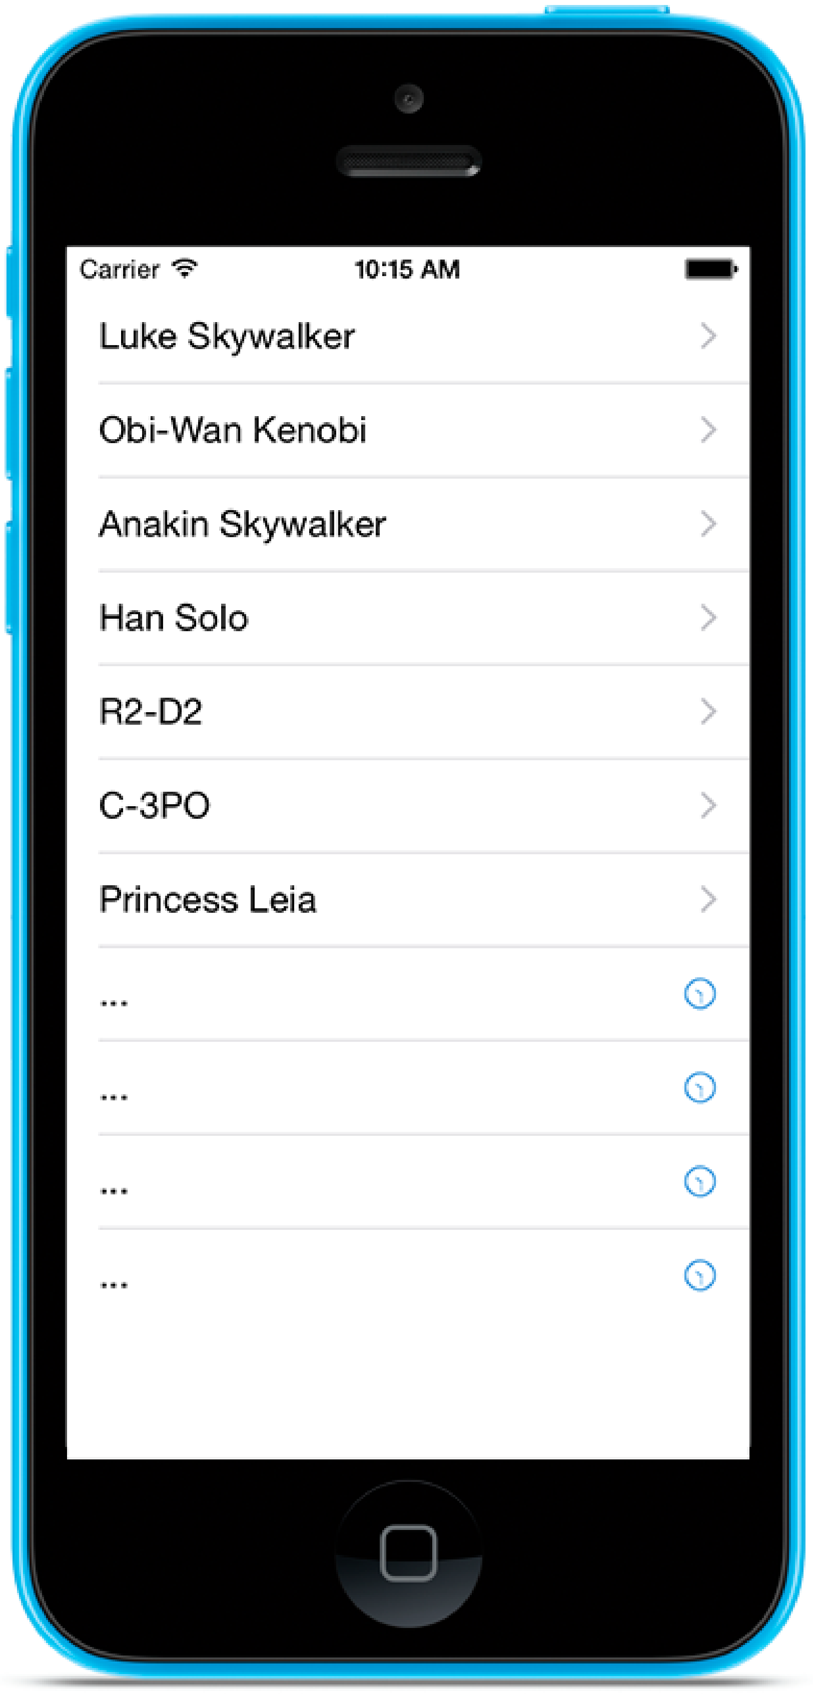

Figure 129.11: The DDL List Screenlet using the Default (`default`) Theme.

Policy | What happens | When to use | `remote-only` | The Screenlet loads the list from the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the list from the portal. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `recordSetId`
- `labelFields`

Attributes

Attribute | Data type | Explanation | `recordSetId` | `number` | The ID of the DDL being called. To find the IDs for your DDLs, first open the Product Menu and select the site that contains your DDLs. Then click *Content* → *Dynamic Data Lists*. Each DDL's ID is in the table's ID column. | `userId` | `number` | The ID of the user to filter records on. Records aren't filtered if the `userId` is `0`. The default value is `0`. | `labelFields` | `string` | The comma-separated names of the DDL fields to show. Refer to the list's data definition to find the field names. To do so, first open the Product Menu and select the site that contains your DDLs. Then click *Content* → *Dynamic Data Lists*, and find the find the icon (⋮) for the Dynamic Data List configuration menu at the upper right. Click this icon and select *Manage Data Definitions*. You can view the fields by clicking on any of the data definitions in the table that appears. Note that the appearance of these values in your app depends on the Theme selected by the user. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. | `autoLoad` | `boolean` | Whether the list loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `refreshControl` | `boolean` | Whether a standard iOS `UIRefreshControl` appears when the user performs the pull to refresh gesture. The default value is `true`. | `firstPageSize` | `number` | The number of items retrieved from the server for display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items retrieved from the server for display on the second and subsequent pages. The default value is `25`. | `obcClassName` | `string` | The name of the `OrderByComparator` class to use to sort the results. Omit this property if you don't want to sort the results. Click here to see some comparator classes. Note, however, that not all of these classes can be used with `obcClassName`. You can only use comparator classes that extend `OrderByComparator<DDLRecord>`. You can also create your own comparator classes that extend `OrderByComparator<DDLRecord>`. |

Methods

Method | Return | Explanation | `loadList()` | `boolean` | Starts the request to load the list of records. The list is shown when the response is received. This method returns true if the request is sent. |

Delegate

The DDL List Screenlet delegates some events in an object that conforms to the `DDLListScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onDDLListResponseRecords:`: Called when a page of contents is received. Note that this method may be called more than once; once for each retrieved page.
- `- screenlet:onDDLListError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onDDLSelectedRecord:`: Called when an item in the list is selected.

129.7 Asset List Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Asset List Screenlet can be used to show lists of assets from a Liferay instance. For example, you can use the Screenlet to show a scrollable collection of assets. It also implements fluent pagination with configurable page size. The Asset List Screenlet can show assets of the following classes:

- `BlogsEntry`
- `BookmarksEntry`
- `BookmarksFolder`
- `CalendarEvent`
- `DLFileEntry`
- `DDLRecord`
- `DDLRecordSet`
- `Group`

- `JournalArticle` (Web Content)
- `JournalFolder`
- `Layout`
- `LayoutRevision`
- `MBThread`
- `MBCategory`
- `MBDiscussion`
- `MBMailingList`
- `Organization`
- `User`
- `WikiPage`
- `WikiPageResource`
- `WikiNode`

The Asset List Screenlet also supports i18n in asset values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensddlrecordService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensddlrecordService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`
`AssetEntryService`	`getEntriesCount`	

Module

- None

Themes

- Default

The Default Theme uses a standard `UITableView` to show the scrollable list. Other Themes may use a different component, such as `UICollectionView` or others, to show the items.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

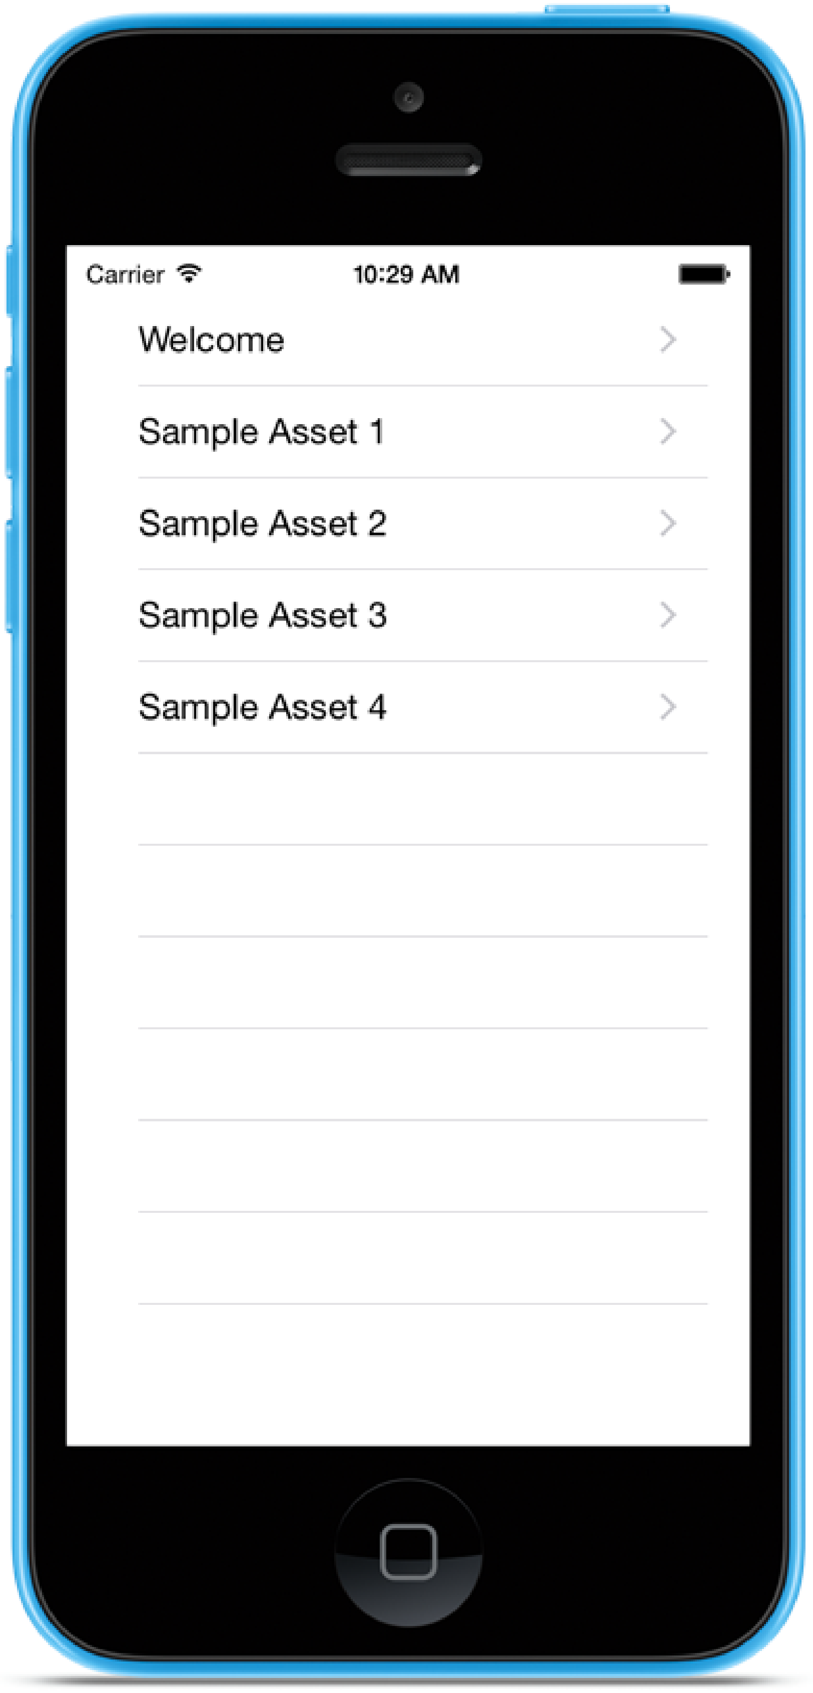

Figure 129.12: Asset List Screenlet using the Default (`default`) Theme.

Policy | What happens | When to use | `remote-only` | The Screenlet loads the list from the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the list from the portal. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `classNameId`

If you don't use `classNameId`, you must use this attribute:

- `portletItemName`

Attributes

Attribute | Data type | Explanation | `groupId` | `number` | The ID of the site (group) where the asset is stored. If set to `0`, the `groupId` specified in `LiferayServerContext` is used. The default value is `0`. | `classNameId` | `number` | The ID of the asset's class name. Use values from the `AssetClassNameId` class or the Liferay Instance's `classname_` database table. | `portletItemName` | `string` | The name of the configuration template you used in the Asset Publisher. To use this feature, add an Asset Publisher to one of your site's pages (it may be a hidden page), configure the Asset Publisher's filter (in *Configuration → Setup → Asset Selection*), and then use the Asset Publisher's *Configuration Templates* option to save this configuration with a name. Use this name as this attribute's value. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. | `autoLoad` | `boolean` | Whether the list loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `refreshControl` | `boolean` | Defines whether a standard ios `UIRefreshControl` appears when the user does the pull to refresh gesture. The default value is `true`. | `firstPageSize` | `number` | The number of items retrieved from the server for display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items retrieved from the server for display on the second and subsequent pages. The default value is `25`. | `customEntryQuery` | `Dictionary` | The set of keys (string) and values (string or number) to be used in the `AssetEntryQuery` object. These values filter the assets returned by the Liferay instance. |

Methods

Method | Return | Explanation | `loadList()` | `boolean` | Starts the request to load the list of assets. This list is shown when the response is received. Returns `true` if the request is sent. |

Delegate

The Asset List Screenlet delegates some events to an object that conforms to the `AssetListScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onAssetListResponse:`: Called when a page of assets is received. Note that this method may be called more than once; one call for each page received.
- `- screenlet:onAssetListError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onAssetSelected:`: Called when an item in the list is selected.

129.8 Web Content Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

The Web Content Display Screenlet shows web content elements in your app, rendering the inner HTML of the web content. The Screenlet also supports i18n, rendering contents differently depending on the device's current locale.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`DDMStructureService`	`getStructureWithStructureId`	
`JournalArticleService`	`getArticleWithGroupId`	
`JournalArticleService`	`getArticleContent`	
`ScreensddlrecordService` (Screens compatibility plugin)	`getJournalArticleContent`	With `entryQuery`

Module

- WebContent

Themes

- Default

The Default Theme uses a standard `UIWebView` to render the HTML. Other Themes may use a different component, such as iOS 8's.

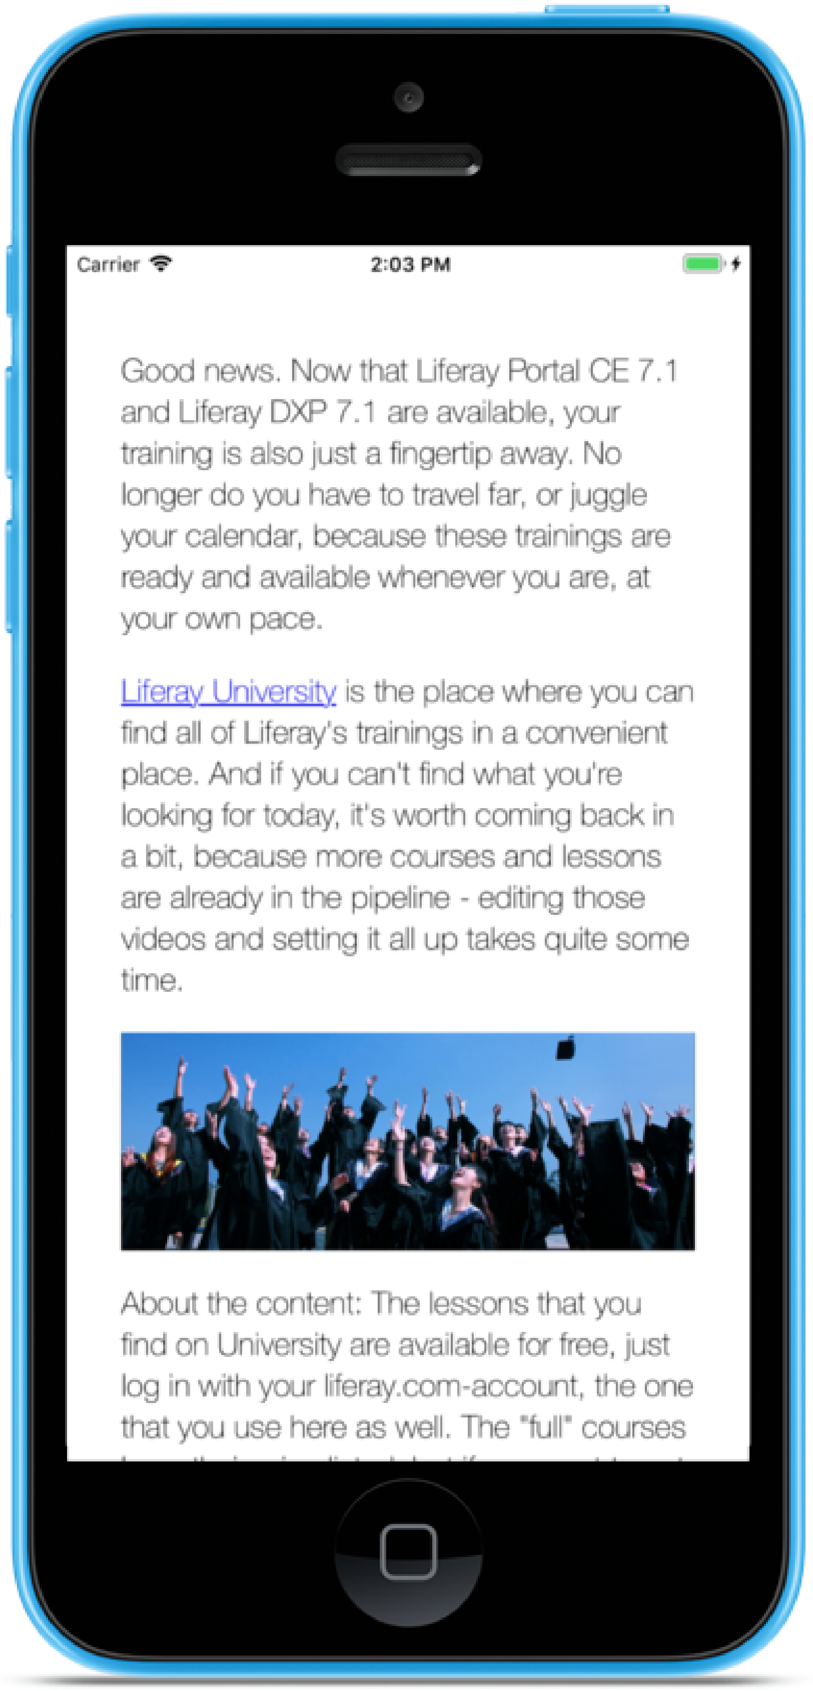
Portal Configuration

For the Web Content Display Screenlet to function properly, there should be web content in the Liferay instance your app connects to. For more details on web content, please refer to the Creating Web Content section of the Liferay User Guide.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the content from the portal. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the content, it stores the data in the local cache for later use. | Use this policy when you always need to show updated content, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the content from the local cache. If the content isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local content, without retrieving remote content under any circumstance. | `remote-first` | The Screenlet loads the content from the portal. If this succeeds, the Screenlet shows the content to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the content from the local cache. If the content doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the content when connected, but show a possibly outdated version when there's no connection. | `cache-first` | The Screenlet loads the content from the local cache. If the content isn't there, the Screenlet requests it from the portal and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) content. |



Carrier 2:03 PM

Good news. Now that Liferay Portal CE 7.1 and Liferay DXP 7.1 are available, your training is also just a fingertip away. No longer do you have to travel far, or juggle your calendar, because these trainings are ready and available whenever you are, at your own pace.

Liferay University is the place where you can find all of Liferay's trainings in a convenient place. And if you can't find what you're looking for today, it's worth coming back in a bit, because more courses and lessons are already in the pipeline - editing those videos and setting it all up takes quite some time.

About the content: The lessons that you find on University are available for free, just log in with your liferay.com-account, the one that you use here as well. The "full" courses

Figure 129.13: The Web Content Display Screenlet using the Default (`default`) Theme

Required Attributes

- `articleId`

If you have structured web content, you can alternatively use `templateId` or `structureId` with `articleId`.

Attributes

Attribute | Data type | Explanation | `groupId` | `number` | The site (group) identifier where the asset is stored. If this value is `0`, the `groupId` specified in `LiferayServerContext` is used. | `articleId` | `string` | The identifier of the web content to display. You can find the identifier by clicking *Edit* on the web content in the portal. | `templateId` | `number` | The identifier of the template used to render the web content. This is applicable only with structured web content. | `structureId` | `number` | The identifier of the `DDMStructure` used to model the web content. This parameter lets the Screenlet retrieve and parse the structure. | `autoLoad` | `boolean` | Whether the content should be retrieved from the portal as soon as the Screenlet appears. The default value is `true`. |

Methods

Method | Return | Explanation | `loadWebContent()` | `boolean` | Starts the request to load the web content. The HTML is rendered when the response is received. Returns `true` if the request is sent. |

Delegate

The Web Content Display Screenlet delegates some events to an object that conforms to the `WebContentDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onWebContentResponse:`: Called when the web content's HTML is received.
- `- screenlet:onWebContentError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onRecordContentResponse:`: Called when a web content record is received.
- `- screenlet:onUrlClicked:`: Called when a URL is clicked in the web content. Return `true` to handle the navigation, or `false` to cancel it.

129.9 Web Content List Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Web Content List Screenlet can show lists of web content from a Liferay instance. It can show both basic and structured web content. The Screenlet also implements fluent pagination with configurable page size, and supports i18n in asset values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`JournalArticleService`	`getArticlesWithGroupId`	
`JournalArticleService`	`getArticlesCount`	

Module

- WebContent

Themes

- Default

The Default Theme uses a standard `UITableView` to show the scrollable list. Other Themes may use a different component, such as `UICollectionView` or others, to show the contents.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the list from the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving

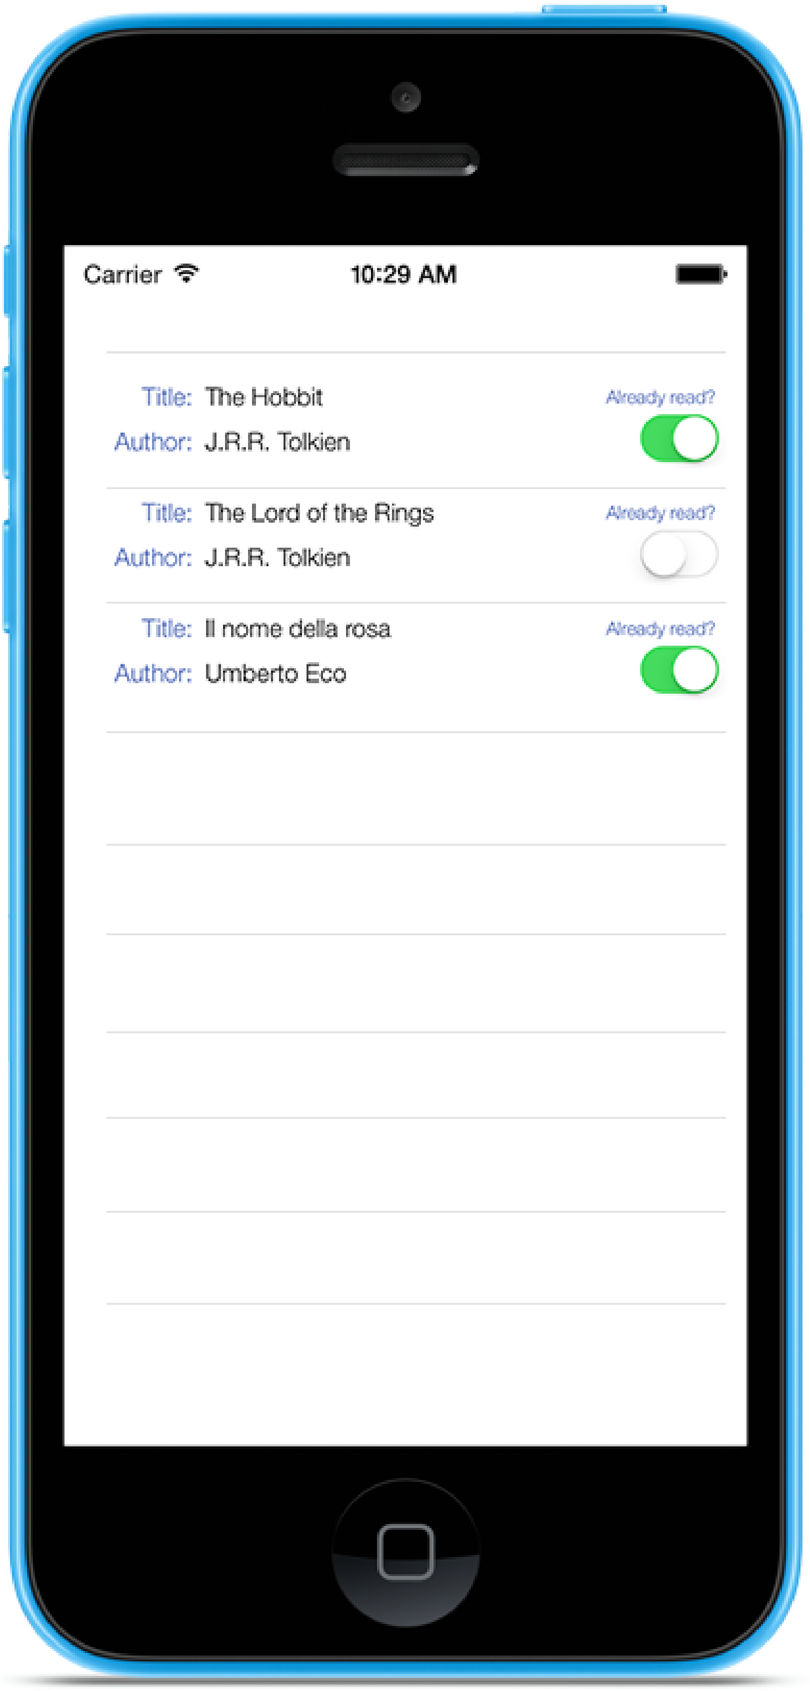


Figure 129.14: Web Content List Screenlet using the Default (`default`) Theme.

remote information under any circumstance. | `remote-first` | The Screenlet loads the list from the Liferay instance. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show a possibly outdated version when there's no connection. | `cache-first` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but possibly outdated) data. |

Required Attributes

- `folderId`

Attributes

Attribute | Data type | Explanation | `groupId` | `number` | The ID of the site (group) where the web content exists. If set to `0`, the `groupId` specified in `LiferayServerContext` is used. The default value is `0`. | `folderId` | `number` | The ID of the web content folder. If set to `0`, the root folder is used. The default value is `0`. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. | `autoLoad` | `boolean` | Whether the list loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `refreshControl` | `boolean` | Whether a standard iOS `UIRefreshControl` appears when the user does the pull to refresh gesture. The default value is `true`. | `firstPageSize` | `number` | The number of items to display on the first page. The default value is `50`. | `pageSize` | `number` | The number of items to display on the second and subsequent pages. The default value is `25`. | `obcClassName` | `string` | The name of the `OrderByComparator` class to use to sort the results. Omit this property if you don't want to sort the results. Click here to see some comparator classes. Note, however, that not all of these classes can be used with `obcClassName`. You can only use comparator classes that extend `OrderByComparator<JournalArticle>`. You can also create your own comparator classes that extend `OrderByComparator<JournalArticle>`. |

Methods

Method | Return | Explanation | `loadList()` | `boolean` | Starts the request to load the web content list. This list is shown when the response is received. Returns `true` if the request is sent successfully. |

Delegate

Web Content List Screenlet delegates some events to an object that conforms to the `WebContentListScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onWebContentListResponse:`: Called when a page of contents is received. Note that this method may be called more than once: one call for each page received.

- `- screenlet:onWebContentListError:`: Called when an error occurs in the process. The `NSError` object describes the error.

- - `screenlet:onWebContentSelected:`: Called when an item in the list is selected.

129.10 Image Gallery Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Image Gallery Screenlet shows a list of images from a Documents and Media folder in a Liferay instance. You can also use Image Gallery Screenlet to upload images to and delete images from the same folder. The Screenlet implements fluent pagination with configurable page size, and supports i18n in asset values.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`DLAppService`	`getFileEntries`	Load
`DLAppService`	`getFileEntriesCount`	
`DLAppService`	`addFileEntry`	Upload
`DLAppService`	`deleteFileEntry`	Delete

Module

- None

Themes

The default Theme uses a standard iOS `UICollectionView` to show the scrollable list as a grid. Other Themes may use a different component, such as `UITableView` or others, to show the contents.

This screenlet has three different Themes:

1. Grid (default)
2. Slideshow
3. List

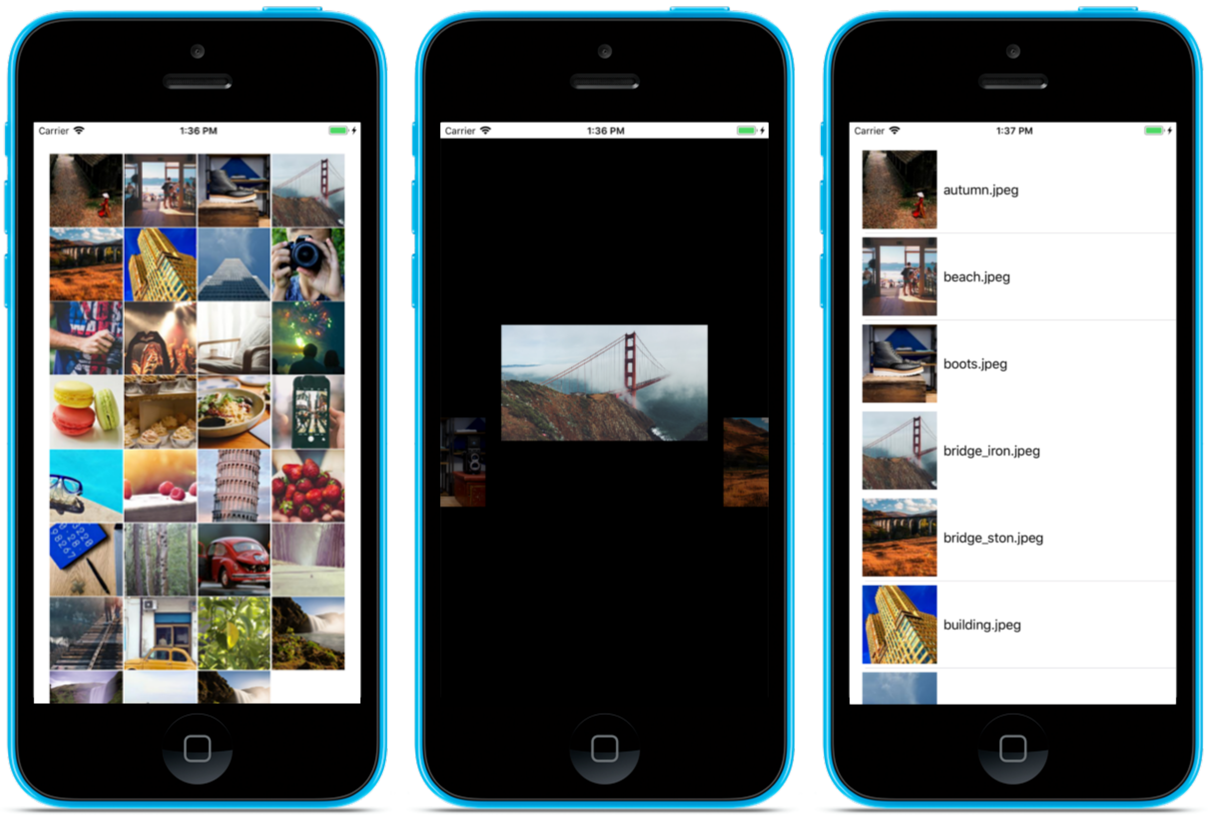

Figure 129.15: Image Gallery Screenlet using the Grid, Slideshow, and List Themes.

Offline

This Screenlet supports offline mode so it can function without a network connection when loading or uploading images (deleting images while offline is unsupported). For more information on how offline mode works, see the tutorial on its architecture. This Screenlet supports the `remote-only`, `cache-only`, `remote-first`, and `cache-first` offline mode policies.

These policies take the following actions when loading images from a Liferay instance:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show a possibly outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but possibly outdated) data. |

These policies take the following actions when uploading an image to a Liferay instance:

Policy | What happens | When to use | `remote-only` | The Screenlet sends the image to the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error, but it also discards the image. | Use this policy to make sure the Liferay instance always has the most recent version of the image. | `cache-only` | The Screenlet stores the image in the local cache. | Use this policy when you need to save the image locally, but don't want to update it in the Liferay instance. | `remote-first` | The Screenlet sends the image to the Liferay instance. If this succeeds, it also stores the image in the local cache for later use. If a connection issue occurs, the Screenlet stores the image in the local cache and sends it to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the image to the Liferay instance as soon as the connection is restored. | `cache-first` | The Screenlet stores the image in the local cache and then attempts to send it to the Liferay instance. If a connection issue occurs, the Screenlet sends the image to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the image to the Liferay instance as soon as the connection is restored. Compared to `remote-first`, this policy always stores the image in the cache. The `remote-first` policy only stores the image in the event of a network error. |

Required Attributes

- `repositoryId`
- `folderId`

Attributes

Attribute | Data type | Explanation | `repositoryId` | `number` | The ID of the Liferay instance's Documents and Media repository that contains the image gallery. If you're using a site's default Documents and Media repository, then the `repositoryId` matches the site ID (`groupId`). | `folderId` | `number` | The ID of the Documents and Media repository folder that contains the image gallery. When accessing the folder in your browser, the `folderId` is at the end of the URL. | `mimeTypes` | `string` | The comma-separated list of MIME types for the Screenlet to support. | `filePrefix` | `string` | The prefix to use on uploaded image file names. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. | `autoLoad` | `boolean` | Whether the list automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `refreshControl` | `boolean` | Whether a standard iOS `UIRefreshControl` appears when the user does the pull to refresh gesture. The default value is true. | firstPageSize | number | The number of items to display on the first page. The default value is 50. | pageSize | number | The number of items to display on the second and subsequent pages. The default value is 25. | obcClassName | string | The name of the OrderByComparator class to use to sort the results. Omit this property if you don't want to sort the results. Note that you can only use comparator classes that extend OrderByComparator<DLFileEntry>. Liferay contains no such comparator classes. You must therefore create your own by extending OrderByComparator<DLFileEntry>. To see examples of some comparator classes that extend other Document Library classes, click here. |

Methods

Method | Return | Explanation | loadList() | boolean | Starts the request to load the list of images. This list is shown when the response is received. Returns true if the request is sent successfully. |

Delegate

Image Gallery Screenlet delegates some events to an object that conforms to the ImageGalleryScreenletDelegate protocol. This protocol lets you implement the following methods:

- - screenlet:onImageEntriesResponse:: Called when a page of contents is received. Note that this method may be called more than once: one call for each page received.
- - screenlet:onImageEntriesError:: Called when an error occurs in the process. The NSError object describes the error.
- - screenlet:onImageEntrySelected:: Called when an item in the list is selected.
- - screenlet:onImageEntryDeleted:: Called when an image in the list is deleted.
- - screenlet:onImageEntryDeleteError:: Called when an error occurs during image file deletion. The NSError object describes the error.
- - screenlet:onImageUploadStart:: Called when an image is prepared for upload.
- - screenlet:onImageUploadProgress:: Called when the image upload progress changes.
- - screenlet:onImageUploadError:: Called when an error occurs in the image upload process. The NSError object describes the error.
- - screenlet:onImageUploaded:: Called when the image upload finishes.
- - screenlet:onImageUploadDetailViewCreated:: Called when the image upload View is instantiated. By default, the Screenlet uses a modal view controller to present this View. You only need to implement this method if you want to override this behavior. This method should present the View, passed as parameter, and then return true. For example, the following example implementation presents ImageUploadDetailViewBase as a parameter, and then uses it to customize the View's appearance:

```
func screenlet(screenlet: ImageGalleryScreenlet,
    onImageUploadDetailViewCreated uploadView: ImageUploadDetailViewBase) -> Bool {
        self.cardDeck?.cards[safe: 0]?.addPage(uploadView)
        self.cardDeck?.cards[safe: 0]?.moveRight()
        return true
}
```

129.11 Rating Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Rating Screenlet shows an asset's rating. It also lets users update or delete the rating. This Screenlet comes with different Themes that display ratings as thumbs, stars, and emojis.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensratingsentryService` (Screens compatibility plugin)	`getRatingsEntries`	With `entryId`
`ScreensratingsentryService` (Screens compatibility plugin)	`getRatingsEntries`	With `classPK` and `className`
`ScreensratingsentryService` (Screens compatibility plugin)	`updateRatingsEntry`	
`ScreensratingsentryService` (Screens compatibility plugin)	`deleteRatingsEntry`	

Module

- None

Themes

The default Theme uses the `CosmosView` library to show an asset's rating. Other custom Themes may use a different component, such as `UIButton` or others, to show the items.

This screenlet has four different Themes:

1. Like
2. Thumbs (default)
3. Stars
4. Emojis

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show a possibly outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but possibly outdated) data. |

Required Attributes

- `entryId`

If you don't use `entryId`, you must use these attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `layoutId` | `@layout` | The ID of the layout to use to show the Theme. | `autoLoad` | `boolean` | Whether the rating loads automatically when the Screenlet appears in the app's UI. The default value is `true`. | `editable` | `boolean` | Whether the user can change the rating. | `entryId` | `number` |

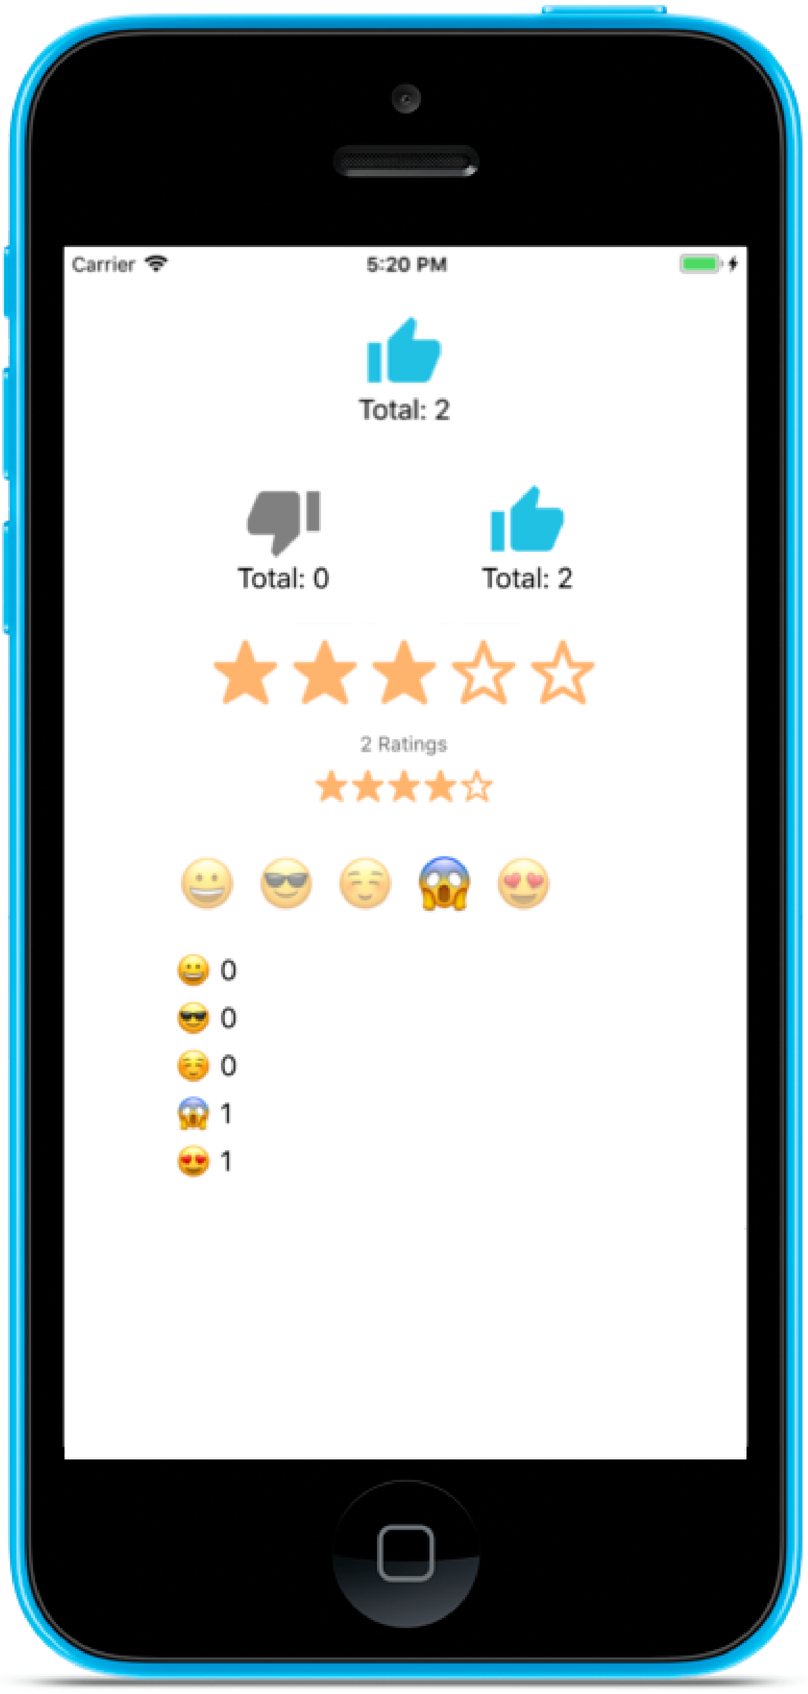

Figure 129.16: Rating Screenlet's different Themes.

The primary key of the asset with the rating to display. | `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` attribute is required when using it with `classPK` to instantiate the Screenlet.. | `classPK` | `number` | The asset's unique identifier. Only use this attribute when also using `className` to instantiate the Screenlet. | `groupId` | `number` | The ID of the site (group) containing the asset. | `offlinePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Methods

Method | Return | Explanation | `loadRatings()` | `boolean` | Starts the request to load the asset's ratings. |

Delegate

Rating Screenlet delegates some events to an object that conforms to the `RatingScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onRatingRetrieve:`: Called when the ratings are received.
- `- screenlet:onRatingDeleted:`: Called when a rating is deleted.
- `- screenlet:onRatingUpdated:`: Called when a rating is updated.
- `- screenlet:onRatingError:`: Called when an error occurs in the process. The `NSError` object describes the error.

129.12 Comment List Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment List Screenlet can list all the comments of an asset in a Liferay instance. It also lets the user update or delete comments.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`getCommentsWithClassName`	
`ScreenscommentService` (Screens compatibility plugin)	`getCommentsCount`	

Module

- None

Themes

- Default

The Default Theme uses an iOS `UITableView` to show an asset's comments. Other Themes may use a different component, such as iOS's `UICollectionView` or others, to show the items.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the list from the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error. If the Screenlet successfully loads the list, it stores the data in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the list from the Liferay instance. If this succeeds, the Screenlet shows the list to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the list from the local cache. If the list doesn't exist there, the Screenlet uses the delegate to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show a possibly outdated version when there's no connection. | `cache-first` | The Screenlet loads the list from the local cache. If the list isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but possibly outdated) data. |

You're doing great!

Emma Kelty
2 months ago - Edited
Hello my friend :) How are u?

Figure 129.17: Comment List Screenlet using the Default Theme.

Required Attributes

- `className`
- `classPK`

Attributes

Attribute	Data type	Explanation
`className`	`string`	The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet.
`classPK`	`number`	The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet.
`offlinePolicy`	`string`	The offline mode setting. The default is `remote-first`. See the Offline section for details.
`editable`	`boolean`	Whether the user can edit the comment.
`autoLoad`	`boolean`	Whether the list should automatically load when the Screenlet appears in the app's UI. The default value is `true`.
`refreshControl`	`boolean`	Defines whether a standard iOS `UIRefreshControl` is shown when the user does the pull to refresh gesture. The default value is `true`.
`firstPageSize`	`number`	The number of items retrieved from the server for display on the first page. The default value is `50`.
`pageSize`	`number`	The number of items retrieved from the server for display on the second and subsequent pages. The default value is `25`.
`obcClassName`	`string`	The name of the `OrderByComparator` class to use to sort the results. You can only use classes that extend `OrderByComparator<MBMessage>`. If you don't want to sort the results, you can omit this property.

Methods

Method	Return	Explanation
`loadList()`	`boolean`	Starts the request to load the list. This list is shown when the response is received. Returns `true` if the request is sent.

Delegate

Comment List Screenlet delegates some events to an object that conforms to the `ComentListScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onListResponseComments:`: Called when the Screenlet receives the comments.
- `- screenlet:onCommentListError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onSelectedComment:`: Called when a comment is selected.
- `- screenlet:onDeletedComment:`: Called when a comment is deleted.
- `- screenlet:onCommentDelete:`: Called when the Screenlet prepares a comment for deletion.
- `- screenlet:onUpdatedComment:`: Called when a comment is updated.
- `- screenlet:onCommentUpdate:`: Called when the Screenlet prepares a comment for update.

129.13 Comment Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment Display Screenlet can show one comment of an asset in a Liferay instance. It also lets the user update or delete the comment.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`getCommentWithCommentId`	
`ScreenscommentService` (Screens compatibility plugin)	`updateComment`	
`CommentmanagerjsonwsService`	`deleteComment`	

Module

- None

Themes

- Default

The Default Theme uses User Portrait Screenlet and iOS `UILabel` elements to show an asset's comment. Other Themes may use different components to show the comment.

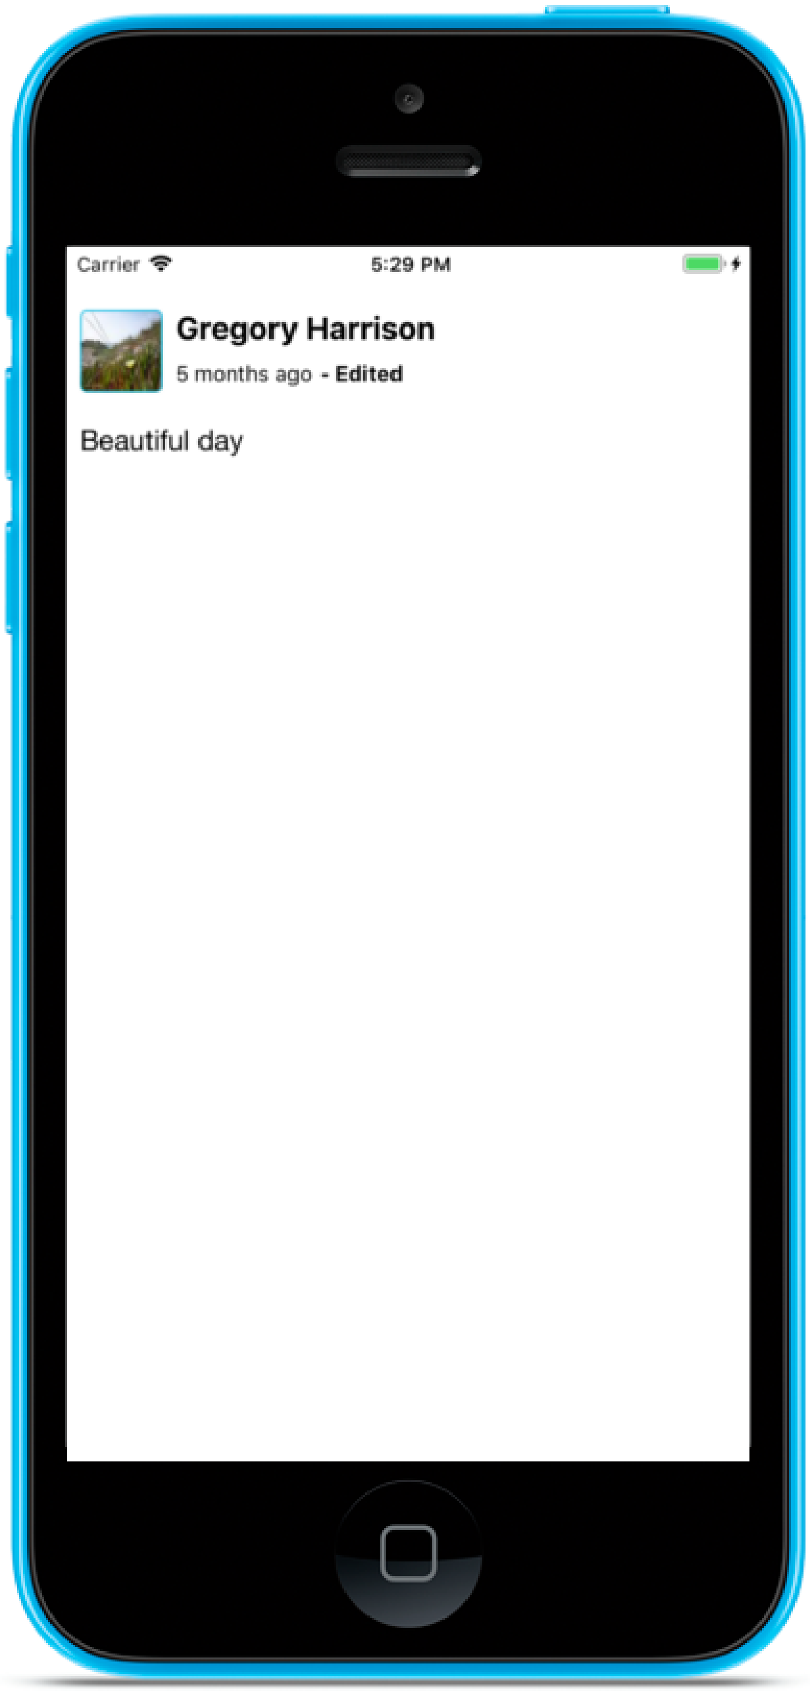

Figure 129.18: Comment Display Screenlet using the Default Theme.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. This Screenlet supports the `remote-only`, `cache-only`, `remote-first`, and `cache-first` offline mode policies.

These policies take the following actions when loading a comment from a Liferay instance:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

These policies take the following actions when updating or deleting a comment in a Liferay instance:

Policy | What happens | When to use | `remote-only` | The Screenlet sends the data to the Liferay instance. If a connection issue occurs, the Screenlet uses the delegate to notify the developer about the error, but it also discards the data. | Use this policy to make sure the Liferay instance always has the most recent version of the data. | `cache-only` | The Screenlet stores the data in the local cache. | Use this policy when you need to save the data locally, but don't want to update it in the Liferay instance. | `remote-first` | The Screenlet sends the data to the Liferay instance. If this succeeds, it also stores the data in the local cache for later use. If a connection issue occurs, the Screenlet stores the data in the local cache and sends it to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the data to the Liferay instance as soon as the connection is restored. | `cache-first` | The Screenlet stores the data in the local cache and then attempts to send it to the Liferay instance. If a connection issue occurs, the Screenlet sends the data to the Liferay instance when the connection is re-established. | Use this policy when you need to make sure the Screenlet sends the data to the Liferay instance as soon as the connection is restored. Compared to `remote-first`, this policy always stores the data in the cache. The `remote-first` policy only stores the data in the event of a network error. |

Required Attributes

- `commentId`

Attributes

Attribute | Data type | Explanation | `commentId` | `number` | The primary key of the comment to display. | `autoLoad` | `boolean` | Whether the list should automatically load when the Screenlet appears in the app's UI. The default value is `true`. | `editable` | `boolean` | Whether the user can edit the comment. | `offlinePolicy` | `string` | The offline mode setting. The default is `remote-first`. See the Offline section for details. |

Methods

Method | Return | Explanation | `load()` | none | Starts the request to load the comment. |

Delegate

Comment Display Screenlet delegates some events to an object that conforms to the `CommentDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onCommentLoaded:`: Called when the Screenlet loads the comment.
- `- screenlet:onLoadCommentError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onSelectedComment:`: Called when a comment is selected.
- `- screenlet:onDeletedComment:`: Called when a comment is deleted.
- `- screenlet:onCommentDelete:`: Called when the Screenlet prepares the comment for deletion.
- `- screenlet:onUpdatedComment:`: Called when a comment is updated.
- `- screenlet:onCommentUpdate:`: Called when the Screenlet prepares the comment for update.

129.14 Comment Add Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Comment Add Screenlet can add a comment to an asset in a Liferay instance.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreenscommentService` (Screens compatibility plugin)	`addComment`	

Module

- None

Themes

- Default

The Default Theme uses the iOS elements `UITextField` and `UIButton` to add a comment to an asset. Other Themes may use other components to show the comment.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet sends the data to the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully sends the data, it also stores it in the local cache. | Use this policy when you always need to send updated data, and send nothing when there's no connection. | `cache-only` | The Screenlet sends the data to the local cache. If an error occurs, the Screenlet uses the listener to notify the developer. | Use this policy when you always need to store local data without sending remote information under any circumstance. | `remote-first` | The Screenlet sends the data to the Liferay instance. If this succeeds, the Screenlet also stores the data in the local cache. If a connection issue occurs, the Screenlet stores the data to the local cache and sends it to the Liferay instance when the connection is restored. If an error occurs, the Screenlet uses the listener to notify the developer. | Use this policy to send the most recent version of the data when connected, and store the data for later synchronization when there's no connection. | `cache-first` | The Screenlet sends the data to the local cache, then sends it to the Liferay instance. If sending the data to the Liferay instance fails, the Screenlet still stores the data locally and then notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and store local (but possibly outdated) data. |

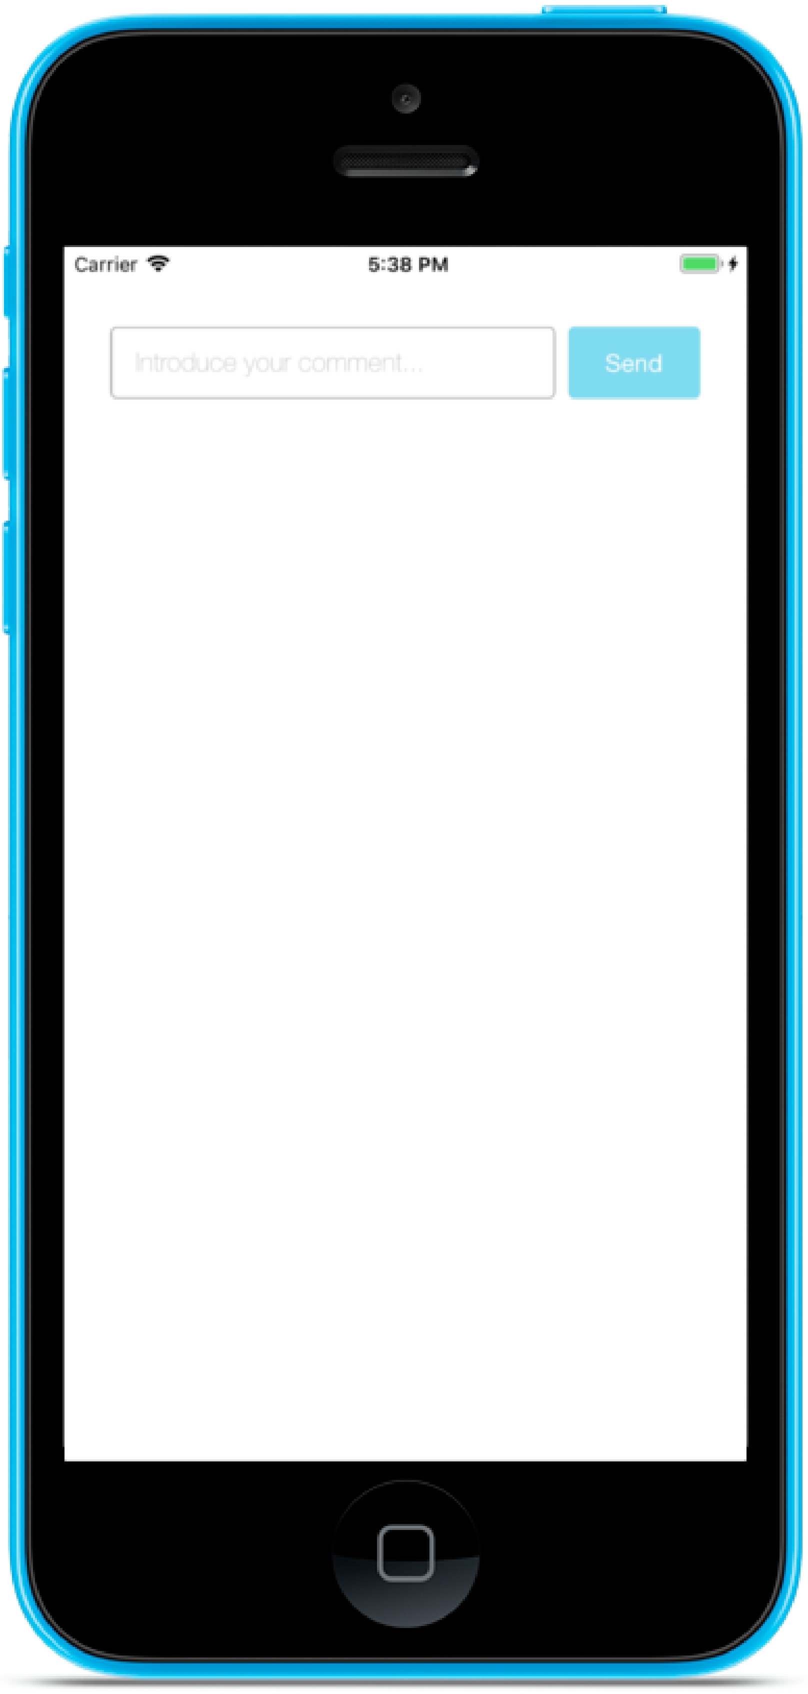

Figure 129.19: Comment Add Screenlet using the Default Theme.

Required Attributes

- `className`
- `classPK`

Attributes

Attribute	Data type	Explanation
`className`	`string`	The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet.
`classPK`	`number`	The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet.
`offlinePolicy`	`string`	The offline mode setting. The default value is `remote-first`. See the Offline section for details.

Delegate

Comment Add Screenlet delegates some events to an object that conforms to the `CommentAddScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onCommentAdded:`: Called when the Screenlet adds a comment.

- `- screenlet:onAddCommentError:`: Called when an error occurs while adding a comment. The `NSError` object describes the error.

- `- screenlet:onCommentUpdated:`: Called when the Screenlet prepares a comment for update.

- `- screenlet:onUpdateCommentError:`: Called when an error occurs while updating a comment. The `NSError` object describes the error.

129.15 Asset Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Asset Display Screenlet can display an asset from a Liferay instance. The Screenlet can currently display Documents and Media files (`DLFileEntry` images, videos, audio files, and PDFs), blogs entries (`BlogsEntry`) and web content articles (`WebContent`).

Asset Display Screenlet can also display your custom asset types. See the delegate section of this document for details.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default Theme uses different UI elements to show each asset type. For example, it displays images with `UIImageView`, and blogs with `UILabel`.

This Screenlet can also render other Screenlets:

- Images: Image Display Screenlet
- Videos: Video Display Screenlet
- Audio: Audio Display Screenlet
- PDFs: PDF Display Screenlet
- Blog entries: Blogs Entry Display Screenlet
- Web content: Web Content Display Screenlet

These Screenlets can also be used alone without Asset Display Screenlet.

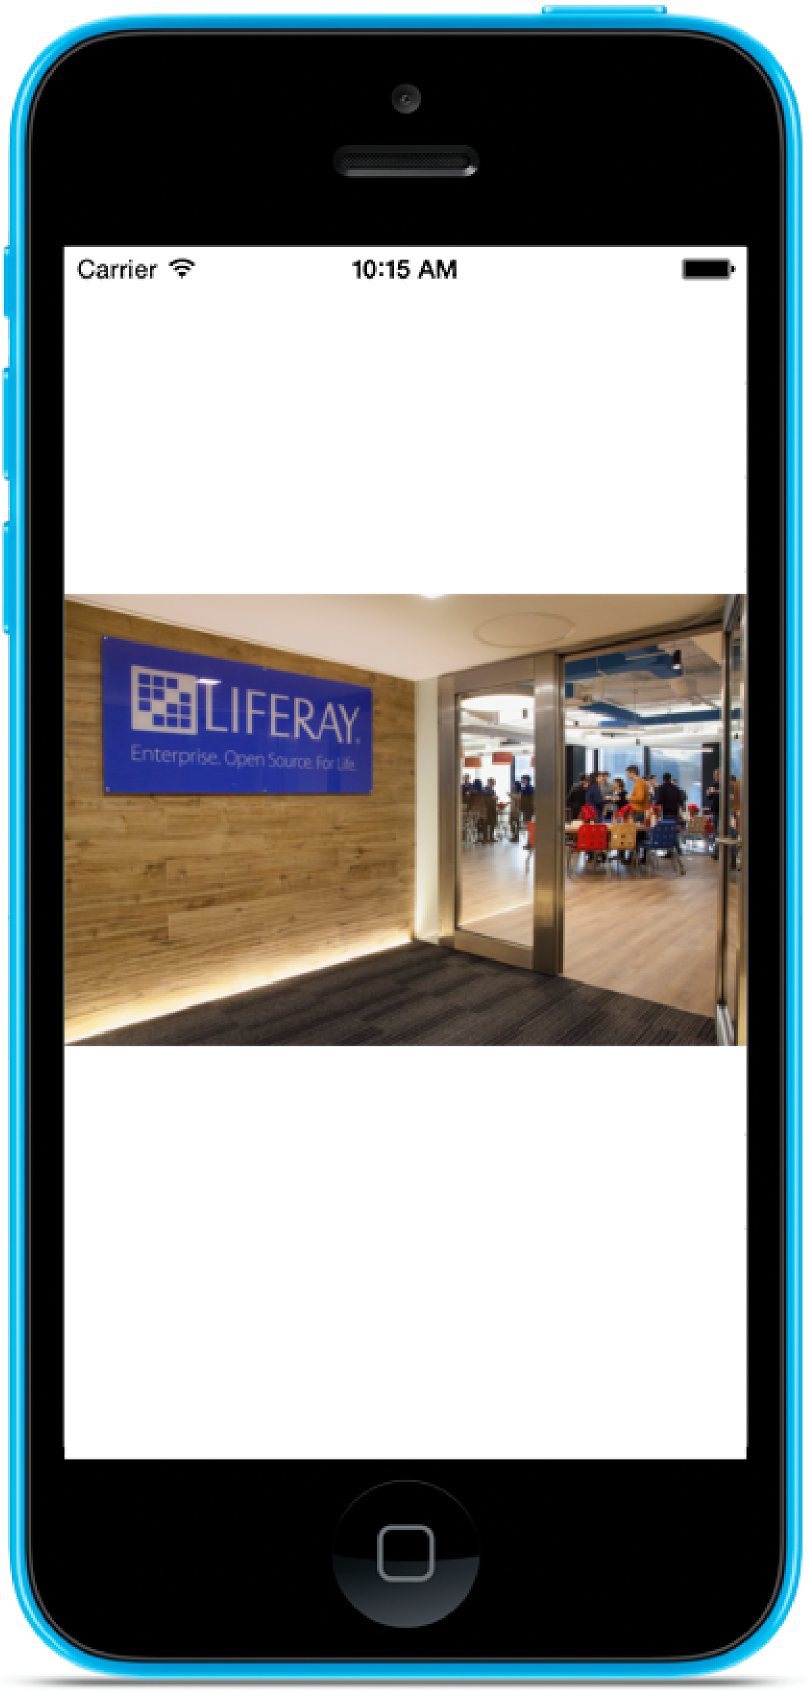

Figure 129.20: Asset Display Screenlet using the Default Theme.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId`

Instead of `assetEntryId`, you can use both of these attributes:

- `className`
- `classPK`

If you don't use the above attributes, you must use this attribute:

- `portletItemName`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the asset. | `className` | `string` | The asset's fully qualified class name. For example, a blog entry's `className` is `com.liferay.blogs.kernel.model.BlogsEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The asset's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `portletItemName` | `string` | The name of the configuration template you used in the Asset Publisher. To use this feature, add an Asset Publisher to one of your site's pages (it may be a hidden page), configure the Asset Publisher's filter (in *Configuration → Setup → Asset Selection*), and then use the Asset Publisher's *Configuration Templates* option to save this configuration with a name. Use this name as this attribute's value. If there is more than one asset in the configuration, the Screenlet displays only the first one. | `assetEntry` | `Asset` | The `Asset` object to display, selected from a list of assets. Note that if you use this attribute, the Screenlet doesn't need to call the server. | `autoLoad` | `boolean` | Whether the asset automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. |

Delegate

Asset Display Screenlet delegates some events to an object that conforms to the `AssetDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onAssetResponse:`: Called when the Screenlet receives the asset.
- `- screenlet:onAssetError:`: Called when an error occurs in the process. The `NSError` object describes the error.
- `- screenlet:onConfigureScreenlet:`: Called when the child Screenlet (the Screenlet rendered inside Asset Display Screenlet) has been successfully initialized. Use this method to configure or customize it. The example implementation here sets the child Blogs Entry Display Screenlet's background color to gray:

```
func screenlet(screenlet: AssetDisplayScreenlet, onConfigureScreenlet,
    childScreenlet: BaseScreenlet?, onAsset asset: Asset) {
        if childScreenlet is BlogsEntryDisplayScreenlet {
            childScreenlet?.screenletView?.backgroundColor = UIColor.grayColor()
        }
}
```

- `- screenlet:onAsset:`: Called to render a custom asset. The following example implementation renders a portal user (`User`). If the asset is a user, this method instantiates a custom `UserProfileView` to render that user:

```
public func screenlet(screenlet: AssetDisplayScreenlet, onAsset asset: Asset) -> UIView? {
    if let type = asset.attributes["object"]?.allKeys.first as? String {
        if type == "user" {
            let view = NSBundle.mainBundle().loadNibNamed("UserProfileView", owner: self,
                options: nil)![0] as? UserProfileView

            view?.user = User(attributes: asset.attributes)

            return view
        }
    }
    return nil
}
```

129.16 Blogs Entry Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Blogs Entry Display Screenlet displays a single blog entry. Image Display Screenlet renders any header image the blogs entry may have.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

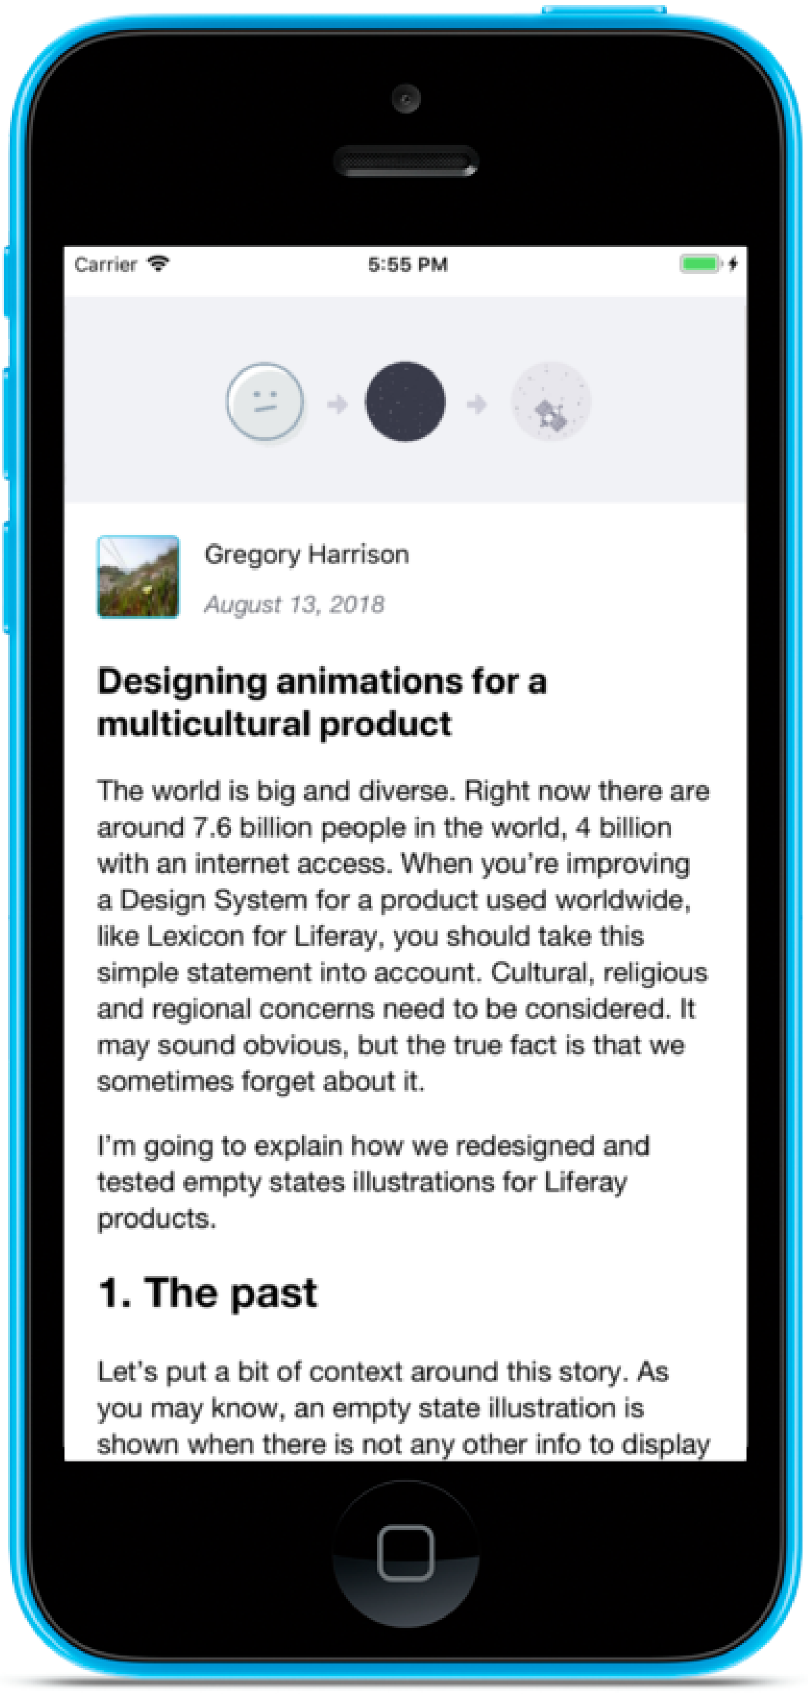
Themes

- Default

The Default Theme can use different components to show a blogs entry (`BlogsEntry`). For example, it uses `UILabel` to show a blog's text, and User Portrait Screenlet to show the profile picture of the Liferay user who posted it. Note that other Themes may use different components.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:



Carrier 5:55 PM

Gregory Harrison

Designing animations for a multicultural product

The world is big and diverse. Right now there are around 7.6 billion people in the world, 4 billion with an internet access. When you're improving a Design System for a product used worldwide, like Lexicon for Liferay, you should take this simple statement into account. Cultural, religious and regional concerns need to be considered. It may sound obvious, but the true fact is that we sometimes forget about it.

I'm going to explain how we redesigned and tested empty states illustrations for Liferay products.

1. The past

Let's put a bit of context around this story. As you may know, an empty state illustration is shown when there is not any other info to display

Figure 129.21: Blogs Entry Display Screenlet using the Default Theme.

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote data under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId` or `classPK`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the blog entry (`BlogsEntry`). | `classPK` | `number` | The `BlogsEntry` object's unique identifier. | `autoLoad` | `boolean` | Whether the blog entry automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. |

Delegate

Blogs Entry Display Screenlet delegates some events to an object that conforms to the `BlogsEntryDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onBlogEntryResponse:`: Called when the Screenlet receives the `BlogsEntry` object.

- `- screenlet:onBlogEntryError:`: Called when an error occurs in the process. The `NSError` object describes the error.

129.17 Image Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Image Display Screenlet displays an image file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default Theme uses an iOS `UIImageView` for displaying the image.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when

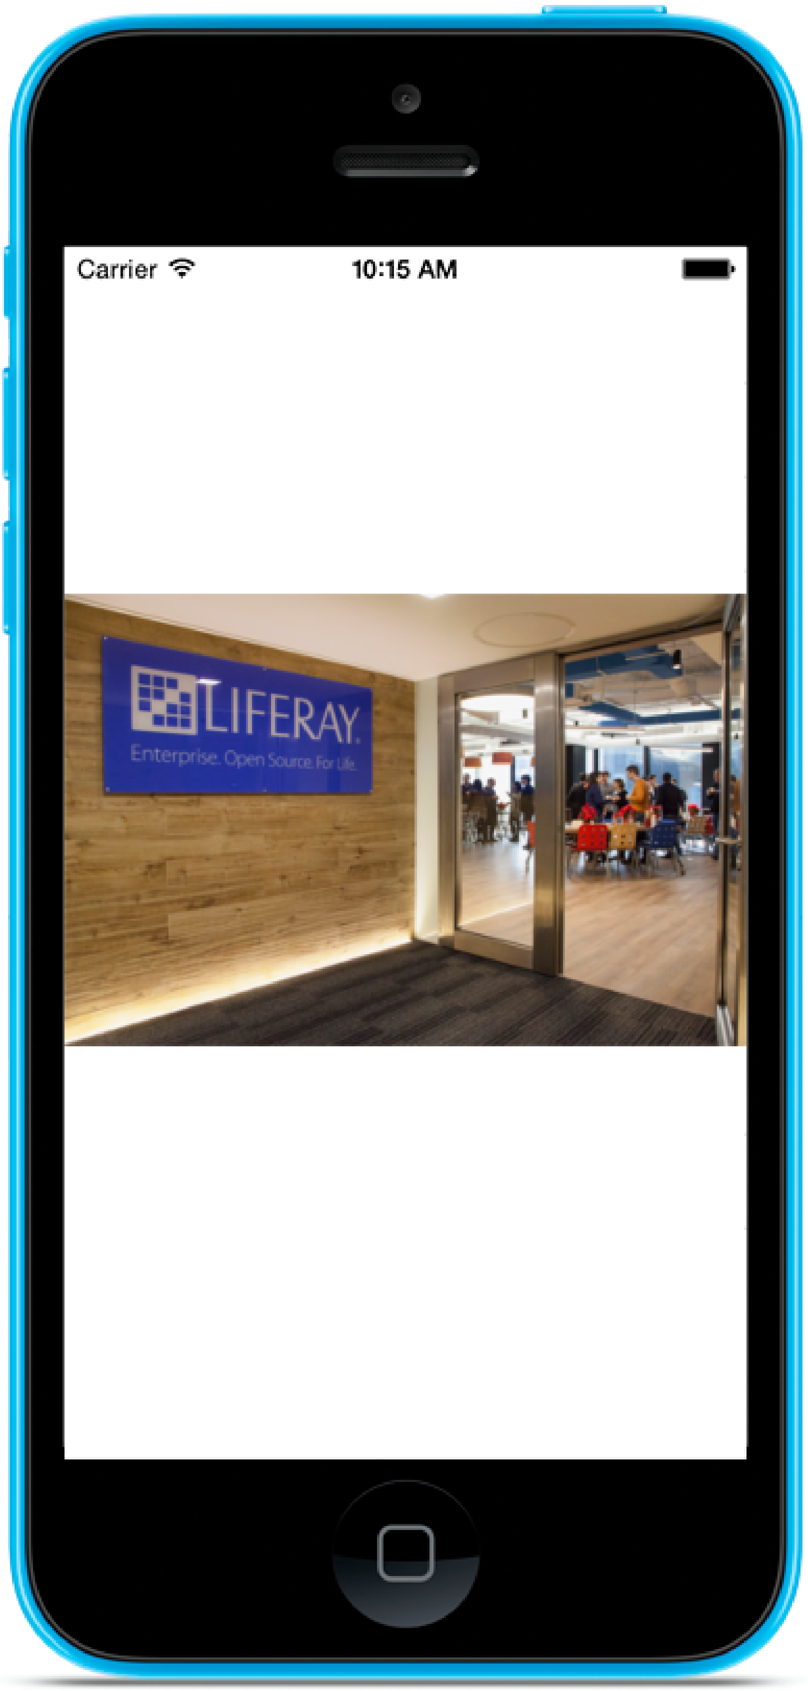

Figure 129.22: Image Display Screenlet using the Default Theme.

you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId`

If you don't use `assetEntryId`, you must use these attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the image. | `className` | `string` | The image's fully qualified class name. Since files in a Documents and Media Library are `DLFileEntry` objects, their `className` is `com.liferay.document.library.kernel.model.DLFileEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The image's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `autoLoad` | `boolean` | Whether the image automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. The default value is `remote-first`. See the Offline section for details. |

Delegate

Because images are files, Image Display Screenlet delegates its events to an object that conforms to the `FileDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFileAssetResponse:`: Called when the Screenlet receives the image file.

- `- screenlet:onFileAssetError:`: Called when an error occurs in the process. The `NSError` object describes the error.

129.18 Video Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Video Display Screenlet displays a video file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default Theme uses an iOS `AVPlayerViewController` to display the video.

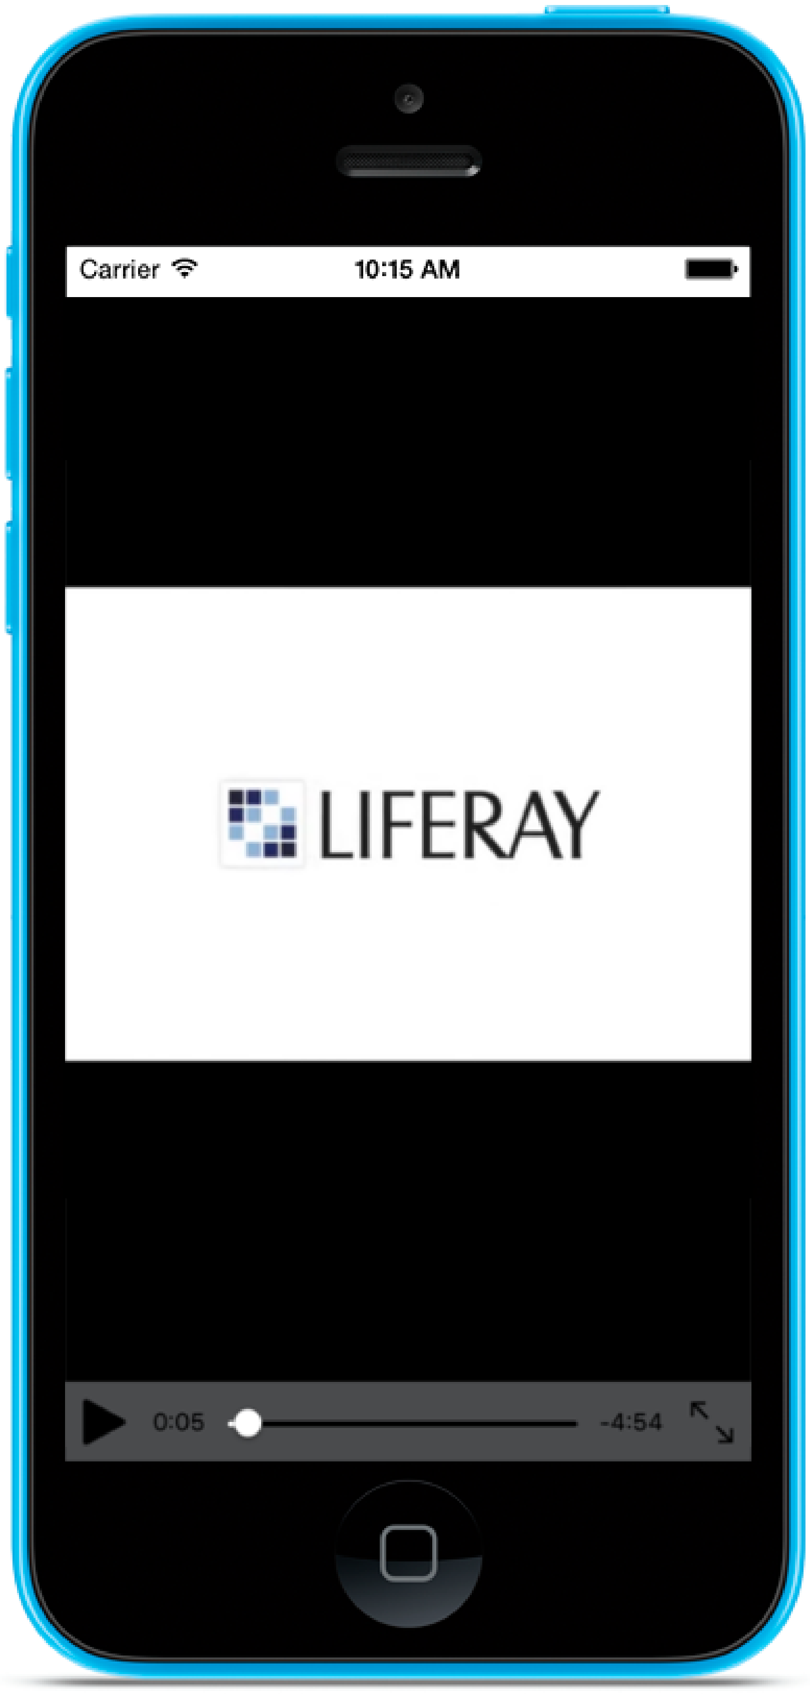

Figure 129.23: Video Display Screenlet using the Default Theme.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId`

If you don't use `assetEntryId`, you must use these attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the video file. | `className` | `string` | The video file's fully qualified class name. Since files in a Documents and Media Library are `DLFileEntry` objects, the `className` is `com.liferay.document.library.kernel.model.DLFileEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The video file's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `autoLoad` | `boolean` | Whether the video automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Delegate

Because images are files, Video Display Screenlet delegates its events to an object that conforms to the `FileDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFileAssetResponse:`: Called when the Screenlet receives the image file.

- `- screenlet:onFileAssetError:`: Called when an error occurs in the process. The `NSError` object describes the error.

129.19 Audio Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Audio Display Screenlet displays an audio file from a Liferay instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default Theme uses an iOS `AVAudioPlayer` to display the audio player. For the player components, this Theme uses `UIButton`, `UISlider`, and several `UILabel` instances.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId`

If you don't use `assetEntryId`, you must use these attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the audio file. | `className` | `string` | The audio file's fully qualified class name. Since files in a Documents and Media Library are `DLFileEntry` objects, their `className` is `com.liferay.document.library.kernel.model.DLFileEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The audio file's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `autoLoad` | `boolean` | Whether the audio file automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. See the Offline section for details. |

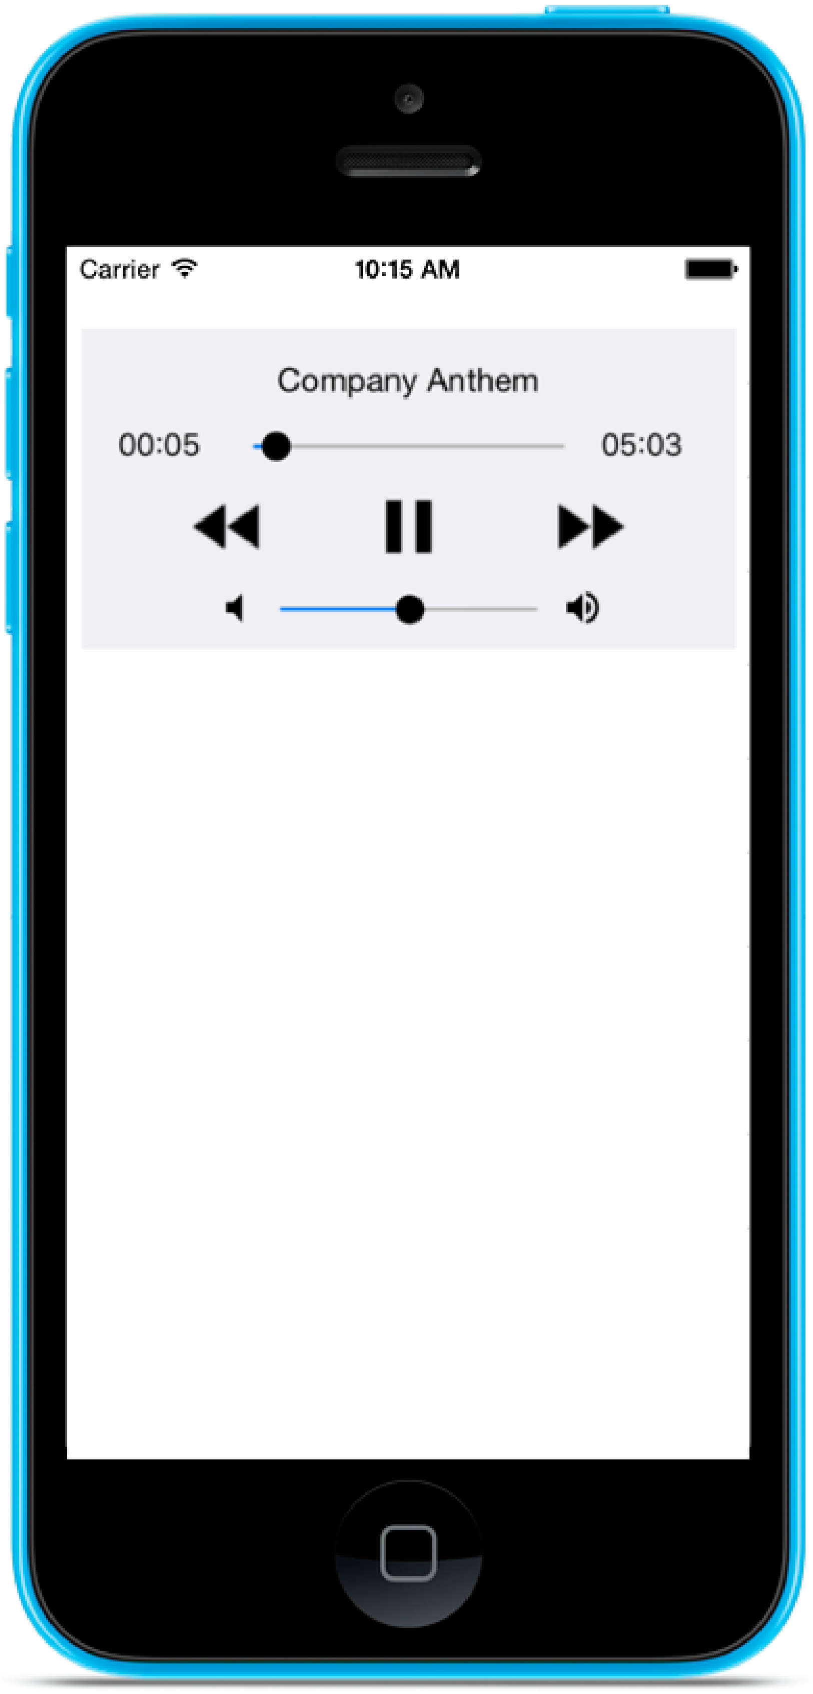

Figure 129.24: Audio Display Screenlet using the Default Theme.

Delegate

Audio Display Screenlet delegates its events to an object that conforms to the `FileDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFileAssetResponse:`: Called when the Screenlet receives the audio file.
- `- screenlet:onFileAssetError:`: Called when an error occurs in the process. An `NSError` object describes the error.

129.20 PDF Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

PDF Display Screenlet displays a PDF file from a Liferay Instance's Documents and Media Library.

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default Theme uses an iOS `UIWebView` for displaying the PDF file.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Required Attributes

- `assetEntryId`

If you don't use `assetEntryId`, you must use these attributes:

- `className`
- `classPK`

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the PDF file. | `className` | `string` | The PDF file's fully qualified class name. Since files in a Documents and Media Library are `DLFileEntry` objects, their `className` is `com.liferay.document.library.kernel.model.DLFileEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The PDF file's unique identifier. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `autoLoad` |

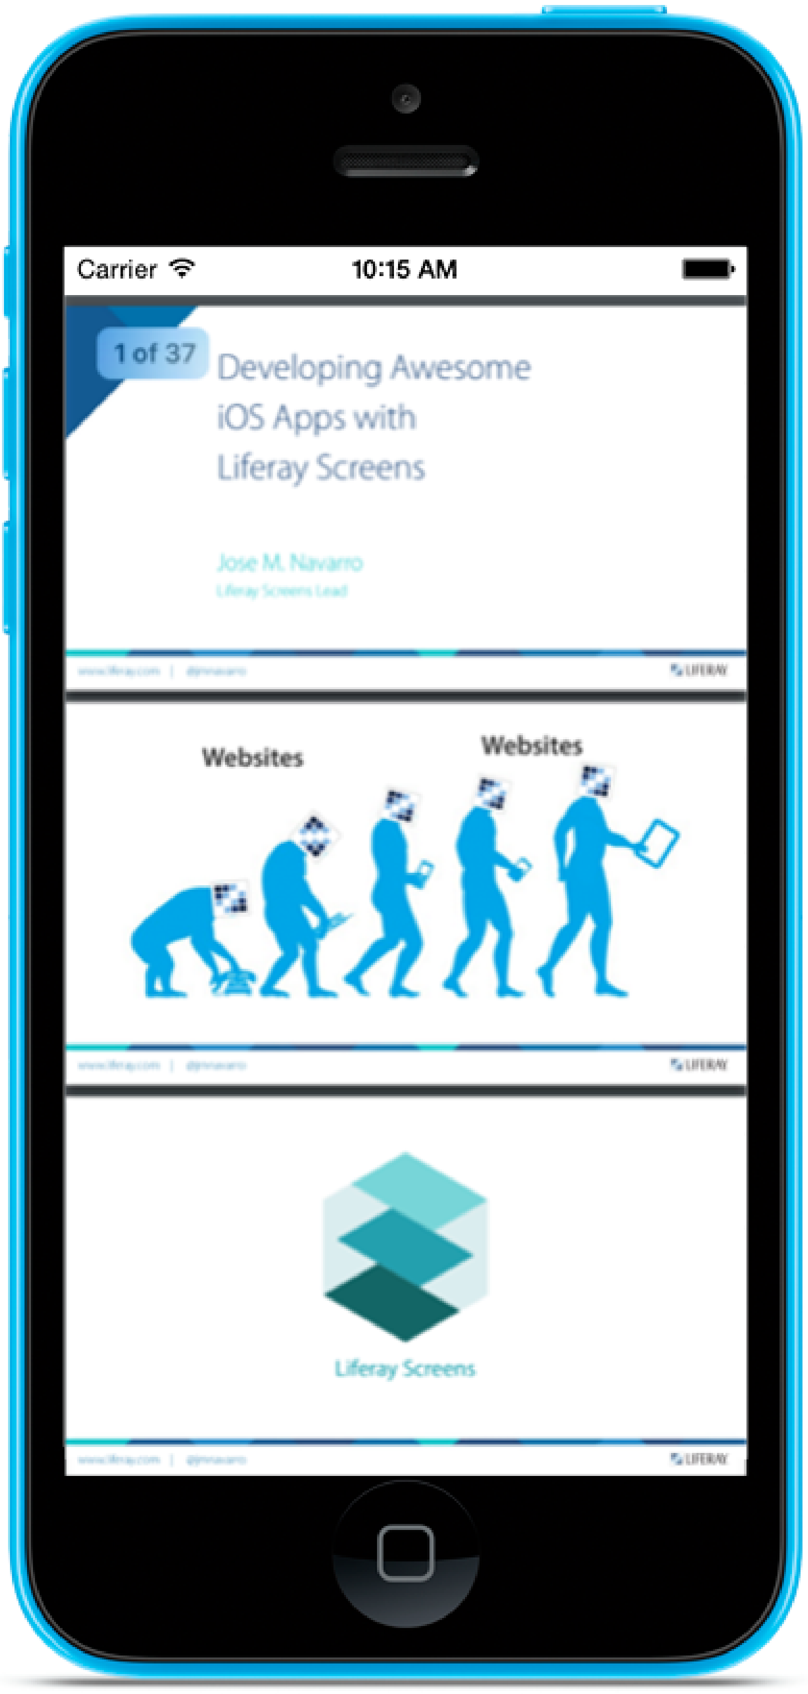

Figure 129.25: PDF Display Screenlet using the Default Theme.

`boolean` | Whether the PDF automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Delegate

Because PDFs are files, PDF Display Screenlet delegates some events to an object that conforms to the `FileDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFileAssetResponse:`: Called when the Screenlet receives the PDF.
- `- screenlet:onFileAssetError:`: Called when an error occurs in the process. An `NSError` object describes the error.

129.21 File Display Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

File Display Screenlet shows a single file from a Liferay DXP instance's Documents and Media Library. Use this Screenlet to display file types not covered by the other display Screenlets (e.g., DOC, PPT, XLS).

JSON Services Used

Screenlets in Liferay Screens call JSON web services in the portal. This Screenlet calls the following services and methods.

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `entryId`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntry`	With `classPK` and `className`

Service	Method	Notes
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `entryQuery`
`ScreensassetentryService` (Screens compatibility plugin)	`getAssetEntries`	With `companyId`, `groupId`, and `portletItemName`

Module

- None

Themes

- Default

The Default View uses an iOS `UIWebView` for displaying the file.

Offline

This Screenlet supports offline mode so it can function without a network connection. For more information on how offline mode works, see the tutorial on its architecture. Here are the offline mode policies that you can use with this Screenlet:

Policy | What happens | When to use | `remote-only` | The Screenlet loads the data from the Liferay instance. If a connection issue occurs, the Screenlet uses the listener to notify the developer about the error. If the Screenlet successfully loads the data, it stores it in the local cache for later use. | Use this policy when you always need to show updated data, and show nothing when there's no connection. | `cache-only` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet uses the listener to notify the developer about the error. | Use this policy when you always need to show local data, without retrieving remote information under any circumstance. | `remote-first` | The Screenlet loads the data from the Liferay instance. If this succeeds, the Screenlet shows the data to the user and stores it in the local cache for later use. If a connection issue occurs, the Screenlet retrieves the data from the local cache. If the data doesn't exist there, the Screenlet uses the listener to notify the developer about the error. | Use this policy to show the most recent version of the data when connected, but show an outdated version when there's no connection. | `cache-first` | The Screenlet loads the data from the local cache. If the data isn't there, the Screenlet requests it from the Liferay instance and notifies the developer about any errors that occur (including connectivity errors). | Use this policy to save bandwidth and loading time in case you have local (but probably outdated) data. |

Attributes

Attribute | Data type | Explanation | `assetEntryId` | `number` | The primary key of the file. | `className` | `string` | The file's fully qualified class name. Since files in a Documents and Media Library are `DLFileEntry` objects, their `className` is `com.liferay.document.library.kernel.model.DLFileEntry`. The `className` and `classPK` attributes are required to instantiate the Screenlet. | `classPK` | `number` | The file's unique identifier.

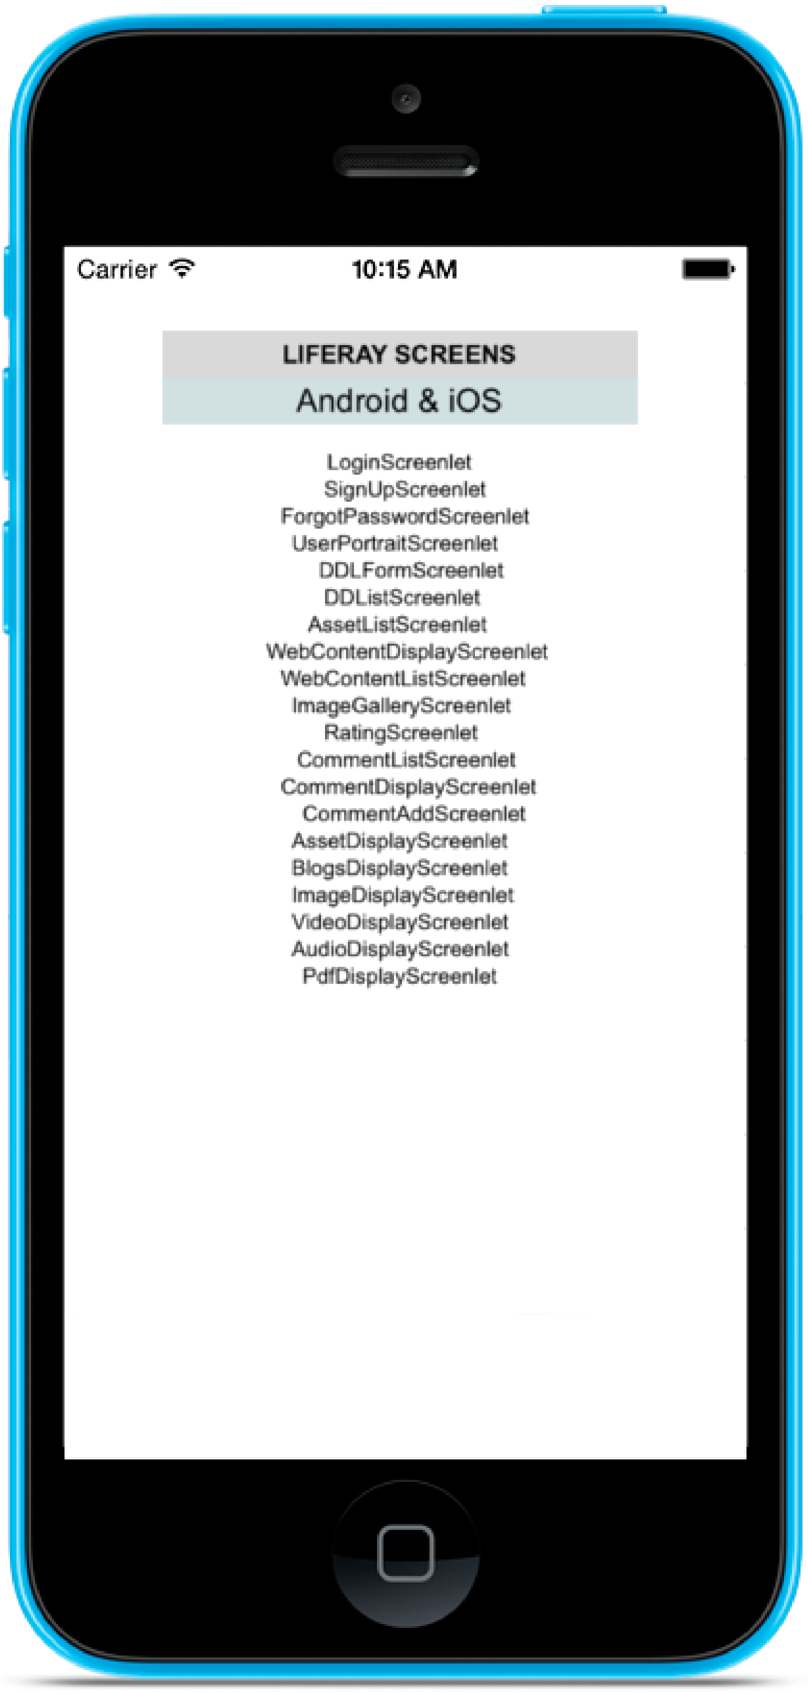

Figure 129.26: File Display Screenlet using the Default View.

The `className` and `classPK` attributes are required to instantiate the Screenlet. | `autoLoad` | `boolean` | Whether the file automatically loads when the Screenlet appears in the app's UI. The default value is `true`. | `offlinePolicy` | `string` | The offline mode setting. See the Offline section for details. |

Delegate

File Display Screenlet delegates some events to an object that conforms to the `FileDisplayScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `- screenlet:onFileAssetResponse:`: Called when the Screenlet receives the file.
- `- screenlet:onFileAssetError:`: Called when an error occurs in the process. An `NSError` object describes the error.

129.22 Web Screenlet for iOS

Requirements

- Xcode 9.3 or above
- iOS 11 SDK
- Liferay Portal 6.2 CE/EE, Liferay CE Portal 7.0/7.1, Liferay DXP 7.0+
- Liferay Screens Compatibility app (CE or EE/DXP). This app is preinstalled in Liferay CE Portal 7.0/7.1 and Liferay DXP 7.0+.

Compatibility

- iOS 9 and above

Xamarin Requirements

- Visual Studio 7.2
- Mono .NET framework 5.4.1.6

Features

Web Screenlet lets you display any web page. It also lets you customize the web page through injection of local and remote JavaScript and CSS files. If you're using Liferay DXP as backend, you can use Application Display Templates in your page to customize its content from the server side.

Module

- None

Themes

- Default

The Default Theme uses an iOS `WKWebView` for displaying the web page.

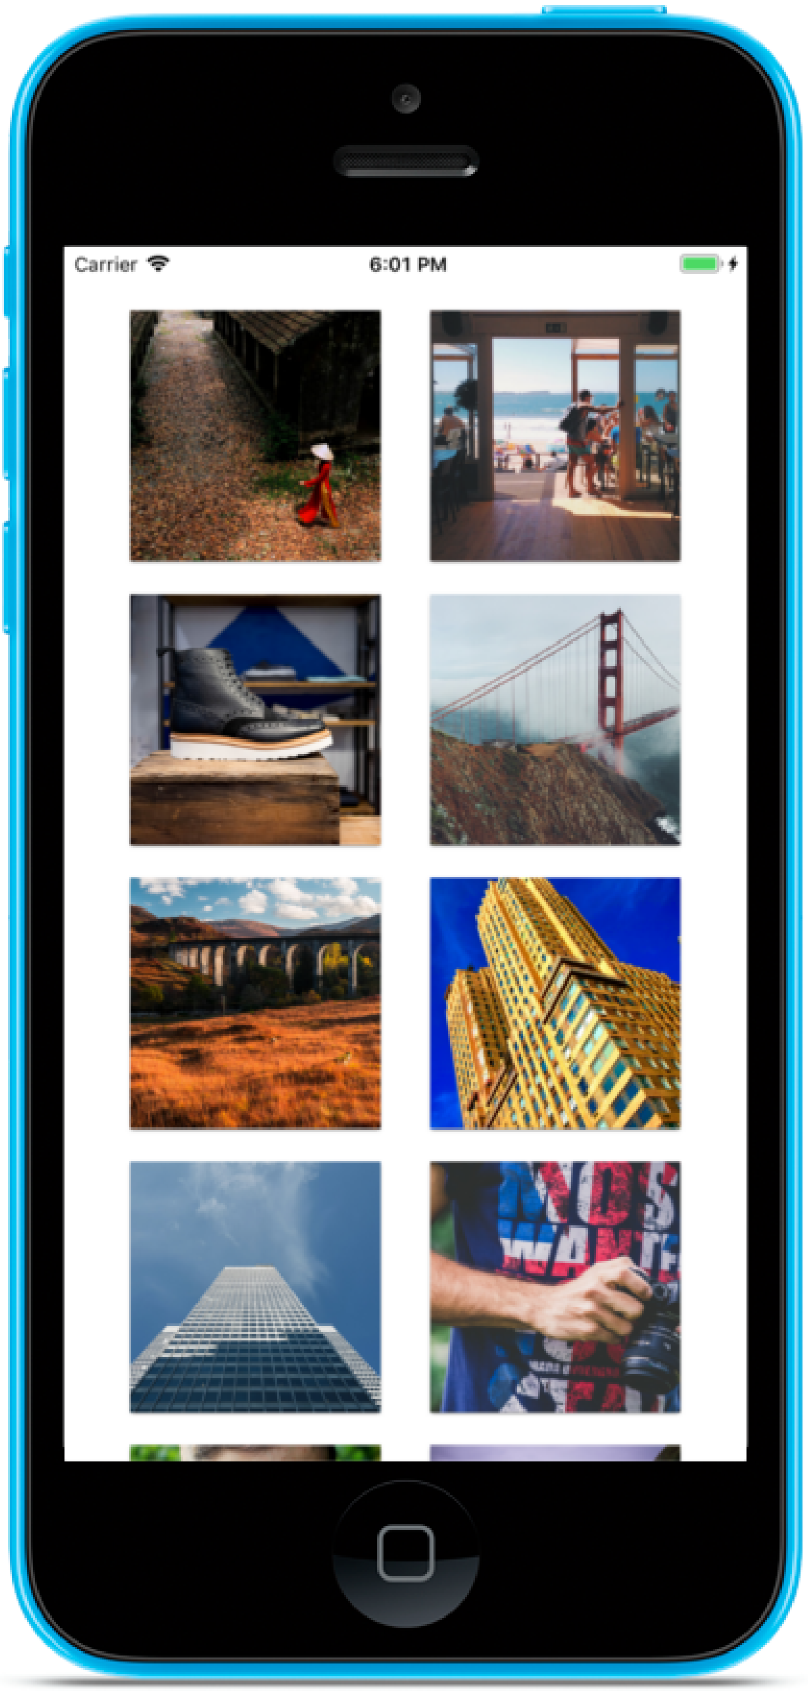

Figure 129.27: Web Screenlet using the Default Theme.

Configuration

To learn how to use Web Screenlet, follow the steps in the tutorial Rendering Web Pages in Your iOS App. That tutorial gives detailed instructions for using the configuration items described here.

Web Screenlet has `WebScreenletConfiguration` and `WebScreenletConfigurationBuilder` objects that you can use together to supply the parameters that the Screenlet needs to work. `WebScreenletConfigurationBuilder` has the following methods, which let you supply the described configuration parameters:

Method | Returns | Explanation | `addJs(localFile: String)` | `WebScreenletConfigurationBuilder` | Adds a local JavaScript file with the supplied filename. | `addCss(localFile: String)` | `WebScreenletConfigurationBuilder` | Adds a local CSS file with the supplied filename. | `addJs(url: String)` | `WebScreenletConfigurationBuilder` | Adds a JavaScript file from the supplied URL. | `addCss(url: String)` | `WebScreenletConfigurationBuilder` | Adds a CSS file from the supplied URL. | `set(webType: WebType)` | `WebScreenletConfigurationBuilder` | Sets the `WebType`. | `enableCordova()` | `WebScreenletConfigurationBuilder` | Enables Cordova inside the Web Screenlet. | `load()` | `WebScreenletConfiguration` | Returns the `WebScreenletConfiguration` object that you can set to the Screenlet instance. |

Note: If you want to add comments in the scripts, use the `/**/` notation.

WebType

- **WebType.liferayAuthenticated** (default): Displays a Liferay DXP page that requires authentication. The user must therefore be logged in with Screens via Login Screenlet or a `SessionContext` method. For this `WebType`, the URL you must pass to the `WebScreenletConfigurationBuilder` constructor is a relative URL. For example, if the full URL is `http://screens.liferay.org.es/web/guest/blog`, then the URL you must supply to the constructor is `/web/guest/blog`.

- **WebType.other**: Displays any other page. For this `WebType`, the URL you must pass to the `WebScreenletConfigurationBuilder` constructor is a full URL. For example, if the full URL is `http://screens.liferay.org.es/web/guest/blog`, then you must supply that URL to the constructor.

Attributes

Attribute | Data type | Explanation | `autoLoad` | `boolean` | Whether to load the page automatically when the Screenlet appears in the app's UI. The default value is `true`. | `loggingEnabled` | `boolean` | Whether logging is enabled. | `isScrollEnabled` | `boolean` | Whether to enable scrolling on the page inside the Screenlet. |

Delegate

Web Screenlet delegates some events to an object that conforms to the `WebScreenletDelegate` protocol. This protocol lets you implement the following methods:

- `onWebLoad(_:url:)`: Called when the Screenlet loads the page.

```
func onWebLoad(_ screenlet: WebScreenlet, url: String) {
    ...
}
```

- `screenlet(_:onScriptMessageNamespace:onScriptMessage:)`: Called when the `WKWebView` sends a message.

  ```
  func screenlet(_ screenlet: WebScreenlet,
            onScriptMessageNamespace namespace: String,
            onScriptMessage message: String) {
      ...
  }
  ```

- `screenlet(_:onError:)`: Called when an error occurs in the process. The `NSError` object describes the error.

  ```
  func screenlet(_ screenlet: WebScreenlet, onError error: NSError) {
      ...
  }
  ```

129.23 SyncManagerDelegate

The `SyncManagerDelegate` class is required to use Screenlets with offline mode. This class receives the events produced in the synchronization process. This document describes the class's methods.

Methods

The following method is invoked when the synchronization process is started. The number of items to be synced are passed.

```
syncManager(manager: SyncManager, itemsCount: UInt)
```

The following method is invoked when an item synchronization is about to start.

```
syncManager(manager: SyncManager, onItemSyncScreenlet screenlet: String,
    startKey: String, attributes: [String:AnyObject])
```

- `screenlet`: the screenlet name that stored this cache element
- `startKey`: the cache key where the item is stored
- `attributes`: some attributes stored together with the element. The specific attributes depend on the type of the entry. For more details, read the screenlet reference documentation.

The following method is invoked when an item synchronization is successfully completed.

```
syncManager(manager: SyncManager, onItemSyncScreenlet screenlet: String,
    completedKey: String, attributes: [String:AnyObject])
```

- `screenlet`: the screenlet name that stored this cache element
- `completedKey`: the cache key where the item is stored
- `attributes`: some attributes stored together with the element. The specific attributes depend on the type of the entry. For more details, read the screenlet reference documentation.

The following method is invoked when an item synchronization fails.

```
syncManager(manager: SyncManager, onItemSyncScreenlet screenlet: String,
    failedKey: String, attributes: [String:AnyObject], error: NSError)
```

- `screenlet`: the screenlet name that stored this cache element

- `failedKey`: the cache key where the item is stored
- `attributes`: some attributes stored together with the element. The specific attributes will depend on the type of the entry. For more details, read the screenlet reference documentation.
- `error`: the error occurred in the synchronization

The following method is invoked when an item synchronization detects a conflict. The method must invoke asynchronously a continuation argument with the conflict action result.

```
syncManager(manager: SyncManager, onItemSyncScreenlet screenlet: String,
    conflictedKey: String, remoteValue: AnyObject, localValue: AnyObject,
    resolve: SyncConflictResolution -> ())
```

- `screenlet`: the screenlet name that stored this cache element
- `conflictedKey`: the cache key where the item is stored
- `remoteValue`: the value stored in the server for the item being synchronized
- `localValue`: the value stored in the cache for the item being synchronized
- `resolve`: this is the continuation function to be called with the action result.

Supported values for `resolve` are:

- `UseRemote`: the remote version is overwritten with the local one. Both the local cache and the portal have the same version.
- `UseLocal`: the local version is overwritten with the remote one. Both the local cache and the portal have the same version
- `Discard`: the local version is removed and the remote one isn't overwritten.
- `Ignore`: data is not changed, so the next synchronization will detect the conflict again.

Chapter 130

Liferay Faces

Liferay Faces is an umbrella project that provides support for the JavaServer™ Faces (JSF) standard within Liferay Portal. It encompasses the following projects:

- **Liferay Faces Bridge** enables you to deploy JSF web apps as portlets without writing portlet-specific Java code. It also contains innovative features that make it possible to leverage the power of JSF 2.x inside a portlet application. Liferay Faces Bridge implements the JSR 329 Portlet Bridge Standard.
- **Liferay Faces Alloy** enables you to use AlloyUI components in a way that is consistent with JSF development.
- **Liferay Faces Portal** enables you to leverage Liferay-specific utilities and UI components in JSF portlets.

In this section of reference documentation, you'll learn more about each of these projects. You'll also learn about the Liferay Faces version scheme.

130.1 Liferay Faces Version Scheme

In this article, you'll learn which Liferay Faces artifacts should be used with your portlet and explore the Liferay Faces versioning scheme by discovering what each component of a version means. Once you have the versioning scheme mastered, you can view several example configurations.

Using The Liferay Faces Archetype Portlet

The Liferay Faces Archetype portlet can be used to determine the Liferay Faces artifacts and versions that you must include in your portlet. Select your preferred Liferay Portal version, JSF version, component suite (optional), and build tool, and the portlet will provide you with both a command to generate your portlet from a Maven archetype and a list of dependencies that can be copied into your build files. In the next section, you'll be provided with compatibility information about each version of the Liferay Faces artifacts.

Liferay Faces Alloy

Provides a suite of JSF components that utilize AlloyUI.

Branch|Example Artifact|AlloyUI|JSF API|Additional Info| master (3.x)|com.liferay.faces.alloy-3.0.1.jar|3.0.x|2.2+|*AlloyUI 3.0.x is the version that comes bundled with Liferay Portal 7.0+.*| 2.x|com.lif-eray.faces.alloy-2.0.1.jar|2.0.x|2.1+|*AlloyUI 2.0.x is the version that comes bundled with Liferay Portal 6.2.*| 1.x|com.liferay.faces.alloy-1.0.1.jar|2.0.x|1.2|*AlloyUI 2.0.x is the version that comes bundled with Liferay Portal 6.2.*|

Liferay Faces Bridge

Provides the ability to deploy JSF web applications as portlets within Apache Pluto, the reference implementation for JSR 286 (Portlet 2.0) and JSR 362 (Portlet 3.0).

Branch|Example Artifacts|Portlet API|JSF API|JCP Specification|Additional Info| API: 5.xIMPL: 5.x|com.liferay.faces.bridge.api-5.0.0.jarcom.liferay.faces.bridge.impl-5.0.0.jar|3.0|2.2|JSR 378|*The Expert Group began work in September 2015 and the Specification is currently under development.*| API: 4.xIMPL: 4.x|com.liferay.faces.bridge.api-4.1.0.jarcom.liferay.faces.bridge.impl-4.0.0.jar|2.0|2.2|JSR 329|*Includes non-standard bridge extensions for JSF 2.2.*| API: 3.xIMPL: 3.x|com.liferay.faces.bridge.api-3.1.0.jarcom.lif-eray.faces.bridge.impl-3.0.0.jar|2.0|2.1|JSR 329|*Includes non-standard bridge extensions for JSF 2.1.*| API: 2.xIMPL: 2.x|com.liferay.faces.bridge.api-2.1.0.jarcom.liferay.faces.bridge.impl-2.0.0.jar|2.0|1.2|JSR 329 (MR1)|*Includes support for Maintenance Release 1 (MR1).*| 1.x|N/A|1.0|1.2|JSR 301|*N/A (Not Applicable) since Liferay Faces Bridge has never implemented JSR 301.*|

Liferay Faces Bridge Ext

Extension to Liferay Faces Bridge that provides compatibility with Liferay Portal and also takes advantage of Liferay-specific features such as friendly URLs.

Branch |Example Artifact | Liferay Portal API | Bridge API | Portlet API |JSF API| 8.x|com.lif-eray.faces.bridge.ext-8.0.0.jar|7.3.0+|5.x|3.0|2.3| 7.x|com.liferay.faces.bridge.ext-7.0.0.jar|7.3.0+|5.x|3.0|2.2| 6.x|com.liferay.faces.bridge.ext-6.0.0.jar|7.3.0+|4.x|2.0|2.2| 5.x|com.liferay.faces.bridge.ext-5.0.4.jar|7.0.x/7.1.x/7.2.x|4.x| 4.x|UNUSED|N/A|N/A|N/A|N/A| 3.x|com.liferay.faces.bridge.ext-3.0.1.jar|6.2.x|4.x|2.0|2.2| 2.x|com.lif-eray.faces.bridge.ext-2.0.1.jar|6.2.x|3.x|2.0|2.1| 1.x|com.liferay.faces.bridge.ext-1.0.1.jar|6.2.x|2.x|2.0|1.2|

Liferay Faces Portal

Provides a suite of JSF components that are based on the JSP tags provided by Liferay Portal.

Branch|Example Artifact|Liferay Portal API | JSF API| 3.x|com.liferay.faces.portal-3.0.1.jar|7.0.x+|2.2+| 2.x|com.liferay.faces.portal-2.0.1.jar|6.2.x|2.1+| 1.x|com.liferay.faces.portal-1.0.1.jar|6.2.x|1.2|

Liferay Faces Util

Library that contains general purpose JSF utilities to support many of the sub-projects that comprise Liferay Faces.

Branch|Example Artifact| JSF API| 4.x|com.liferay.faces.util-3.1.0.jar|2.3| 3.x|com.liferay.faces.util-3.1.0.jar|2.2| 2.x|com.liferay.faces.util-2.1.0.jar|2.1| 1.x|com.liferay.faces.util-1.1.0.jar|1.2|

Now that you know all about the Liferay Faces versioning scheme, you may be curious as to how these components interact with each other. Refer to the following figure to view the Liferay Faces dependency diagram.

Figure 130.1: The Liferay Faces dependency diagram helps visualize how components interact and depend on each other.

Next, you can view some example configurations to see the new versioning scheme in action.

130.2 Understanding Liferay Faces Bridge

The Liferay Faces Bridge enables you to deploy JSF web apps as portlets without writing portlet-specific code. It also contains innovative features that make it possible to leverage the power of JSF 2.x inside a portlet application.

Liferay Faces Bridge is distributed in a .jar file. You can add Liferay Faces Bridge as a dependency to your portlet projects, in order to deploy your JSF web applications as portlets within JSR 286 (Portlet 2.0) compliant portlet containers, like Liferay Portal 5.2, 6.0, 6.1, 6.2, and 7.0.

The Liferay Faces Bridge project home page can be found here.

To fully understand Liferay Faces Bridge, you must first understand the portlet bridge standard. Because the Portlet 1.0 and JSF 1.0 specs were being created at essentially the same time, the Expert Group (EG) for the JSF specification constructed the JSF framework to be compliant with portlets. For example, the ExternalContext.getRequest() method returns an `Object` instead of an javax.servlet.http.HttpServletRequest. When this method is used in a portal, the `Object` can be cast to a javax.portlet.PortletRequest. Despite the EG's consciousness of portlet compatibility within the design of JSF, the gap between the portlet and JSF lifecycles had to be bridged.

Portlet bridge standards and implementations evolved over time.

Starting in 2004, several different JSF portlet bridge implementations were developed in order to provide JSF developers with the ability to deploy their JSF web apps as portlets. In 2006, the JCP formed the Portlet Bridge 1.0 (JSR 301) EG in order to define a standard bridge API, as well as detailed requirements for bridge implementations. JSR 301 was released in 2010, targeting Portlet 1.0 and JSF 1.2.

When the Portlet 2.0 (JSR 286) standard was released in 2008, it became necessary for the JCP to form the Portlet Bridge 2.0 (JSR 329) EG. JSR 329 was also released in 2010, targeting Portlet 2.0 and JSF 1.2.

After the JSR 314 EG released JSF 2.0 in 2009 and JSF 2.1 in 2010, it became evident that a Portlet Bridge 3.0 standard would be beneficial. In 2015 the JCP formed JSR 378) which is defining a bridge for Portlet 3.0 and JSF 2.2. There are also variants of *Liferay Faces Bridge* that support Portlet 2.0 and JSF 1.2/2.1/2.2.

Liferay Faces Bridge is the Reference Implementation (RI) of the Portlet Bridge Standard. It also contains innovative features that make it possible to leverage the power of JSF 2.x inside a portlet application.

Now that you're familiar with some of the history of the Portlet Bridge standards, you'll learn about the responsibilities required of the portlet bridge.

A JSF portlet bridge aligns the correct phases of the JSF lifecycle with each phase of the portlet lifecycle. For instance, if a browser sends an HTTP GET request to a portal page with a JSF portlet in it, the `RENDER_PHASE` is perfomed in the portlet's lifecycle. The JSF portlet bridge then initiates the `RESTORE_VIEW` and `RENDER_RESPONSE` phases in the JSF lifecycle. Likewise, when an HTTP POST is executed on a portlet and the portlet enters the `ACTION_PHASE`, then the full JSF lifecycle is initiated by the bridge.

Besides ensuring that the two lifecycles connect correctly, the JSF portlet bridge also acts as a mediator between the portal URL generator and JSF navigation rules. JSF portlet bridges ensure that URLs created by the portal comply with JSF navigation rules, so that a JSF portlet is able to switch to different views.

The JSR 329/378 standards defines several configuration options prefixed with the `javax.portlet.faces` namespace. Liferay Faces Bridge defines additional implementation-specific options prefixed with the `com.liferay.faces.bridge` namespace.

Liferay Faces Bridge is an essential part of the JSF development process for Liferay DXP.

What is Service Builder?

130.3 Understanding Liferay Faces Alloy

Liferay Faces Alloy is distributed in a `.jar` file. You can add Liferay Faces Alloy as a dependency to your portlet projects, in order to use AlloyUI in a way that is consistent with JSF development.

During the creation of a JSF portlet in Liferay IDE/Developer Studio, you have the option of choosing the portlet's JSF Component Suite. The options include *JSF standard*, *ICEfaces*, *PrimeFaces*, *RichFaces*, and *Liferay Faces Alloy*.

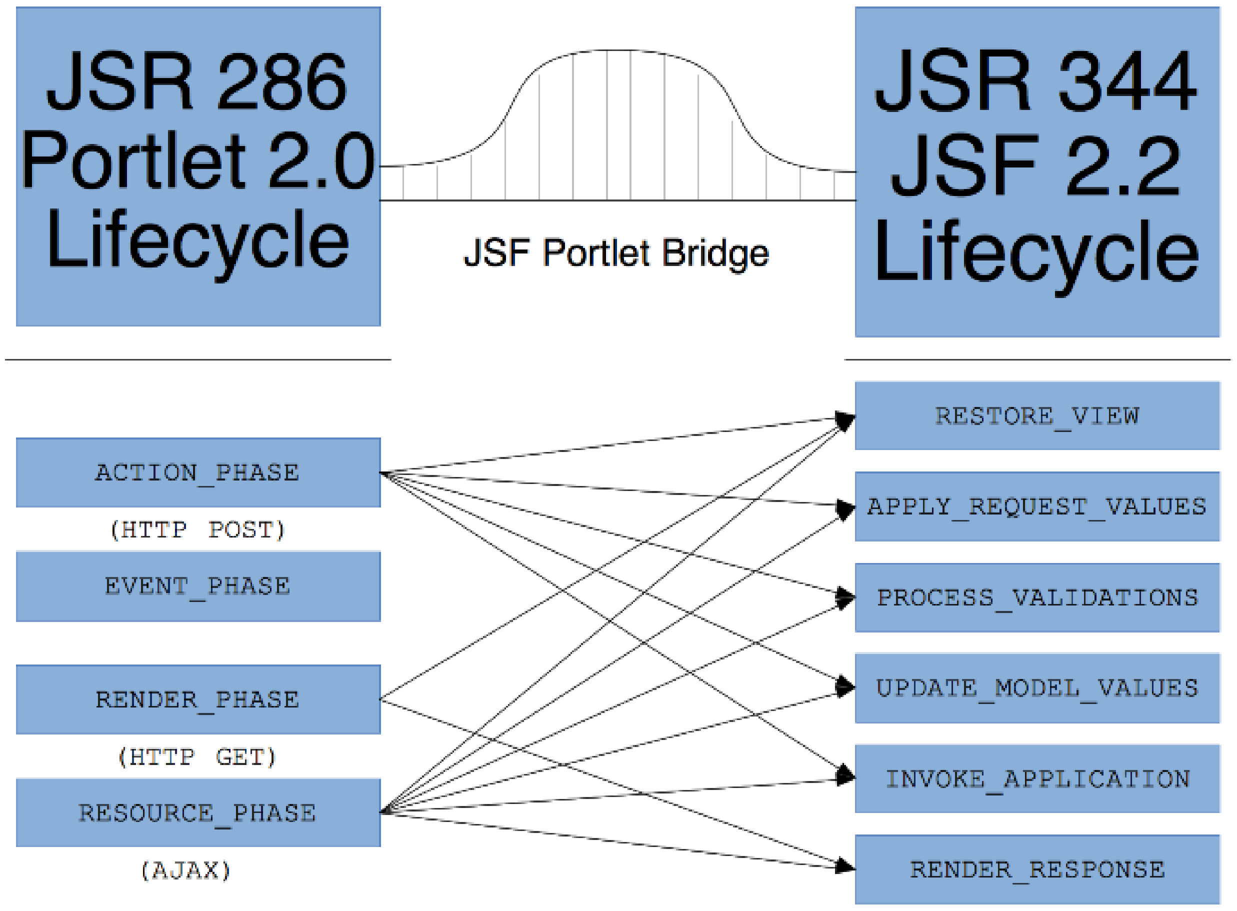

Figure 130.2: The different phases of the JSF Lifecycle are executed depending on which phase of the Portlet lifecycle is being executed.

If you selected the Liferay Faces Alloy JSF Component Suite during your portlet's setup, the `.jar` file is included in your portlet project.

The Liferay Faces Alloy project provides a set of UI components that utilize AlloyUI. For example, a brief list of some of the supported `aui:` tags are listed below:

- Input: `alloy:inputText`, `alloy:inputDate`, `alloy:inputFile`
- Panel: `alloy:accordion`, `alloy:column`, `alloy:fieldset`, `alloy:row`
- Select: `alloy:selectOneMenu`, `alloy:selectOneRadio`, `alloy:selectStarRating`

If you want to utilize Liferay's AlloyUI technology based on YUI3, you must include the Liferay Faces Alloy `.jar` file in your JSF portlet project. If you selected *Liferay Faces Alloy* during your JSF portlet's setup, you have Liferay Faces Alloy preconfigured in your project, so you're automatically able to use the `alloy:` tags.

As you can see, it's extremely easy to configure your JSF application to use Liferay's AlloyUI tags.

130.4 Understanding Liferay Faces Portal

Liferay Faces Portal is distributed in a `.jar` file. You can add Liferay Faces Portal as a dependency for your portlet projects to use its Liferay-specific utilities and UI components. When Liferay Faces Portal is included in a JSF portlet project, the `com.liferay.faces.portal.[version].jar` file resides in the portlet's library.

Some of the features included in Liferay Faces Portal are:

- Utilities: Provides the `LiferayPortletHelperUtil` which contains a variety Portlet-API and Liferay-specific convenience methods.
- JSF Components: Provides a set of JSF equivalents for popular Liferay DXP JSP tags (not exhaustive):
  - `liferay-ui:captcha` → `portal:captcha`
  - `liferay-ui:input-editor` → `portal:inputRichText`
  - `liferay-ui:search` → `portal:inputSearch`
  - `liferay-ui:header` → `portal:header`
  - `aui:nav` → `portal:nav`
  - `aui:nav-item` → `portal:navItem`
  - `aui:nav-bar` → `portal:navBar`
  - `liferay-security:permissionsURL` → `portal:permissionsURL`
  - `liferay-portlet:runtime` → `portal:runtime`

  For more information, visit https://liferayfaces.org/web/guest/portal-showcase.
- Expression Language: Adds a set of EL keywords such as `liferay` for getting Liferay-specific info, and `i18n` for integration with out-of-the-box Liferay internationalized messages.

Great! You now have an understanding of what Liferay Faces Portal is, and what it accomplishes in your JSF application.

Chapter 131

Gradle

Liferay provides plugins that you can apply to your Gradle project. This reference documentation describes how to apply and use Liferay's Gradle plugins.

Important: If you're using Liferay Workspace to create Liferay apps, many Liferay Gradle plugins are already applied by default. The `com.liferay.workspace` plugin provides the following plugins to all your apps in a Liferay Workspace:

- `com.liferay.css.builder`
- `com.liferay.js.module.config.generator`
- `com.liferay.js.transpiler`
- `com.liferay.javadoc.formatter`
- `com.liferay.jspc`
- `com.liferay.lang.builder`
- `com.liferay.source.formatter`
- `com.liferay.soy`
- `com.liferay.soy.translation`
- `com.liferay.tlddoc.builder`
- `com.liferay.tld.formatter`
- `com.liferay.test.integration`
- `com.liferay.xml.formatter`

Do not apply a Liferay Gradle plugin to an app that already has access to it.

Each article in this section describes how to apply the plugin, what Gradle tasks the plugin provides, the plugin's configuration properties, and the plugin's dependencies.

131.1 App Javadoc Builder Gradle Plugin

The App Javadoc Builder Gradle plugin lets you generate API documentation as a single, combined HTML document for an application that spans different subprojects, each one representing a different component of the same application.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in the build script of the root project:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.app.javadoc.builder", version: "1.2.2"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.app.javadoc.builder"
```

The App Javadoc Builder plugin automatically applies the `base` and `reporting-base` plugins.

Project Extension

The App Javadoc Builder plugin exposes the following properties through the extension named `appJavadocBuilder`:

Property Name | Type | Default Value | Description `copyTags` | `boolean` | `true` | Whether to copy the custom block tags configuration from the subprojects. It sets the Javadoc `-tag` argument for the `appJavadoc` task. `doclintDisabled` | `boolean` | `true` on JDK8+, `false` otherwise. | Whether to ignore Javadoc errors. It sets the Javadoc `-Xdoclint` and `-quiet` arguments for the `appJavadoc` task. `groupNameClosure` | `Closure<String>` | The subproject's description, or the subproject's name if the description is empty. | The closure invoked in order to get the group heading for a subproject. The given closure is passed a `Project` as its parameter. If `groupPackages` is `false`, this property is not used. `groupPackages` | `boolean` | `true` | Whether to separate packages on the overview page based on the subprojects they belong to. It sets the `-group` argument for the `appJavadoc` task. `subprojects` | `Set<Project>` | `project.subprojects` | The subprojects to include in the API documentation of the app.

The same extension exposes the following methods:

Method | Description `AppJavadocBuilderExtension onlyIf(Closure<Boolean> onlyIfClosure)` | Includes a subproject in the API documentation if the given closure returns `true`. The closure is evaluated at the end of the subproject configuration phase and is passed a single parameter: the subproject. If the closure returns `false`, the subproject is not included in the API documentation. `AppJavadocBuilderExtension onlyIf(Spec<Project> onlyIfSpec)` | Includes a subproject in the API documentation if the given spec is satisfied. The spec is evaluated at the end of the subproject configuration phase. If the spec is not satisfied, the subproject is not included in the API documentation. `AppJavadocBuilderExtension subprojects(Iterable<Project> subprojects)` | Include additional projects in the API documentation of the app. `AppJavadocBuilderExtension subprojects(Project... subprojects)` | Include additional projects in the API documentation of the app.

Tasks

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `appJavadoc` | The `javadoc` tasks of the subprojects. | `Javadoc` | Generates Javadoc API documentation for the app. `jarAppJavadoc` | `appJavadoc` | `Jar` | Assembles a JAR archive containing the Javadoc files for this app.

The `appJavadoc` task is automatically configured with sensible defaults:

Property Name | Default Value classpath | The javadoc.classpath of all the subprojects. destinationDir | ${project.buildDir}/docs/javadoc options.encoding | "UTF-8" source | The javadoc.source of all the subprojects. title | project.reporting.apiDocTitle

131.2 Baseline Gradle Plugin

The Baseline Gradle plugin lets you verify that the OSGi semantic versioning rules are obeyed by your OSGi bundle.

When you run the baseline task, the plugin *baselines* the new bundle against the latest released non-snapshot bundle (i.e., the *baseline*). That is, it compares the public exported API of the new bundle with the baseline. If there are any changes, it uses the OSGi semantic versioning rules to calculate the minimum new version. If the new bundle has a lower version, errors are thrown.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.baseline", version: "2.1.0"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.baseline"
```

The Baseline plugin automatically applies the java and reporting-base plugins.

Since the plugin needs to download the baseline, you have to configure a repository that hosts it; for example, the central Maven 2 repository:

```
repositories {
    mavenCentral()
}
```

Project Extension

The Baseline plugin exposes the following properties through the baselineConfiguration extension:

Property Name | Type | Default Value | Description allowMavenLocal | boolean | false | Whether to let the baseline come from the local Maven cache (by default: ${user.home}/.m2). If the local Maven cache is not configured as a project repository, this property has no effect. lowestBaselineVersion | String | "1.0.0" | The greatest project version to ignore for the baseline check. If the project version is less than or equal to the value of this property, the baseline task is skipped. lowestMajorVersion | Integer | Content of the file ${project.projectDir}/.lfrbuild-lowest-major-version, where the default file name can be changed by setting the project property baseline.lowest.major.version.file. | The lowest major version of the released artifact to use in the baseline check. lowestMajorVersionRequired | boolean | false | Whether to fail the build if the lowestMajorVersion is not specified.

If the lowestMajorVersion is not specified, the plugin runs the check using the most recent released non-snapshot bundle as baseline, which matches the version range (,${project.version}). Otherwise, if the lowestMajorVersion is equal to a value L and the project has version M.x.y (with L less or equal than M), multiple checks are performed in order, using the following version ranges as baseline:

1. [L.0.0, (L + 1).0.0)
2. [(L + 1).0.0, (L + 2).0.0)
3. ...
4. [(M - 2).0.0, (M - 1).0.0)
5. [(M - 1).0.0, M.0.0)
6. [M.0.0, M.x.y)

The first failing check fails the whole build.

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description baseline | jar | BaselineTask | Compares the public API of this project with the public API of the previous released version, if found.

The baseline task is automatically configured with sensible defaults:

Property Name | Default Value baselineConfiguration | configurations.baseline bndFile | ${project.projectDir}/bnd.bnd newJarFile | project.tasks.jar.archivePath sourceDir | The first resources directory of the main source set (by default: src/main/resources).

BaselineTask

Task Properties Property Name | Type | Default Value | Description baselineConfiguration | Configuration | null | The configuration that contains exactly one dependency to the baseline bundle. bndFile | File | null | The BND file of the project. If provided, the task will automatically update the Bundle-Version header. forceCalculatedVersion | boolean | false | Whether to fail the baseline check if the Bundle-Version has been excessively increased. ignoreExcessiveVersionIncreases | boolean | false | Whether to ignore excessive package version increase warnings. ignoreFailures | boolean | false | Whether the build should not break when semantic versioning errors are found. logFile | File | null | The file to which the results of the baseline check are written. *(Read-only)* logFileName | String | "baseline/${task.name}.log" | The name of the file to which the results of the baseline check are written. If the reporting-base plugin is applied, the file name is relative to reporting.baseDir; otherwise, it's relative to the project directory. newJarFile | File | null | The file of the new OSGi bundle. reportDiff | boolean | true if the project property baseline.jar.report.level has either value "diff" or "persist"; false otherwise | Whether to show a granular, differential report of all changes that occurred in the exported packages of the OSGi bundle. reportOnlyDirtyPackages | boolean | Value of the project property baseline.jar.report.only.dirty.packages if specified; true otherwise. | Whether to show only packages with API changes in the report. sourceDir | File | null | The directory to which the packageinfo files are generated or updated.

The properties of type File support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the String properties to defer evaluation until task execution.

Helper Tasks

If the lowestMajorVersion property is specified with a value L, the plugin creates a series of helper tasks of type BaselineTask at the end of the project evaluation, one for each major version between L and the major version M of the project:

1. Task `baseline${L + 1}`, which depends on `baseline${L + 2}` and uses the version range `[(L + 1).0.0, (L + 2).0.0)` as baseline.
2. Task `baseline${L + 2}`, which depends on `baseline${L + 3}` and uses the version range `[(L + 2).0.0, (L + 3).0.0)` as baseline.
3. …
4. Task `baseline${M - 2}`, which depends on `baseline${M - 1}` and uses the version range `[(M - 2).0.0, (M - 1).0.0)` as baseline.
5. Task `baseline${M - 1}`, which depends on `baseline${M}` and uses the version range `[(M - 1).0.0, M.0.0)` as baseline.
6. Task `baseline${M}`, which uses the version range `[M.0.0, M.x.y)` as baseline.

The `baseline` task is also configured to use the version range `[L.0.0, (L + 1).0.0)` as baseline, and to depend on the task `baseline${L + 1}`. This means that running the `baseline` task runs the baseline check against multiple versions, starting from the most recent `M` and going back to `L`.

Moreover, all tasks except `baseline${M}` have the property `ignoreExcessiveVersionIncreases` set to `true`.

Additional Configuration

There are additional configurations that can help you baseline your OSGi bundle.

Baseline Dependency

The plugin creates a configuration called `baseline` with a default dependency to a released non-snapshot version of the bundle:

- version range `[L.0.0, (L + 1).0.0)` if the `lowestMajorVersion` property is specified with a value `L`.
- version range `(,${project.version})` otherwise.

It is possible to override this setting and use a different version of the bundle as baseline.

System Properties

It is possible to set the default values of the `ignoreFailures` property for a `BaselineTask` task via system properties:

```
-D${task.name}.ignoreFailures=true
```

For example, run the following Bash command to execute the baseline check without breaking the build, in case of errors:

```
./gradlew baseline -Dbaseline.ignoreFailures=true
```

131.3 Change Log Builder Gradle Plugin

The Change Log Builder Gradle plugin lets you generate and maintain a change log file based on the Git commits in your project. A change log file generated by this plugin looks like this

```
#
# Bundle Version 1.0.1
#
9c77ff4c95cb1a325db3bdd089be105206e8b63c^..b421f00ac84b065685b131833fecc594fc01c760=LPS-123 LPS-1321

#
# Bundle Version 1.0.2
#
b421f00ac84b065685b131833fecc594fc01c760^..bc15d8d84e12b9544f78e4e3743c510dbaec2d89=LPS-456
```

Every time the `buildChangeLog` task is executed, a new line is added to the change log, which lists all Git commit prefixes (usually issue ticket IDs) that occurred in a certain range. The end of the range is always the tip of the current branch. The start range can vary, depending on the case:

- If `buildChangeLog` has never been executed for the project, the change log does not exist. Therefore, the most recent commit from two years ago is used for the range start.
- If a change log already exists for your project, the start range begins at the range end of the last line in the change log.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.change.log.builder", version: "1.1.3"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.change.log.builder"
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildChangeLog` | - | `BuildChangeLogTask` | Builds the change log file for this project.

The `buildChangeLog` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `changeLogHeader` | `"Bundle Version ${project.version}"` `changeLogFile` |

If the `java` plugin is applied: The `META-INF/liferay-releng.changelog` file in the first `resources` directory of the `main` source set (by default, `src/main/resources/META-INF/liferay-releng.changelog`).

Otherwise: `"${project.projectDir}/liferay-releng.changelog"`

`dirs` | `[project.projectDir]`

BuildChangeLogTask

Task Properties Property Name | Type | Default Value | Description `changeLogFile` | `File` | `null` | The change log file to build. `changeLogHeader` | `String` | `null` | The header for the new line in the change log. `dirs` | `FileCollection` | `[]` | The directories to consider when listing the commits in the range specified. `gitDir` | `File` | `project.rootDir` | The base directory to start searching for the `.git` directory. The search proceeds in all the ancestors of the directory specified. `rangeEnd` | `String` | `null` | The hash of the last commit to consider. If not set, it corresponds to the range end of the last line in the change log, or the most recent commit from at least two years ago if the change log file does not exist yet. `rangeStart` | `String` | `null` | The hash of the first commit to consider. If not set, it corresponds to the hash of the tip of the current branch. `ticketIdPrefixes` | `Set<String>` | `["CLDSVCS", "LPS", "SOS", "SYNC"]` | The valid prefix of the Git commit messages to add to the change log. For example, if a commit message is `"LPS-123 Bugfix"`, `"LPS-123"` will be added to the change log.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

Task Methods Method | Description `BuildChangeLogTask dirs(Iterable<?> dirs)` | Adds directories to consider when listing the commits in the range specified. `BuildChangeLogTask dirs(Object... dirs)` | Adds directories to consider when listing the commits in the range specified. `BuildChangeLogTask ticketIdPrefixes(Iterable<String> ticketIdPrefixes)` | Adds valid prefixes of the Git commit messages to add to the change log. `BuildChangeLogTask ticketIdPrefixes(String... ticketIdPrefixes)` | Adds valid prefixes of the Git commit messages to add to the change log.

131.4 CSS Builder Gradle Plugin

The CSS Builder Gradle plugin lets you run the Liferay CSS Builder tool to compile Sass files in your project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.css.builder", version: "3.0.0"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.css.builder"
```

Since the plugin automatically resolves the Liferay CSS Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description buildCSS | - | BuildCSSTask | Compiles the Sass files in this project.

The plugin also adds the following dependencies to tasks defined by the java plugin:

Name | Depends On processResources | buildCSS

The buildCSS task is automatically configured with sensible defaults, depending on whether the java or the war plugins are applied:

Property Name | Default Value baseDir |

If the java plugin is applied: The first resources directory of the main source set (by default: src/main/resources).

If the war plugin is applied: project.webAppDir.

Otherwise: null

BuildCSSTask

Tasks of type BuildCSSTask extend JavaExec, so all its properties and methods, such as args and maxHeapSize, are available. They also have the following properties set by default:

Property Name | Default Value args | CSS Builder command line arguments classpath | project.configurations.cssBuilder defaultCharacterEncoding | "UTF-8" main | "com.liferay.css.builder.CSSBuilder" systemProperties | ["sass.compiler.jni.clean.temp.dir", true]

Task Properties Property Name | Type | Default Value | Description appendCssImportTimestamps | boolean | true | Whether to append the current timestamp to the URLs in the @import CSS at-rules. It sets the sass.append.css.import.timestamps argument. baseDir | File | null | The base directory that contains the SCSS files to compile. It sets the sass.docroot.dir argument. cssFiles | FileCollection | - | The SCSS files to compile. *(Read-only)* dirNames | List<String> | ["/"] | The name of the directories, relative to baseDir, which contain the SCSS files to compile. All sub-directories are searched for SCSS files as well. It sets the sass.dir argument. generateSourceMap | boolean | false | Whether to generate source maps for easier debugging. It sets the sass.generate.source.map argument. importDir | File | null | The META-INF/resources directory of the Liferay Frontend Common CSS artifact. This is required in order to make Bourbon and other CSS libraries available to the compilation. importFile | File | configurations.portalCommonCSS.singleFile | The Liferay Frontend Common CSS JAR file. If importDir is set, this property has no effect. importPath | File | - | The value of the importDir property if set; otherwise importFile. It sets the sass.portal.common.path argument. *(Read-only)* outputDirName | String | ".sass-cache/" | The name of the sub-directories where the SCSS files are compiled to. For each directory that contains SCSS files, a sub-directory with this name is created. It sets the sass.output.dir argument. outputDirs | FileCollection | - | The directories where the SCSS files are compiled to. Usually, these directories are ignored by the Version Control System. *(Read-only)* precision | int | 5 | The numeric precision of numbers in Sass. It sets the sass.precision argument. rtlExcludedPathRegexps | List<String> | [] | The SCSS file patterns to exclude when converting for right-to-left (RTL) support. It sets the sass.rtl.excluded.path.regexps argument. sassCompilerClassName | String | null | The type of Sass compiler to use. Supported values are "jni" and "ruby". If not set, defaults to "jni". It sets the sass.compiler.class.name argument.

Note: Liferay's CSS Builder is supported for Oracle's JDK and uses a native compiler for increased speed. If you're using an IBM JDK, you may experience issues when building your Sass files (e.g., when building a theme). It's recommended to switch to using the Oracle JDK, but if you prefer using the IBM JDK, you must use the fallback Ruby compiler. You can do this two ways:

- If you're working in a Liferay Workspace or using the Liferay Gradle Plugins plugin, set `sass.compiler.class.name=ruby` in your `gradle.properties` file.
- Otherwise, set `buildCSS.sassCompilerClassName='ruby'` in the project's `build.gradle` file.

The `sass.compiler.class.name=ruby` Gradle property only works for modules, so if you're using the Ruby compiler in a WAR project (e.g., theme), you must use the second option.

Be aware that the Ruby-based compiler doesn't perform as well as the native compiler, so expect longer compile times.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `int` and `String` properties, to defer evaluation until task execution.

Task Methods Method | Description `BuildCSSTask dirNames(Iterable<Object> dirNames)` | Adds sub-directory names, relative to `baseDir`, which contain the SCSS files to compile. `BuildCSSTask dirNames(Object... dirNames)` | Adds sub-directory names, relative to `baseDir`, which contain the SCSS files to compile. `BuildCSSTask rtlExcludedPathRegexps(Iterable<Object> rtlExcludedPathRegexps)` | Adds SCSS file patterns to exclude when converting for right-to-left (RTL) support. `BuildCSSTask rtlExcludedPathRegexps(Object... rtlExcludedPathRegexps)` | Adds SCSS file patterns to exclude when converting for right-to-left (RTL) support.

Additional Configuration

There are additional configurations that can help you use the CSS Builder.

Liferay CSS Builder Dependency

By default, the plugin creates a configuration called `cssBuilder` and adds a dependency to the latest released version of the Liferay CSS Builder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `cssBuilder` configuration:

```
dependencies {
    cssBuilder group: "com.liferay", name: "com.liferay.css.builder", version: "3.0.0"
}
```

Liferay Frontend Common CSS Dependency

By default, the plugin creates a configuration called `portalCommonCSS` and adds a dependency to the latest released version of the Liferay Frontend Common CSS artifact. It is possible to override this setting and use a specific version of the artifact by manually adding a dependency to the `portalCommonCSS` configuration:

```
dependencies {
    portalCommonCSS group: "com.liferay", name: "com.liferay.frontend.css.common", version: "2.0.1"
}
```

131.5 DB Support Gradle Plugin

The DB Support Gradle plugin lets you run the Liferay DB Support tool to execute certain actions on a local Liferay database. So far, the following actions are available:

- Cleans the Liferay database from the Service Builder tables and rows of a module.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.db.support", version: "1.0.5"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.portal.tools.db.support"
```

Since the plugin automatically resolves the Liferay DB Support library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `cleanServiceBuilder` | - | `CleanServiceBuilderTask` | Cleans the Liferay database from the Service Builder tables and rows of a module.

The `cleanServiceBuilder` task is automatically configured with sensible defaults, depending on whether the `base` plugin is applied:

Property Name | Default Value `servletContextName` |

If the `base` plugin is applied: The bundle symbolic name of the project inferred via the `OsgiHelper` class.

Otherwise: `null`

`serviceXmlFile` | `"${project.projectDir}/service.xml"`

CleanServiceBuilderTask

Tasks of type `BuildDeploymentHelperTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | The DB Support command line arguments. `classpath` | `project.configurations.dbSupport + project.configurations.dbSupportTool` `main` | `"com.liferay.portal.tools.db.support.D`

Task Properties Property Name | Type | Default Value | Description password | String | null | The user password for connecting to the Liferay database. It sets the --password argument. If propertiesFile is set, this property has no effect. propertiesFile | File | null | The portal-ext.properties file that contains the JDBC settings for connecting to the Liferay database. It sets the --properties-file argument. servletContextName | String | null | The servlet context name (usually the value of the Bundle-Symbolic-Name manifest header) of the module. It sets the --servlet-context-name argument. serviceXmlFile | File | null | The service.xml file of the module. It sets the --service-xml-file argument. url | String | null | The JDBC URL for connecting to the Liferay database. It sets the --url argument. If propertiesFile is set, this property has no effect. userName | String | null | The user name for connecting to the Liferay database. It sets the --user-name argument. If propertiesFile is set, this property has no effect.

The properties of type File support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the int and String properties to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use the Deployment Helper.

JDBC Drivers Dependency

The plugin creates a configuration called dbSupport, which can be used to provide the suitable JDBC driver for your Liferay database:

```
dependencies {
    dbSupport group: "mysql", name: "mysql-connector-java", version: "5.1.23"
    dbSupport group: "org.mariadb.jdbc", name: "mariadb-java-client", version: "1.1.9"
    dbSupport group: "org.postgresql", name: "postgresql", version: "9.4-1201-jdbc41"
}
```

Liferay DB Support Dependency

By default, the plugin creates a configuration called dbSupportTool and adds a dependency to the latest released version of the Liferay DB Support. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the dbSupportTool configuration:

```
dependencies {
    dbSupportTool group: "com.liferay", name: "com.liferay.portal.tools.db.support", version: "1.0.8"
}
```

131.6 Dependency Checker Gradle Plugin

The Dependency Checker Gradle plugin lets you warn users if a specific configuration dependency is not the latest one available from the Maven central repository. The plugin eventually fails the build if the dependency age (the difference between the timestamp of the current version and the latest version) is above a predetermined threshold.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.dependency.checker", version: "1.0.3"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.dependency.checker"
```

Project Extension

The Dependency Checker Gradle plugin exposes the following properties through the extension named `dependencyChecker`:

Property Name | Type | Default Value | Description `ignoreFailures` | `boolean` | `true` | Whether to print an error message instead of failing the build when the dependency check fails, either for a network error or because the dependency is out-of-date.

The same extension exposes the following methods:

Method | Description `void maxAge(Map<?, ?> args)` | Declares the max age allowed for a dependency. The `args` map must contain the following entries:

`configuration`: the configuration name

`group`: the dependency group

`name`: the dependency name

`maxAge`: an instance of `groovy.time.Duration` that represents the maximum age allowed for the dependency

`throwError`: a `boolean` value representing whether to throw an error if the dependency is out-of-date

Additional Configuration

There are additional configurations that can help you use the Deployment Helper.

Project Properties

It is possible to set the default values of the `ignoreFailures` property via the project property `dependencyCheckerIgnoreFailures`:

```
-PdependencyCheckerIgnoreFailures=false
```

131.7 Deployment Helper Gradle Plugin

The Deployment Helper Gradle plugin lets you run the Liferay Deployment Helper tool to create a cluster deployable WAR from your OSGi artifacts.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.deployment.helper", version: "1.0.5"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.deployment.helper"
```

Since the plugin automatically resolves the Liferay Deployment Helper library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildDeploymentHelper` | - | `BuildDeploymentHelperTask` | Builds a WAR which contains one or more files that are copied once the WAR is deployed.

BuildDeploymentHelperTask

Tasks of type `BuildDeploymentHelperTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | The Deployment Helper command line arguments. `classpath` | `project.configurations.deploymentHelper` `deploymentFiles` | The output files of the `jar` tasks of this project and all its sub-projects. `main` | `"com.liferay.deployment.helper.DeploymentHelper"` `outputFile` | `"${project.buildDir}/${project.name}.war"`

Task Properties Property Name | Type | Default Value | Description `deploymentFiles` | `FileCollection` | `[]` | The files or directories to include in the WAR and copy once the WAR is deployed. If a directory is added to this collection, all the JAR files contained in the directory are included in the WAR. `deploymentPath` | `File` | `null` | The directory to which the included files are copied. `outputFile` | `File` | `null` | The WAR file to build.

The properties of type `File` support any type that can be resolved by `project.file`.

Task Methods Method | Description `BuildDeploymentHelperTask deploymentFiles(Iterable<?> deploymentFiles)` | Adds files or directories to include in the WAR and copy once the WAR is deployed. The values are evaluated as per `project.files`. `BuildDeploymentHelperTask deploymentFiles(Object... deploymentFiles)` | Adds files or directories to include in the WAR and copy once the WAR is deployed. The values are evaluated as per `project.files`.

Additional Configuration

There are additional configurations that can help you use the Deployment Helper.

Liferay Deployment Helper Dependency

By default, the plugin creates a configuration called `deploymentHelper` and adds a dependency to the latest released version of the Liferay Deployment Helper. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `deploymentHelper` configuration:

```
dependencies {
    deploymentHelper group: "com.liferay", name: "com.liferay.deployment.helper", version: "1.0.4"
}
```

131.8 Go Gradle Plugin

The Go Gradle plugin lets you run Go as part of your build.

The plugin has been successfully tested with Gradle 3.5.1 up to 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.go", version: "1.0.0"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.go"
```

Project Extension

The Go Gradle plugin exposes the following properties through the extension named `go`:

Property Name | Type | Default Value | Description `goDir` | `File` | `"${project.buildDir}/go"` | The directory where the Go distribution is unpacked. `goUrl` | `String` | `"https://dl.google.com/go/go${go.goVersion}.${platform}-${bitMode}.${extension}` | The URL of the Go distribution to download. `goVersion` | `String` | `"1.11.4"` | The Go distribution's version to use. `workingDir` | `File` | `"${project.projectDir}"` | The directory that contains the project's Go source code.

Tasks

The plugin adds a series of tasks to your project:

Name | Depends On | Type | Description `downloadGo` | `-` | `DownloadGoTask` | Downloads and unpacks the local Go distribution for the project. `goBuild${programName}` | `downloadGo` | `ExecuteGoTask` | Compiles packages and dependencies for the Go program. `goClean${programName}` | `downloadGo` | `ExecuteGoTask` | Removes object files for the Go program. `goRun${programName}` | `downloadGo` | `ExecuteGoTask` | Compiles and runs the Go program. `goTest${programName}` | `downloadGo` | `ExecuteGoTask` | Tests packages for the Go program.

DownloadGoTask

The purpose of this task is to download and unpack a Go distribution.

Task Properties Property Name | Type | Default Value | Description goDir | File | null | The directory where the Go distribution is unpacked. goUrl | String | null | The URL of the Go distribution to download.

The File type properties support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the String properties, to defer evaluation until task execution.

ExecuteGoTask

This is the base task to run Go in a Gradle build. All tasks of type ExecuteGoTask automatically depend on downloadGo.

Task Properties Property Name | Type | Default Value | Description args | List<Object> | [] | The arguments for the Go invocation. command | String | "go" | The file name of the executable to invoke. environment | Map<Object, Object> | [] | The environment variables for the Go invocation. inheritProxy | boolean | true | Whether to set the http_proxy, https_proxy, and no_proxy environment variables in the Go invocation based on the values of the system properties https.proxyHost, https.proxyPort, https.proxyUser, https.proxyPassword, https.nonProxyHosts, https.proxyHost, https.proxyPort, https.proxyUser, https.proxyPassword, and https.nonProxyHosts. If these environment variables are already set, their values will not be overwritten. goDir | File | go.goDir](#godir) | The directory that contains the executable to invoke. useGradleExec | boolean |

If running in a Gradle Daemon: true

Otherwise: false

| Whether to invoke Go using project.exec, which can solve hanging problems with the Gradle Daemon. workingDir | File | go.workingDir](#workingdir) | The working directory to use in the Go invocation.

The File type properties support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the String properties to defer evaluation until task execution.

Task Methods Method | Description ExecuteGoTask args(Iterable<?> args) | Adds arguments for the Go invocation. ExecuteGoTask args(Object... args) | Adds arguments for the Go invocation. ExecuteGoTask environment(Map<?, ?> environment) | Adds environment variables for the Go invocation. ExecuteGoTask environment(Object key, Object value) | Adds an environment variable for the Go invocation.

gocommand{programName} Task

For each Go program in workingDir, four tasks of type ExecuteGoTask are added. Each of these tasks are automatically configured with sensible defaults:

Property Name | Default Value args | ["${command}", "${programFile.absolutePath}"]

131.9 Gulp Gradle Plugin

The Gulp Gradle plugin lets you run Gulp tasks as part of your build.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.gulp", version: "2.0.59"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.gulp"
```

The Gulp plugin automatically applies the `com.liferay.node` plugin.

Tasks

The plugin adds one task rule to your project:

Name | Depends On | Type | Description `gulp<Task>` | `downloadNode`, `npmInstall` | `ExecuteGulpTask` | Executes a named Gulp task.

ExecuteGulpTask

Tasks of type `ExecuteGulpTask` extend `ExecuteNodeScriptTask`, so all its properties and methods, such as `args` and `inheritProxy`, are available. They also have the following properties set by default:

Property Name | Default Value `scriptFile` | `"node_modules/gulp/bin/gulp.js"`

Gulp must be already installed in the `node_modules` directory of the project; otherwise, it will not be downloaded by the task. In order to ensure Gulp is installed, you can add the Gulp dependency to the project's `package.json` file.

Task Properties Property Name | Type | Default Value | Description `gulpCommand` | `String` | `null` | The Gulp task to execute.

It is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

131.10 Jasper JSPC Gradle Plugin

The Jasper JSPC Gradle plugin lets you run the Liferay Jasper JSPC tool to compile the JavaServer Pages (JSP) files in your project. This can be useful to

- check for errors in the JSP files.
- pre-compile the JSP files for better performance.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.jasper.jspc", version: "2.0.5"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.jasper.jspc"
```

The Jasper JSPC plugin automatically applies the `java` plugin.

Since the plugin automatically resolves the Liferay Jasper JSPC library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `compileJSP` | `generateJSPJava` | `JavaCompile` | Compiles JSP files to check for errors. `generateJSPJava` | `jar` | `CompileJSPTask` | Compiles JSP files to Java source files to check for errors.

The `generateJSPJava` task is automatically configured with sensible defaults, depending on whether the `war` plugin is applied:

Property Name | Default Value `classpath` | `project.configurations.jspCTool` `destinationDir` | `"${project.buildDir}/jspc"` `jspCClasspath` | `project.configurations.jspC` `webAppDir` |

If the `war` plugin is applied: `project.webAppDir`.

Otherwise: The first `resources` directory of the `main` source set (by default, `src/main/resources`).

The `compileJSP` task is also configured with the following defaults:

Property Name | Default Value `classpath` | `project.configurations.jspCTool + project.configurations.jspC` `destinationDir` | `compileJSP.temporaryDir` `source` | `generateJSPJava.outputs`

CompileJSPTask

Tasks of type `CompileJSPTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `main` | `"com.liferay.jasper.jspc.JspC"`

Task Properties Property Name | Type | Default Value | Description `destinationDir` | `File` | `null` | The directory where the the JSP files are compiled to. Package directories are automatically generated based on the directories containing the uncompiled JSP files. It sets the `-d` argument. `jspCClasspath` | `FileCollection` | `null` | The classpath to use for the JSP files compilation. `webAppDir` | `File` | `null` | The directory containing the web application. All JSP files in the directory and its subdirectories are compiled. It sets the `-webapp` argument.

The properties of type `File` support any type that can be resolved by `project.file`.

Additional Configuration

There are additional configurations that can help you use Jasper JSPC.

JSP Compilation Classpath

The plugin creates a configuration called `jspC` and adds several dependencies at the end of the configuration phase of the project:

- the JAR file of the project generated by the `jar` task.
- the output files of the `main` source set.
- the `compileClasspath` file collection of the `main` source set.

If necessary, it is possible to add more dependencies to the `jspC` configuration.

Liferay Jasper JSPC Dependency

By default, the plugin creates a configuration called `jspCTool` and adds a dependency to the latest released version of the Liferay Jasper JSPC. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `jspCTool` configuration:

```
dependencies {
    jspCTool group: "com.liferay", name: "com.liferay.jasper.jspc", version: "1.0.11"
    jspCTool group: "org.apache.ant", name: "ant", version: "1.9.4"
}
```

131.11 Javadoc Formatter Gradle Plugin

The Javadoc Formatter Gradle plugin lets you format project Javadoc comments using the Liferay Javadoc Formatter tool. The tool lets you generate:

- Default `@author` tags to all classes.
- Comment stubs to classes, fields, and methods.
- Missing `@Override` annotations.
- An XML representation of the Javadoc comments, which can be used by tools in order to index the Javadocs of the project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.javadoc.formatter", version: "1.0.27"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.javadoc.formatter"
```

Since the plugin automatically resolves the Liferay Javadoc Formatter library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `formatJavadoc` | - | `FormatJavadocTask` | Runs the Liferay Javadoc Formatter to format files.

FormatJavadocTask

Tasks of type `FormatJavadocTask` extend `JavaExec`, so all its properties and methods, like `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | Javadoc Formatter command line arguments `classpath` | `project.configurations.javadocFormatter` `main` | `"com.liferay.javadoc.formatter.JavadocFormatter"`

Task Properties Property Name | Type | Default Value | Description `author` | `String` | `"Brian Wing Shun Chan"` | The value of the `@author` tag to add at class level if missing. It sets the `javadoc.author` argument. `generateXML` | `boolean` | `false` | Whether to generate a XML representation of the Javadoc comments. The XML files are generated in the `src/main/resources` directory only if the Java files are contained in `src/main/java`. It sets the `javadoc.generate.xml` argument. `initializeMissingJavadocs` | `boolean` | `false` | Whether to add comment stubs at the class, field, and method levels. If `false`, only the class-level `@author` is added. It sets the `javadoc.init` argument. `limits` | `List<String>` | `[]` | The Java file name patterns, relative to `workingDir`, to include when formatting Javadoc comments. The patterns must be specified without the `.java` file type suffix. If empty, all Java files are formatted. It sets the `javadoc.limit` argument. `lowestSupportedJavaVersion` | `double` | `1.7` | If a method is annotated with the `@SinceJava` annotation and its `value` argument is greater than the value specified for the `lowestSupportedJavaVersion` property, then the `@Override` annotation is not automatically added, even if it is missing. It sets the `javadoc.lowest.supported.java.version` argument. See LPS-37353. `outputFilePrefix` | `String` | `"javadocs"` | The file name prefix of the XML representation of the Javadoc comments. If `generateXML` is `false`, this property is not used. It sets the `javadoc.output.file.prefix` argument. `updateJavadocs` | `boolean` | `false` | Whether to fix existing comment blocks by adding missing tags. It sets the `javadoc.update` argument.

It is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

Task Methods Method | Description `FormatJavadocTask dirNames(Iterable<Object> limits)` | Adds Java file name patterns, relative to `workingDir`, to include when formatting Javadoc comments. `FormatJavadocTask dirNames(Object... limits)` | Adds Java file name patterns, relative to `workingDir`, to include when formatting Javadoc comments.

Additional Configuration

There are additional configurations that can help you use the Javadoc Formatter.

Liferay Javadoc Formatter Dependency

By default, the plugin creates a configuration called `javadocFormatter` and adds a dependency to the latest released version of the Liferay Javadoc Formatter. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `javadocFormatter` configuration:

```
dependencies {
    javadocFormatter group: "com.liferay", name: "com.liferay.javadoc.formatter", version: "1.0.32"
}
```

If the `java` plugin is applied, the `javadocFormatter` configuration automatically extends from the `compile` configuration.

System Properties

It is possible to set the default values of the `generateXML`, `initializeMissingJavadocs`, `limits`, and `updateJavadocs` properties for a `FormatJavadocTask` task via system properties:

- `-D${task.name}.generate.xml=true`
- `-D${task.name}.init=SomeClassName1,SomeClassName2,com.liferay.portal.**`
- `-D${task.name}.limit=**/com/example/`
- `-D${task.name}.update=true`

131.12 JS Module Config Generator Gradle Plugin

The JS Module Config Generator Gradle plugin lets you run the Liferay AMD Module Config Generator to generate the configuration file needed to load AMD files via combo loader in Liferay.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.js.module.config.generator", version: "2.1.57"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.js.module.config.generator"
```

The JS Module Config Generator plugin automatically applies the `com.liferay.node` plugin.

Project Extension

The JS Module Config Generator plugin exposes the following properties through the extension named `jsModuleConfigGenerator`:

Property Name | Type | Default Value | Description `version` | `String` | `"1.2.1"` | The version of the Liferay AMD Module Config Generator to use.

Tasks

The plugin adds two tasks to your project:

Name | Depends On | Type | Description configJSModules | downloadLiferayModuleConfigGenerator, processResources | ConfigJSModulesTask | Generates the configuration file needed to load AMD files via combo loader in Liferay. downloadLiferayModuleConfigGenerator | downloadNode | DownloadNodeModuleTask | Downloads the Liferay AMD Module Config Generator in the project's node_modules directory.

By default, the downloadLiferayModuleConfigGenerator task downloads the version of liferay-module-config-generator declared in the jsModuleConfigGenerator.version property. If the project's package.json file, however, already lists the liferay-module-config-generator package in its dependencies or devDependencies, the downloadLiferayModuleConfigGenerator task is disabled.

The configJSModules task is automatically configured with sensible defaults, depending on whether the java plugin is applied:

Property Name | Default Value moduleConfigFile | "${project.projectDir}/package.json" outputFile | "${sourceSets.main.output.resourcesDir}/META-INF/config.json" sourceDir | "${sourceSets.main.output.resourcesDir}/ME INF/resources"

The plugin also adds the following dependencies to tasks defined by the java plugin:

Name | Depends On classes | configJSModules

If the com.liferay.js.transpiler plugin is applied, the configJSModules task is configured to always run after the transpileJS task.

ConfigJSModulesTask

Tasks of type ConfigJSModulesTask extend ExecuteNodeScriptTask, so all its properties and methods, such as args, inheritProxy, and workingDir, are available. The ConfigJSModulesTask instances also implement the PatternFilterable interface, which lets you specify include and exclude patterns for the files in sourceDir to process.

They also have the following properties set by default:

Property Name | Default Value includes | ["**/*.es.js*", "**/*.soy.js*"] scriptFile | "${downloadLiferayModuleConfig

The purpose of this task is to run the Liferay AMD Module Config Generator from the included files in sourceDir. The generator processes these files and creates a configuration file in the location specified by the outputFile property.

Task Properties Property Name | Type | Default Value | Description configVariable | String | null | The configuration variable to which the modules should be added. It sets the --config argument. customDefine | String | "Liferay.Loader" | The namespace of the define(...) call to use in the JS files. It sets the --namespace argument. ignorePath | boolean | false | Whether not to create module path and fullPath properties. It sets the --ignorePath argument. keepFileExtension | boolean | false | Whether to keep the file extension when generating the module name. It sets the --keepExtension argument. lowerCase | boolean | false | Whether to convert file name to lower case before using it as the module name. It sets the --lowerCase argument. moduleConfigFile | File | null | The JSON file which contains configuration data for the modules. It sets the --moduleConfig argument. moduleExtension | String | null | The extension for the module file (e.g., .js). If specified, use the provided string as an extension instead to get it automatically from the file name. It sets the --extension argument. moduleFormat | String | null | The regular expression and value to apply to the file name when generating the module name. It sets the --format argument. outputFile | File | null | The file where the generated configuration is stored. It sets the --output argument. sourceDir | File | null | The directory that contains the files to process.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `int` and `String` properties to defer evaluation until task execution.

131.13 JS Transpiler Gradle Plugin

The JS Transpiler Gradle plugin lets you run `metal-cli` to build Metal.js code, compile Soy files, and transpile ES6 to ES5.

Important: If you're using Liferay Workspace to create your app, the JS Transpiler Gradle plugin is applied by default. Do not apply the JS Transpiler Gradle plugin if you're using Liferay Workspace.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.js.transpiler", version: "2.4.36"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.js.transpiler"
```

There are two JS Transpiler Gradle plugins you can apply to your project:

- *JS Transpiler Plugin*: builds Metal.js code, compiles Soy files, and transpiles ES6 to ES5:

  ```
  apply plugin: "com.liferay.js.transpiler"
  ```

- *JS Transpiler Base Plugin*: provides a way to use Gradle dependencies (such as an external module or project dependencies) in Node.js scripts:

  ```
  apply plugin: "com.liferay.js.transpiler.base"
  ```

JS Transpiler Plugin

The JS Transpiler plugin automatically applies the *JS Transpiler Base Plugin*.

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `downloadMetalCli` | `downloadNode` | `DownloadNodeModuleTask` | Downloads `metal-cli` in the project's `node_modules` directory. `transpileJS` | `downloadMetalCli`, `expandJSCompileDependencies`, `npmInstall`, `processResources` | `TranspileJSTask` | Builds Metal.js code.

By default, the `downloadMetalCli` task downloads the version 1.3.1 of `metal-cli`. If the project's `package.json` file, however, already lists the `metal-cli` package in its `dependencies` or `devDependencies`, the `downloadMetalCli` task is disabled.

The transpileJS task is automatically configured with sensible defaults, depending on whether the java plugin is applied:

Property Name | Default Value sourceDir | The directory META-INF/resources in the first resources directory of the main source set (by default, src/main/resources/META-INF/resources). workingDir | "${sourceSets.main.output.resourcesDir}/META-INF/resources"

The plugin also adds the following dependencies to tasks defined by the java plugin:

Name | Depends On classes | transpileJS

The plugin adds a new configuration to the project called soyCompile. If one or more dependencies are added to this configuration, they will be expanded into temporary directories and passed to the transpileJS task as additional soyDependencies values.

JS Transpiler Base Plugin

The JS Transpiler Base plugin automatically applies the com.liferay.node plugin.

The plugin adds a new configuration to the project called jsCompile. If one or more dependencies are added to this configuration, they will be expanded into sub-directories of the node_modules directory, with names equal to the names of the dependencies.

The plugin also adds one task to your project:

Name | Depends On | Type | Description expandJSCompileDependencies | - | DefaultTask | Expands the additional configured JavaScript dependencies. The task itself does not do any work, but depends on a series of Copy tasks called expandJSCompileDependency${file}, which expand each dependency declared in the jsCompile configuration into the node_modules directory.

All the tasks of type ExecuteNpmTask whose name starts with "npmRun" are configured to depend on expandJSCompileDependencies. This means that, before running any script declared in the package.json file of the project, all the jsCompile dependencies will be expanded into the node_modules directory.

Tasks

TranspileJSTask

Tasks of type TranspileJSTask extend ExecuteNodeScriptTask, so all its properties and methods, such as args, inheritProxy, and workingDir, are available. They also have the following properties set by default:

Property Name | Default Value scriptFile | "${downloadMetalCli.moduleDir}/index.js" soySrcIncludes | ["**/*.soy"] srcIncludes | ["**/*.es.js*", "**/*.soy.js*"]

The purpose of this task is to run the build command of metal-cli to build Metal.js code from sourceDir into the workingDir directory.

Task Properties Property Name | Type | Default Value | Description bundleFileName | String | null | The name of the final bundle file for formats (e.g., *globals*) that create one. It sets the --bundleFileName argument. globalName | String | null | The name of the global variable that holds exported modules. It sets the --globalName argument. This is only used by the *globals* format build. moduleName | String | null | The name of the project that is being compiled. All built modules are stored in a folder with this name. It sets the --moduleName argument. This is only used by the *amd* format build. modules | String | "amd" | The format(s) that the source files are built to. It sets the --format argument. skipWhenEmpty | boolean | true | Whether to disable the task and remove its dependencies if the sourceFiles property does not return any file at the end of the project evaluation. sourceDir | File | null | The directory that contains the files to build. sourceFiles | FileCollection | [] | The Soy and JS files to compile. *(Read-only)* sourceMaps | SourceMaps | enabled | Whether to generate source map files. Available values include disabled, enabled, and enabled_inline. soyDependencies | Set<String> | ["${npmInstall.workingDir}/node_modules/clay*/src/**/*.soy",

"${npmInstall.workingDir}/node_modules/metal*/src/**/*.soy"] | The path GLOBs of Soy files that the main source files depend on, but that should not be compiled. It sets the --soyDeps argument. soySkipMetalGeneration | boolean | false | Whether to just compile Soy files, without adding Metal.js generated code, like the component class. It sets the --soySkipMetalGeneration argument. soySrcIncludes | Set<String> | [] | The path GLOBs of the Soy files to compile. It sets the --soySrc argument. srcIncludes | Set<String> | [] | The path GLOBs of the JS files to compile. It sets the --src argument.

The properties of type File support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the int and String properties to defer evaluation until task execution.

Task Methods Method | Description TranspileJSTask soyDependency(Iterable<?> soyDependencies) | Adds path GLOBs of Soy files that the main source files depend on, but that should not be compiled. TranspileJSTask soyDependency(Object... soyDependencies) | Adds path GLOBs of Soy files that the main source files depend on, but that should not be compiled. TranspileJSTask soySrcInclude(Iterable<?> soySrcIncludes) | Adds path GLOBs of Soy files to compile. TranspileJSTask soySrcInclude(Object... soySrcIncludes) | Adds path GLOBs of Soy files to compile. TranspileJSTask srcInclude(Iterable<?> srcIncludes) | Adds path GLOBs of JS files to compile. TranspileJSTask srcInclude(Object... srcIncludes) | Adds path GLOBs of JS files to compile.

131.14 JSDoc Gradle Plugin

The JSDoc Gradle plugin lets you run the JSDoc tool in order to generate documentation for your project's JavaScript files.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.jsdoc", version: "2.0.33"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}
```

There are two JSDoc Gradle plugins you can apply to your project:

- Apply the JSDoc Plugin to generate JavaScript documentation for your project:

  ```
  apply plugin: "com.liferay.jsdoc"
  ```

- Apply the App JSDoc Plugin in a parent project to generate the JavaScript documentation as a single, combined HTML document for an application that spans different subprojects, each one representing a different component of the same application:

  ```
  apply plugin: "com.liferay.app.jsdoc"
  ```

Both plugins automatically apply the com.liferay.node plugin.

JSDoc Plugin

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `downloadJSDoc` | `downloadNode` | `DownloadNodeModuleTask` | Downloads JSDoc in the project's `node_modules` directory. `jsdoc` | `downloadJSDoc` | `JSDocTask` | Generates API documentation for the project's JavaScript code.

By default, the `downloadJSDoc` task downloads version `3.5.5` of the `jsdoc` package. If the project's `package.json` file, however, already lists the `jsdoc` package in its `dependencies` or `devDependencies`, the `downloadJSDoc` task is disabled.

The `jsdoc` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `destinationDir` |

If the `java` plugin is applied: `"${project.docsDir}/jsdoc"`

Otherwise: `"${project.buildDir}/jsdoc"`

`sourceDirs` | The directory `META-INF/resources` in the first `resources` directory of the `main` source set (by default, `src/main/resources/META-INF/resources`).

AppJSDoc Plugin

To use the App JSDoc plugin, it is required to apply the `com.liferay.app.jsdoc` plugin in a parent project (that is, a project that is a common ancestor of all the subprojects representing the various components of the app). It is also required to apply the `com.liferay.jsdoc` plugin to all the subprojects that contain JavaScript files.

The App JSDoc plugin adds three tasks to your project:

Name | Depends On | Type | Description `appJSDoc` | `downloadJSDoc` | `JSDocTask` | Generates API documentation for the app's JavaScript code. `downloadJSDoc` | `downloadNode` | `DownloadNodeModuleTask` | Downloads JSDoc in the app's `node_modules` directory. `jarAppJSDoc` | `appJSDoc` | `Jar` | Assembles a JAR archive containing the JavaScript documentation files for this app.

By default, the `downloadJSDoc` task downloads version `3.5.5` of the `jsdoc` package. If the project's `package.json` file, however, already lists the `jsdoc` package in its `dependencies` or `devDependencies`, the `downloadJSDoc` task is disabled.

The `appJSDoc` task is automatically configured with sensible defaults:

Property Name | Default Value `destinationDir` | `${project.buildDir}/docs/jsdoc` `sourceDirs` | The sum of all the `jsdoc.sourceDirs` values of the subprojects.

Project Extension

The App JSDoc plugin exposes the following properties through the extension named `appJSDocConfiguration`:

Property Name | Type | Default Value | Description `subprojects` | `Set<Project>` | `project.subprojects` | The subprojects to include in the JavaScript documentation of the app.

The same extension exposes the following methods:

Method | Description `AppJSDocConfigurationExtension subprojects(Iterable<Project> subprojects)` | Include additional projects in the JavaScript documentation of the app. `AppJSDocConfigurationExtension subprojects(Project... subprojects)` | Include additional projects in the JavaScript documentation of the app.

Tasks

JSDocTask

Tasks of type `JSDocTask` extend `ExecuteNodeScriptTask`, so all its properties and methods, such as `args`, `inheritProxy`, and `workingDir`, are available.

They also have the following properties set by default:

Property Name | Default Value `scriptFile` | `"${downloadJSDoc.moduleDir}/jsdoc.js"`

Task Properties Property Name | Type | Default Value | Description `configuration` | `TextResource` | `null` | The JSDoc configuration file. It sets the `--configure` argument. `destinationDir` | `File` | `null` | The directory where the JavaScript API documentation files are saved. It sets the `--destination` argument. `packageJsonFile` | `File` | `"${project.projectDir}/package.json"` | The path to the project's package file. It sets the `--package` argument. `sourceDirs` | `FileCollection` | `[]` | The directories that contains the files to process. `readmeFile` | `File` | `null` | The path to the project's README file. It sets the `--readme` argument. `tutorialsDir` | `File` | `null` | The directory in which JSDoc should search for tutorials. It sets the `--tutorials` argument.

The properties of type `File` support any type that can be resolved by `project.file`.

131.15 Lang Builder Gradle Plugin

The Lang Builder Gradle plugin lets you run the Liferay Lang Builder tool to sort and translate the language keys in your project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.lang.builder", version: "3.0.12"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.lang.builder"
```

Since the plugin automatically resolves the Liferay Lang Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

See this page on the *Liferay Developer Network* for more information about usage of the Lang Builder Gradle plugin.

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildLang` | - | `BuildLangTask` | Runs Liferay Lang Builder to translate language property files.

The `buildLang` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `langDir` |

If the `java` plugin is applied: The directory `content` in the first `resources` directory of the `main` source set (by default: `src/main/resources/content`).

Otherwise: `null`

BuildLangTask

Tasks of type `BuildLangTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | Lang Builder command line arguments `classpath` | `project.configurations.langBuilder` `main` | `"com.liferay.lang.builder.LangBuilder"`

Task Properties Property Name | Type | Default Value | Description `excludedLanguageIds` | `Set<String>` | `["da", "de", "fi", "ja", "nl", "pt_PT", "sv"]` | The language IDs to exclude in the automatic translation. It sets the `lang.excluded.language.ids` argument. `langDir` | `File` | `null` | The directory where the language properties files are saved. It sets the `lang.dir` argument. `langFileName` | `String` | `"Language"` | The file name prefix of the language properties files (e.g., `Language_it.properties`). It sets the `lang.file` argument. `plugin` | `boolean` | `true` | Whether to check for duplicate language keys between the project and the portal. If `portalLanguagePropertiesFile` is not set, this property has no effect. It sets the `lang.plugin` argument. `portalLanguagePropertiesFile` | `File` | `null` | The `Language.properties` file of the portal. It sets the `lang.portal.language.properties.file` argument. `translate` | `boolean` | `true` | Whether to translate the language keys and generate a language properties file for each locale that's supported by Liferay. It sets the `lang.translate` argument. `translateSubscriptionKey` | `String` | `null` | The subscription key for Microsoft Translation integration. Subscription to the Translator Text Translation API on Microsoft Cognitive Services is required. Basic subscriptions, up to 2 million characters a month, are free. See here for more information. It sets the `lang.translate.subscription.key` argument.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

Task Methods Method | Description `BuildLangTask excludedLanguageIds(Iterable<Object> excludedLanguageIds)` | Adds language IDs to exclude in the automatic translation. `BuildLangTask excludedLanguageIds(Object... excludedLanguageIds)` | Adds language IDs to exclude in the automatic translation.

Additional Configuration

There are additional configurations that can help you use the Lang Builder.

Liferay Lang Builder Dependency

By default, the plugin creates a configuration called `langBuilder` and adds a dependency to the latest released version of the Liferay Lang Builder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `langBuilder` configuration:

```
dependencies {
    langBuilder group: "com.liferay", name: "com.liferay.lang.builder", version: "1.0.31"
}
```

131.16 Maven Plugin Builder Gradle Plugin

The Maven Plugin Builder Gradle Plugin lets you generate the Maven plugin descriptor for any Mojos found in your project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.maven.plugin.builder", version: "1.2.4"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.maven.plugin.builder"
```

Tasks

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `buildPluginDescriptor` |`compileJava`, `WriteMavenSettings` | `BuildPluginDescriptorTask` | Generates the Maven plugin descriptor for the project. `WriteMavenSettings` | - | `WriteMavenSettingsTask` | Writes a temporary Maven settings file to be used during subsequent Maven invocations.

The Maven Plugin Builder Plugin automatically applies the `java` plugin.

The plugin also adds the following dependencies to tasks defined by the `maven` plugin:

Name | Depends On `install`, `uploadArchives`, and all the other tasks of type `Upload` | `buildPluginDescriptor`

The `buildPluginDescriptor` task is automatically configured with sensible defaults:

Property Name | Default Value `classesDir` | `sourceSets.main.output.classesDir` `mavenEmbedderClasspath` | `configurations.mavenEmbedder` `mavenSettingsFile` | `writeMavenSettings.outputFile` `outputDir` | The directory `META-INF/maven` in the first `resources` directory of the `main` source set (by default: `src/main/resources/META-INF/maven`). `pomArtifactId` | The bundle symbolic name of the project inferred via the `OsgiHelper` class. `pomGroupId` | `project.group` `pomVersion` | `project.version` (if it ends with `"-SNAPSHOT"`, the suffix will be removed) `sourceDir` | The first `java` directory of the `main` source set (by default: `src/main/java`).

The plugin ensures that the `processResources` task always runs before `buildPluginDescriptor` to let `processResources` copy the newly generated files in the `buildPluginDescriptor.outputDir` directory.

The `writeMavenSettings` task is also automatically configured with sensible defaults:

Property Name | Default Value `localRepositoryDir` | `maven.repo.local` system property `nonProxyHosts` | `http.nonProxyHosts` system property `outputFile` | `"${project.buildDir}/settings.xml"` `proxyHost` | `http.ProxyHost` or `https.proxyHost` system property (depending on the protocol of `repositoryUrl`) `proxyPassword` | `http.ProxyPassword` or `https.proxyPassword` system property (depending on the protocol of repositoryUrl) proxyPort | http.ProxyPort or https.proxyPort system property (depending on the protocol of repositoryUrl) proxyUser | http.ProxyUser or https.proxyUser system property (depending on the protocol of repositoryUrl) repositoryUrl | repository.url system property

If running on JDK8+, the plugin also disables the *doclint* feature in all tasks of type Javadoc.

BuildPluginDescriptorTask

Tasks of type BuildPluginDescriptorTask work by generating a temporary pom.xml file based on the project, and then invoking the Maven Embedder to build the Maven plugin descriptor.

It is possible to declare information for the plugin descriptor generation using either Java 5 Annotations or Javadoc Tags.

Task Properties Property Name | Type | Default Value | Description classesDir | File | null | The directory that contains the compiled classes. It sets the value of the build.outputDirectory element in the generated pom.xml file. configurationScopeMappings | Map<String, String> | ["compile": "compile", "provided", "provided"] | The mapping between the configuration names in the Gradle project and the dependency scopes in the pom.xml file. It is used to add dependencies.dependency elements in the generated pom.xml file. forcedExclusions | Set<String> | [] | The *group:name:version* notation of the dependencies to always exclude from the ones added in the pom.xml file. It adds dependencies.dependency.exclusions.exclusion elements to the generated pom.xml file. goalPrefix | String | null | The goal prefix for the Maven plugin specified in the descriptor. It sets the value of the build.plugins.plugin.configuration.goalPrefix element in the generated pom.xml file. mavenDebug | boolean | false | Whether to invoke the Maven Embedder in debug mode. mavenEmbedderClasspath | FileCollection | null | The classpath used to invoke the Maven Embedder. mavenEmbedderMainClassName | String | "org.apache.maven.cli.MavenCli" | The Maven Embedder's main class name. mavenPluginPluginVersion | String | "3.4" | The version of the Maven Plugin Plugin to use to generate the plugin descriptor for the project. mavenSettingsFile | File | null | The custom settings.xml file to use. It sets the --settings argument on the Maven Embedder invocation. outputDir | File | null | The directory where the Maven plugin descriptor files are saved. pomArtifactId | String | null | The identifier for the artifact that is unique within the group. It sets the value of the project.artifactId element in the generated pom.xml file. pomGroupId | String | null | The universally unique identifier for the project. It sets the value of the project.groupId element in the generated pom.xml file. pomRepositories | Map<String, Object> | ["liferay-public": "http://repository.liferay.com/nexus/content/groups/public"] | The name and URL of the remote repositories. It adds repositories.repository elements in the generated pom.xml file. pomVersion | String | null | The version of the artifact produced by this project. It sets the value of the project.version element in the generated pom.xml file. sourceDir | String | null | The directory that contains the source files. It sets the value of the build.sourceDirectory element in the generated pom.xml file. useSetterComments | boolean | true | Whether to allow Mojo Javadoc Tags in the setter methods of the Mojo.

The properties of type File support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the String properties, to defer evaluation until task execution.

Task Methods

Method | Description void configurationScopeMapping(String configurationName, String scope) | Adds a mapping between a configuration name in the Gradle project and the dependency scope in the pom.xml file. BuildPluginDescriptorTask forcedExclusions(Iterable<String> forcedExclusions) | Adds *group:name:version* notations of dependencies to always exclude from the ones added in the pom.xml file. BuildPluginDescriptorTask forcedExclusions(String... forcedExclusions) | Adds *group:name:version* notations of dependencies to always exclude from the ones added in the pom.xml file. BuildPluginDescriptorTask pomRepositories(Map<String, ?> pomRepositories | Adds names and URLs of remote repositories in the pom.xml file. BuildPluginDescriptorTask pomRepository(String id, Object url) | Adds the name and URL of a remote repository in the pom.xml file.

WriteMavenSettingsTask

Task Properties Property Name | Type | Default Value | Description localRepositoryDir | String | null | The directory of the system's local repository. It sets the value of the localRepository element in the generated settings.xml file. nonProxyHosts | String | null | The patterns of the host that should be accessed without going through the proxy. It sets the value of the proxies.proxy.nonProxyHosts element in the generated settings.xml file. outputFile | File | null | The generated settings.xml file. proxyHost | String | null | The host name or address of the proxy server. It sets the value of the proxies.proxy.host element in the generated settings.xml file. proxyPassword | String | null | The password to use to access a protected proxy server. It sets the value of the proxies.proxy.password element in the generated settings.xml file. proxyPort | String | null | The port number of the proxy server. It sets the value of the proxies.proxy.port element in the generated settings.xml file. proxyUser | String | null | The user name to use to access a protected proxy server. It sets the value of the proxies.proxy.username element in the generated settings.xml file. repositoryUrl | String | null | The URL of the repository mirror. It sets the value of the mirrors.mirror.url element in the generated settings.xml file.

The properties of type File support any type that can be resolved by project.file. Moreover, it is possible to use Closures and Callables as values for the String properties, to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use the Maven Plugin Builder.

Maven Embedder Dependency

By default, the plugin creates a configuration called mavenEmbedder and adds a dependency to the 3.3.9 version of the Maven Embedder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the mavenEmbedder configuration:

```
dependencies {
    mavenEmbedder group: "org.apache.maven", name: "maven-embedder", version: "3.3.9"
    mavenEmbedder group: "org.apache.maven.wagon", name: "wagon-http", version: "2.10"
    mavenEmbedder group: "org.eclipse.aether", name: "aether-connector-basic", version: "1.0.2.v20150114"
    mavenEmbedder group: "org.eclipse.aether", name: "aether-transport-wagon", version: "1.0.2.v20150114"
    mavenEmbedder group: "org.slf4j", name: "slf4j-simple", version: "1.7.5"
}
```

System Properties

It is possible to set the default value of the mavenDebug property for a BuildPluginDescriptorTask task via system property:

- -D${task.name}.maven.debug=true

For example, run the following Bash command to invoke the Maven Embedder in debug mode to attach a remote debugger:

```
./gradlew buildPluginDescriptor -DbuildPluginDescriptor.maven.debug=true
```

131.17 Node Gradle Plugin

The Node Gradle plugin lets you run Node.js and NPM as part of your build.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.node", version: "4.6.18"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.node"
```

Project Extension

The Node Gradle plugin exposes the following properties through the extension named `node`:

Property Name | Type | Default Value | Description `download` | `boolean` | `true` | Whether to download and use a local and isolated Node.js distribution instead of the one installed in the system. `global` | `boolean` | `false` | Whether to use a single Node.js installation for the whole multi-project build. This reduces the time required to unpack the Node.js distribution and the time required to download NPM packages thanks to a shared packages cache. If `download` is `false`, this property has no effect. `nodeDir` | `File` |

If `global` is `true`: `"${rootProject.buildDir}/node"`

Otherwise: `"${project.buildDir}/node"`

| The directory where the Node.js distribution is unpacked. If `download` is `false`, this property has no effect. `nodeUrl` | `String` | `"http://nodejs.org/dist/v${node.nodeVersion}/node-v${node.nodeVersion}-${platform}-x${bitMode}.${extension}"` | The URL of the Node.js distribution to download. If `download` is `false`, this property has no effect. `nodeVersion` | `String` | `"5.5.0"` | The version of the Node.js distribution to use. If `download` is `false`, this property has no effect. `npmArgs` | `List<String>` | `[]` | The arguments added automatically to every task of type `ExecuteNpmTask`. `npmUrl` | `String` | `"https://registry.npmjs.org/npm/-/npm-${node.npmVersion}.tgz"` | The URL of the NPM version to download. If `download` is `false`, this property has no effect. `npmVersion` | `String` | `null` | The version of NPM to use. If `null`, the version of NPM embedded inside the Node.js distribution is used. If `download` is `false`, this property has no effect.

It is possible to override the default value of the `download` property by setting the `nodeDownload` project property. For example, this can be done via command line argument:

```
./gradlew -PnodeDownload=false npmInstall
```

The same extension exposes the following methods:

Method | Description `NodeExtension npmArgs(Iterable<?> npmArgs)` | Adds arguments to automatically add to every task of type `ExecuteNpmTask`. `NodeExtension npmArgs(Object... npmArgs)` | Adds arguments to automatically add to every task of type `ExecuteNpmTask`.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for `String`, to defer evaluation until execution.

Please note that setting the `global` property of the `node` extension via the command line is not supported. It can only be set via Gradle script, which can be done by adding the following code to the `build.gradle` file in the root of a project (e.g., Liferay Workspace):

```
allprojects {
    plugins.withId("com.liferay.node") {
        node.global = true
    }
}
```

Tasks

The plugin adds a series of tasks to your project:

Name | Depends On | Type | Description `cleanNPM` | - | `Delete` | Deletes the `node_modules` directory, the `npm-shrinkwrap.json` file and the `package-lock.json` files from the project, if present. `downloadNode` | - | `DownloadNodeTask` | Downloads and unpacks the local Node.js distribution for the project. If `node.download` is `false`, this task is disabled. `npmInstall` | `downloadNode` | `NpmInstallTask` | Runs `npm install` to install the dependencies declared in the project's `package.json` file, if present. By default, the task is configured to run `npm install` two more times if it fails. `npmRun${script}` | `npmInstall` | `ExecuteNpmTask` | Runs the `${script}` NPM script. `npmPackageLock` | `cleanNPM`, `npmInstall` | `DefaultTask` | Deletes the NPM files and runs `npm install` to install the dependencies declared in the project's `package.json` file, if present. `npmShrinkwrap` | `cleanNPM`, `npmInstall` | `NpmShrinkwrapTask` | Locks down the versions of a package's dependencies in order to control which dependency versions are used.

DownloadNodeTask

The purpose of this task is to download and unpack a Node.js distribution.

Task Properties Property Name | Type | Default Value | Description `nodeDir` | `File` | `null` | The directory where the Node.js distribution is unpacked. `nodeExeUrl` | `String` | `null` | The URL of `node.exe` to download when on Windows. `nodeUrl` | `String` | `null` | The URL of the Node.js distribution to download. `npmUrl` | `String` | `null` | The URL of the NPM version to download.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

ExecuteNodeTask

This is the base task to run Node.js in a Gradle build. All tasks of type `ExecuteNodeTask` automatically depend on `downloadNode`.

Task Properties Property Name | Type | Default Value | Description `args` | `List<Object>` | `[]` | The arguments for the Node.js invocation. `command` | `String` | `"node"` | The file name of the executable to invoke. `environment` | `Map<Object, Object>` | `[]` | The environment variables for the Node.js invocation. `inheritProxy` | `boolean` | `true` | Whether to set the `http_proxy`, `https_proxy`, and `no_proxy` environment variables in the Node.js invocation based on the values of the system properties `https.proxyHost`, `https.proxyPort`, `https.proxyUser`, `https.proxyPassword`, `https.nonProxyHosts`, `https.proxyHost`, `https.proxyPort`, `https.proxyUser`, `https.proxyPassword`, and `https.nonProxyHosts`. If these environment variables are already set, their values will not be overwritten. `nodeDir` | `File` |

If `node.download` is `true`: `node.nodeDir`

Otherwise: `null`

| The directory that contains the executable to invoke. If `null`, the executable must be available in the system `PATH`. `npmInstallRetries` | `int` | `0` | The number of times the `node_modules` is deleted, the NPM cached data is verified (`npm cache verify`), and `npm install` is retried in case the Node.js invocation defined by this task fails. This can help solving corrupted `node_modules` directories by re-downloading the project's dependencies. `workingDir` | `File` | `project.projectDir` | The working directory to use in the Node.js invocation.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

Task Methods Method | Description `ExecuteNodeTask args(Iterable<?> args)` | Adds arguments for the Node.js invocation. `ExecuteNodeTask args(Object... args)` | Adds arguments for the Node.js invocation. `ExecuteNodeTask environment(Map<?, ?> environment)` | Adds environment variables for the Node.js invocation. `ExecuteNodeTask environment(Object key, Object value)` | Adds an environment variable for the Node.js invocation.

ExecuteNodeScriptTask

The purpose of this task is to execute a Node.js script. Tasks of type `ExecuteNodeScriptTask` extend `ExecuteNodeTask`.

Task Properties Property Name | Type | Default Value | Description `scriptFile` | `File` | `null` | The Node.js script to execute.

The properties of type `File` support any type that can be resolved by `project.file`.

ExecuteNpmTask

The purpose of this task is to execute an NPM command. Tasks of type `ExecuteNpmTask` extend `ExecuteNodeScriptTask` with the following properties set by default:

Property Name | Default Value `command` |

If `nodeDir` is `null`: `"npm"`

Otherwise: `"node"`

`scriptFile` |

If `nodeDir` is `null`: `null`

Otherwise: `"${nodeDir}/lib/node_modules/npm/bin/npm-cli.js"` or `"${nodeDir}/node_modules/npm/bin/npm-cli.js"` on Windows.

Task Properties Property Name | Type | Default Value | Description `cacheConcurrent` | `boolean` |

If `node.npmVersion` is greater than or equal to `5.0.0`, or `node.nodeVersion` is greater than or equal to `8.0.0`: `true`

Otherwise: `false`

| Whether to run this task concurrently, in case the version of NPM in use supports multiple concurrent accesses to the same cache directory. `cacheDir` | `File` |

If `nodeDir` is `null`, or `node.npmVersion` is greater than or equal to `5.0.0`, or `node.nodeVersion` is greater than or equal to `8.0.0`: `null`

Otherwise: `"${nodeDir}/.cache"`

| The location of NPM's cache directory. It sets the `--cache` argument. Leave the property `null` to keep the default value. `logLevel` | `String` | Value to mirror the log level set in the task's `logger` object. | The NPM log level. It sets the –loglevel argument. `production` | `boolean` | `false` | Whether to run in production mode during the NPM invocation. It sets the `--production` argument. `progress` | `boolean` | `true` | Whether to show

a progress bar during the NPM invocation. It sets the `--progress` argument. `registry` | `String` | `null` | The base URL of the NPM package registry. It sets the `--registry` argument. Leave the property `null` or empty to keep the default value.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

DownloadNodeModuleTask

The purpose of this task is to download a Node.js package. The packages are downloaded in the `${workingDir}/node_modules` directory, which is equal, by default, to the `node_modules` directory of the project. Tasks of type `DownloadNodeModuleTask` extend `ExecuteNpmTask` in order to execute the command `npm install ${moduleName}@${moduleVersion}`.

`DownloadNodeModuleTask` instances are automatically disabled if the project's `package.json` file already lists a module with the same name in its `dependencies` or `devDependencies` object.

Task Properties Property Name | Type | Default Value | Description `moduleName` | `String` | `null` | The name of the Node.js package to download. `moduleVersion` | `String` | `null` | The version of the Node.js package to download.

It is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

NpmInstallTask

Purpose of these tasks is to install the dependencies declared in a `package.json` file. Tasks of type `NpmInstallTask` extend `ExecuteNpmTask` in order to run the command `npm install`.

`NpmInstallTask` instances are automatically disabled if the `package.json` file does not declare any dependency in the `dependency` or `devDependencies` object.

Task Properties Property Name | Type | Default Value | Description `nodeModulesCacheDir` | `File` | `null` |

The directory where `node_modules` directories are cached. By setting this property, it is possible to cache the `node_modules` directory of a project and avoid unnecessary invocations of `npm install`, useful especially in Continuous Integration environments.

The `node_modules` directory is cached based on the content of the project's `package-lock.json` (or `npm-shrinkwrap.json`, or `package.json` if absent). Therefore, if `NpmInstallTask` tasks in multiple projects are configured with the same `nodeModulesCacheDir`, and their `package-lock.json`, `npm-shrinkwrap.json` or `package.json` declare the same dependencies, their `node_modules` caches will be shared.

This feature is not available if the `com.liferay.cache` plugin is applied.

`nodeModulesCacheNativeSync` | `boolean` | `true` | Whether to use `rsync` (on Linux/macOS) or `robocopy` (on Windows) to cache and restore the `node_modules` directory. If `nodeModulesCacheDir` is not set, this property has no effect. `nodeModulesDigestFile` | `File` | `null` |

If this property is set, the content of the project's `package-lock.json` (or `npm-shrinkwrap.json`, or `package.json` if absent) is checked with the digest from the `node_modules` directory. If the digests match, do nothing. If the digests don't match, the `node_modules` directory is deleted before running `npm install`.

This feature is not available if the `com.liferay.cache` plugin is applied or if the property `nodeModulesCacheDir` is set.

`removeShrinkwrappedUrls` | `boolean` | `true` if the registry property has a value, `false` otherwise. | Whether to temporarily remove all the hard-coded URLs in the `from` and `resolved` fields of the `npm-shinkwrap.json` file before invoking `npm install`. This way, it is possible to force NPM to download all dependencies from a custom registry declared in the `registry` property. `useNpmCI` | `boolean` | `false` | Whether to run `npm ci` instead of `npm install`. If the `package-lock.json` file does not exist, this property has no effect.

The properties of type `File` support any type that can be resolved by `project.file`.

NpmShrinkwrapTask

The purpose of this task is to lock down the versions of a package's dependencies so that you can control exactly which dependency versions are used when your package is installed. Tasks of type `NpmShrinkwrapTask` extend `ExecuteNpmTask` to execute the command `npm shrinkwrap`.

The generated `npm-shrinkwrap.json` file is automatically sorted and formatted, so it's easier to see the changes with the previous version.

`NpmShrinkwrapTask` instances are automatically disabled if the `package.json` file does not exist.

Task Properties Property Name | Type | Default Value | Description `excludedDependencies` | `List<String>` | `[]` | The package names to exclude from the generated `npm-shrinkwrap.json` file. `includeDevDependencies` | `boolean` | `true` | Whether to include the package's `devDependencies`. It sets the `--dev` argument.

It is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

Task Methods Method | Description `NpmShrinkwrapTask excludeDependencies(Iterable<?> excludedDependencies)` | Adds package names to exclude from the generated `npm-shrinkwrap.json` file. `NpmShrinkwrapTask excludeDependencies(Object... excludedDependencies)` | Adds package names to exclude from the generated `npm-shrinkwrap.json` file.

PublishNodeModuleTask

The purpose of this task is to publish a package to the NPM registry. Tasks of type `PublishNodeModuleTask` extend `ExecuteNpmTask` in order to execute the command `npm publish`.

These tasks generate a new temporary `package.json` file in the directory assigned to the `workingDir` property; then the `npm publish` command is executed. If the `package.json` file in that location does not exist, the one in the root of the project directory (if found) is copied; otherwise, a new file is created.

The `package.json` is then processed by adding the values provided by the task properties, if not already present in the file itself. It is still possible to override one or more fields of the `package.json` file with the values provided by the task properties by adding one or more keys (e.g., `"version"`) to the `overriddenPackageJsonKeys` property.

Task Properties Property Name | Type | Default Value | Description `moduleAuthor` | `String` | `null` | The value of the `author` field in the generated `package.json` file. `moduleBugsUrl` | `String` | `null` | The value of the `bugs.url` field in the generated `package.json` file. `moduleDescription` | `String` | `project.description` | The value of the `description` field in the generated `package.json` file. `moduleKeywords` | `List<String>` | `[]` | The value of the `keywords` field in the generated `package.json` file. `moduleLicense` | `String` | `null` | The value of the `license` field in the generated `package.json` file. `moduleMain` | `String` | `null` | The value of the `main` field in the generated `package.json` file. `moduleName` | `String` | Name based on `osgiHelper.bundleSymbolicName`: for example, if `osgiHelper.bundleSymbolicName` is `"com.liferay.gradle.plugins.node"`, the default value for the `moduleName` property is `"liferay-gradle-plugins-node"`. | The value of the `name` field in the generated `package.json` file. `moduleRepository` | `String` | `null` | The value of the `repository` field in the generated `package.json` file. `moduleVersion` | `String` | `project.version` | The value of the `version` field in the generated `package.json` file. `npmEmailAddress` | `String` | `null` | The email address of the npmjs.com user that publishes the package. npmPassword | String | null | The password of the npmjs.com user that publishes the package. npmUserName | String | null | The name of the npmjs.com user that publishes the package. overriddenPackageJsonKeys | Set<String> | [] | The field values to override in the generated package.json file.

Task Methods

Method	Description
PublishNodeModuleTask overriddenPackageJsonKeys(Iterable<String> overriddenPackageJsonKeys)	Adds field values to override in the generated package.json file.
PublishNodeModuleTask overriddenPackageJsonKeys(String... overriddenPackageJsonKeys)	Adds field values to override in the generated package.json file.

npmRun${script} Task

For each script declared in the package.json file of the project, one task npmRun${script} of type ExecuteNpmTask is added. Each of these tasks is automatically configured with sensible defaults:

Property Name | Default Value args | ["run-script", "${script}"]

If the java plugin is applied and the package.json file declares a script named "build", the script is executed before the classes task but after the processResources task.

If the lifecycle-base plugin is applied and the package.json file declares a script named test, the script is executed when running the check task.

131.18 Service Builder Gradle Plugin

The Service Builder Gradle plugin lets you generate a service layer defined in a Service Builder service.xml file.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.service.builder", version: "2.2.46"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.portal.tools.service.builder"
```

The Service Builder plugin automatically applies the java plugin.

Since the plugin automatically resolves the Liferay Service Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildService` | - | `BuildServiceTask` | Runs the Liferay Service Builder.

The `buildService` task is automatically configured with sensible defaults, depending on whether the `war` plugin is applied, or whether the `osgiModule` property is `true`:

Property Name | Default Value `apiDir` |

If the `war` plugin is applied: `${project.webAppDir}/WEB-INF/service`

Otherwise: `null`

`hbmFile` |

If `osgiModule` is true: `${buildService.resourcesDir}/META-INF/module-hbm.xml`

Otherwise: `${buildService.resourcesDir}/META-INF/portlet-hbm.xml`

`implDir` | The first `java` directory of the `main` source set (by default: `src/main/java`). `inputFile` |

If the `war` plugin is applied: `${project.webAppDir}/WEB-INF/service.xml`

Otherwise: `${project.projectDir}/service.xml`

`modelHintsFile` | The file `META-INF/portlet-model-hints.xml` in the first `resources` directory of the `main` source set (by default: `src/main/resources/META-INF/portlet-model-hints.xml`). `pluginName` |

If `osgiModule` is true: `""`

Otherwise: `project.name`

`propsUtil` |

If `osgiModule` is true: `"${bundleSymbolicName}.util.ServiceProps"`The `bundleSymbolicName` of the project is inferred via the `OsgiHelper` class.

Otherwise: `"com.liferay.util.service.ServiceProps"`

`resourcesDir` | The first `resources` directory of the `main` source set (by default: `src/main/resources`). `springFile` |

If `osgiModule` is true: the file `META-INF/spring/module-spring.xml` in the first `resources` directory of the `main` source set (by default: `src/main/resources/META-INF/spring/module-spring.xml`)

Otherwise: the file `META-INF/portlet-spring.xml` in the first `resources` directory of the `main` source set (by default: `src/main/resources/META-INF/portlet-spring.xml`)

`sqlDir` |

If the `war` plugin is applied: `${project.webAppDir}/WEB-INF/sql`

Otherwise: The directory `META-INF/sql` in the first `resources` directory of the `main` source set (by default: `src/main/resources/META-INF/sql`).

In the typical scenario of a data-driven Liferay OSGi application split in `myapp-app`, `myapp-service` and `myapp-web` modules, the `service.xml` file is usually contained in the root directory of `myapp-service`. In the `build.gradle` of the same module, it is enough to apply the `com.liferay.service.builder` plugin as described, and then add the following snippet to enable the use of Liferay Service Builder:

```
buildService {
    apiDir = "../myapp-api/src/main/java"
    testDir = "../myapp-test/src/testIntegration/java"
}
```

While apiDir is required, the testDir property assignment can be left out, in which case Arquillian-based integration test classes are generated.

BuildServiceTask

Tasks of type BuildWSDDTask extend JavaExec, so all its properties and methods, such as args and maxHeapSize are available. They also have the following properties set by default:

Property Name | Default Value args | Service Builder command line arguments classpath | project.configurations.serviceBuilder main | "com.liferay.portal.tools.service.builder.ServiceBuilder" systemProperties | ["file.encoding": "UTF-8"]

Task Properties Property Name | Type | Default Value | Description apiDir | File | null | A directory where the service API Java source files are generated. It sets the service.api.dir argument. autoImportDefaultReferences | boolean | true | Whether to automatically add default references, like com.liferay.portal.ClassName, com.liferay.portal.Resource and com.liferay.portal.User, to the services. It sets the service.auto.import.default.references argument. autoNamespaceTables | boolean | true | Whether to prefix table names by the namespace specified in the service.xml file. It sets the service.auto.namespace.tables argument. beanLocatorUtil | String | "com.liferay.util.bean.PortletBeanLocatorUtil" | The fully qualified class name of a bean locator class to use in the generated service classes. It sets the service.bean.locator.util argument. buildNumber | long | 1 | A specific value to assign the build.number property in the service.properties file. It sets the service.build.number argument. buildNumberIncrement | boolean | true | Whether to automatically increment the build.number property in the service.properties file by one at every service generation. It sets the service.build.number.increment argument. databaseNameMaxLength | int | 30 | The upper bound for database table and column name lengths to ensure it works on all databases. It sets the service.database.name.max.length argument. hbmFile | File | null | A Hibernate Mapping file to generate. It sets the service.hbm.file argument. implDir | File | null | A directory where the service Java source files are generated. It sets the service.impl.dir argument. inputFile | File | null | The project's service.xml file. It sets the service.input.file argument. modelHintsConfigs | Set | ["classpath*:META-INF/portal-model-hints.xml", "META-INF/portal-model-hints.xml", "classpath*:META-INF/ext-model-hints.xml", "classpath*:META-INF/portlet-model-hints.xml"] | Paths to the model hints files for Liferay Service Builder to use in generating the service layer. It sets the service.model.hints.configs argument. modelHintsFile | File | null | A model hints file for the project. It sets the service.model.hints.file argument. osgiModule | boolean | false | Whether to generate the service layer for OSGi modules. It sets the service.osgi.module argument. pluginName | String | null | If specified, a plugin can enable additional generation features, such as Clp class generation, for non-OSGi modules. It sets the service.plugin.name argument. propsUtil | String | null | The fully qualified class name of the service properties util class to generate. It sets the service.props.util argument. readOnlyPrefixes | Set | ["fetch", "get", "has", "is", "load", "reindex", "search"] | Prefixes of methods to consider read-only. It sets the service.read.only.prefixes argument. resourceActionsConfigs | Set | ["META-INF/resource-actions/default.xml", "resource-actions/default.xml"] | Paths to the resource actions files for Liferay Service Builder to use in generating the service layer. It sets the service.resource.actions.configs argument. resourcesDir | File | null | A directory where the service non-Java files are generated. It sets the service.resources.dir argument. springFile | File | null | A service Spring file to generate. It sets the service.spring.file argument. springNamespaces | Set | ["beans"] | Namespaces of Spring XML Schemas to add to the service Spring file. It sets the service.spring.namespaces argument. sqlDir | File | null | A directory where the SQL files are generated. It sets the service.sql.dir argument. sqlFileName | String | "tables.sql" | A name (relative to sqlDir) for the file in which the SQL table creation instructions are generated. It sets the service.sql.file argument. sqlIndexesFileName | String | "indexes.sql" |

A name (relative to sqlDir) for the file in which the SQL index creation instructions are generated. It sets the `service.sql.indexes.file` argument. `sqlSequencesFileName` | `String` | `"sequences.sql"` | A name (relative to sqlDir) for the file in which the SQL sequence creation instructions are generated. It sets the `service.sql.sequences.file` argument. `targetEntityName` | `String` | `null` | If specified, it's the name of the entity for which Liferay Service Builder should generate the service. It sets the `service.target.entity.name` argument. `testDir` | `File` | `null` | If specified, it's a directory where integration test Java source files are generated. It sets the `service.test.dir` argument. `uadDir` | `File` | `null` | A directory where the UAD (user-associated data) Java source files are generated. It sets the `service.uad.dir` argument. `uadTestIntegrationDir` | `File` | `null` | A directory where integration test UAD (user-associated data) Java source files are generated. It sets the `service.uad.test.integration.dir` argument.

The properties of type `File` supports any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use Service Builder.

Liferay Service Builder Dependency

By default, the plugin creates a configuration called `serviceBuilder` and adds a dependency to the latest released version of Liferay Service Builder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `serviceBuilder` configuration:

```
dependencies {
    serviceBuilder group: "com.liferay", name: "com.liferay.portal.tools.service.builder", version: "1.0.292"
}
```

If you're applying the `com.liferay.gradle.plugins` or `com.liferay.gradle.plugins.workspace` plugins to your project, the Service Builder dependency is already added to the `serviceBuilder` configuration. Therefore, if you try to apply a customized version of Service Builder, it's not recognized; you must override the configuration already applied.

To do this, you must customize the classpath of the `buildService` task. If you're supplying the customized Service Builder plugin through a module named `custom-sb-api`, you could modify the `buildService` task like this:

```
buildService {
    apiDir = "../custom-sb-api/src/main/java"
    classpath = configurations.serviceBuilder.filter { file -> !file.name.contains("com.liferay.portal.tools.service.builder") }
}
```

If you do this in conjunction with the `serviceBuilder` dependency configuration, the custom Service Builder version is used.

131.19 Source Formatter Gradle Plugin

The Source Formatter Gradle plugin lets you format project files using the Liferay Source Formatter tool.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.source.formatter", version: "2.3.413"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.source.formatter"
```

Since the plugin automatically resolves the Liferay Source Formatter library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds two tasks to your project:

Name | Depends On | Type | Description `checkSourceFormatting` | - | `FormatSourceTask` | Runs the Liferay Source Formatter to check for source formatting errors. `formatSource` | - | `FormatSourceTask` | Runs the Liferay Source Formatter to format the project files.

If desired, it is possible to check for source formatting errors while executing the `check` task by adding the following dependency:

```
check {
    dependsOn checkSourceFormatting
}
```

The same can be achieved by adding the following snippet to the `build.gradle` file in the root directory of a *Liferay Workspace*:

```
subprojects {
    afterEvaluate {
        if (plugins.hasPlugin("base") && plugins.hasPlugin("com.liferay.source.formatter")) {
            check.dependsOn checkSourceFormatting
        }
    }
}
```

The tasks `checkSourceFormatting` and `formatSource` are automatically skipped if another task with the same name is being executed in a parent project.

FormatSourceTask

Tasks of type `FormatSourceTask` extend `JavaExec`, so all its properties and methods, like `args` and `maxHeapSize` are available. They also have the following properties set by default:

Property Name | Default Value `args` | Source Formatter command line arguments `classpath` | `project.configurations.sourceFormatter` `main` | `"com.liferay.source.formatter.SourceFormatter"`

Task Properties Property Name | Type | Default Value | Description `autoFix` | `boolean` | `false` | Whether to automatically fix source formatting errors. It sets the `source.auto.fix` argument. `baseDir` | `File` | | The Source Formatter base directory. It sets the `source.base.dir` argument. *(Read-only)* `baseDirName` | `String` | `"./"` | The name of the Source Formatter base directory, relative to the project directory. `fileExtensions` | `List<String>` | `[]` | The file extensions to format. If empty, all file extensions will be formatted. It sets the `source.file.extensions` argument. `files` | `List<File>` | | The list of files to format. It sets the `source.files` argument. *(Read-only)* `fileNames` | `List<String>` | `null` | The file names to format, relative to the project directory. If `null`, all files contained in `baseDir` will be formatted. `formatCurrentBranch` | `boolean` | `false` | Whether to format only the files contained in `baseDir` that are added or modified in the current Git branch. It sets the `format.current.branch` argument. `formatLatestAuthor` | `boolean` | `false` | Whether to format only the files contained in `baseDir` that are added or modified in the latest Git commits of the same author. It sets the `format.latest.author` argument. `formatLocalChanges` | `boolean` | `false` | Whether to format only the unstaged files contained in `baseDir`. It sets the `format.local.changes` argument. `gitWorkingBranchName` | `String` | `"master"` | The Git working branch name. It sets the `git.working.branch.name` argument. `includeSubrepositories` | `boolean` | `false` | Whether to format files that are in read-only subrepositories. It sets the `include.subrepositories` argument. `maxLineLength` | `int` | `80` | The maximum number of characters allowed in Java files. It sets the `max.line.length` argument. `printErrors` | `boolean` | `true` | Whether to print formatting errors on the Standard Output stream. It sets the `source.print.errors` argument. `processorThreadCount` | `int` | `5` | The number of threads used by Source Formatter. It sets the `processor.thread.count` argument. `showDebugInformation` | `boolean` | `false` | Whether to show debug information, if present. It sets the `show.debug.information` argument. `showDocumentation` | `boolean` | `false` | Whether to show the documentation for the source formatting issues, if present. It sets the `show.documentation` argument. `showStatusUpdates` | `boolean` | `false` | Whether to show status updates during source formatting, if present. It sets the `show.status.updates` argument. `throwException` | `boolean` | `false` | Whether to fail the build if formatting errors are found. It sets the `source.throw.exception` argument.

Additional Configuration

There are additional configurations that can help you use the Source Formatter.

Liferay Source Formatter Dependency

By default, the plugin creates a configuration called `sourceFormatter` and adds a dependency to the latest released version of Liferay Source Formatter. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `sourceFormatter` configuration:

```
dependencies {
    sourceFormatter group: "com.liferay", name: "com.liferay.source.formatter", version: "1.0.885"
}
```

System Properties

It is possible to set the default values of the `fileExtensions`, `fileNames`, `formatCurrentBranch`, `formatLatestAuthor`, and `formatLocalChanges` properties for a `FormatSourceTask` task via system properties:

- `-D${task.name}.file.extensions=java,xml`
- `-D${task.name}.file.names=README.markdown,src/main/resources/hello.txt`
- `-D${task.name}.format.current.branch=true`
- `-D${task.name}.format.latest.author=true`
- `-D${task.name}.format.local.changes=true`

For example, run the following Bash command to format only the unstaged files in the project:

```
./gradlew formatSource -DformatSource.format.local.changes=true
```

131.20 Soy Gradle Plugin

The Soy Gradle plugin lets you compile Closure Templates into JavaScript functions. It also lets you use a custom localization mechanism in the generated `.soy.js` files by replacing `goog.getMsg` definitions with a different function call (e.g., `Liferay.Language.get`).

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.soy", version: "3.1.8"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}
```

There are two Soy Gradle plugins you can apply to your project:

- Apply the *Soy Plugin* to compile Closure Templates into JavaScript functions:

  ```
  apply plugin: "com.liferay.soy"
  ```

- Apply the *Soy Translation Plugin* to use a custom localization mechanism in the generated `.soy.js` files:

  ```
  apply plugin: "com.liferay.soy.translation"
  ```

Since the Soy Gradle plugin automatically resolves the Soy library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Soy Plugin

The Soy plugin adds two tasks to your project:

Name | Depends On | Type | Description `buildSoy` | - | `BuildSoyTask` | Compiles Closure Templates into JavaScript functions. `wrapSoyAlloyTemplate` | - `configJSModules` if `com.liferay.js.module.config.generator` is applied - `processResources` if `java` is applied - `transpileJS` if `com.liferay.js.transpiler` is applied | `WrapSoyAlloyTemplateTask` | Wraps the JavaScript functions compiled from Closure Templates into AlloyUI modules.

The plugin also adds the following dependencies to tasks defined by the `java` plugin:

Name | Depends On `classes` | `wrapSoyAlloyTemplate`

The `buildSoy` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `includes` | `["**/*.soy"]` `source` |

If the `java` plugin is applied: The first `resources` directory of the `main` source set (by default, `src/main/resources`).

Otherwise: `[]`

The `wrapSoyAlloyTemplate` task is **disabled by default**, and it is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `enabled` | `false` `includes` | `["**/*.soy.js"]` `source` |

If the `java` plugin is applied: `project.sourceSets.main.output.resourcesDir`

Otherwise: `[]`

Additional Configuration

There are additional configurations that can help you use the Soy library.

Soy Dependency By default, the plugin creates a configuration called soy and adds a dependency to the `2015-04-10` version of the Soy library. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the soy configuration:

```
dependencies {
    soy group: "com.google.template", name: "soy", version: "2015-04-10"
}
```

Soy Translation Plugin

The Soy Translation plugin adds one task to your project:

Name | Depends On | Type | Description `replaceSoyTranslation` | - `configJSModules` if `com.liferay.js.module.config.gene` is applied - `processResources` if `java` is applied - `transpileJS` if `com.liferay.js.transpiler` is applied | `ReplaceSoyTranslationTask` | Replaces `goog.getMsg` definitions with `Liferay.Language.get` calls.

The plugin also adds the following dependencies to tasks defined by the `java` plugin:

Name | Depends On `classes` | `replaceSoyTranslation`

The `replaceSoyTranslation` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `includes` | `["**/*.soy.js"]` `replacementClosure` | Replaces `goog.getMsg` definitions with `Liferay.Language.get` calls. `source` |

If the `java` plugin is applied: `project.sourceSets.main.output.resourcesDir`

Otherwise: `[]`

Tasks

BuildSoyTask

Tasks of type `BuildSoyTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Task Properties Property Name | Type | Default Value | Description `classpath` | `FileCollection` | `project.configurations.soy` | The classpath for executing the Liferay Portal Tools Soy Builder.

WrapSoyAlloyTemplateTask

Tasks of type `WrapSoyAlloyTemplateTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Task Properties Property Name | Type | Default Value | Description `moduleName` | `String` | `null` | The name of the AlloyUI module. `namespace` | `String` | `null` | The namespace of the Closure Templates of the project.

It is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

ReplaceSoyTranslationTask

The `ReplaceSoyTranslationTask` task type finds all the `goog.getMsg` definitions in the project's files and replaces them with a custom function call.

```
var MSG_EXTERNAL_123 = goog.getMsg('welcome-to-{$releaseInfo}', { 'releaseInfo': opt_data.releaseInfo });
```

A `goog.getMsg` definition looks like the example above, and it has the following components:

- *variable name*: `MSG_EXTERNAL_123`
- *language key*: `welcome-to-{$releaseInfo}`
- *arguments object*: `{ 'releaseInfo': opt_data.releaseInfo }`

Tasks of type `ReplaceSoyTranslationTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Task Properties Property Name | Type | Default Value | Description `replacementClosure` | `Closure<String>` | `null` | The Closure invoked in order to get the replacement for `goog.getMsg` definitions. The given Closure is passed the *variable name*, *language key*, and *arguments object* as its parameters.

131.21 Target Platform Gradle Plugin

The Target Platform Gradle plugin helps with building multiple projects against a declared API target platform. Java dependencies can be managed with Maven BOMs and OSGi modules can be resolved against an OSGi distribution.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.target.platform", version: "1.1.13"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}
```

There are two Target Platform Gradle plugins you can apply to your project:

- The *Target Platform Plugin* helps to configure your projects to build against an established set of platform artifacts, including Java and OSGi dependencies.

  ```
  apply plugin: "com.liferay.target.platform"
  ```

- The *Target Platform IDE Plugin* is a superset of the Target Platform Plugin (it applies the above plugin) and also adds IDE integration for searching and debugging source code in the target platform artifacts.

  ```
  apply plugin: "com.liferay.target.platform.ide"
  ```

Since the plugin automatically resolves target platform configurations as dependencies, you must configure a repository that hosts these artifacts. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Target Platform Plugin

The plugin applies the Spring Dependency Management Plugin and then adds several specific configurations to configure the BOMs that are imported to manage Java dependencies and the various artifacts used in resolving OSGi dependencies. Also, a new `resolve` task is added to resolve all OSGi requirements against a declared distribution artifact.

The plugin adds a series of configurations to your project:

Name | Description `targetPlatformBOMs` | Configures all the BOMs to import as managed dependencies. `targetPlatformBundles` | Configures all the bundles in addition to the distro to resolve against. `targetPlatformDistro` | Configures the distro JAR file to use as base for resolving against. `targetPlatformRequirements` | Configures the list of JAR files to use as run requirements for resolving.

The plugin adds a task `resolve` of type `ResolveTask` to your project that performs an OSGi resolve operation using the `targetPlatformRequirements` configuration as the basis of the requirements. The `targetPlatformBundles` configuration is used as a repository for the resolver to resolve requirements. Lastly, the `targetPlatformDistro` configuration is used to provide the *distro* artifact for the resolve process. The *distro* is the artifact that provides all the OSGi capabilities of the target platform. All of these parameters are used to create a `bndrun` file that can be used as input into the Bndrun resolve operation.

Target Platform IDE Plugin

The plugin applies the Target Platform and the `eclipse` plugins to your project, and also adds a special `targetPlatformIDE` configuration, which is used to configure both the `eclipse` and `idea` plugin model in Gradle to add all target platform artifacts to the classpath so they are visible to both Eclipse and IntelliJ's Java Model Search (for looking up sources to classes).

Project Extension

The Target Platform plugin exposes the following properties through the extension named `targetPlatform`:

Property Name | Type | Default Value | Description `ignoreResolveFailures` | `boolean` | `true` | Whether to ignore resolve failures found when executing tasks of type `ResolveTask`. `subprojects` | `Set<Project>` | `project.subprojects` | The subprojects to configure with target platform support, including dependency management and the `resolve` task.

The same extension exposes the following methods:

Method | Description `TargetPlatformExtension applyToConfiguration(Iterable<?> configurationNames)` | Adds additional configurations to configure the BOMs that are imported to manage Java dependencies and the various artifacts used in resolving OSGi dependencies. `TargetPlatformExtension applyToConfiguration(Object... configurationNames)` | Adds additional configurations to configure the BOMs that are imported to manage Java dependencies and the various artifacts used in resolving OSGi dependencies. `TargetPlatformExtension onlyIf(Closure<Boolean> onlyIfClosure)` | Includes a subproject in the target platform configuration if the given closure returns `true`. The closure is evaluated at the end of the subproject configuration phase and is passed a single parameter: the subproject. If the closure returns `false`, the subproject is not included in the target platform configuration `TargetPlatformExtension onlyIf(Spec<Project> onlyIfSpec)` | Includes a subproject in the target platform configuration if the given spec is satisfied. The spec is evaluated at the end of the subproject configuration phase. If the spec is not satisfied, the subproject is not included in the target platform configuration. `TargetPlatformExtension resolveOnlyIf(Closure<Boolean> resolveOnlyIfClosure)` | Includes a subproject in the resolving process (including both the requirements and bundles configuration) if the given closure returns `true`. The closure is evaluated at the end of the subproject configuration phase and is passed a single parameter: the subproject. If the closure returns `false`, the subproject is the resolution process. `TargetPlatformExtension resolveOnlyIf(Spec<Project> resolveOnlyIfSpec)` | Includes a subproject in the resolving platform configuration if the given spec is satisfied. The spec is evaluated at the end of the subproject configuration phase. If the spec is not satisfied, the subproject is not included in the target platform configuration. `TargetPlatformExtension subprojects(Iterable<Project> subprojects)` | Includes additional projects to be configured with Target Platform support. `TargetPlatformExtension subprojects(Project... subprojects)` | Includes additional projects to be configured with Target Platform support.

Tasks

ResolveTask

The purpose of this task is to resolve an OSGi module (or all OSGi modules of subprojects) against the available `targetPlatformBundles` and `targetPlatformDistro` configurations. By default, the `targetPlatformBundles` are all the artifacts created by all the subprojects. The `targetPlatformDistro` must be set explicitly to a valid distribution artifact. When the task is performed, a `bndrun` file is generated using the specified `targetPlatformDistro` as the `-distro` instruction; the `-runrequirements` are a set of `osgi.identity` requirements for the `targetPlatformRequirements` configuration. If the resolve operation is able to find a valid set of `-runbundles` that match the `-runrequirements`, then the task passes successfully (the resolution is valid). If a set of run bundles can't be found, the resolution has failed and the failed requirements are listed as output of the task.

Task Properties Property Name | Type | Default Value | Description `bndrunFile` | `File` | `null` | If this property is specified, it is used as the `bndrun` file to input into the resolver. `bundlesFileCollection` | `FileCollection` | All JAR files of subprojects with `jar` task | The input to `bndrun` resolve operation. `distroFileCollection` | `FileCollection` | `null` | The *distro* parameter for the generated `bndrun` file. `ignoreFailures` | `boolean` | `false` | Whether the `resolve` task should ignore failing the build for resolution errors. `offline` | `boolean` | `null` | Whether to run the bndrun resolve operation in offline mode. `requirementsFileCollection` | `FileCollection` |

For the root project: All the output JAR files of the subprojects.

For subprojects: The output JAR file of the subproject.

| For each resolve operation, the requirements must be specified in the `bndrun` file; each of the JARs in this collection generate an `osgi.identify` requirement in the `bndrun` file.

Additional Configuration

There are additional configurations that you can use to configure the target platform.

Target Platform BOMs Dependency

The plugin creates a configuration called `targetPlatformBOMs` with no defaults. You can use this dependency to set which BOMs to import to configure your target platform.

```
dependencies {
    targetPlatformBOMs group: "com.liferay", name: "com.liferay.ce.portal.bom", version: "7.1.0"
    targetPlatformBOMs group: "com.liferay", name: "com.liferay.ce.portal.compile.only", version: "7.1.0"
}
```

Target Platform Bundles Dependency

The plugin creates a configuration called `targetPlatformBundles`. It is configured with default dependencies to all resolvable bundles in a multi-project build (e.g., all projects in multi-project build that have a `jar` task). This can be used to specify additional bundles that should be added to the set of bundles given to `resolve` task to resolve against when checking for OSGi requirements.

```
dependencies {
    targetPlatformBundles group: "com.google.guava", name: "guava", version: "23.0"
}
```

Target Platform Distro Dependency

The plugin creates a configuration called `targetPlatformDistro`. It is has no default so you must specify which artifact you want to use as the distribution to resolve against.

```
dependencies {
    targetPlatformDistro group: "com.liferay", name: "com.liferay.ce.portal.distro", version: "7.1.0"
}
```

If you have created your own custom distro JAR that is available locally, you can use the `files` method to add it to the configuration.

```
dependencies {
    targetPlatformDistro files("custom-distro.jar")
}
```

Target Platform Requirements Dependency

The plugin creates a configuration called `targetPlatformRequirements`. It is configured with default dependencies to all resolvable bundles in a multi-project build (e.g., all projects in multi-project build that have a `jar` task). This is can be used to specify additional bundles that should be added to the set of bundles given to the `resolve` task to set as `osgi.identity` requirements.

```
dependencies {
    targetPlatformRequirements group: "com.liferay", name: "com.liferay.other.bundle", version: "1.0"
}
```

131.22 Theme Builder Gradle Plugin

The Theme Builder Gradle plugin lets you run the Liferay Theme Builder tool to build the Liferay theme files in your project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.theme.builder", version: "2.0.7"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.portal.tools.theme.builder"
```

The Theme Builder plugin automatically applies the `war` plugin. It also applies the `com.liferay.css.builder` plugin to compile the Sass files in the theme.

Since the plugin automatically resolves the Liferay Theme Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildTheme` | - | `BuildThemeTask` | Builds the theme files.

The plugin also adds the following dependencies to tasks defined by the `com.liferay.css.builder` and `war` plugins:

Name | Depends On `buildCSS` | `buildTheme` `war` | `buildTheme`

The `buildCSS` dependency compiles the Sass files contained in the directory specified by the `buildTheme.outputDir` property. Moreover, the `war` task is configured as follows

- exclude the directory specified in the `buildTheme.diffsDir` property from the WAR file.
- include the files contained in the `buildTheme.outputDir` directory into the WAR file.
- include only the compiled CSS files, not SCSS files, into the WAR file.

The `buildTheme` task is automatically configured with sensible defaults:

Property Name | Default Value `diffsDir` | `project.webAppDir` `outputDir` | `"${project.buildDir}/buildTheme"` `parentFile` | The first JAR file in the `parentThemes` configuration that contains a `META-INF/resources/${buildTheme.parentName}` directory, or the first WAR file in the `parentThemes` configuration whose name starts with `${parentName}-theme-`. `parentName` | `"_styled"` `templateExtension` | `"ftl"` `themeName` | `project.name` `unstyledFile` | The first JAR file in the `parentThemes` configuration that contains a `META-INF/resources/_unstyled` directory.

BuildThemeTask

Tasks of type `BuildThemeTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | Theme Builder command line arguments `classpath` | `project.configurations.themeBuilder` `main` | `"com.liferay.portal.tools.theme.builder.ThemeBuilder"`

Task Properties Property Name | Type | Default Value | Description `diffsDir` | `File` | `null` | The directory that contains the files to copy over the parent theme. It sets the `--diffs-dir` argument. `outputDir` | `File` | `null` | The directory where to build the theme. It sets the `--output-dir` argument. `parentDir` | `File` | `null` | The directory of the parent theme. It sets the `--parent-path` argument. `parentFile` | `File` | `null` | The JAR file of the parent theme. If `parentDir` is specified, this property has no effect. It sets the `--parent-path` argument. `parentName` | `String` | `null` | The name of the parent theme. It sets the `--parent-name` argument. `templateExtension` | `String` | `null` | The extension of the template files, usually `"ftl"` or `"vm"`. It sets the `--template-extension` argument. `themeName` | `String` | `null` | The name of the new theme. It sets the `--name` argument. `unstyledDir` | `File` | `null` | The directory of Liferay Frontend Theme Unstyled. It sets the `--unstyled-dir` argument. `unstyledFile` | `File` | `null` | The JAR file of Liferay Frontend Theme Unstyled. If `unstyledDir` is specified, this property has no effect. It sets the `--unstyled-dir` argument.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use the CSS Builder.

Liferay Theme Builder Dependency

By default, the plugin creates a configuration called `themeBuilder` and adds a dependency to the latest released version of the Liferay Theme Builder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `themeBuilder` configuration:

```
dependencies {
    themeBuilder group: "com.liferay", name: "com.liferay.portal.tools.theme.builder", version: "1.1.7"
}
```

Parent Theme Dependencies

By default, the plugin creates a configuration called `parentThemes` and adds dependencies to the latest released versions of the Liferay Frontend Theme Styled, Liferay Frontend Theme Unstyled, and Liferay Frontend

Theme Classic artifacts. It is possible to override this setting and use a specific version of the artifacts by manually adding dependencies to the `parentThemes` configuration. For example,

```
dependencies {
    parentThemes group: "com.liferay", name: "com.liferay.frontend.theme.styled", version: "VERSION"
    parentThemes group: "com.liferay", name: "com.liferay.frontend.theme.unstyled", version: "VERSION"
    parentThemes group: "com.liferay.plugins", name: "classic-theme", version: "VERSION"
}
```

Specifying dependency versions is not required when leveraging workspace's Target Platform functionality. All dependencies with the group ID `com.liferay` or `com.liferay.portal` are automatically set when targeting a platform. For external theme dependencies (e.g., `classic-theme` with the group ID `com.liferay.plugins`), you can find the version used by your specific Liferay DXP instance by leveraging the Gogo shell. In a Gogo shell prompt, execute the following command:

```
lb -s theme
```

This lists the deployed theme bundles and their versions. Extract the versions for the theme dependencies you want to leverage and add them to your configuration.

131.23 TLDDoc Builder Gradle Plugin

The TLDDoc Builder Gradle plugin lets you run the Tag Library Documentation Generator tool in order to generate documentation for the JSP Tag Library Descriptor (TLD) files in your project.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.tlddoc.builder", version: "1.3.3"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}
```

There are two TLDDoc Builder Gradle plugins you can apply to your project:

- Apply the *TLDDoc Builder Plugin* to generate tag library documentation for your project:

  ```
  apply plugin: "com.liferay.tlddoc.builder"
  ```

- Apply the *App TLDDoc Builder Plugin* in a parent project to generate the tag library documentation as a single, combined HTML document for an application that spans different subprojects, each one representing a different component of the same application:

  ```
  apply plugin: "com.liferay.app.tlddoc.builder"
  ```

Since the plugin automatically resolves the Tag Library Documentation Generator library as a dependency, you must configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

TLDDoc Builder Plugin

The plugin adds three tasks to your project:

Name | Depends On | Type | Description `copyTLDDocResources` | - | `Copy` | Copies the tag library documentation resources from `src/main/tlddoc` to the destination directory of the `tlddoc` task. `tlddoc` | `copyTLDDocResources`, `validateTLD` | `TLDDocTask` | Generates the tag library documentation. `validateTLD` | - | `ValidateSchemaTask` | Validates the TLD files in the project.

The `tlddoc` task is automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value with the `java` plugin `destinationDir` | `${project.docsDir}/tlddoc` `includes` | `["**/*.tld"]` `source` | `project.sourceSets.main.resources.srcDirs`

The `validateTLD` task is also automatically configured with sensible defaults, depending on whether the `java` plugin is applied:

Property Name | Default Value `includes` |

If the `java` plugin is applied: `["**/*.tld"]`

Otherwise: `[]`

`source` |

If the `java` plugin is applied: `project.sourceSets.main.resources.srcDirs`

Otherwise: `null`

By default, the `tlddoc` task generates the documentation for all the TLD files that are found in the resources directories of the `main` source set. The documentation files are saved in `build/docs/tlddoc` and include the files copied from `src/main/tlddoc`.

The `copyTLDDocResources` task lets you add references to images and other resources directly in the TLD files. For example, if the project includes an image called `breadcrumb.png` in the `src/main/tlddoc/images` directory, you can reference it in a TLD file contained in the `src/main/resources` directory:

```
<description>Hello World <![CDATA[<img src="../images/breadcrumb.png"]]></description>
```

App TLDDoc Builder Plugin

In order to use the App TLDDoc Builder plugin, it is required to apply the `com.liferay.app.tlddoc.builder` plugin in a parent project (that is, a project that is a common ancestor of all the subprojects representing the various components of the app). It is also required to apply the `com.liferay.tlddoc.builder` plugin to all the subprojects that contain TLD files.

The App TLDDoc Builder plugin automatically applies the `base` plugin. It also adds three tasks to your project:

Name | Depends On | Type | Description `appTLDDoc` | `copyAppTLDDocResources`, the `validateTLD` tasks of the subprojects | `TLDDocTask` | Generates tag library documentation for the app. `copyAppTLDDocResources` | - | `Copy` | Copies the tag library documentation resources defined as inputs for the `copyTDLDocResources` tasks of the subprojects, aggregating them into the destination directory of the `appTLDDoc` task. `jarAppTLDDoc` | `appTLDDoc` | `Jar` | Assembles a JAR archive containing the tag library documentation files for this app.

The `appTLDDoc` task is automatically configured with sensible defaults:

Property Name | Default Value `destinationDir` | `${project.buildDir}/docs/tlddoc` `source` | The sum of all the `tlddoc.source` values of the subprojects

Project Extension

The App TLDDoc Builder plugin exposes the following properties through the extension named `appTLDDocBuilder`:

Property Name | Type | Default Value | Description `subprojects` | `Set<Project>` | `project.subprojects` | The subprojects to include in the tag library documentation of the app.

The same extension exposes the following methods:

Method | Description `AppTLDDocBuilderExtension subprojects(Iterable<Project> subprojects)` | Include additional projects in the tag library documentation of the app. `AppTLDDocBuilderExtension subprojects(Project... subprojects)` | Include additional projects in the tag library documentation of the app.

Tasks

TLDDocTask

Tasks of type `TLDDocTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | Tag Library Documentation Generator command line arguments `classpath` | `project.configurations.tlddoc` `main` | `"com.sun.tlddoc.TLDDoc"` `maxHeapSize` | `"256m"`

The `TLDDocTask` class is also very similar to `SourceTask`, which means it provides a `source` property and lets you specify include and exclude patterns.

Task Properties Property Name | Type | Default Value | Description `destinationDir` | `File` | `null` | The directory where the tag library documentation files are saved. `excludes` | `Set<String>` | `[]` | The TLD file patterns to exclude. `includes` | `Set<String>` | `[]` | The TLD file patterns to include. `source` | `FileTree` | `[]` | The TLD files to generate documentation for, after the include and exclude patterns have been applied. `xsltDir` | `File` | `null` | The directory that contains the custom XSLT stylesheets used by the Tag Library Documentation Generator to produce the final documentation files. It sets the `-xslt` argument.

The properties of type `File` support any type that can be resolved by `project.file`.

Task Methods The methods available for `TLDDocTask` are exactly the same as the one defined in the `SourceTask` class.

ValidateSchemaTask

Tasks of type `ValidateSchemaTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Tasks of this type invoke the `schemavalidate` Ant task in order to validate XML files described by an XML schema.

Task Properties Property Name | Type | Default Value | Description `dtdDisabled` | `boolean` | `false` | Whether to disable DTD support. `fullChecking` | `boolean` | `true` | Whether to enable full schema checking. `lenient` | `boolean` | `false` | Whether to only check if the XML document is well-formed. `xmlParserClassName` | `String` |

null | The class name of the XML parser to use. xmlParserClasspath | FileCollection | null | The classpath with the XML parser.

It is possible to use Closures and Callables as values for the String properties to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use the TLDDoc Builder.

Tag Library Documentation Generator Dependency

By default, the plugin creates a configuration called tlddoc and adds a dependency to the 1.3 version of the Tag Library Documentation Generator. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the tlddoc configuration:

```
dependencies {
    tlddoc group: "taglibrarydoc", name: "tlddoc", version: "1.3"
}
```

131.24 TLD Formatter Gradle Plugin

The TLD Formatter Gradle plugin lets you format a project's TLD files using the Liferay TLD Formatter tool.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.tld.formatter", version: "1.0.9"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.tld.formatter"
```

Since the plugin automatically resolves the Liferay TLD Formatter library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description formatTLD | - | FormatTLDTask | Runs the Liferay TLD Formatter to format files.

FormatTLDTask

Tasks of type `FormatTLDTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | TLD Formatter command line arguments `classpath` | `project.configurations.tldFormatter` `main` | `"com.liferay.tld.formatter.TLDFormatter"`

Task Properties Property Name | Type | Default Value | Description `plugin` | `boolean` | `true` | Whether to format all the TLD files contained in the `workingDir` directory. If `false`, all `liferay-portlet-ext.tld` files are ignored. It sets the `tld.plugin` argument.

Additional Configuration

There are additional configurations that can help you use the TLD Formatter.

Liferay TLD Formatter Dependency

By default, the plugin creates a configuration called `tldFormatter` and adds a dependency to the latest released version of Liferay TLD Formatter. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `tldFormatter` configuration:

```
dependencies {
    tldFormatter group: "com.liferay", name: "com.liferay.tld.formatter", version: "1.0.5"
}
```

131.25 Whip Gradle Plugin

The Whip Gradle plugin lets you use the Liferay Whip library to ensure that unit tests fully cover your project's code. See here for a usage sample.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.whip", version: "1.0.7"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.whip"
```

Since the plugin automatically resolves the Liferay Whip library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

By default, Whip is automatically applied to all tasks of type `Test`. If a task has Whip applied and Whip is enabled, then Whip is configured as a Java Agent.

Project Extension

The Whip Gradle plugin exposes the following properties through the extension named `whip`:

Property Name | Type | Default Value | Description `version` | `String` | `latest.release` | The version of the Liferay Whip library to use.

The same extension exposes the following methods:

Method | Description `void applyTo(Task task)` | Applies Whip to a task. The task instance must implement the `JavaForkOptions` interface.

Task Extension

If Whip is applied, the following task properties are available through the extension named `whip`:

Property Name | Type | Default Value | Description `dataFile` | `File` | `test-coverage/whip.dat` | `enabled` | `boolean` | `true` | Whether to configure Whip as a Java Agent. `excludes` | `List<String>` | `[]` | The class name patterns to exclude when checking for unit test code coverage. For example, a value could be `['.*Test', '.*Test\\$.*', '.*\\$Proxy.*', 'com/liferay/whip/.*']`. `includes` | `List<String>` | `[]` | The class name patterns to include when checking for unit test code coverage. `instrumentDump` | `boolean` | `false` | `whipJarFile` | `File` | The first file in the `whip` configuration whose name starts with `com.liferay.whip-`. | The Whip JAR file.

The same extension exposes the following methods:

Method | Description `WhipTaskExtension excludes(Iterable<Object> excludes)` | Adds class name patterns to exclude when checking for unit test coverage. `WhipTaskExtension excludes(Object... excludes)` | Adds class name patterns to exclude when checking for unit test coverage. `WhipTaskExtension includes(Iterable<Object> includes)` | Adds class name patterns to include when checking for unit test coverage. `WhipTaskExtension includes(Object... includes)` | Adds class name patterns to include when checking for unit test coverage.

Additional Configuration

There are additional configurations that can help you use Whip.

Liferay Whip Dependency

By default, the Whip Gradle plugin creates a configuration called `whip` and adds a dependency to the version of Liferay Whip configured in the `whip.version` extension property. It is possible to override this setting and use a specific version of the library by manually adding a dependency to the `whip` configuration:

```
dependencies {
    whip group: "com.liferay", name: "com.liferay.whip", version: "1.0.1"
}
```

In order to leverage the sensible default of the `whip.whipJarFile` task property, the name of the dependency must be `com.liferay.whip`. Otherwise, it will be necessary to set the value of the `whip.whipJarFile` property manually.

131.26 WSDD Builder Gradle Plugin

The WSDD Builder Gradle plugin lets you run the Liferay WSDD Builder tool to generate the Apache Axis Web Service Deployment Descriptor (WSDD) files from a Service Builder `service.xml` file.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.wsdd.builder", version: "1.0.13"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.portal.tools.wsdd.builder"
```

The WSDD Builder plugin automatically applies the `java` plugin.

Since the plugin automatically resolves the Liferay WSDD Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `buildWSDD` | `compileJava` | `BuildWSDDTask` | Runs the Liferay WSDD Builder.

By default, the `buildWSDD` task uses the `${project.projectDir}/service.xml` file as input. Then, it generates `${project.projectDir}/server-config.wsdd` and the `*_deploy.wsdd` and `*_undeploy.wsdd` files in the first `resources` directory of the `main` source set (by default: `src/main/resources`).

If the `war` plugin is applied, the task uses `${project.webAppDir}/WEB-INF/service.xml` as input to generate `${project.webAppDir}/WEB-INF/server-config.wsdd`. The `*_deploy.wsdd` and `*_undeploy.wsdd` files are still generated in the first resources directory of the `main` source set.

Liferay WSDD Build Service requires an additional classpath (configured with the `buildWSDD.builderClasspath` property), to correctly generate the WSDD files. The `buildWSDD` task uses the following default value, which creates an implicit dependency to the `compileJava` task:

```
tasks.compileJava.outputs.files + sourceSets.main.compileClasspath + sourceSets.main.runtimeClasspath
```

BuildWSDDTask

Tasks of type `BuildWSDDTask` extend `JavaExec`, so all its properties and methods, such as `args` and `maxHeapSize`, are available. They also have the following properties set by default:

Property Name | Default Value `args` | WSDD Builder command line arguments `classpath` | `project.configurations.wsddBuilder` `main` | `"com.liferay.portal.tools.wsdd.builder.WSDDBuilder"`

Task Properties Property Name | Type | Default Value | Description `builderClasspath` | `String` | `null` | A classpath that the Liferay WSDD Builder uses to generate WSDD files. It sets the `wsdd.class.path` argument. `inputFile` | `File` | `null` | A `service.xml` from which to generate the WSDD files. It sets the `wsdd.input.file` argument. `outputDir` | `File` | `null` | A directory where the `*_deploy.wsdd` and `*_undeploy.wsdd` files are generated. It sets the `wsdd.output.path` argument. `serverConfigFile` | `File` | `${project.projectDir}/server-config.wsdd` | A `server-config.wsdd` file to generate. It sets the `wsdd.server.config.file` argument. `serviceNamespace` | `String` | `"Plugin"` | A namespace for the WSDD Service. It sets the `wsdd.service.namespace` argument.

The properties of type `File` support any type that can be resolved by `project.file`. Moreover, it is possible to use Closures and Callables as values for the `String` properties, to defer evaluation until task execution.

Additional Configuration

There are additional configurations that can help you use the WSDD Builder.

Liferay WSDD Builder Dependency

By default, the plugin creates a configuration called `wsddBuilder` and adds a dependency to the latest released version of the Liferay WSDD Builder. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `wsddBuilder` configuration:

```
dependencies {
    wsddBuilder group: "com.liferay", name: "com.liferay.portal.tools.wsdd.builder", version: "1.0.10"
}
```

131.27 WSDL Builder Gradle Plugin

The WSDL Builder Gradle plugin lets you generate Apache Axis client stubs from Web Service Description (WSDL) files.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.wsdl.builder", version: "2.0.3"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.wsdl.builder"
```

The WSDL Builder plugin automatically applies the java plugin.

Since the plugin automatically resolves the Apache Axis library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one main task to your project:

Name | Depends On | Type | Description `buildWSDL` | - | `BuildWSDLTask` | Generates WSDL client stubs.

By default, the `buildWSDL` task looks for WSDL files in the `${project.projectDir}/wsdl` directory. If the `war` plugin is applied, it looks in the `${project.webAppDir}/WEB-INF/wsdl` directory.

For each WSDL file that can be found, the task generates client stubs via direct invocation of the *WSDL2Java* tool, saving them in the first `java` directory of the `main` source set (by default: `src/main/java`).

If configured to do so, `buildWSDL` can instead save the client stub Java files in a temporary directory, compile them, and package them in JAR files. The JAR files are named after the WSDL file and saved in `${project.projectDir}/lib`, by default, or in `${project.webAppDir}/WEB-INF/lib`, if the `war` plugin is applied.

BuildWSDLTask

Tasks of type `FormatWSDLTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Task Properties Property Name | Type | Default Value | Description `buildLibs` | `boolean` | `true` | Whether to package the client stub classes of each WSDL file in JAR files, saved to the directory the `destinationDir` property references. If `false`, the task generates the client stub Java files to the `destinationDir` directory. `destinationDir` | `File` | `null` | A directory where the client stub Java files (if `buildLibs` is `false`) or the client stub JAR files (if `buildLibs` is `true`) are saved. `generateOptions.mapping` | `Map` | `[:]` | Namespace-to-package mappings (sets the `--NStoPkg` argument in the *WSDL2Java* invocation). It is possible to use a `Closure` or a `Callable`, to defer evaluation until task execution.. `generateOptions.noWrapped` | `boolean` | `false` | Whether to turn off support for "wrapped" document/literal (sets the `--noWrapped` argument in the *WSDL2Java* invocation). `generateOptions.serverSide` | `boolean` | `false` | Whether to emit server-side bindings for the web service (sets the `--server-side` argument in the *WSDL2Java* invocation). `generateOptions.verbose` | `boolean` | `false` | Whether to print informational messages (sets the `--verbose` argument in the *WSDL2Java* invocation). `includeSource` | `boolean` | `true` | Whether to package the client stub Java files in the JAR file's `OSGI-OPT/src` directory. If `buildLibs` is `false`, this property has no effect. `includeWSDLs` | `boolean` | `true` | Whether to configure the `processResources` task to include the WSDL files in the project JAR's `wsdl` directory.

The properties of type `File` support any type that can be resolved by `project.file`.

Task Methods Method Signature | Description `generateOptions.mapping(Object namespace, Object packageName)` | Adds a namespace-to-package mapping. `generateOptions.mappings(Map mappings)` | Adds multiple namespace-to-package mappings.

Helper Tasks At the end of the project evaluation, a series of helper tasks are created for each WSDL file returned by the `source` property of the `BuildWSDLTask` tasks. The names of the helper tasks start with the WSDL file name, without any extension.

- `${WSDL file title}Generate` of type `JavaExec`: invokes *WSDL2Java* to generate the client stubs for the WSDL file.

If `buildWSDLTask.buildLibs` is `true`, the following helper tasks are also created:

- `${WSDL file title}Compile` of type `JavaCompile`: compiles the client stub Java files for the WSDL file.
- `${WSDL file title}Jar` of type `Jar`: packages in a JAR file called `${WSDL file title}-ws.jar`, the client stub for the WSDL file.

Additional Configuration

There are additional configurations that can help you use WSDL Builder.

Apache Axis Dependency

By default, the plugin creates a configuration called `wsdlBuilder` and adds the following dependencies:

- `axis:axis-wsdl4j:1.5.1`
- `com.liferay:org.apache.axis:1.4.LIFERAY-PATCHED-1`
- `commons-discovery:commons-discovery:0.2`
- `commons-logging:commons-logging:1.0.4`
- `javax.activation:activation:1.1`
- `javax.mail:mail:1.4`
- `org.apache.axis:axis-jaxrpc:1.4`
- `org.apache.axis:axis-saaj:1.4`

It is possible to override this setting and use a specific version of Apache Axis, by manually populating the `wsdlBuilder` configuration with the desired dependencies.

131.28 XML Formatter Gradle Plugin

The XML Formatter Gradle plugin lets you format a project's XML files using the Liferay XML Formatter tool.
The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.xml.formatter", version: "1.0.11"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.xml.formatter"
```

Since the plugin automatically resolves the Liferay XML Formatter library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds one task to your project:

Name | Depends On | Type | Description `formatXML` | - | `FormatXMLTask` | Runs the Liferay XML Formatter to format the project files.

If the `java` plugin is applied, the task formats XML files contained in the `resources` directories of the `main` source set (by default: `src/main/resources/**/*.xml`).

FormatXMLTask

Tasks of type `FormatXMLTask` extend `SourceTask`, so all its properties and methods, such as `include` and `exclude`, are available.

Task Properties Property Name | Type | Default Value | Description `classpath` | `FileCollection` | `project.configurations.xmlFormatter` | The classpath for executing the main class. `mainClassName` | `String` | `"com.liferay.xml.formatter.XMLFormatter"` | The fully qualified name of the XML Formatter Main class. `stripComments` | `boolean` | `false` | Whether to remove all the comments from the XML files. It sets the `xml.formatter.strip.comments` argument.

Additional Configuration

There are additional configurations that can help you use the XML Formatter.

Liferay XML Formatter Dependency

By default, the plugin creates a configuration called `xmlFormatter` and adds a dependency to the latest released version of the Liferay XML Formatter. It is possible to override this setting and use a specific version of the tool by manually adding a dependency to the `xmlFormatter` configuration:

```
dependencies {
    xmlFormatter group: "com.liferay", name: "com.liferay.xml.formatter", version: "1.0.5"
}
```

131.29 XSD Builder Gradle Plugin

The XSD Builder Gradle plugin lets you generate Apache XMLBeans bindings from XML Schema (XSD) files.

The plugin has been successfully tested with Gradle 4.10.2.

Usage

To use the plugin, include it in your build script:

```
buildscript {
    dependencies {
        classpath group: "com.liferay", name: "com.liferay.gradle.plugins.xsd.builder", version: "1.0.7"
    }

    repositories {
        maven {
            url "https://repository-cdn.liferay.com/nexus/content/groups/public"
        }
    }
}

apply plugin: "com.liferay.xsd.builder"
```

The XSD Builder plugin automatically applies the `java` plugin.

Since the plugin automatically resolves the Liferay Service Builder library as a dependency, you have to configure a repository that hosts the library and its transitive dependencies. The Liferay CDN repository hosts them all:

```
repositories {
    maven {
        url "https://repository-cdn.liferay.com/nexus/content/groups/public"
    }
}
```

Tasks

The plugin adds three tasks to your project:

Name | Depends On | Type | Description `buildXSD` | `buildXSDCompile` | `BuildXSDTask` | Generates XMLBeans bindings and compiles them in a JAR file. `buildXSDGenerate` | `cleanBuildXSDGenerate` | `JavaExec` | Invokes the XMLBeans Schema Compiler to generate Java types from XML Schema. `buildXSDCompile` | `buildXSDGenerate`, `cleanBuildXSDCompile` | `JavaCompile` | Compiles the generated Java types.

By default, the `buildXSD` task looks for XSD files in the `${project.projectDir}/xsd` directory, and saves the generated JAR file as `${project.projectDir}/lib/${project.archivesBaseName}-xbean.jar`.

If the `war` plugin is applied, the task looks for XSD files in the `${project.webAppDir}/WEB-INF/xsd` directory, and saves the generated JAR file as `${project.webAppDir}/WEB-INF/lib/${project.archivesBaseName}-xbean.jar`.

BuildXSDTask

Tasks of type `BuildXSDTask` extend `Zip`. They also have the following properties set by default:

Property Name | Default Value `appendix` | `"xbean"` `extension` | `"jar"` `version` | `null`

For each task of type `BuildXSDTask`, the following helper tasks are created:

- `${buildXSDTask.name}Compile`
- `${buildXSDTask.name}Generate`

Task Properties Property Name | Type | Default Value | Description `inputDir` | `File` | `null` | A directory containing XSD files from which to generate Apache XMLBeans bindings.

The properties of type `File` support any type that can be resolved by `project.file`.

Additional Configuration

There are additional configurations that can help you use the XSD Builder.

Apache XMLBeans Dependency

By default, the XSD Builder Gradle plugin creates a configuration called `xsdBuilder` and adds a dependency to the 2.5.0 version of Apache XMLBeans. It is possible to override this setting and use a specific version of the library by manually adding a dependency to the `xsdBuilder` configuration:

```
dependencies {
    xsdBuilder group: "org.apache.xmlbeans", name: "xmlbeans", version: "2.6.0"
}
```

131.30 Felix Gogo Shell

To interact with Liferay DXP's module framework on a local server machine, you can use the Felix Gogo shell within Blade CLI.

Here's the command syntax:

```
blade sh <gogoShellCommand>
```

If you're not using Blade CLI, you can start the Gogo shell from a local telnet session.

```
telnet localhost 11311
```

To disconnect the session, execute the `disconnect` command.

Warning: Commands `shutdown`, `close`, and `exit` stop the OSGi framework. So make sure to use the `disconnect` command to end the telnet Gogo Shell session.

Here are some useful Gogo shell commands:

`help`: lists all the available Gogo shell commands. Notice that each command has two parts to its name, separated by a colon. For example, the full name of the `help` command is `felix:help`. The first part is the command scope while the second part is the command function. The scope allows commands with the same name to be disambiguated. E.g., scope allows the `felix:refresh` command to be distinguished from the `equinox:refresh` command.

`help [COMMAND_NAME]`: lists information about a specific command including a description of the command, the scope of the command, and information about any flags or parameters that can be supplied when invoking the command.

`lb`: lists all of the bundles installed in Liferay's module framework. Use the `-s` flag to list the bundles using the bundles' symbolic names.

`b [BUNDLE_ID]`: lists information about a specific bundle including the bundle's symbolic name, bundle ID, data root, registered (provided) and used services, imported and exported packages, and more

`headers [BUNDLE_ID]`: lists metadata about the bundle from the bundle's `MANIFEST.MF` file

`diag [BUNDLE_ID]`: lists information about why the specified bundle is not working (e.g., unresolved dependencies, etc.)

`packages [PACKAGE_NAME]`: lists all of the named package's dependencies

`scr:list`: lists all of the components registered in the module framework (*scr* stands for service component runtime) `scr:info [COMPONENT_NAME]`: lists information about a specific component including the component's description, services, properties, configuration, references, and more.

`services`: lists all of the services that have been registered in Liferay's module framework

`inspect capability service [BUNDLE_ID]`: lists services exposed by a bundle

`install [PATH_TO_JAR_FILE]`: installs the specified bundle into Liferay's module framework

`start [BUNDLE_ID]`: starts the specified bundle

`stop [BUNDLE_ID]`: stops the specified bundle

`uninstall [BUNDLE_ID]`: uninstalls the specified bundle from Liferay's module framework

`system:getproperties`: lists all of the system properties

For more information about the Gogo shell, please visit http://felix.apache.org/documentation/subprojects/apache-felix-gogo.html.

Chapter 132

Maven

Liferay provides plugins that you can apply to your Maven project. This reference documentation describes configuration properties for your Maven project's `pom.xml` for each plugin. If you're looking for instructions on using Maven with your Liferay modules, see the Maven tutorials.

132.1 Bundle Support Plugin

The Bundle Support plugin lets you use Liferay Workspace as a Maven project. For more information on how a Maven Workspace works and the features it provides, see the Maven Workspace tutorial.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.bundle.support</artifactId>
            <version>3.2.5</version>
            <executions>
                <execution>
                    <id>clean</id>
                    <goals>
                        <goal>clean</goal>
                    </goals>
                    <phase>clean</phase>
                    <configuration>
                    </configuration>
                </execution>
                <execution>
                    <id>deploy</id>
                    <goals>
                        <goal>deploy</goal>
                    </goals>
                    <phase>pre-integration-test</phase>
                    <configuration>
                    </configuration>
                </execution>
            </executions>
        </plugin>
        ...
    </plugins>
</build>
```

Goals

The plugin adds five Maven goals to your project:

Name | Description bundle-support:clean | Deletes a file from the `deploy` directory of a Liferay bundle. bundle-support:create-token | Creates a token used to validate your user credentials when downloading a DXP bundle. bundle-support:deploy | Deploys the Maven project to the specified Liferay DXP bundle. bundle-support:dist | Creates a distributable Liferay DXP bundle archive file (e.g., ZIP). bundle-support:init | Downloads and installs the specified Liferay DXP version.

clean Goal's Available Parameters

You can set the following parameters in the `clean` execution's `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `liferayHome` | `String` | `bundles` | The directory where your Liferay DXP instance resides. This can be specified from the command line as `-DliferayHome=`. `fileName` | `String` | `${project.artifactId}.${project.packaging}` | The name of the file to delete from your bundle.

create-token Goal's Available Parameters

You can change the default parameter values of the `create-token` goal by creating an `<execution>` section containing `<configuration>` tags. For example,

```
<execution>
    <id>create-token</id>
    <goals>
        <goal>create-token</goal>
    </goals>
    <configuration>
    </configuration>
</execution>
```

You can set the following parameters in the `create-token` execution's `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `emailAddress` | `String` | `null` | The email address to use when downloading a DXP bundle. This email address must match the one registered for your DXP subscription. `force` | `boolean` | `false` | Whether to override the existing token with a newly generated one. `password` | `String` | `null` | The password to use when downloading a DXP bundle. This password must match the one registered for your DXP subscription. `passwordFile` | `File` | `null` | The file to hold your password used when downloading a DXP bundle. `tokenFile` | `File` | `${user.home}/.liferay/token` | The file to hold the Liferay bundle authentication token. `tokenUrl` | `URL` | `https://releases-cdn.liferay.com/portal/7.0.6-ga7/liferay-ce-portal-tomcat-7.0-ga7-20180507111753223.zip` | The URL pointing to the bundle Zip to download.

After executing the `create-token` goal, you're prompted for your email address and password, both of which are used to generate your token. It's recommended to configure your email and password from the command line rather than specifying them in your POM file.

deploy Goal's Available Parameters

You can set the following parameters in the `deploy` execution's `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `liferayHome` | `String` | `bundles` | The directory where your Liferay DXP instance resides. This can be specified from the command line as `-DliferayHome=`.

deployFile | File | ${project.build.directory}/${project.build.finalName}.${project.packaging} | The packaged file (e.g., JAR) to deploy to the Liferay bundle. outputFileName | String | ${project.artifactId}.${project.packaging | The name of the output file.

dist Goal's Available Parameters

You can change the default parameter values of the dist goal by creating an <execution> section containing <configuration> tags. For example,

```
<execution>
    <id>dist</id>
    <goals>
        <goal>dist</goal>
    </goals>
    <configuration>
    </configuration>
</execution>
```

You can set the following parameters in the dist execution's <configuration> section of the POM:

Parameter Name | Type | Default Value | Description liferayHome | String | bundles | The directory where your Liferay DXP instance resides. This can be specified from the command line as -DliferayHome=. archiveFileName | String | null | The name for the generated archive file. cacheDir | File | ${user.home}/.liferay/bundles | The directory where the downloaded bundle Zip files are stored. configs | String | configs | The directory that contains the configuration files. deployFile | File |${project.build.directory}/${project.build.finalName}.${project.packaging} | The packaged file (e.g., JAR) to deploy to the Liferay bundle. environment | String | ${liferay.workspace.environment} | The environment of your Liferay home deployment. (e.g., common, dev, local, prod, and uat). format | String | zip | The format type to use when packaging the Liferay bundle as an archive. includeFolder | boolean | true | Whether to add a parent folder to the archive. outputFileName | String | ${project.artifactId}.${project.packaging} | The path to the archive file. password | String | null | The password if your Liferay bundle's URL requires authentication. stripComponents | int | 1 | The number of directories to strip when expanding your bundle. token | boolean | false | Whether to use a token to download a Liferay DXP bundle. This should be set to true when downloading a DXP bundle. tokenFile | File | ${user.home}/.liferay/token | The file to hold the Liferay bundle authentication token. url | URL | ${liferay.workspace.bundle.url} | The URL of the Liferay bundle to expand. userName | String | null | The user name if your Liferay bundle's URL requires authentication.

init Goal's Available Parameters

You can change the default parameter values of the init goal by creating an <execution> section containing <configuration> tags. For example,

```
<execution>
    <id>init</id>
    <goals>
        <goal>init</goal>
    </goals>
    <configuration>
    </configuration>
</execution>
```

You can set the following parameters in the init execution's <configuration> section of the POM:

Parameter Name | Type | Default Value | Description liferayHome | String | bundles | The directory where your Liferay DXP instance resides. This can be specified from the command line as -DliferayHome=.

cacheDir | File | ${user.home}/.liferay/bundles | The directory where the downloaded bundle Zip files are stored. configs | String | configs | The directory that contains the configuration files. environment | String | ${liferay.workspace.environment} | The environment with the settings appropriate for current development (e.g., common, dev, local, prod, and uat). password | String | null | The password if your Liferay bundle's URL requires authentication. stripComponents | int | 1 | The number of directories to strip when expanding your bundle. token | boolean | false | Whether to use a token to download a Liferay DXP bundle. This should be set to true when downloading a DXP bundle. tokenFile | File | ${user.home}/.liferay/token | The file to hold the Liferay bundle authentication token. url | URL | ${liferay.workspace.bundle.url} | The URL of the Liferay bundle to expand. userName | String | null | The user name if your Liferay bundle's URL requires authentication.

132.2 CSS Builder Plugin

The CSS Builder plugin lets you compile Sass files in your project.

Usage

To use the plugin, include it in your project's root pom.xml file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.css.builder</artifactId>
            <version>3.0.0</version>
            <executions>
                <execution>
                    <id>default-build</id>
                    <phase>compile</phase>
                    <goals>
                        <goal>build</goal>
                    </goals>
                </execution>
            </executions>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the CSS Builder configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description css-builder:build | Compiles the Sass files in the project.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description appendCssImportTimestamps | boolean | true | Whether to append the current timestamp to the URLs in the @import CSS at-rules. baseDir | File | "src/META-INF/resources" | The base directory that contains the SCSS files to compile. dirNames | List<String> | ["/"] |

The name of the directories, relative to baseDir, which contain the SCSS files to compile. generateSourceMap | boolean | false | Whether to generate source maps for easier debugging. importDir | File | null | The META-INF/resources directory of the Liferay Frontend Common CSS artifact. This is required in order to make Bourbon and other CSS libraries available to the compilation. outputDirName | String | ".sass-cache/" | The name of the sub-directories where the SCSS files are compiled to. For each directory that contains SCSS files, a sub-directory with this name is created. precision | int | 9 | The numeric precision of numbers in Sass. rtlExcludedPathRegexps | List<String> | | The SCSS file patterns to exclude when converting for right-to-left (RTL) support. sassCompilerClassName | String | "jni" | The type of Sass compiler to use. Supported values are "jni" and "ruby". The Ruby Sass compiler requires com.liferay.sass.compiler.ruby.jar, com.liferay.ruby.gems.jar, and jruby-complete.jar to be added to the classpath.

You can also manage the com.liferay.frontend.css.common default theme dependency provided by the CSS Builder in your pom.xml. This can be modified by adding it as a project dependency:

```
<project>
    ...
    <dependencies>
        <dependency>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.frontend.css.common</artifactId>
            <version>3.0.1</version>
            <scope>provided</scope>
        </dependency>
        ...
    </dependencies>
</project>
```

There are additional Liferay theme-related dependencies you can manage this way that are provided by the Theme Builder. See this section for more information.

132.3 DB Support Plugin

The DB Support plugin lets you run the Liferay DB Support tool to execute certain actions on a local Liferay DXP database. The following actions are available:

- Cleans the Liferay database from the Service Builder tables and rows of a module.

Usage

To use the plugin, include it in your project's pom.xml file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.db.support</artifactId>
            <version>1.0.6</version>
            <configuration>
            </configuration>
            <dependencies>
                <dependency>
                    <groupId>org.hsqldb</groupId>
                    <artifactId>hsqldb</artifactId>
                    <version>2.4.0</version>
                </dependency>
            </dependencies>
        </plugin>
    ...
    </plugins>
</build>
```

Also notice the configured plugin dependency. You must configure the JDBC driver used by your Liferay DXP bundle so the DB Support plugin can properly manage your database. Replace the HSQLDB driver listed above with your custom database's JDBC driver.

Goals

The plugin adds one Maven goal to your project:

Name | Description `db-support:clean-service-builder` | Cleans the Liferay DXP database from the Service Builder tables and rows of a module.

Available Parameters

You can set the following parameters in the `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `password` | `String` | `jdbc.default.password` | The user password for connecting to the Liferay DXP database. `propertiesFile` | `File` | `null` | The `portal-ext.properties` file which contains the JDBC settings for connecting to the Liferay DXP database. `serviceXmlFile` | `File` | `null` | The `service.xml` file of the module. `servletContextName` | `String` | `null` | The servlet context name (usually the value of the `Bundle-Symbolic-Name` manifest header) of the module. `url` | `String` | `jdbc.default.url` | The JDBC URL for connecting to the Liferay DXP database. `userName` | `String` | `jdbc.default.username` | The user name for connecting to the Liferay DXP database.

132.4 Deployment Helper Plugin

The Deployment Helper plugin lets you create a cluster deployable WAR from your OSGi artifacts.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.deployment.helper</artifactId>
            <version>1.0.4</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the Deployment Helper configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description `deployment-helper:build` | Builds a WAR which contains one or more files that are copied once the WAR is deployed.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description deploymentFileNames | String | null | The files or directories to include in the WAR and copy once the WAR is deployed. If a directory is added to this collection, all the JAR files contained in the directory are included in the WAR. deploymentPath | String | null | The directory to which the included files are copied. outputFileName | String | null | The WAR file to build.

132.5 Javadoc Formatter Plugin

The Javadoc Formatter plugin lets you format project Javadoc comments. The tool lets you generate:

- Default @author tags to all classes.
- Comment stubs to classes, fields, and methods.
- Missing @Override annotations.
- An XML representation of the Javadoc comments, which can be used by tools in order to index the Javadocs of the project.

Usage

To use the plugin, include it in your project's root pom.xml file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.javadoc.formatter</artifactId>
            <version>1.0.32</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the Javadoc Formatter configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description javadoc-formatter:format | Runs the Liferay Javadoc Formatter to format files.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description author | String | "Brian Wing Shun Chan" | The value of the @author tag to add at class level if missing. generateXml | boolean | false | Whether to generate a XML representation of the Javadoc comments. The XML files are generated in the src/main/resources directory only if the Java files are contained in src/main/java. initializeMissingJavadocs | boolean | false | Whether to add comment stubs at the class, field, and method levels. If false, only the class-level @author is added. inputDirName | String | "./" | The root directory to begin searching for Java files to format. limits | String[] | [] | The Java file name patterns, relative to the working directory, to include when formatting

Javadoc comments. The patterns must be specified without the `.java` file type suffix. If empty, all Java files are formatted. `outputFilePrefix` | `String` | `"javadocs"` | The file name prefix of the XML representation of the Javadoc comments. If `generateXML` is `false`, this property is not used. `updateJavadocs` | `boolean` | `false` | Whether to fix existing comment blocks by adding missing tags.

132.6 Lang Builder Plugin

The Lang Builder plugin lets you sort and translate the language keys in your project.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.lang.builder</artifactId>
            <version>1.0.31</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the Lang Builder configuration here.

Goals

The plugin adds one Maven goal to your project:
Name | Description `lang-builder:build` | Runs Liferay Lang Builder to translate language property files.

Available Parameters

You can set the following parameters in the `<configuration>` section of the POM:
Parameter Name | Type | Default Value | Description `excludedLanguageIds` | `String[]` | `{"da", "de", "fi", "ja", "nl", "pt_PT", "sv"}` | The language IDs to exclude in the automatic translation. `langDirName` | `String` | `"src/content"` | The directory where the language properties files are saved. `langFileName` | `String` | `"Language"` | The file name prefix of the language properties files (e.g., `Language_it.properties`). `plugin` | `boolean` | `true` | Whether to check for duplicate language keys between the project and the portal. `portalLanguagePropertiesFileName` | `String` | `null` | The `Language.properties` file of the portal. `translate` | `boolean` | `true` | Whether to translate the language keys and generate a language properties file for each locale that's supported by Liferay DXP. `translateSubscriptionKey` | `String` | `null` | The subscription key for Microsoft Translation integration. Subscription to the Translator Text Translation API on Microsoft Cognitive Services is required. Basic subscriptions, up to 2 million characters a month, are free.

132.7 Service Builder Plugin

The Service Builder plugin lets you generate a service layer defined in a Service Builder `service.xml` file. Visit the Using Service Builder in a Maven Project tutorial to learn more about applying Service Builder to your Maven project.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.service.builder</artifactId>
            <version>1.0.292</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the Service Builder configuration here.

Goals

The plugin adds one Maven goal to your project:
Name | Description `service-builder:build` | Runs the Liferay Service Builder.

Available Parameters

You can set the following parameters in the `<configuration>` section of the POM:
Parameter Name | Type | Default Value | Description `apiDirName` | `String` | `"../portal-kernel/src"` | A directory where the service API Java source files are generated. `autoImportDefaultReferences` | `boolean` | `true` | Whether to automatically add default references, like `com.liferay.portal.ClassName`, `com.liferay.portal.Resource` and `com.liferay.portal.User`, to the services. `autoNamespaceTables` | `boolean` | `null` | Whether to prefix table names by the namespace specified in the `service.xml` file. `beanLocatorUtil` | `String` | `"com.liferay.portal.kernel.bean.PortalBeanLocatorUtil"` | The fully qualified class name of a bean locator class to use in the generated service classes. `buildNumber` | `long` | `1` | A specific value to assign the `build.number` property in the `service.properties` file. `buildNumberIncrement` | `boolean` | `true` | Whether to automatically increment the `build.number` property in the `service.properties` file by one at every service generation. `databaseNameMaxLength` | `int` | `30` | The upper bound for database table and column name lengths to ensure it works on all databases. `hbmFileName` | `String` | `"src/META-INF/portal-hbm.xml"` | A Hibernate Mapping file to generate. `implDirName` | `String` | `"src"` | A directory where the service Java source files are generated. `inputFileName` | `String` | `"service.xml"` | The project's `service.xml` file. `modelHintsConfigs` | `String` | `"classpath*:META-INF/portal-model-hints.xml, META-INF/portal-model-hints.xml, classpath*:META-INF/ext-model-hints.xml, classpath*:META-INF/portlet-model-hints.xml"` | Paths to the model hints files for Liferay Service Builder to use in generating the service layer. `modelHintsFileName` | `String` | `"src/META-INF/portal-model-hints.xml"` | A model hints file for the project. `osgiModule` | `boolean` | `null` | Whether to generate the service layer for OSGi modules. `pluginName` | `String` | `null` | If specified, a plugin can enable additional generation features, such as `Clp` class generation, for non-OSGi modules. `propsUtil` | `String` | `"com.liferay.portal.util.PropsUtil"` | The fully qualified class name of the service properties util class to generate. `readOnlyPrefixes` | `String` | `"fetch, get, has, is, load, reindex, search"` | Prefixes of methods to consider read-only. `resourceActionsConfigs` | `String` | `"META-INF/resource-actions/default.xml, resource-actions/default.xml"` | Paths to the resource actions files for Liferay Service Builder to use in generating the service layer. `resourcesDirName` | `String` | `"src"` | A directory where the service non-Java files are generated. `springFileName` | `String` | `"src/META-INF/portal-spring.xml"` | A service Spring file to

generate. springNamespaces | String | "beans" | Namespaces of Spring XML Schemas to add to the service Spring file. sqlDirName | String | "../sql" | A directory where the SQL files are generated. sqlFileName | String | "portal-tables.sql" | A name (relative to sqlDir) for the file in which the SQL table creation instructions are generated. sqlIndexesFileName | String | "indexes.sql" | A name (relative to sqlDir) for the file in which the SQL index creation instructions are generated. sqlSequencesFileName | String | "sequences.sql" | A name (relative to sqlDir) for the file in which the SQL sequence creation instructions are generated. targetEntityName | String | null | If specified, it's the name of the entity for which Liferay Service Builder should generate the service. testDirName | String | "test/integration" | If specified, it's a directory where integration test Java source files are generated.

132.8 Source Formatter Plugin

The Source Formatter plugin formats project files according to Liferay's source formatting standards. For more documentation on Source Formatter specific functionality, visit the tool's documentation folder.

Usage

To use the plugin, include it in your project's root pom.xml file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.source.formatter</artifactId>
            <version>1.0.885</version>
            <executions>
                <execution>
                    <phase>process-sources</phase>
                    <goals>
                        <goal>format</goal>
                    </goals>
                </execution>
            </executions>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the Source Formatter configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description source-formatter:format | Runs the Liferay Source Formatter to format source formatting errors.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description autoFix | boolean | true | Whether to automatically fix source formatting errors. baseDir | String | "./" | The Source Formatter base directory. *(Read-only)* fileNames | String[] | null | The file names to format, relative to the project directory. If null, all files contained in `baseDir` will be formatted. `formatCurrentBranch` | `boolean` | `false` | Whether to format only the files contained in `baseDir` that are added or modified in the current Git branch. `formatLatestAuthor` | `boolean` | `false` | Whether to format only the files contained in `baseDir` that are added or modified in the latest Git commits of the same author. `formatLocalChanges` | `boolean` | `false` | Whether to format only the unstaged files contained in `baseDir`. `gitWorkingBranchName` | `String` | `"master"` | The Git working branch name. `includeSubrepositories` | `boolean` | `false` | Whether to format files that are in read-only subrepositories. `maxLineLength` | `int` | `80` | The maximum number of characters allowed in Java files. `printErrors` | `boolean` | `true` | Whether to print formatting errors on the Standard Output stream. `processorThreadCount` | `int` | `5` | The number of threads used by Source Formatter. `showDocumentation` | `boolean` | `false` | Whether to show the documentation for the source formatting issues, if present. `throwException` | `boolean` | `false` | Whether to fail the build if formatting errors are found.

132.9 Theme Builder Plugin

The Theme Builder plugin lets you build Liferay theme files in your project. Visit the Building Themes in a Maven Project tutorial to learn more about applying Theme Builder to your Maven project.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.theme.builder</artifactId>
            <version>1.1.7</version>
            <executions>
                <execution>
                    <phase>generate-resources</phase>
                    <goals>
                        <goal>build</goal>
                    </goals>
                    <configuration>
                    </configuration>
                </execution>
            </executions>
        </plugin>
        ...
    </plugins>
</build>
```

You can view an example POM containing the Theme Builder configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description `theme-builder:build` | Builds the theme files.

Available Parameters

You can set the following parameters in the `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `diffsDir` | `File` | `${maven.war.src}` | The directory that contains the files to copy over the parent theme. `name` | `String` | `${project.artifactId}` | The name of the new theme. `outputDir` | `File` | `${project.build.directory}/${project.build.finalName}` | The directory where to build the theme. `parentDir` | `File` | `null` | The directory of the parent theme. `parentName` | `String` | `null` | The name of the parent theme. `templateExtension` | `String` | `"ftl"` | The extension of the template files, usually `"ftl"` or `"vm"`. `unstyledDir` | `File` | `null` | The directory of Liferay Frontend Theme Unstyled.

You can also manage the `com.liferay.frontend.theme.styled` and `com.liferay.frontend.theme.unstyled` default theme dependencies provided by the Theme Builder in your `pom.xml`. They can be modified by adding them as project dependencies:

```
<project>
    ...
    <dependencies>
        ...
        <dependency>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.frontend.theme.styled</artifactId>
            <version>3.0.4</version>
            <scope>provided</scope>
        </dependency>
        <dependency>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.frontend.theme.unstyled</artifactId>
            <version>3.0.4</version>
            <scope>provided</scope>
        </dependency>
    </dependencies>
</project>
```

There is an additional Liferay theme-related dependency you can manage this way that's provided by the CSS Builder. See this section for more information.

132.10 TLD Formatter Plugin

The TLD Formatter plugin lets you format a project's TLD files.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.tld.formatter</artifactId>
            <version>1.0.5</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the TLD Formatter configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description `tld-formatter:format` | Runs the Liferay TLD Formatter to format files.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description baseDirName | String | "./" | The base directory to begin searching for TLD files to format. plugin | boolean | true | Whether to format all the TLD files contained in the working directory. If false, all liferay-portlet-ext.tld files are ignored.

132.11 WSDD Builder Plugin

The WSDD Builder plugin lets you generate the Apache Axis Web Service Deployment Descriptor (WSDD) files from a Service Builder service.xml file.

Usage

To use the plugin, include it in your project's root pom.xml file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.portal.tools.wsdd.builder</artifactId>
            <version>1.0.10</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the WSDD Builder configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description wsdd-builder:build | Runs the Liferay WSDD Builder to generate the WSDD files.

Available Parameters

You can set the following parameters in the <configuration> section of the POM:

Parameter Name | Type | Default Value | Description classPath | String | null | The classpath that the Liferay WSDD Builder uses to generate WSDD files. inputFileName | String | "service.xml" | The file from which to generate the WSDD files. outputDirName | String | "src" | The directory where the *_deploy.wsdd and *_undeploy.wsdd files are generated. serverConfigFileName | String | "server-config.wsdd" | The file to generate. serviceNamespace | String | "Plugin" | The namespace for the WSDD Service.

132.12 XML Formatter Plugin

The XML Formatter plugin lets you format a project's XML files.

Usage

To use the plugin, include it in your project's root `pom.xml` file:

```
<build>
    <plugins>
    ...
        <plugin>
            <groupId>com.liferay</groupId>
            <artifactId>com.liferay.xml.formatter</artifactId>
            <version>1.0.5</version>
            <configuration>
            </configuration>
        </plugin>
    ...
    </plugins>
</build>
```

You can view an example POM containing the XML Formatter configuration here.

Goals

The plugin adds one Maven goal to your project:

Name | Description `xml-formatter:format` | Runs the Liferay XML Formatter to format the project files.

Available Parameters

You can set the following parameters in the `<configuration>` section of the POM:

Parameter Name | Type | Default Value | Description `fileName` | `String` | `null` | The XML file to format. This plugin only lets you format one XML file at a time. `stripComments` | `boolean` | `false` | Whether to remove all the comments from the XML file.

Chapter 133

Project Templates

Liferay provides project templates that you can use to generate starter projects formatted in an opinionated way. These templates can be used by most build tools (e.g., Gradle, Maven, Liferay @ide@) to generate your desired project structure.

Some popular project templates include

- API project
- Fragment project
- MVC Portlet project
- Service Builder project
- Template Context Contributor project
- Theme project (WAR)
- etc.

If you're using Blade CLI, execute the following command to display a full list of project templates:

```
blade create -l
```

If you're using Maven, you can view and use the project templates as Maven archetypes. Execute the following command to list them:

```
mvn archetype:generate -Dfilter=liferay
```

Archetypes with the `com.liferay.project.templates` prefix are the latest templates offered by Liferay.

If you're using Liferay @ide@, navigate to *File* → *New* → *Liferay Module Project* and view the project templates from the *Project Template Name* drop-down menu.

In this section of reference articles, each project template is outlined with the appropriate generation command and folder structure. Visit the project template article you're most interested in to start building your own project!

133.1 Activator Template

In this article, you'll learn how to create a Liferay activator as a Liferay module. To create a Liferay activator via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t activator -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.activator \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `activator`. Suppose you want to create an activator project called `my-activator-project` with a package name of `com.liferay.docs.activator` and a class name of `Activator`. You could run the following command to accomplish this:

```
blade create -t activator -v 7.0 -p com.liferay.docs.activator -c Activator my-activator-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.activator \
    -DgroupId=com.liferay \
    -DartifactId=my-activator-project \
    -Dpackage=com.liferay.docs.activator \
    -Dversion=1.0 \
    -DclassName=Activator \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

Note that in your class, you're implementing the `org.osgi.framework.BundleActivator` interface.

After running the command above, your project's directory structure looks like this:

- `my-activator-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/activator`
      - `Activator.java`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.2 API Template

In this tutorial, you'll learn how to create a Liferay API as a Liferay module. To create a Liferay API via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t api -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.api \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `api`. The `api` template creates a simple `api` module with an empty public interface. For example, suppose you want to create an API project called `my-api-project` with a package name of `com.liferay.docs.api` and a class name of `MyApi`. You could run the following command to accomplish this:

```
blade create -t api -v 7.0 -p com.liferay.docs -c MyApi my-api-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.api \
    -DgroupId=com.liferay \
    -DartifactId=my-api-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=MyApi \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-api-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/api`

            - MyApi.java

            - resources
            - com/liferay/docs/api
            - packageinfo

    - bnd.bnd
    - build.gradle
    - [gradlew|pom.xml]

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.3 Control Menu Entry Template

In this article, you'll learn how to create a Liferay Control Menu entry as a Liferay module. To create a Liferay Control Menu entry via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t control-menu-entry -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.control.menu.entry \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `control-menu-entry`. Suppose you want to create a control menu entry project called `my-control-menu-entry-project` with a package name of `com.liferay.docs.entry.control.menu` and a class name of `SampleProductNavigationControlMenuEntry`. You could run the following command to accomplish this:

```
blade create -t control-menu-entry -v 7.0 -p com.liferay.docs.entry -c Sample my-control-menu-entry-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.control.menu.entry \
    -DgroupId=com.liferay \
    -DartifactId=my-control-menu-entry-project \
    -Dpackage=com.liferay.docs.entry \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this:

- my-control-menu-entry-project
  - gradle (only in Blade CLI generated projects)
    - wrapper
      - gradle-wrapper.jar
      - gradle-wrapper.properties
  - src
    - main
      - java
      - com/liferay/docs/entry/control/menu
      - SampleProductNavigationControlMenuEntry.java

      - resources
      - content
      - Language.properties
  - bnd.bnd
  - build.gradle
  - [gradlew|pom.xml]

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the control-menu-entry sample project for a more expanded sample of a Control Menu entry. Likewise, see the Customizing the Control Menu tutorial for instructions on customizing a Control Menu entry project.

133.4 Form Field Template

In this article, you'll learn how to create a Liferay form field as a Liferay module. To create a Liferay form field via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t form-field -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.form.field \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `form-field`. Suppose you want to create a form field project called `my-form-field-project` with a package name of `com.liferay.docs.form.field` and a class name prefix of `MyFormField`. You could run one of the following commands to accomplish this:

```
blade create -t form-field -v 7.0 -p com.liferay.docs -c MyFormField my-form-field-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.form.field \
    -DgroupId=com.liferay \
    -DartifactId=my-form-field-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=MyFormField \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-form-field-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/form/field`
      - `MyFormFieldDDMFormFieldRenderer.java`
      - `MyFormFieldDDMFormFieldType.java`

      - `resources`
      - `content`
      - `Language.properties`

      - `META-INF`
      - `resources`
      - `config.js`
      - `my-form-field-project.soy`
      - `my-form-field-project_field.js`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is a working form field and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.5 Fragment Template

In this article, you'll learn how to create a Liferay fragment as a Liferay module. You can learn more about fragment modules in the Declaring a Fragment Host article and in section 3.14 of the OSGi Alliance's core specification document.

To create a Liferay fragment via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t fragment -v 7.0 [-h hostBundleName] [-H hostBundleVersion] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.fragment \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `fragment`. Suppose you want to create a fragment project called `my-fragment-project` with a host bundle symbolic name of `com.liferay.login.web` and host bundle version of `1.0.0`. You could run the following command to accomplish this:

```
blade create -t fragment -v 7.0 -h com.liferay.login.web -H 1.0.0 my-fragment-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.fragment \
    -DgroupId=com.liferay \
    -DartifactId=my-fragment-project \
    -Dversion=1.0 \
    -Dpackage= \
    -DhostBundleSymbolicName=com.liferay.login.web \
    -DhostBundleVersion=1.0.0 \
    -DliferayVersion=7.0
```

The folder structure is created, but there are no files. The only files created are the `bnd.bnd` and `build.gradle` files, which specify your host bundle and its information, and your build tool's files. After running the command above, your project's directory structure looks like this:

- `my-fragment-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`

    * main

        · java -resources -META-INF -resources

  - bnd.bnd
  - build.gradle
  - [gradlew|pom.xml]

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.6 FreeMarker Portlet Template

In this article, you'll learn how to create a Liferay FreeMarker portlet application as a Liferay module. To create a Liferay FreeMarker portlet application via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t freemarker-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.freemarker.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `freemarker-portlet`. Suppose you want to create a FreeMarker portlet project called `my-freemarker-portlet-project` with a package name of `com.liferay.docs.freemarkerportlet` and a class name of `MyFreemarkerPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.util.bridges.freemarker.FreeMarkerPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t freemarker-portlet -v 7.0 -p com.liferay.docs.freemarkerportlet -c MyFreemarkerPortlet my-freemarker-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.freemarker.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-freemarker-portlet-project \
    -Dpackage=com.liferay.docs.freemarkerportlet \
    -Dversion=1.0 \
    -DclassName=MyFreemarkerPortlet \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- my-freemarker-portlet-project
    - gradle (only in Blade CLI generated projects)
        - wrapper
            - gradle-wrapper.jar
            - gradle-wrapper.properties
    - src
        - main
            - java
            - com/liferay/docs/freemarkerportlet
            - constants
            - MyFreemarkerPortletKeys.java

            - portlet
            - MyFreemarkerPortlet.java

            - resources
            - content
            - Language.properties

            - META-INF
            - resources
            - css
            - main.scss

            - templates
            - init.ftl
            - view.ftl
    - bnd.bnd
    - build.gradle
    - [gradlew|pom.xml]

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.7 Layout Template

In this article, you'll learn how to create a Liferay layout template as a WAR project. To create a Liferay layout template via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t layout-template -v 7.0 projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.layout.template \
    -DartifactId=[projectName] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `layout-template`. Suppose you want to create a layout template project called `my-layout-template-project`. You could run one of the following commands to accomplish this:

```
blade create -t layout-template -v 7.0 my-layout-template-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.layout.template \
    -DgroupId=com.liferay \
    -DartifactId=my-layout-template-project \
    -Dversion=1.0 \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-layout-template-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`
            - `webapp`
            - `WEB-INF`
            - `liferay-layout-templates.xml`
            - `liferay-plugin-package.properties`

            - `my-layout-template-project.png`
            - `my-layout-template-project.tpl`
    - `build.gradle`
    - `[gradlew|pom.xml]`

The generated WAR is a working layout template and is deployable to a Liferay DXP instance. To build upon the generated layout template, modify the project by adding logic and additional files to the folders outlined above.

133.8 MVC Portlet Template

In this article, you'll learn how to create a Liferay MVC portlet application as a Liferay module. To create a Liferay MVC portlet application via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t mvc-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.mvc.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `mvc-portlet`. Suppose you want to create an MVC portlet project called `my-mvc-portlet-project` with a package name of `com.liferay.docs.mvcportlet` and a class name of `MyMvcPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t mvc-portlet -v 7.0 -p com.liferay.docs.mvcportlet -c MyMvcPortlet my-mvc-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.mvc.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-mvc-portlet-project \
    -Dpackage=com.liferay.docs.mvcportlet \
    -Dversion=1.0 \
    -DclassName=MyMvcPortlet \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-mvc-portlet-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`

    - java
    - com/liferay/docs/mvcportlet
    - MyMvcPortlet.java

    - resources
    - content
    - Language.properties

    - META-INF
    - resources
    - init.jsp
    - view.jsp

- bnd.bnd
- build.gradle
- [gradlew|pom.xml]

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.9 npm Angular Portlet Template

In this article, you'll learn how to create an npm Angular portlet as a Liferay module. To create an npm Angular portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-angular-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.angular.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-angular-portlet`. Suppose you want to create an npm Angular portlet project called `my-npm-angular-portlet` with a package name of `com.liferay.npm.angular` and a class name of `MyNpmAngularPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-angular-portlet -v 7.0 -p com.liferay.npm.angular -c MyNpmAngularPortlet my-npm-angular-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.angular.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-angular-portlet \
    -Dpackage=com.liferay.npm.angular \
    -Dversion=1.0 \
    -DclassName=MyNpmAngularPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-angular-portlet`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/npm/angular`
      - `constants`
      - `MyNpmAngularPortletKeys.java`

      - `portlet`
      - `MyNpmAngularPortlet.java`

      - `resources`
      - `content`
      - `Language.properties`

      - `META-INF`
      - `resources`
      - `js`
      - `app`
      - `app.component.ts`
      - `app.module.ts`

      - `angular-loader.ts`
      - `main.ts`

      - `init.jsp`

        · view.jsp

    – .babelrc
    – .npmbundlerrc
    – bnd.bnd
    – [build.gradle|pom.xml]
    – [gradlew|mvnw]
    – package.json
    – tsconfig.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.10 npm Billboard.js Portlet Template

In this article, you'll learn how to create an npm Billboard.js portlet as a Liferay module. To create an npm Billboard.js portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-billboardjs-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.billboardjs.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-billboardjs-portlet`. Suppose you want to create an npm Billboard.js portlet project called `my-npm-billboardjs-portlet` with a package name of `com.liferay.npm.billboardjs` and a class name of `MyNpmBillboardjsPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-billboardjs-portlet -v 7.0 -p com.liferay.npm.billboardjs -c MyNpmBillboardjsPortlet my-npm-billboardjs-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.billboardjs.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-billboardjs-portlet \
    -Dpackage=com.liferay.npm.billboardjs \
    -Dversion=1.0 \
    -DclassName=MyNpmBillboardjsPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-billboardjs-portlet`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/npm/billboardjs`
      - `constants`
      - `MyNpmBillboardjsPortletKeys.java`

      - `portlet`
      - `MyNpmBillboardjsPortlet.java`

      - `resources`
      - `content`
      - `Language.properties`

      - `META-INF`
      - `resources`
      - `js`
      - `data.json`
      - `index.es.js`

      - `init.jsp`
      - `view.jsp`
  - `.babelrc`
  - `.npmbundlerrc`
  - `bnd.bnd`
  - `[build.gradle|pom.xml]`
  - `[gradlew|mvnw]`
  - `package.json`

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.11 npm Isomorphic Portlet Template

In this article, you'll learn how to create an npm Isomorphic portlet as a Liferay module. To create an npm Isomorphic portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-isomorphic-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.isomorphic.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-isomorphic-portlet`. Suppose you want to create an npm Isomorphic portlet project called `my-npm-isomorphic-portlet` with a package name of `com.liferay.npm.isomorphic` and a class name of `MyNpmIsomorphicPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-isomorphic-portlet -v 7.0 -p com.liferay.npm.isomorphic -c MyNpmIsomorphicPortlet my-npm-isomorphic-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.isomorphic.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-isomorphic-portlet \
    -Dpackage=com.liferay.npm.isomorphic \
    -Dversion=1.0 \
    -DclassName=MyNpmIsomorphicPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-isomorphic-portlet`

- [gradle|.mvn]

  * wrapper

    · [gradle|maven]-wrapper.jar
    · [gradle|maven]-wrapper.properties

- src

  * main

    · java
    · com/liferay/npm/isomorphic
    · constants
    · MyNpmIsomorphicPortletKeys.java

    · portlet
    · MyNpmIsomorphicPortlet.java

    · resources
    · content
    · Language.properties

    · META-INF
    · resources
    · js
    · index.es.js

    · init.jsp
    · view.jsp

- .babelrc
- .npmbundlerrc
- bnd.bnd
- [build.gradle|pom.xml]
- [gradlew|mvnw]
- package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.12 npm jQuery Portlet Template

In this article, you'll learn how to create an npm jQuery portlet as a Liferay module. To create an npm jQuery portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-jquery-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.jquery.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-jquery-portlet`. Suppose you want to create an npm jQuery portlet project called `my-npm-jquery-portlet` with a package name of `com.liferay.npm.jquery` and a class name of `MyNpmjQueryPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-jquery-portlet -v 7.0 -p com.liferay.npm.jquery -c MyNpmjQueryPortlet my-npm-jquery-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.jquery.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-jquery-portlet \
    -Dpackage=com.liferay.npm.jquery \
    -Dversion=1.0 \
    -DclassName=MyNpmjQueryPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-jquery-portlet`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`

            · com/liferay/npm/jquery
            · constants
            · MyNpmjQueryPortletKeys.java

            · portlet
            · MyNpmjQueryPortlet.java

            · resources
            · content
            · Language.properties

            · META-INF
            · resources
            · js
            · index.es.js

            · init.jsp
            · view.jsp

- .babelrc
- .npmbundlerrc
- bnd.bnd
- [build.gradle|pom.xml]
- [gradlew|mvnw]
- package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.13 npm Metal.js Portlet Template

In this article, you'll learn how to create an npm Metal.js portlet as a Liferay module. To create an npm Metal.js portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-metaljs-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.metaljs.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-metaljs-portlet`. Suppose you want to create an npm Metal.js portlet project called `my-npm-metaljs-portlet` with a package name of `com.liferay.npm.metaljs` and a class name of `MyNpmMetaljsPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-metaljs-portlet -v 7.0 -p com.liferay.npm.metaljs -c MyNpmMetaljsPortlet my-npm-metaljs-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.metaljs.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-metaljs-portlet \
    -Dpackage=com.liferay.npm.metaljs \
    -Dversion=1.0 \
    -DclassName=MyNpmMetaljsPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-metaljs-portlet`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/npm/metaljs`
      - `constants`
      - `MyNpmMetaljsPortletKeys.java`

      - `portlet`
      - `MyNpmMetaljsPortlet.java`

      - `resources`
      - `content`
      - `Language.properties`

            - META-INF
            - resources
            - js
            - HelloWorld.soy
            - index.es.js
            - init.jsp
            - view.jsp

    - .babelrc
    - .npmbundlerrc
    - bnd.bnd
    - [build.gradle|pom.xml]
    - [gradlew|mvnw]
    - package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.14 npm Portlet Template

In this article, you'll learn how to create an npm portlet as a Liferay module. To create an npmportlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-portlet`. Suppose you want to create an npm portlet project called `my-npm-portlet` with a package name of `com.liferay.npm` and a class name of `MyNpmPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-portlet -v 7.0 -p com.liferay.npm -c MyNpmPortlet my-npm-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-portlet \
    -Dpackage=com.liferay.npm \
    -Dversion=1.0 \
    -DclassName=MyNpmPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-npm-portlet`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/npm`
      - `constants`
      - `MyNpmPortletKeys.java`

      - `portlet`
      - `MyNpmPortlet.java`

      - `resources`
      - `content`
      - `Language.properties`

      - `META-INF`
      - `resources`
      - `js`
      - `index.es.js`

      - `init.jsp`
      - `view.jsp`
  - `.babelrc`
  - `.npmbundlerrc`
  - `bnd.bnd`
  - `[build.gradle|pom.xml]`
  - `[gradlew|mvnw]`

- package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.15 npm React Portlet Template

In this article, you'll learn how to create an npm React portlet as a Liferay module. To create an npm React portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-react-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.react.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-react-portlet`. Suppose you want to create an npm React portlet project called `my-npm-react-portlet` with a package name of `com.liferay.npm.react` and a class name of `MyNpmReactPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-react-portlet -v 7.0 -p com.liferay.npm.react -c MyNpmReactPortlet my-npm-react-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.react.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-react-portlet \
    -Dpackage=com.liferay.npm.react \
    -Dversion=1.0 \
    -DclassName=MyNpmReactPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- my-npm-react-portlet
  - [gradle|.mvn]
    - wrapper
      - [gradle|maven]-wrapper.jar
      - [gradle|maven]-wrapper.properties
  - src
    - main
      - java
      - com/liferay/npm/react
      - constants
      - MyNpmReactPortletKeys.java

      - portlet
      - MyNpmReactPortlet.java

      - resources
      - content
      - Language.properties

      - META-INF
      - resources
      - js
      - index.es.js

      - init.jsp
      - view.jsp
  - .babelrc
  - .npmbundlerrc
  - bnd.bnd
  - [build.gradle|pom.xml]
  - [gradlew|mvnw]
  - package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.16 npm Vue.js Portlet Template

In this article, you'll learn how to create an npm Vue.js portlet as a Liferay module. To create an npm Vue.js portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t npm-vuejs-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.vuejs.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

The template for this kind of project is `npm-vuejs-portlet`. Suppose you want to create an npm Vue.js portlet project called `my-npm-vuejs-portlet` with a package name of `com.liferay.npm.vuejs` and a class name of `MyNpmVuejsPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t npm-vuejs-portlet -v 7.0 -p com.liferay.npm.vuejs -c MyNpmVuejsPortlet my-npm-vuejs-portlet
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.npm.vuejs.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-npm-vuejs-portlet \
    -Dpackage=com.liferay.npm.vuejs \
    -Dversion=1.0 \
    -DclassName=MyNpmVuejsPortlet \
    -DpackageJsonVersion=1.0.0 \
    -DliferayVersion=7.0
```

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.
After running the command above, your project's directory structure looks like this:

- `my-npm-vuejs-portlet`
    - `.mvn` (only in Maven Blade CLI generated projects)
        - `wrapper`

        · maven-wrapper.jar
        · maven-wrapper.properties

  – src

      * main

        · java
        · com/liferay/npm/vuejs
        · constants
        · MyNpmVuejsPortletKeys.java

        · portlet
        · MyNpmVuejsPortlet.java

        · resources
        · content
        · Language.properties

        · META-INF
        · resources
        · lib
        · index.es.js

        · init.jsp
        · view.jsp

  – .babelrc
  – .npmbundlerrc
  – bnd.bnd
  – [build.gradle|pom.xml]
  – mvnw (only in Maven Blade CLI generated projects)
  – mvnw.cmd (only in Maven Blade CLI generated projects)
  – package.json

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated portlet, modify the project by adding logic and additional files to the folders outlined above.

133.17 Panel App Template

In this article, you'll learn how to create a Liferay panel app and category as a Liferay module. To create a Liferay panel app and category via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t panel-app -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.panel.app \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `panel-app`. Suppose you want to create a panel app project called `my-panel-app-project` with a package name prefix of `com.liferay.docs` and a class name prefix of `Sample`. You could run the following command to accomplish this:

```
blade create -t panel-app -v 7.0 -p com.liferay.docs -c Sample my-panel-app-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.panel.app \
    -DgroupId=com.liferay \
    -DartifactId=my-panel-app-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-panel-app-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/`
      - `application/list`
      - `SamplePanelApp.java`
      - `SamplePanelCategory.java`

      - `constants`
      - `SamplePanelCategoryKeys.java`
      - `SamplePortletKeys.java`

      - `portlet`

    - SamplePortlet.java
    - resources
    - content
    - Language.properties
    - META-INF
    - resources
    - init.jsp
    - view.jsp
- bnd.bnd
- build.gradle
- [gradlew|pom.xml]

The generated module is functional and is deployable to a Liferay DXP instance. The generated module, by default, creates a panel category with a panel app in Liferay DXP's Product Menu. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the Customizing the Product Menu tutorial for instructions on customizing a panel app project.

133.18 Portlet Configuration Icon

In this article, you'll learn how to create a Liferay portlet configuration icon as a Liferay module. To create a portlet configuration icon via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t portlet-configuration-icon -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.configuration.icon \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `portlet-configuration-icon`. Suppose you want to create a portlet configuration icon project called `my-portlet-config-icon` with a package name of `com.liferay.docs.portlet.configuration.icon` and a class name of `SamplePortletConfigurationIcon`. You could run the following command to accomplish this:

```
blade create -t portlet-configuration-icon -v 7.0 -p com.liferay.docs -c Sample my-portlet-config-icon
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.configuration.icon \
    -DgroupId=com.liferay \
    -DartifactId=my-portlet-config-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-portlet-config-icon`
    - `gradle` (only in Blade CLI generated projects)
        * `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        * `main`
            - `java`
            - `com/liferay/docs/portlet/configuration/icon`
            - `SamplePortletConfigurationIcon.java`

            - `resources`
            - `content`
            - `Language.properties`
    - `bnd.bnd`
    - `build.gradle`
    - `[gradlew|pom.xml]`

The generated module is functional and is deployable to a Liferay DXP instance. The generated module, by default, creates a sample link in the Hello World portlet's Options menu. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the portlet-configuration-icon sample project for a more expanded sample of a portlet configuration icon.

133.19 Portlet Template

In this article, you'll learn how to create a Liferay portlet application as a Liferay module. To create a Liferay portlet application via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `portlet`. Suppose you want to create a portlet project called `my-portlet-project` with a package name of `com.liferay.docs.portlet` and a class name of `MyPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `javax.portlet.GenericPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t portlet -v 7.0 -p com.liferay.docs.portlet -c MyPortlet my-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-portlet-project \
    -Dpackage=com.liferay.docs.portlet \
    -Dversion=1.0 \
    -DclassName=MyPortlet \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-portlet-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`
            - `java`
            - `com/liferay/docs/portlet`
            - `MyPortlet.java`
    - `bnd.bnd`
    - `build.gradle`
    - `[gradlew|pom.xml]`

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.20 Portlet Provider Template

In this article, you'll learn how to create a Liferay portlet provider as a Liferay module. To create a Liferay portlet provider via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t portlet-provider -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.provider \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `portlet-provider`. Suppose you want to create a portlet provider project called `my-portlet-provider-project` with a package name of `com.liferay.docs.portlet` and a class name prefix of `Sample`. You could run the following command to accomplish this:

```
blade create -t portlet-provider -v 7.0 -p com.liferay.docs -c Sample my-portlet-provider-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.provider \
    -DgroupId=com.liferay \
    -DartifactId=my-portlet-provider-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-portlet-provider-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/portlet`

- SampleAddPortletProvider.java
- SamplePortlet.java

- resources
- META-INF
- resources
- init.jsp
- view.jsp

- bnd.bnd
- build.gradle
- [gradlew|pom.xml]

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the Providing Portlets to Manage Requests tutorial for instructions on customizing a portlet provider project.

133.21 Portlet Toolbar Contributor Template

In this article, you'll learn how to create a Liferay portlet toolbar contributor as a Liferay module. To create a portlet toolbar contributor entry via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t portlet-toolbar-contributor -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.toolbar.contributor \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `portlet-toolbar-contributor`. Suppose you want to create a portlet toolbar contributor project called `my-portlet-toolbar-contributor` with a package name of `com.liferay.docs.portlet.toolbar.contributor` and a class name of `SamplePortletToolbarContributor`. You could run the following command to accomplish this:

```
blade create -t portlet-toolbar-contributor -v 7.0 -p com.liferay.docs -c Sample my-portlet-toolbar-contributor
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.portlet.toolbar.contributor \
    -DgroupId=com.liferay \
    -DartifactId=my-portlet-toolbar-contributor \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-portlet-toolbar-contributor`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/portlet/toolbar/contributor`
      - `SamplePortletToolbarContributor.java`

      - `resources`
      - `content`
      - `Language.properties`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. This generated project, by default, creates a new button on the Hello World portlet's toolbar. You can visit the portlet-toolbar-contributor sample project for a more expanded sample of a portlet toolbar contributor.

133.22 REST Template

In this article, you'll learn how to create a Liferay RESTful web service packaged in a Liferay module. To create a Liferay RESTful web service via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t rest -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.rest \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `rest`. Suppose you want to create a RESTful web service project called `my-rest-project` with a package name of `com.liferay.docs.application` and a class name prefix of `Rest`. You could run one of the following commands to accomplish this:

```
blade create -t rest -v 7.0 -p com.liferay.docs -c Rest my-rest-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.rest \
    -DgroupId=com.liferay \
    -DartifactId=my-rest-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Rest \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-rest-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/application`
      - `RestApplication.java`

      - `resources`
      - `configuration`
      - `com.liferay.portal.remote.cxf.common.configuration.CXFEndpointPublisherConfiguration-cxf`
      - `com.liferay.portal.remote.rest.extender.configuration.RestExtenderConfiguration-rest`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is a working RESTful web service and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.23 Service Template

In this article, you'll learn how to create a Liferay service as a Liferay module. To create a Liferay service via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t service -v 7.0 [-p packageName] [-c className] [-s serviceName] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DserviceName=[serviceName] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `service`. Suppose you want to create a service project called `my-service-project` with a package name of `com.liferay.docs.service` and a class name of `Service`. Also, you'd like to create a service of type `com.liferay.portal.kernel.events.LifecycleAction` that also implements that same service. You could run the following command to accomplish this:

```
blade create -t service -v 7.0 -p com.liferay.docs.service -c Service -s com.liferay.portal.kernel.events.LifecycleAction  my-service-
project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service \
    -DgroupId=com.liferay \
    -DartifactId=my-service-project \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Service \
    -DclassName=com.liferay.portal.kernel.events.LifecycleAction \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-service-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`

        - java
        - com/liferay/docs/service
        - Service.java

  - bnd.bnd
  - build.gradle
  - [gradlew|pom.xml]

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.24 Service Builder Template

In this article, you'll learn how to create a Liferay portlet application that uses Service Builder as Liferay modules. To create a Liferay Service Builder project via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t service-builder -v 7.0 [-p packageName] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service.builder \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DapiPath=[apiPath] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `service-builder`. Suppose you want to create a Service Builder project called tasks with a package name of `com.liferay.docs.tasks`. You could run the following command to accomplish this:

```
blade create -t service-builder -v 7.0 -p com.liferay.docs.tasks tasks
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service.builder \
    -DgroupId=com.liferay \
    -DartifactId=tasks \
    -Dpackage=com.liferay.docs.tasks \
    -Dversion=1.0 \
    -DapiPath=com.liferay.api.path \
    -DliferayVersion=7.0
```

This task creates the `tasks-api` and `tasks-service` folders. In many cases, a Service Builder project also requires a `-web` folder to hold, for example, portlet classes. This should be created manually. After running the command above, your project's directory structure looks like this:

- tasks

- `gradle` (only in Blade CLI generated projects)
    - `wrapper`
        - `gradle-wrapper.jar`
        - `gradle-wrapper.properties`
- `tasks-api`
    - `bnd.bnd`
    - `build.gradle`
- `tasks-service`
    - `bnd.bnd`
    - `build.gradle`
    - `service.xml`
- `build.gradle`
- `[gradlew|pom.xml]`
- `settings.gradle`

To generate your service and API classes for the `*-api` and `*-service` modules, replace the `service.xml` file in the `*-service` module. Depending on your build tool, you can build your services by executing

```
blade gw buildService
```

or

```
mvn service-builder:build
```

from the tasks root directory. Note that `blade gw` only works if the Gradle wrapper can be detected. To ensure the availability of the Gradle wrapper, be sure to work in a Liferay Workspace.

The `mvn service-builder:build` command only works if you're using the `com.liferay.portal.tools.service.builder` plugin version 1.0.145+. Maven projects using an earlier version of the Service Builder plugin should update their POM accordingly.

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

Service Builder with Maven

133.25 Service Wrapper Template

In this article, you'll learn how to create a Liferay service wrapper as a Liferay module. To create a Liferay service wrapper via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t service-wrapper -v 7.0 [-p packageName] [-c className] [-s serviceWrapperClass] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service.wrapper \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DserviceWrapperClass=[serviceWrapperClass] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `service-wrapper`. Suppose you want to create a service wrapper project called `service-override` with a package name of `com.liferay.docs.serviceoverride` and a class name of `UserLocalServiceOverride`. Also, you'd like to create a service of type `com.liferay.portal.kernel.service.ServiceWrapper` that extends the `com.liferay.portal.service.UserLocalServiceWrapper` class. You could run the following command to accomplish this:

```
blade create -t service-wrapper -v 7.0 -p com.liferay.docs.serviceoverride -c UserLocalServiceOverride -s com.liferay.portal.kernel.service.UserLocalService
override
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.service.wrapper \
    -DgroupId=com.liferay \
    -DartifactId=service-override \
    -Dpackage=com.liferay.docs.serviceoverride \
    -Dversion=1.0 \
    -DclassName=UserLocalServiceOverride \
    -DserviceWrapperClass=com.liferay.portal.kernel.service.UserLocalServiceWrapper \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*.

After running the command above, your project's directory structure looks like this:

- `service-override`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`

  - src

    * main

      · java
      · com/liferay/docs/serviceoverride
      · UserLocalServiceOverride.java

  - bnd.bnd
  - build.gradle
  - [gradlew|pom.xml]

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.26 Simulation Panel Entry Template

In this article, you'll learn how to create a Liferay simulation panel entry as a Liferay module. To create a simulation panel entry via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t simulation-panel-entry -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.simulation.panel.entry \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `simulation-panel-entry`. Suppose you want to create a simulation panel entry project called `my-simulation-panel-entry` with a package name of `com.liferay.docs.application.list` and a class name of `SampleSimulationPanelApp`. You could run the following command to accomplish this:

```
blade create -t simulation-panel-entry -v 7.0 -p com.liferay.docs -c Sample my-simulation-panel-entry
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.simulation.panel.entry \
    -DgroupId=com.liferay \
    -DartifactId=my-simulation-panel-entry \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-simulation-panel-entry`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/application/list`
      - `SampleSimulationPanelApp.java`

      - `resources`
      - `content`
      - `Language.properties`

      - `META-INF`
      - `resources`
      - `simulation_panel.jsp`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the simulation-panel-app sample project for a more expanded sample of a control menu entry. Likewise, see the Extending the Simulation Menu tutorial for instructions on customizing a simulation panel entry project.

133.27 Soy Portlet Template

In this article, you'll learn how to create a Soy portlet application as a Liferay module. To create a Soy portlet as a module via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t soy-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.soy.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `soy-portlet`. Suppose you want to create an Soy portlet project called `my-soy-portlet-project` with a package name of `com.liferay.docs.soyportlet` and a class name of `MySoyPortlet`. Also, you'd like to create a service of type `javax.portlet.Portlet` that extends the `com.liferay.portal.portlet.bridge.soy.SoyPortlet` class. Here, *service* means an OSGi service, not a Liferay API. Another way to say *service type* is to say *component type*. You could run the following command to accomplish this:

```
blade create -t soy-portlet -v 7.0 -p com.liferay.docs.soyportlet -c MySoyPortlet my-soy-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.soy.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-soy-portlet-project \
    -Dpackage=com.liferay.docs.soyportlet \
    -Dversion=1.0 \
    -DclassName=MySoyPortlet \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-soy-portlet-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`
            - `java`
            - `com/liferay/docs/soyportlet`
            - `constants`
            - `MySoyPortletKeys.java`

            - `portlet`
            - `action`
            - `MySoyPortletNavigationMVCRenderCommand.java`

            - `MySoyPortlet.java`

            - `resources`
            - `content`
            - `Language.properties`

        - META-INF
        - resources
        - Footer.es
        - Footer.soy
        - Header.es
        - Header.soy
        - Navigation.es
        - Navigation.soy
        - View.es
        - View.soy

    - bnd.bnd
    - build.gradle
    - package.json
    - [gradlew|pom.xml]

The generated module is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above.

133.28 Spring MVC Portlet Template

In this article, you'll learn how to create a Liferay Spring MVC portlet application as a WAR. To create a Liferay Spring MVC portlet via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t spring-mvc-portlet -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.spring.mvc.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `spring-mvc-portlet`. Suppose you want to create a Spring MVC portlet project called `my-spring-mvc-portlet-project` with a package name of `com.liferay.docs.springmvcportlet` and a class name of `MySpringMvcPortlet`. Also, you'd like to create a Spring-annotated portlet class named `MySpringMvcPortletViewController`.

```
blade create -t spring-mvc-portlet -v 7.0 -p com.liferay.docs.springmvcportlet -c MySpringMvcPortlet my-spring-mvc-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.spring.mvc.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-spring-mvc-portlet-project \
    -Dpackage=com.liferay.docs.springmvcportlet \
    -Dversion=1.0 \
    -DclassName=MySpringMvcPortlet \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure looks like this:

- `my-spring-mvc-portlet-project`
    - `gradle` (only in Blade CLI generated projects)
        - `wrapper`
            - `gradle-wrapper.jar`
            - `gradle-wrapper.properties`
    - `src`
        - `main`
            - `java`
            - `com/liferay/docs/springmvcportlet/portlet`
            - `MySpringMvcPortletViewController`

            - `resources`
            - `content`
            - `Language.properties`

            - `webapp`
            - `css`
            - `main.scss`

            - `WEB-INF`
            - `jsp`
            - `init.jsp`
            - `view.jsp`

            - `spring-context`
            - `portlet`
            - `my-spring-mvc-portlet-project.xml`

            - `portlet-application-context.xml`

            - `tld`
            - `liferay-portlet.tld`
            - `liferay-portlet-ext.tld`
            - `liferay-security.tld`
            - `liferay-theme.tld`
            - `liferay-ui.tld`
            - `liferay-util.tld`

            · liferay-display.xml
            · liferay-plugin-package.properties
            · liferay-portlet.xml
            · portlet.xml
            · web.xml

            · icon.png

    – build.gradle
    – [gradlew|pom.xml]

The generated WAR is a working application and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the springmvc-portlet sample project for a more expanded sample of a Spring MVC portlet.

133.29 Template Context Contributor Template

In this article, you'll learn how to create a Liferay template context contributor as a Liferay module. To create a template context contributor via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t template-context-contributor -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.template.context.contributor \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `template-context-contributor`. Suppose you want to create a template context contributor project called `my-template-context-contributor` with a package name of `com.liferay.docs.theme.contributor` and a class name of `SampleTemplateContextContributor`. You could run the following command to accomplish this:

```
blade create -t template-context-contributor -v 7.0 -p com.liferay.docs -c Sample my-template-context-contributor
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.template.context.contributor \
    -DgroupId=com.liferay \
    -DartifactId=my-template-context-contributor \
    -Dpackage=com.liferay.docs \
    -Dversion=1.0 \
    -DclassName=Sample \
    -Dauthor=Joe Bloggs \
    -DliferayVersion=7.0
```

After running the command above, your project's directory structure would look like this

- `my-template-context-contributor`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/theme/contributor`
      - `SampleTemplateContextContributor.java`
  - `bnd.bnd`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the template-context-contributor sample project for a more expanded sample of a template context contributor. Likewise, see the Context Contributors tutorial for instructions on customizing a template context contributor project.

133.30 Theme Template

In this article, you'll learn how to create a Liferay theme as a WAR project. To create a Liferay theme via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t theme -v 7.0 projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.theme \
    -DartifactId=[projectName] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `theme`. Suppose you want to create a theme project called `my-theme-project` as a WAR file. You could run the following command to accomplish this:

```
blade create -t theme -v 7.0 my-theme-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.theme \
    -DgroupId=com.liferay \
    -DartifactId=my-theme-project \
    -Dversion=1.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's folder structure looks like this:

- `my-theme-project`
  - `gradle` (only in Blade CLI generated projects)
    - `wrapper`
      - `gradle-wrapper.jar`
      - `gradle-wrapper.properties`
  - `src`
    - `main`
      - `resources`
      - `resources-importer`
      - `sitemap.json`

      - `webapp`
      - `css`
      - `_custom.scss`

      - `WEB-INF`
      - `liferay-plugin-package.properties`
      - `web.xml`
  - `build.gradle`
  - `[gradlew|pom.xml]`

The generated theme is functional and is deployable to a Liferay DXP instance. To build upon the generated project, modify the project by adding logic and additional files to the folders outlined above. You can visit the simple-theme project for a more expanded sample of a theme. Likewise, see the Themes and Layout Templates tutorial section for more information on creating themes.

133.31 Theme Contributor Template

In this article, you'll learn how to create a Liferay theme contributor as a Liferay module. To create a theme contributor via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t theme-contributor -v 7.0 [--contributor-type contributorType] [-p packageName] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.theme.contributor \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DcontributorType=[contributorType] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `theme-contributor`. Suppose you want to create a theme contributor project called `my-theme-contributor` with a package name of `com.liferay.docs.theme.contributor` and a contributor type of `my-contributor`. You could run the following command to accomplish this:

```
blade create -t theme-contributor -v 7.0 --contributor-type my-contributor -p com.liferay.docs.theme.contributor my-theme-contributor
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.theme.contributor \
    -DgroupId=com.liferay \
    -DartifactId=my-theme-contributor \
    -Dpackage=com.liferay.docs.theme.contributor \
    -Dversion=1.0 \
    -DcontributorType=my-contributor \
    -DliferayVersion=7.0
```

After running the command above, your project's folder structure would look like this:

- `my-theme-contributor`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/theme/contributor`

      - `resources/META-INF/resources`
      - `css`
      - `my-contributor`
      - `_body.scss`
      - `_control_menu.scss`
      - `_product_menu.scss`
      - `_simulation_panel.scss`

      - `my-contributor.scss`

      - `js`
      - `my-contributor.js`
  - `bnd.bnd`
  - `build.gradle` (only in Gradle Blade CLI generated projects)
  - `mvnw` (only in Maven Blade CLI generated projects)

    - `mvnw.cmd` (only in Maven Blade CLI generated projects)
    - `pom.xml` (only in Maven-related projects)

The generated module is functional and is deployable to a Liferay DXP instance. To build upon the generated app, modify the project by adding logic and additional files to the folders outlined above. You can visit the Blade Theme Contributor sample project for a more expanded sample of a theme contributor. Likewise, see the Theme Contributors tutorial for instructions on customizing a theme contributor project.

133.32 WAR Hook Template

In this article, you'll learn how to create a Liferay WAR hook project. To create a Liferay WAR hook via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t war-hook -v 7.0 [-p packageName] [-c className] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.war.hook \
    -DartifactId=[projectName]
    -Dpackage=[packageName] \
    -DclassName=[className] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `war-hook`. Suppose you want to create a WAR hook project called `my-war-hook-project` with a package name of `com.liferay.docs` and a class name of `MyWarHook`. You could run the following command to accomplish this:

```
blade create -t war-hook -v 7.0 -p com.liferay.docs -c MyWarHook my-war-hook-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.war.hook \
    -DgroupId=com.liferay \
    -DartifactId=my-war-hook-project \
    -Dpackage=com.liferay.docs \
    -DclassName=MyWarHook \
    -Dversion=1.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's folder structure looks like this:

- `my-war-hook-project`
    - `[gradle|.mvn]`
        - `wrapper`
            - `[gradle|maven]-wrapper.jar`
            - `[gradle|maven]-wrapper.properties`

  - src

    * main

      · java
      · com/liferay/docs
      · MyWarHookLoginPostAction
      · MyWarHookStartupAction

      · resources
      · portal.properties

      · webapp
      · WEB-INF
      · liferay-hook.xml
      · liferay-plugin-package.properties
      · web.xml

  - [build.gradle|pom.xml]
  - [gradlew|mvnw]

The generated WAR hook is functional and is deployable to a Liferay DXP instance. To build upon the generated project, modify the project by adding logic and additional files to the folders outlined above. Deploying WAR hooks is supported for 7.0, however, it is recommended to optimize your WAR hooks to fragments or other applicable module projects. You can visit the Customizing section for info on how to do this for many project types. See the Customizing Liferay Portal section for more information on WAR hooks.

133.33 WAR MVC Portlet Template

In this article, you'll learn how to create a Liferay MVC portlet project as a WAR file. To create a Liferay MVC portlet project as a WAR via the command line using Blade CLI or Maven, use one of the commands with the following parameters:

```
blade create -t war-mvc-portlet -v 7.0 [-p packageName] projectName
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.war.mvc.portlet \
    -DartifactId=[projectName] \
    -Dpackage=[packageName] \
    -DliferayVersion=7.0
```

You can also insert the `-b maven` parameter in the Blade command to generate a Maven project using Blade CLI.

The template for this kind of project is `war-mvc-portlet`. Suppose you want to create a WAR MVC portlet project called `my-war-mvc-portlet-project` with a package name of `com.liferay.docs.war.mvc` and a class name of `MyWarMvcPortlet`. You could run the following command to accomplish this:

```
blade create -t war-mvc-portlet -v 7.0 -p com.liferay.docs.war.mvc my-war-mvc-portlet-project
```

or

```
mvn archetype:generate \
    -DarchetypeGroupId=com.liferay \
    -DarchetypeArtifactId=com.liferay.project.templates.war.mvc.portlet \
    -DgroupId=com.liferay \
    -DartifactId=my-war-mvc-portlet-project \
    -Dpackage=com.liferay.docs.war.mvc \
    -Dversion=1.0 \
    -DliferayVersion=7.0
```

After running the command above, your project's folder structure looks like this:

- `my-war-mvc-portlet-project`
  - `[gradle|.mvn]`
    - `wrapper`
      - `[gradle|maven]-wrapper.jar`
      - `[gradle|maven]-wrapper.properties`
  - `src`
    - `main`
      - `java`
      - `com/liferay/docs/war/mvc`

      - `resources`
      - `content`
      - `Language.properties`

      - `webapp`
      - `css`
      - `.sass-cache`
      - `main.css`
      - `main_rtl.css`

      - `main.scss`

      - `WEB-INF`
      - `tld`
      - `liferay-portlet.tld`
      - `liferay-portlet-ext.tld`
      - `liferay-security.tld`
      - `liferay-theme.tld`
      - `liferay-ui.tld`
      - `liferay-util.tld`

      - `liferay-display.xml`
      - `liferay-plugin-package.properties`
      - `liferay-portlet.xml`

        · `portlet.xml`
        · `web.xml`

        · `init.jsp`
        · `view.jsp`

  – `[build.gradle|pom.xml]`
  – `[gradlew|mvnw]`

The generated WAR MVC portlet is functional and is deployable to a Liferay DXP instance. To build upon the generated project, modify the project by adding logic and additional files to the folders outlined above. Deploying WAR MVC portlets is supported for 7.0, however, it is recommended to optimize your WAR portlet to a module project, if possible. You can visit the From Liferay Portal 6 to 7 section for info on how to do this.

Chapter 134

Sample Projects

Note: This section of articles does not provide documentation for *all* sample projects residing in the `liferay-blade-samples` repo. The documentation for these samples is in progress and will grow over time.

Liferay provides sample projects that target different integration points in Liferay DXP. These projects reside in the liferay-blade-samples Github repository and can be easily copy/pasted to your local environment. The sample projects are grouped into three different parent folders based on the build tools used to generate them:

- `gradle`
- `liferay-workspace`
- `maven`

Note: The Liferay Workspace folder stores WAR-type samples in a separate folder named wars. The Gradle and Maven tool folders mix WAR samples with the other sample types (apps, extensions, etc.).

For more information on these sample projects, visit the Liferay Sample Projects tutorial.

Chapter 135

Apps

This section focuses on Liferay sample applications. You can view these sample apps by visiting the apps folder corresponding to your preferred build tool:

- Gradle sample apps
- Liferay Workspace sample apps
- Maven sample apps

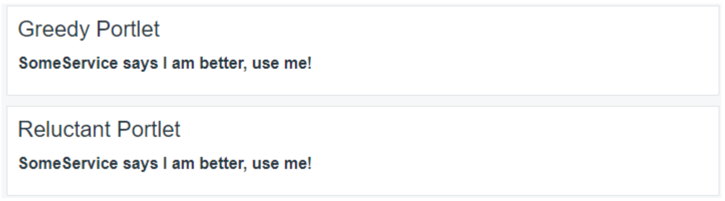
The following samples are documented:

- Greedy Policy Option Portlet
- Kotlin Portlet
- npm Samples
- Service Builder Samples
- Shared Language Keys
- Simulation Panel App
- Spring MVC Portlet

Visit a particular sample page to learn more!

135.1 Greedy Policy Option Application

The Greedy Policy Option sample provides two portlets that can be added to a Liferay DXP page: Greedy Portlet and Reluctant Portlet.



```
SomeService says I am better, use me!
```

```
SomeService says I am better, use me!
```

Figure 135.1: The Greedy Policy Option app provides two portlets that only print text. You'll dive deeper later to discover their interesting capabilities involving services.

These two portlets do not provide anything useful out-of-the-box. They are, however, very effective at demonstrating the ability to reference services using greedy and reluctant policy options. You'll learn how to do this later.

What API(s) and/or code components does this sample highlight?

This sample provides two modules referencing services using greedy and reluctant policy options.

- `service-reference`: Provides an OSGi service interface called `SomeService`, a default implementation of it, and portlets that refer to service instances. One portlet refers to new higher ranked instances of the service automatically. The other portlet is reluctant to use new higher ranked instances and continues to use its bound service. The reluctant portlet can, however, be configured dynamically to use other service instances.
- `higher-ranked-service`: Has a higher ranked `SomeService` implementation.

Here are each module's file structures:

- `service-reference/`
  - `bnd.bnd`
  - `configs/`
    - `com.liferay.blade.reluctant.vs.greedy.portlet.portlet.ReluctantPortlet.config` → `ReluctantPortlet` configuration file for Liferay DXP DE 7.0 Fix Pack 8 or later and Liferay CE Portal 7.0 GA4 or later
    - `com.liferay.blade.reluctant.vs.greedy.portlet.portlet.ReluctantPortlet.cfg` → `ReluctantPortlet` configuration file for Liferay DXP DE 7.0 Fix Packs earlier than Fix Pack 8 and Liferay CE Portal 7.0 GA3 or earlier
  - `src/main/java/com/liferay/blade/reluctant/vs/greedy/portlet/`
    - `api/`
      - `SomeService.java` → Service interface
    - `constants/`
      - `ReluctantPortletVsGreedyPortletKeys.java` → Portlet constants
    - `portlet/`
      - `DefaultSomeService.java` → Zero ranked service implementation
      - `GreedyPortlet.java` → Refers to `SomeService` using a greedy service policy option
      - `ReluctantPortletPortlet.java` → Refers to `SomeService` using a reluctant service policy option by default.
- `higher-ranked-service/`
  - `bnd.bnd`
  - `src/main/java/com/liferay/blade/reluctant/vs/greedy/svc/HigherRankedService.java` → Service implementation with service ranking value of `100`

How does this sample leverage the API(s) and/or code component?

Here are the things you can learn using the sample modules:

1. Binding a component's service reference to the highest ranked service instance that's available initially.
2. Deploying a module with a higher ranked service instance for binding to greedy references immediately.
3. Configuring a component to reference a different service instance dynamically.

Let's walk through the demonstration.

Binding a newly deployed component's service reference to the highest ranking service instance that's available initially

On deploying a component that references a service, it binds to the highest ranking service instance that matches its target filter (if specified).

The portlet classes refer to instances of interface `SomeService`. The `doSomething` method returns a `String`.

```
public interface SomeService {

    public String doSomething();

}
```

Class `DefaultSomeService` implements `SomeService`. Its `doSomething` method returns the `String` "I am Default!".

```
@Component
public class DefaultSomeService implements SomeService {

    @Override
    public String doSomething() {
        return "I am Default!";
    }

}
```

When module's portlets refer to `DefaultSomeService`, they display the `String` "I am Default!".

The `ReluctantPortlet` class's `SomeService` reference's policy option is the default: static and reluctant. This policy option keeps the reference bound to its current service instance unless that instance stops or the reference is reconfigured to refer to a different service instance.

```
@Component(
   immediate = true,
   property = {
       "com.liferay.portlet.display-category=category.sample",
       "com.liferay.portlet.instanceable=true",
       "javax.portlet.display-name=Reluctant Portlet",
       "javax.portlet.init-param.template-path=/",
       "javax.portlet.init-param.view-template=/view.jsp",
       "javax.portlet.name=" + ReluctantVsGreedyPortletKeys.Reluctant,
       "javax.portlet.resource-bundle=content.Language",
       "javax.portlet.security-role-ref=power-user,user"
   },
   service = Portlet.class
)
public class ReluctantPortlet extends MVCPortlet {
   @Override
   public void doView(
           RenderRequest renderRequest, RenderResponse renderResponse)
       throws IOException, PortletException {

       renderRequest.setAttribute("doSomething", _someService.doSomething());

       super.doView(renderRequest, renderResponse);
   }

   @Reference
   private SomeService _someService;

}
```

The `ReluctantPortlet`'s method `doView` sets render request attribute `doSomething` to the value returned from the `SomeService` instance's `doSomething` method (e.g., `DefaultService` returns "I am default!").

The `GreedyPortlet` class is similar to `ReluctantPortlet`, except its `SomeService` reference's policy option is static and greedy (i.e., `ReferencePolicyOption.GREEDY`).

```
public class GreedyPortlet extends MVCPortlet {

    @Override
    public void doView(
            RenderRequest renderRequest, RenderResponse renderResponse)
        throws IOException, PortletException {

        renderRequest.setAttribute("doSomething", _someService.doSomething());

        super.doView(renderRequest, renderResponse);
    }

    @Reference (policyOption = ReferencePolicyOption.GREEDY)
    private SomeService _someService;

}
```

The greedy policy option lets the component switch to using a higher ranked `SomeService` instance if one becomes active in the system. The section *Deploying a module with a higher ranked service instance for binding to greedy references immediately* demonstrates this portlet switching to a higher ranked service.

It's time to see this module's portlets and service in action.

1. Stop module `higher-ranked-service` if it's active.

2. Deploy the `service-reference` module.

3. Add the *Reluctant Portlet* from the *Add* → *Applications* → *Sample* category to a site page.

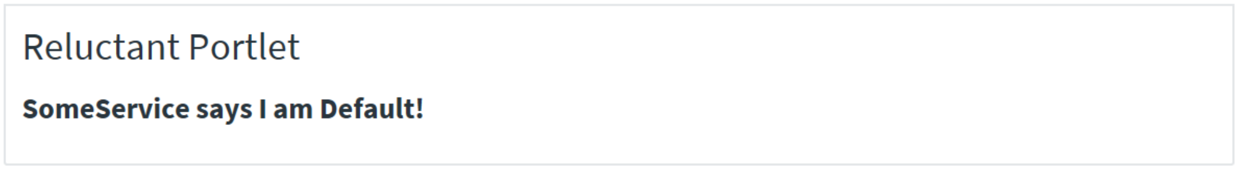
   The portlet displays the message "SomeService says I am default!"–whose latter part comes from the render request attribute set by the `DefaultService` instance.

4. Add the *Greedy Portlet* from the *Add* → *Applications* → *Sample* category to a site page.

   The portlet displays the message "SomeService says I am better, use me!". Both portlets are referencing a `DefaultService` instance.

Since `DefaultService` is the only active `SomeService` instance in the system, the portlets refer to it for their `SomeService` fields.

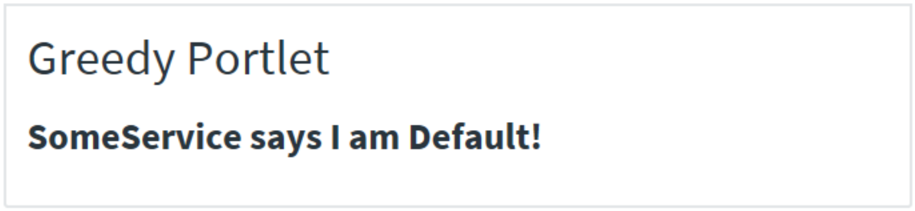
The `DefaultService` and portlets *Reluctant Portlet* and *Greedy Portlet* are active. Let's activate a higher ranked `SomeService` instance and see how the portlets react to it.



Reluctant Portlet

SomeService says I am Default!

Figure 135.2: *Reluctant Portlet* displays the message “SomeService says I am default!”



Greedy Portlet

SomeService says I am Default!

Figure 135.3: *Greedy Portlet* displays the message “SomeService says I am better, use me!”

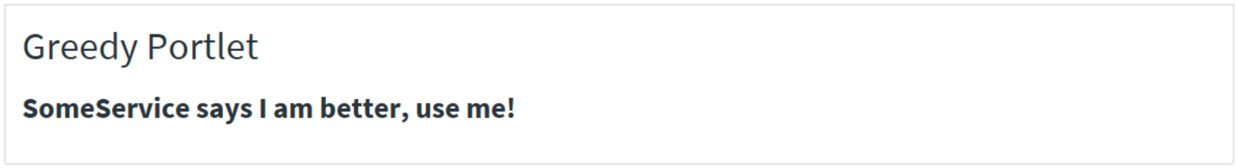
Deploying a module with a higher ranked service instance for binding to greedy references immediately

Module `higher-ranked-service` provides a `SomeService` implementation called `HigherRankedService`. `HigherRankedService`’s service ranking is `100`–that’s `100` more than `DefaultService`’s ranking `0`. Its `doSomething` method returns the `String` “I am better, use me!”.

1. Deploy the `higher-ranked-service` module.
2. Refresh your page that has the portlets *Reluctant Portlet* and *Greedy Portlet*.

Reluctant Portlet continues displaying message “SomeService says I am better, use me!”. It’s “reluctant” to unbind from the `DefaultService` instance and bind to the newly activated `HigherRankedService` service.

Greedy Portlet displays a new message “SomeService says I am better, use me!”. The part of the message “I am better, use me!” comes from the `HigherRankedService` instance to which it refers.



Greedy Portlet

SomeService says I am better, use me!

Figure 135.4: The *Greedy Portlet* is using a `HigherRankedService` instance

Next, learn how to bind the *Reluctant Portlet* to a `HigherRankedService` instance.

Configuring a component to reference a different service instance dynamically

The *Reluctant Portlet* is currently bound to a `DefaultService` instance. It’s “reluctant” to unbind from it and bind to a different service. OSGi Configuration Administration lets you reconfigure service references to filter on and bind to different service instances.

The `service-reference` module's configuration files and `com.liferay.blade.reluctant.vs.greedy.portlet.portlet.Relucta`
and `com.liferay.blade.reluctant.vs.greedy.portlet.portlet.ReluctantPortlet.cfg` configure the `ReluctantPortlet` component to use a `HigherRankedService` instance.

```
_someService.target=(component.name=com.liferay.blade.reluctant.vs.greedy.service.HigherRankedService)
```

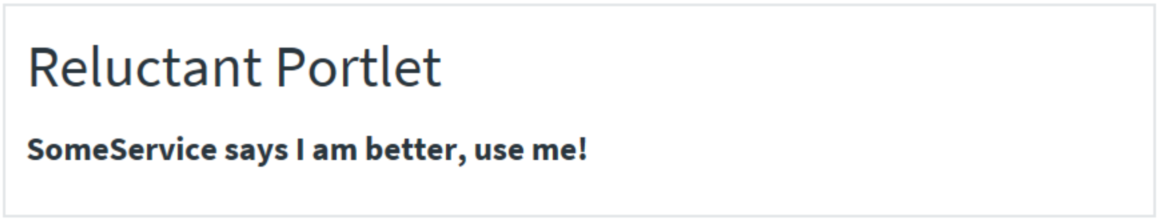
The service configuration filters on a service whose `component.name` is `com.liferay.blade.reluctant.vs.greedy.service.Hig`

Note: For deploying to Liferay DXP DE 7.0 Fix Pack 8 or later or Liferay CE Portal 7.0 GA4 or later, use file with suffix `.config`. For earlier versions, use the file with suffix `.cfg`.

Here are the steps to reconfigure `ReluctantPortlet` to use `HigherRankedService`:

1. Copy the configuration file to `[Liferay-Home]/osgi/configs`.
2. Refresh your browser.

Reluctant Portlet displays a new message "SomeService says I am better, use me!".



Reluctant Portlet

SomeService says I am better, use me!

Figure 135.5: *Reluctant Portlet* is using the `HigherRankedService` instance instead of a `DefaultService` instance.

Reluctant Portlet is using `HigherRankedService` instance instead of a `DefaultService` instance. You've configured *Reluctant Portlet* to use a `HigherRankedService` instance!

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

135.2 Kotlin Portlet

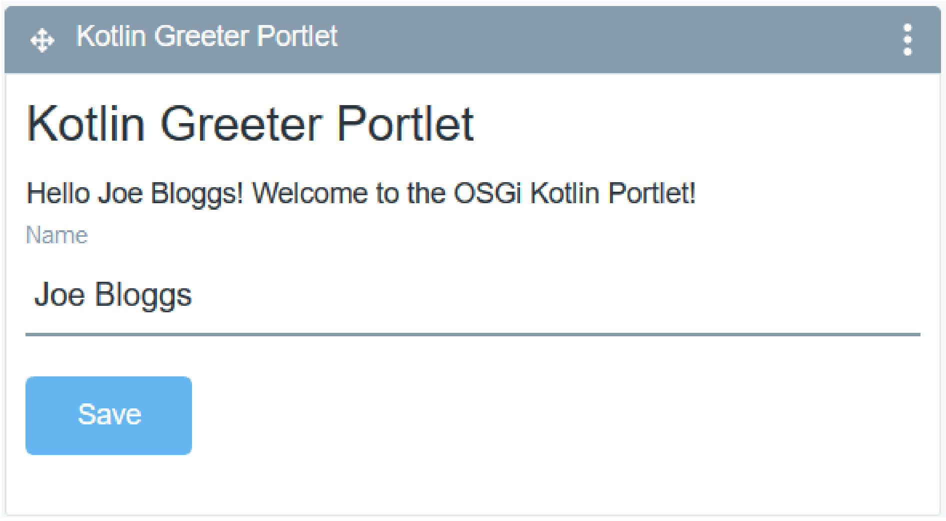
The Kotlin Portlet sample provides an input form that accepts a name. Once submitting a name, the portlet renders a greeting message.

What API(s) and/or code components does this sample highlight?

This sample highlights the use of the Kotlin programming language in conjunction with Liferay's MVC framework. Specifically, this sample leverages the MVCActionCommand interface.

How does this sample leverage the API(s) and/or code component?

This sample uses the MVC Action Command's `processAction(...)` method to process the inputted text (i.e., name). The text is set as an attribute in the `KotlinGreeterActionCommandKt.kt` class using an `ActionRequest` and then is retrieved in the JSP using a `RenderRequest`.



Kotlin Greeter Portlet

Hello Joe Bloggs! Welcome to the OSGi Kotlin Portlet!

Joe Bloggs

Figure 135.6: After saving the inputted name, it's is displayed as a greeting on the portlet page.

Where Is This Sample?

This sample is built with the following build tools:

- Gradle
- Liferay Workspace

CHAPTER 136

npm Samples

This section focuses on Liferay npm sample portlets built with Gradle. You can view these samples by visiting the gradle/apps/npm folder in the `liferay-blade-samples` Github repository.

The following npm samples are documented:

- Angular npm Portlet
- Billboard.js npm Portlet
- Isomorphic npm Portlet
- jQuery npm Portlet
- Metal.js npm Portlet
- React npm Portlet
- Simple npm Portlet
- Vue.js npm Portlet

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Visit a particular sample page to learn more!

136.1 Angular npm Portlet

The Angular npm Portlet sample provides a portlet that uses the Angular framework to render its output.

This portlet showcases Angular's speed and performance when rendering a user interface.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

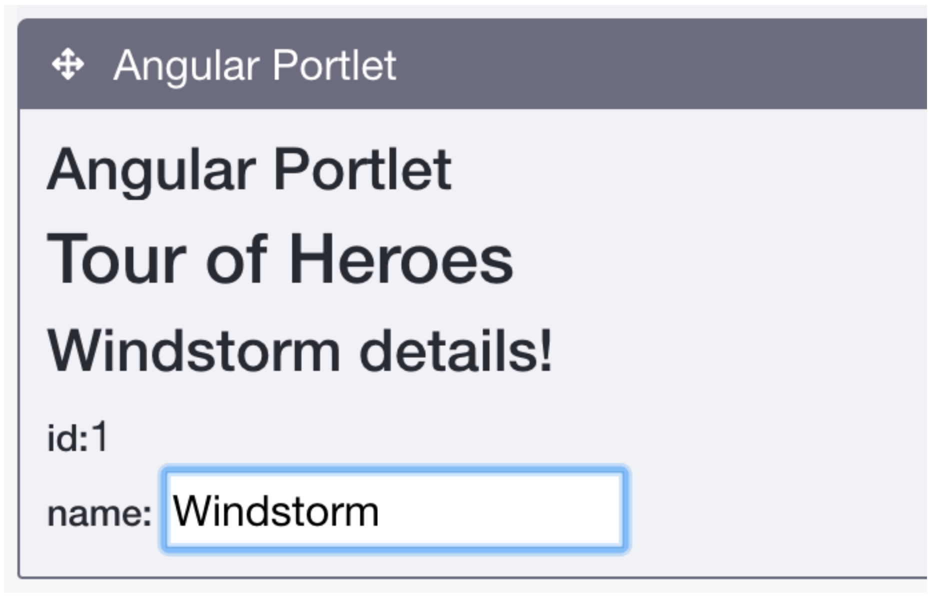


Figure 136.1: Type custom text in the field and watch it instantaneously displayed in the portlet.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "tsc && liferay-npm-bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

- Gradle

136.2 Billboard.js npm Portlet

The Billboard.js npm Portlet sample provides a portlet that uses the Billboard.js framework to render its output.

This portlet showcases the power of graphing by displaying a set of default charts and a more advanced custom chart. These are all built using Billboard.js.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

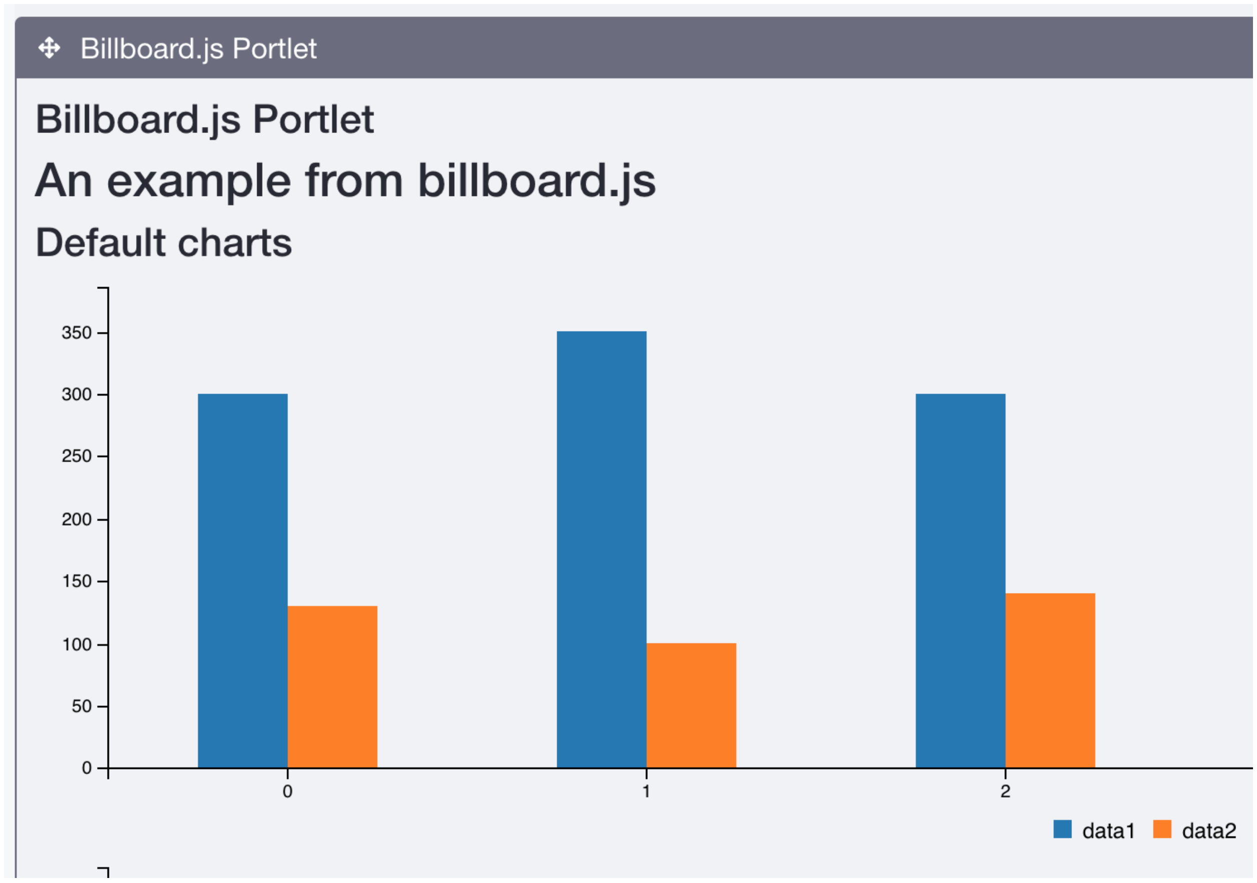

Figure 136.2: The Billboard.js npm Portlet shows off some nice looking graphs using Billboard.js.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-
bundler"
},
```

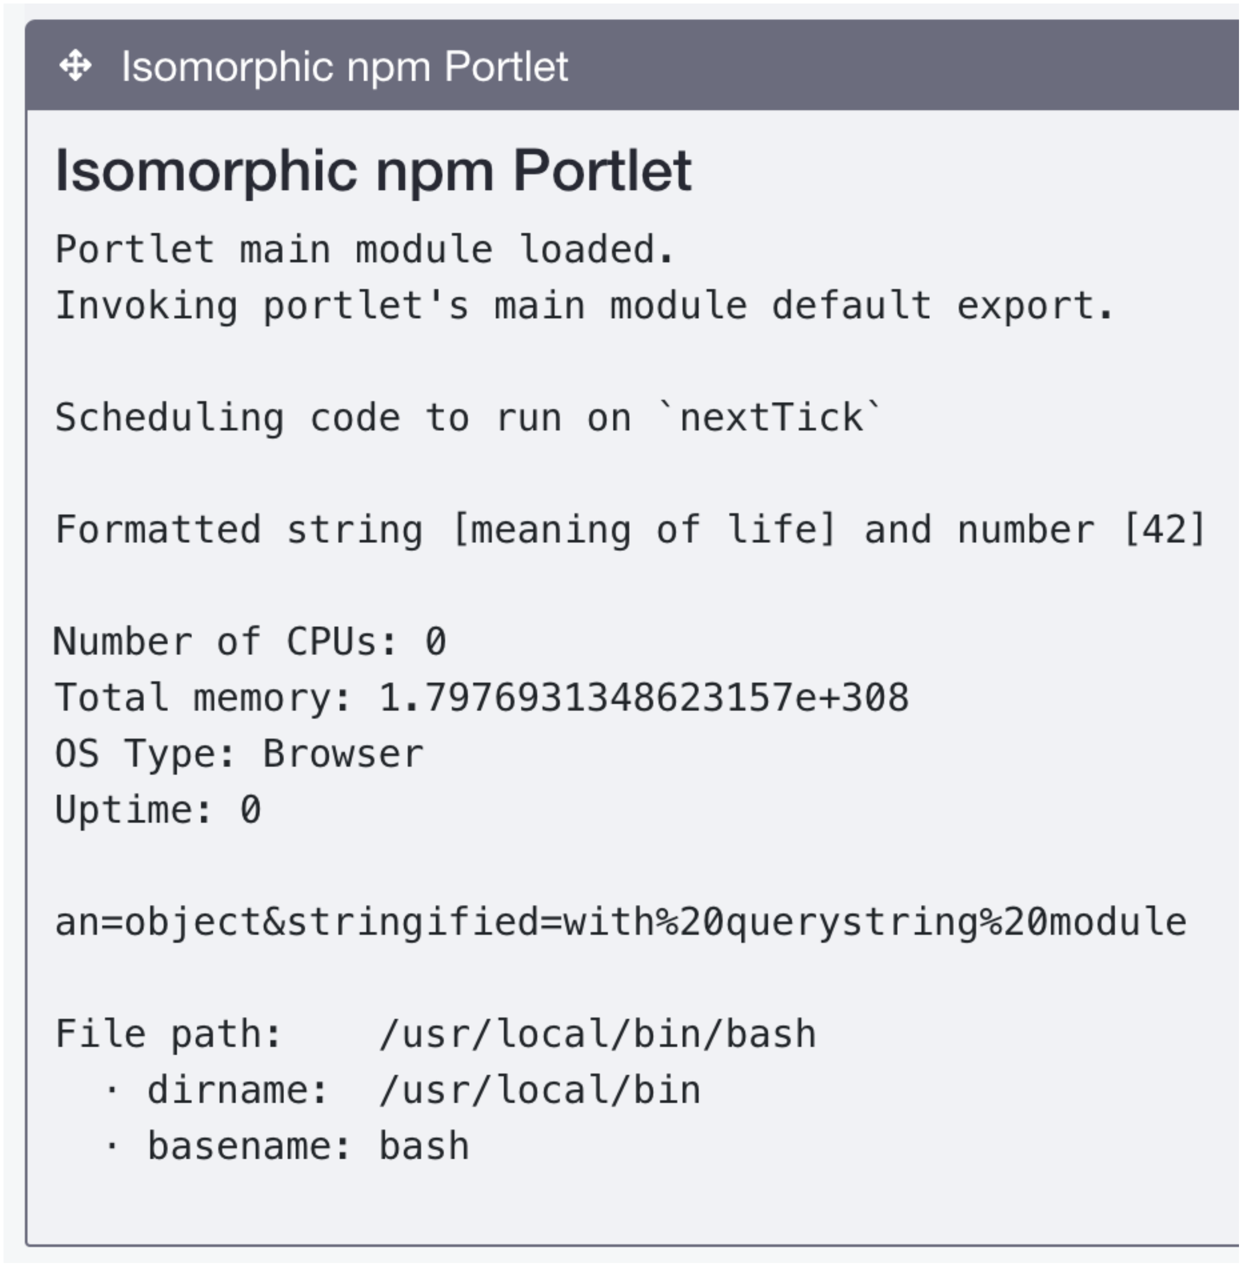
Where Is This Sample?

This sample is built with the following build tool:

- Gradle

136.3 Isomorphic npm Portlet

The Isomorphic npm Portlet sample provides a portlet that uses isomorphic code (i.e., can run from client and/or server side) on the client side.



Isomorphic npm Portlet

```
Portlet main module loaded.
Invoking portlet's main module default export.

Scheduling code to run on `nextTick`

Formatted string [meaning of life] and number [42]

Number of CPUs: 0
Total memory: 1.7976931348623157e+308
OS Type: Browser
Uptime: 0

an=object&stringified=with%20querystring%20module

File path:    /usr/local/bin/bash
   · dirname:  /usr/local/bin
   · basename: bash
```

Figure 136.3: This sample portlet displays the results of running code designed for the server in the browser.

This portlet showcases running code designed to execute in the server in the browser. Note that this portlet does **not** run JavaScript code in the server; it's executing isomorphic JavaScript code in the browser.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

You can do many things with isomorphic code. You can run it in

- the server only (e.g., Node.js)
- the client only (e.g., browser)
- both the server and client (e.g., Node.js + browser)

Isomorphic code cannot run server-side because Liferay DXP is Java based and cannot execute JavaScript that way. This sample portlet shows how Liferay's npm bundler can transform server-side code to make it work in the client (e.g., emulates some of Node.js' APIs in the client).

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

- Gradle

136.4 jQuery npm Portlet

The jQuery npm Portlet sample provides a portlet that uses the jQuery framework to render its output.

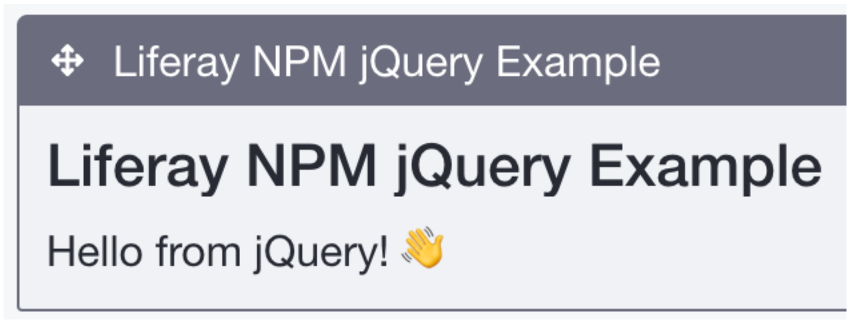
This portlet showcases the fast HTML document traversal jQuery offers.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.



Liferay NPM jQuery Example

Hello from jQuery! 👋

Figure 136.4: Clicking on the portlet's hand symbol displays a message.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-
bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

- Gradle

136.5 Metal.js npm Portlet

The Metal.js npm Portlet sample provides a portlet that uses the Metal.js framework to render its output.

This portlet displays a Metal.js based dialog that has been rendered using SOY templates.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

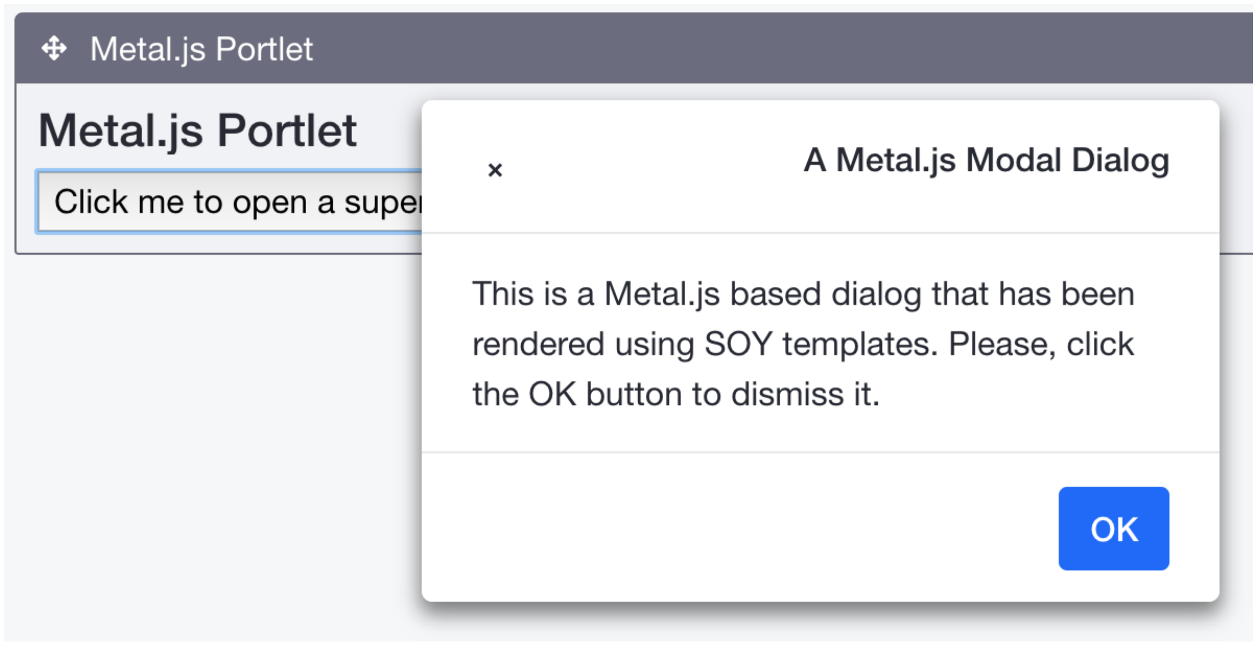
What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:



This is a Metal.js based dialog that has been rendered using SOY templates. Please, click the OK button to dismiss it.

Figure 136.5: Clicking the button returns displays a dialog window.

```
"scripts": {
    "build": "metalsoy && babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-
npm-bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

- Gradle

136.6 React npm Portlet

The React npm Portlet sample provides a portlet that uses the React framework to render its output.

This portlet showcases the how efficiently React can render components based on user interaction.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

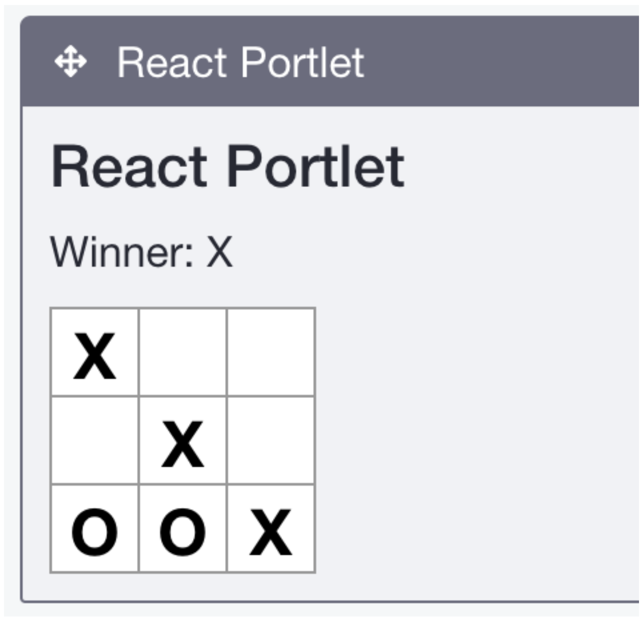


Figure 136.6: You can play the game Tic-tac-toe with this sample portlet.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-
bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

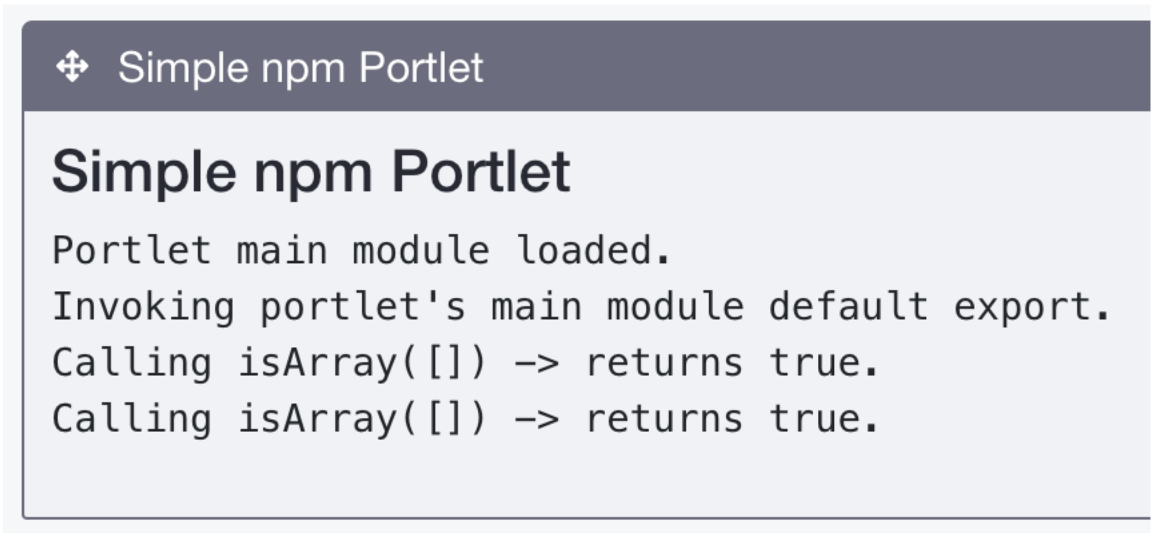
- Gradle

136.7 Simple npm Portlet

The Simple npm Portlet sample provides a portlet that uses the isarray npm package when rendering its output.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.



Simple npm Portlet

```
Portlet main module loaded.
Invoking portlet's main module default export.
Calling isArray([]) -> returns true.
Calling isArray([]) -> returns true.
```

Figure 136.7: The portlet's status and actions are displayed as output.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-
bundler"
},
```

Where Is This Sample?

This sample is built with the following build tool:

- Gradle

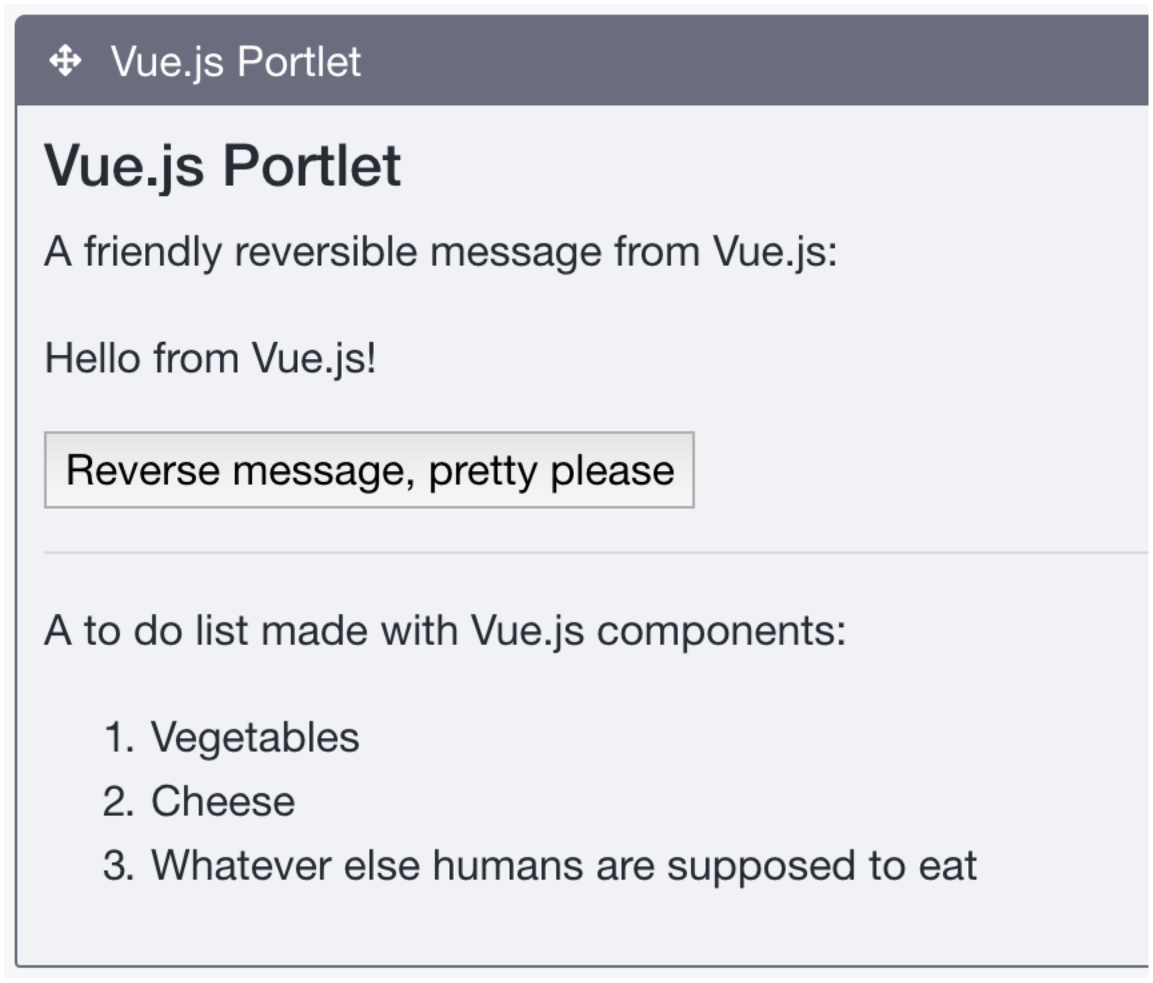
136.8 Vue.js npm Portlet

The Vue.js npm Portlet sample provides a portlet that uses the Vue.js framework to render its output.

This portlet showcases Vue.js's speed and performance when rendering a user interface.

Note: The minifier fails on Liferay DXP 7.0 when JSDoc is present in a portlet. To resolve this, use Grunt uglify to remove the JSDoc comments. This process may take a long time, depending on the number of files that require an update.

Important: This sample works for Liferay DXP 7.0 Fix Pack 44+ and Liferay Portal CE GA7+.



Vue.js Portlet

Vue.js Portlet

A friendly reversible message from Vue.js:

Hello from Vue.js!

A to do list made with Vue.js components:

1. Vegetables
2. Cheese
3. Whatever else humans are supposed to eat

Figure 136.8: Clicking the portlet's button reverses the message.

What API(s) and/or code components does this sample highlight?

This sample leverages the npm development workflow support.

How does this sample leverage the API(s) and/or code component?

This sample uses the npm registry to download project dependencies and uses the liferay-npm-bundler tool to bundle the project dependencies inside the OSGi bundle JAR file.

To accomplish the bundling, the project's build process relies on a `build` script inside its `package.json` file:

```
"scripts": {
    "build": "babel --source-maps -d build/resources/main/META-INF/resources src/main/resources/META-INF/resources && liferay-npm-
bundler"
},

Chapter 137

Service Builder Samples

This section focuses on Liferay Service Builder sample projects built with various build tools. You can view these samples by visiting the `apps/service-builder` folder corresponding to your preferred build tool:

- Gradle Service Builder sample apps
- Liferay Service Builder Workspace sample apps
- Maven Service Builder sample apps

The following Service Builder samples are documented:

- Service Builder application demonstrating Actionable Dynamic Query
- Service Builder application with JDBC connection
- Service Builder application with JNDI connection

Visit a particular sample page to learn more!

137.1 Service Builder Application Demonstrating Actionable Dynamic Query

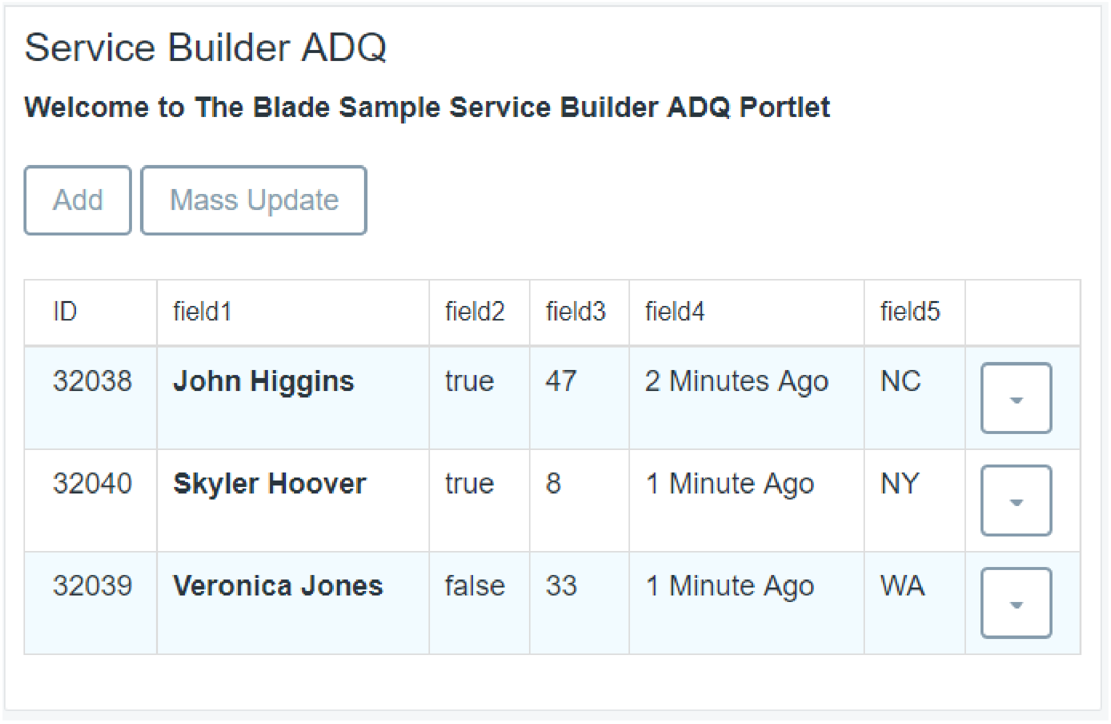
This sample is similar to the `basic` Service Builder sample, which lets you perform CRUD (create, read, update, delete) operations on service builder entities. The distinctive feature of the Service Builder Actionable Dynamic Query (ADQ) sample is that it also lets you perform a mass update on all existing service builder entities.

To see the ADQ Service Builder sample in action, complete the following steps:

1. Add the sample to a page by navigating to *Add* (➕) → *Applications* → *Sample* and dragging it to the page.
2. Select the app's *Add* button and add an entity. Do this several times to create multiple entities.
3. Click the *Mass Update* button and click *Save* to invoke the update.

   After invoking the update, each entity's `field3` value (whose value is less than 100) is incremented.

You've leveraged the actionable dynamic query API in your sample!

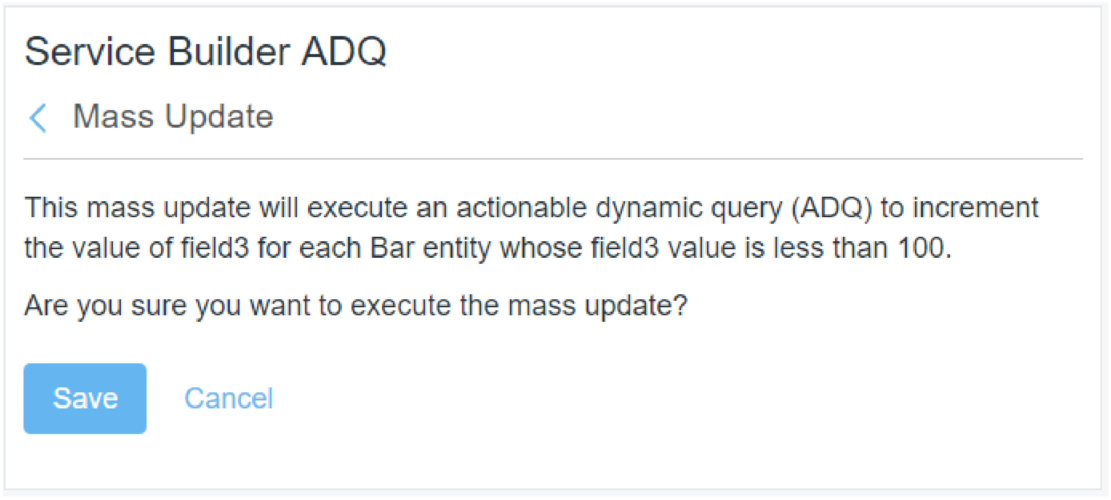


Service Builder ADQ

Welcome to The Blade Sample Service Builder ADQ Portlet

ID	field1	field2	field3	field4	field5	
32038	**John Higgins**	true	47	2 Minutes Ago	NC	
32040	**Skyler Hoover**	true	8	1 Minute Ago	NY	
32039	**Veronica Jones**	false	33	1 Minute Ago	WA	

Figure 137.1: This sample provides options to add entities and perform a mass update.



Service Builder ADQ

This mass update will execute an actionable dynamic query (ADQ) to increment the value of field3 for each Bar entity whose field3 value is less than 100.

Are you sure you want to execute the mass update?

Figure 137.2: Clicking the *Save* button executes the mass update.

What API(s) and/or code components does this sample highlight?

This sample demonstrates Liferay DXP's actionable dynamic query API. Specifically, it demonstrates how to create an ADQ, add criteria to an ADQ, specify an action for the ADQ, and execute the ADQ.

How does this sample leverage the API(s) and/or code component?

An action request is sent to the `JSPPortlet` with a `cmd` request parameter. When the `JSPPortlet`'s `processAction` method processes the request, the value of the `cmd` parameter is parsed and then the portlet's `massUpdate` method is invoked. The `massUpdate` method, in turn, invokes the `massUpdate` method defined in the `adq-service` module's `BarLocalServiceImpl`. This is where the sample leverages the actionable dynamic query API:

```
public void massUpdate() {
    ActionableDynamicQuery adq = getActionableDynamicQuery();

    adq.setAddCriteriaMethod(
        new ActionableDynamicQuery.AddCriteriaMethod() {

            @Override
            public void addCriteria(DynamicQuery dynamicQuery) {
                dynamicQuery.add(RestrictionsFactoryUtil.lt("field3", 100));
            }

        });

    adq.setPerformActionMethod(
        new ActionableDynamicQuery.PerformActionMethod<Bar>() {

            @Override
            public void performAction(Bar bar) {
                int field3 = bar.getField3();

                field3++;
                bar.setField3(field3);

                updateBar(bar);
            }

        });

    try {
        adq.performActions();
    }
    catch (Exception e) {
        e.printStackTrace();
    }
}
```

For more information on the actionable dynamic query API, visit its dedicated tutorial.

137.2 Service Builder Application Using External Database via JDBC

This sample demonstrates how to connect a Liferay Service Builder application to an external database via a JDBC connection. Here, an external database means any database other than Liferay DXP's database. For this sample to work correctly, you must prepare such an external database and configure Liferay DXP to use it. Follow the steps below to make the required preparations before deploying the application.

1. Create the external database to which your Service Builder application will connect. For example, create a MariaDB database called `external`. Add a table to this database called `country` with a `BIGINT`

column called Id and a VARCHAR(255) column called Name. Add at least one record to this table. Here are the MariaDB commands to accomplish this:

```
create database external character set utf8;

use external;

create table country(id bigint not null primary key, name varchar(255));

insert into country(id, name) values(1, 'Australia');
```

Make sure that your database commands were successful: Running select * from country; should return the record you added.

2. Create a portal-ext.properties file in your Liferay DXP instance's [LIFERAY_HOME] folder (this folder should be marked by the presence of a .liferay-home file). In your portal-ext.properties file, define the details of your JDBC data source connection:

```
jdbc.ext.driverClassName=org.mariadb.jdbc.Driver
jdbc.ext.password=userpassword
jdbc.ext.url=jdbc:mariadb://localhost/external?useUnicode=true&characterEncoding=UTF-8&useFastDateParsing=false
jdbc.ext.username=yourusername
```

Note that Liferay DXP's primary data source is specified by the jdbc.default prefix. These details are often specified in a portal-setup-wizard.properties file. Here, we've chosen to use the jdbc.ext prefix for our alternate data source.

3. Create a com.liferay.blade.samples.jdbcservicebuilder.service-log4j-ext.xml in your Liferay instance's [LIFERAY_HOME]/osgi/log4 folder. Create this folder if it doesn't yet exist. Add this content to the XML file that you created:

```
<?xml version="1.0"?>
<!DOCTYPE log4j:configuration SYSTEM "log4j.dtd">

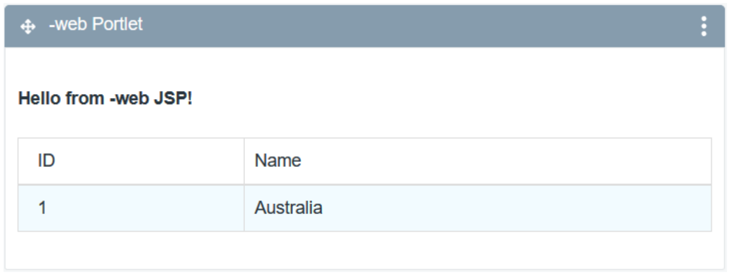
<log4j:configuration xmlns:log4j="http://jakarta.apache.org/log4j/">
    <category name="com.liferay.blade.samples.jdbcservicebuilder.service.impl">
        <priority value="INFO" />
    </category>
</log4j:configuration>
```

This XML file defines the log level for the classes in the com.liferay.blade.samples.jdbcservicebuilder.service.impl package. The com.liferay.blade.samples.jdbcservicebuilder.service.impl.CountryLocalServiceImpl is the class that will produce log messages when the sample portlet is viewed.

Now your sample is ready for deployment! Make sure to build and deploy each of the three modules that comprise the sample application:

- jdbc-api
- jdbc-service
- jdbc-web

After these modules have been deployed, add the -web portlet to a Liferay DXP page.
A sample table is printed in the portlet's view, representing the info inputted into the database.



-web Portlet

Hello from -web JSP!

ID	Name
1	Australia

Figure 137.3: This sample prints out the values previously inputted into the database.

What API(s) and/or code components does this sample highlight?

This sample demonstrates two ways to access data from an external database defined by a JDBC connection:

- extract data directly from the raw data source by explicitly specifying a SQL query.
- read data using the helper methods that Service Builder generates in your application's persistence layer.

How does this sample leverage the API(s) and/or code component?

Once you've added the `-web` portlet to a page, the `CountryLocalService.useJDBC` method is invoked. This method accesses the database defined by the JDBC connection you specified and logs information about the rows in the `country` table to Liferay DXP's log.

The first way of accessing data from the external database is to extract it directly from the raw data source by explicitly specifying a SQL query. This technique is demonstrated by the `CountryLocalServiceImpl.useJDBC` method. That method obtains the Spring-defined data source that's injected into the `countryPersistence` bean, opens a new connection, and reads data from the data source. This is the technique used by the sample application to write the data to Liferay DXP's log.

The second way of accessing data from the external database is to read data using the helper methods that Service Builder generates in your application's persistence layer. This technique is demonstrated by the `UseJDBC.getCountries` method which first obtains an instance of the `CountryLocalService` OSGi service and then invokes `countryLocalService.getCountries`. The `countryLocalService.getCountries` and `countryLocalService.getCountriesCount` methods are two examples of the persistence layer helper methods that Service Builder generates. This is the technique used by the sample application to actually display the data. The portlet's `view.jsp` uses the `<search-container>` JSP tag to display a list of results. The results are obtained by the `UseJDBC.getCountries` method mentioned above.

137.3 Service Builder Application Using External Database via JNDI

This sample demonstrates how to connect a Liferay Service Builder application to an external database via a JNDI connection. Here, an external database means any database other than Liferay DXP's database. For this sample to work correctly, you must prepare such an external database and configure Liferay DXP to use it. Follow the steps below to make the required preparations before deploying the application.

1. Create the external database to which your Service Builder application will connect. For example, create a MariaDB database called `external`. Add a table to this database called `region` with a `BIGINT` column called `Id` and a `VARCHAR(255)` column called `Name`. Add at least one record to this table. Here are the MariaDB commands to accomplish this:

```
create database external character set utf8;

use external;

create table region(id bigint not null primary key, name varchar(255));

insert into region(id, name) values(1, 'Tasmania');
```

Make sure that your database commands were successful: Running `select * from region;` should return the record you added.

2. Now you need to define a JNDI connection to your database. The way this is done depends on your application server. Here we demonstrate how to specify the JNDI connection for Tomcat. First, edit your `[LIFERAY_HOME]/tomcat-8.0.32/conf/server.xml` file and add this resource element inside of the `<GlobalNamingResources>` element:

```
<Resource
    name="jdbc/externalDataSource"
    auth="Container"
    type="javax.sql.DataSource"
    factory="org.apache.tomcat.jdbc.pool.DataSourceFactory"
    driverClassName="org.mariadb.jdbc.Driver"
    url="jdbc:mariadb://localhost/external"
    username="yourusername"
    password="yourpassword"
    maxActive="20"
    maxIdle="5"
    maxWait="10000"
/>
```

   Replace the specified username and password with the correct values for your database.

3. Edit your `[LIFERAY_HOME]/tomcat-8.0.32/conf/context.xml` file and add this resource link element inside of the `<Context>` element:

```
<ResourceLink name="jdbc/externalDataSource" global="jdbc/externalDataSource" type="javax.sql.DataSource"/>
```

   Now your data source is defined at Tomcat's scope.

4. Create a `com.liferay.blade.samples.jndiservicebuilder.service-log4j-ext.xml` in your Liferay DXP instance's `[LIFERAY_HOME]/osgi/log4` folder. Create this folder if it doesn't yet exist. Add this content to the XML file that you created:

```
<?xml version="1.0"?>
<!DOCTYPE log4j:configuration SYSTEM "log4j.dtd">

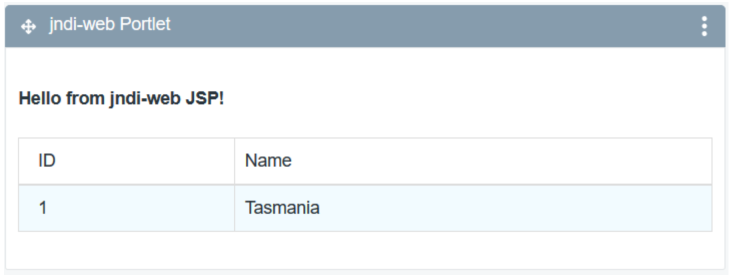
<log4j:configuration xmlns:log4j="http://jakarta.apache.org/log4j/">
    <category name="com.liferay.blade.samples.jndiservicebuilder.service.impl">
        <priority value="INFO" />
    </category>
</log4j:configuration>
```

   This XML file defines the log level for the classes in the `com.liferay.blade.samples.jndiservicebuilder.service.impl` package. The `com.liferay.blade.samples.jndiservicebuilder.service.impl.RegionLocalServiceImpl` is the class that will produce log messages when the sample portlet is viewed.

Now your sample is ready for deployment! Make sure to build and deploy each of the three modules that comprise the sample application:

- `jndi-api`
- `jndi-service`
- `jndi-web`

After these modules have been deployed, add the `jndi-web` portlet to a Liferay DXP page.



Hello from jndi-web JSP!

ID	Name
1	Tasmania

Figure 137.4: This sample prints out the values previously inputted into the database.

A sample table is printed in the portlet's view, representing the info inputted into the database.

What API(s) and/or code components does this sample highlight?

This sample demonstrates two ways to access data from an external database defined by a JNDI connection:

- extract data directly from the raw data source by explicitly specifying a SQL query.
- read data using the helper methods that Service Builder generates in your application's persistence layer.

How does this sample leverage the API(s) and/or code component?

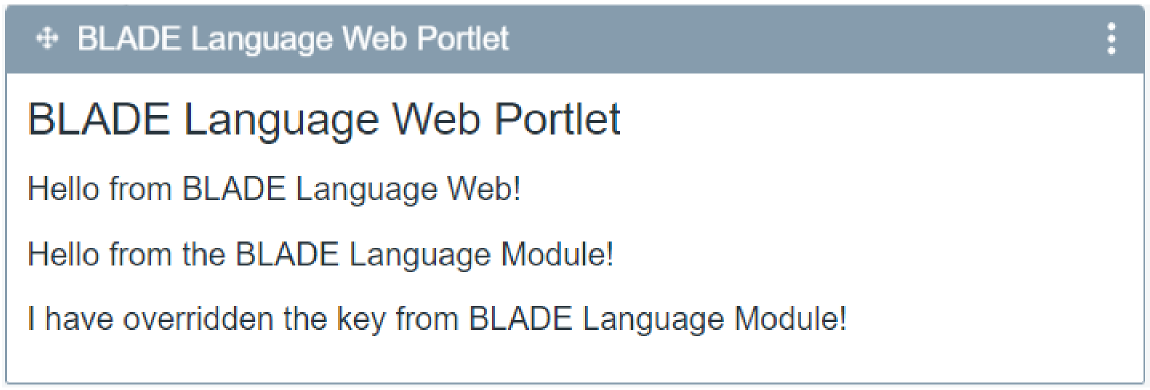
Once you've added the `jndi-web` portlet to a page, the `RegionLocalServiceUtil.useJNDI` method is invoked. This method accesses the database defined by the JNDI connection you specified and logs information about the rows in the `region` table to Liferay DXP's log.

The first way of accessing data from the external database is to extract data directly from the raw data source by explicitly specifying a SQL query. This technique is demonstrated by the `RegionLocalServiceImpl.useJNDI` method. That method obtains the Spring-defined data source that's injected into the `regionPersistence` bean, opens a new connection, and reads data from the data source. This is the technique used by the sample application to write the data to Liferay DXP's log.

The second way of accessing data from the external database is to read data using the helper methods that Service Builder generates in your application's persistence layer. This technique is demonstrated by the `UseJNDI.getRegions` method which first obtains an instance of the `RegionLocalService` OSGi service and then invokes `regionLocalService.getRegions`. The `regionLocalService.getRegions` and `regionLocalService.getRegionsCount` methods are two examples of the persistence layer helper methods that Service Builder generates. This is the technique used by the sample application to actually display the data. The portlet's `view.jsp` uses the `<search-container>` JSP tag to display a list of results. The results are obtained by the `UseJNDI.getRegions` method mentioned above.

137.4 Shared Language Keys

The Shared Language Keys sample provides a JSP portlet that displays language keys.



BLADE Language Web Portlet

BLADE Language Web Portlet

Hello from BLADE Language Web!

Hello from the BLADE Language Module!

I have overridden the key from BLADE Language Module!

Figure 137.5: The sample JSP portlet displays three language keys.

The language keys displayed in the portlet come from two different modules.

What API(s) and/or code components does this sample highlight?

This sample is broken into two modules:

- `language`
- `language-web`

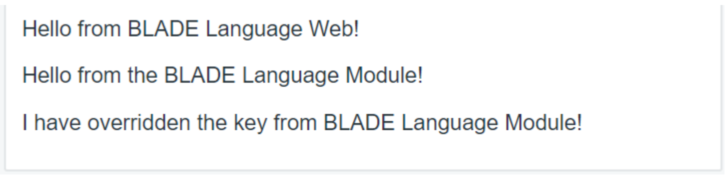
The `language-web` module provides a JSP portlet with unique language keys that it displays. The `language` module provides a resource module which only holds language keys. Its sole purpose is to share language keys with the JSP portlet provided in `language-web`. This sample conveys Liferay's recommended approach to sharing language keys through OSGi services.

How does this sample leverage the API(s) and/or code component?

You must deploy both `language-web` and `language` modules to simulate this sample's targeted demonstration.

First, note the language keys provided by each module:

- `language-web`
  - `blade_language_web_LanguageWebPortlet.caption=Hello from BLADE Language Web!`
  - `blade_language_web_override_LanguageWebPortlet.caption=I have overridden the key from BLADE Language Module!`
- `language`
  - `blade_language_LanguageWebPortlet.caption=Hello from the BLADE Language Module!`
  - `blade_language_web_override_LanguageWebPortlet.caption=Hello from the BLADE Language Module but you won't see me!`



Hello from BLADE Language Web!

Hello from the BLADE Language Module!

I have overridden the key from BLADE Language Module!

Figure 137.6: The Language Web portlet displays three phrases, two of which are shared from a different module.

When you place the sample BLADE Language Web portlet on a Liferay DXP page, you're presented with three language keys.

The first message is provided by the `language-web` module. The second message is from the `language` module. The third message is provided by both modules; as you can see, the `language-web`'s message is used, overriding the `language` module's identically named language key.

This sample shows what takes precedence when displaying language keys. The order for this example goes

1. `language-web` module language keys
2. `language` module language keys
3. Liferay DXP language keys

So how does sharing language keys work?

By default, the `ResourceBundleLoaderAnalyzerPlugin` expands modules with `/content/Language.properties` files to add provided capabilities:

- `bundle.symbolic.name`
- `resource.bundle.base.name`

Then the deployed `LanguageExtender` scans modules with those capabilities to automatically register an associated `ResourceBundleLoader`.

You can leverage this functionality to use keys from common language modules by republishing an aggregate `ResourceBundleLoader`. This can be done two ways:

1. Via Components

   You can get a reference to the registered service in your components as detailed in the Overriding a Module's Language Keys tutorial. The main disadvantage of this approach is that it forces you to provide a specific implementation of the `ResourceBundleLoader`, making it harder to modularize in the future.

2. Via Provide Capability

   The same `LanguageExtender` that registers the services supports an extended syntax that lets you register an aggregate of a collection of bundles:

   ```
   -liferay-aggregate-resource-bundles: \
       blade.language
   ```

   This approach has the advantage of easier extensibility. When language keys change, only the common language modules must be built and redeployed for the modules referencing them to recognize their updates.

For more information on sharing language keys, visit the Internationalization tutorials.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

137.5 Simulation Panel App

The Simulation Panel App provides new functionality in @product's Simulation Menu. When deploying this sample with no customizations, the *Simulation Sample* feature is provided in the Simulation Menu with four options.

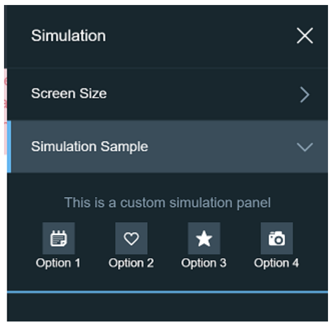


Figure 137.7: A simulation panel app adds new functionality to the Simulation Menu.

What API(s) and/or code components does this sample highlight?

This sample leverages the PanelApp API.

How does this sample leverage the API(s) and/or code component?

This sample leverages the `PanelApp` interface as an OSGi service via the `@Component` annotation:

```
@Component(
    immediate = true,
    property = {
        "panel.app.order:Integer=500",
        "panel.category.key=" + SimulationPanelCategory.SIMULATION
    },
    service = PanelApp.class
)
```

There are also two properties provided via the `@Component` annotation:

- `panel.app.order`: the order in which the panel app is displayed among other panel apps in the chosen category. Entries are ordered from top to bottom. For example, an entry with order 1 will be listed above an entry with order 2. If the order is not specified, it's chosen at random based on which service was registered first in the OSGi container.
- `panel.category.key`: the host panel category for your panel app, which should be the Simulation Menu category.

The simulation panel app extends the BaseJSPPanelApp, which provides a skeletal implementation of the PanelApp interface with JSP support. JSPs, however, are not the only way to provide frontend functionality to your panel categories/apps. You can create your own class implementing `PanelApp` to use other technologies, such as FreeMarker.

To learn more about Liferay Portal's product navigation using panel categories and panel apps, see the Customizing the Product Menu tutorial. For more information on extending the Simulation Menu, see the Extending the Simulation Menu tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

137.6 Spring MVC Portlet

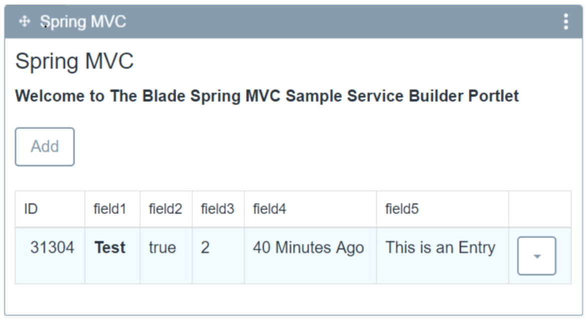
The Spring MVC portlet provides a way to add various different fields into the database and display them in a table. This project is a Spring MVC based portlet WAR that implements the same functionality as the `apps/service-builder/basic-web` sample project. It manages JSP pages for display, uses a Spring-annotated portlet class, and invokes the `apps/service-builder/basic-api` module to call services.

Note: If you're planning to package this sample using Maven, you must complete a few additional steps to avoid build errors. This sample relies on the `service-builder/basic-api` module. Since the `basic-api` bundle is not available on Liferay's CDN repo or Maven Central, this sample can not reference it, resulting in build failures.

To satisfy this dependency, you must install the bundle dependency to your local `~/.m2 repo`, along with the parent BND plugin and root Maven project. Here are the steps to accomplish this:

1. Run `mvn clean install` on `maven/apps/service-builder/basic-api`.
2. Run `mvn clean install` on `maven/parent.bnd.bundle.plugin`.
3. Run `mvn clean install -N` in the root `liferay-blade-samples/maven` folder.

Now you can build this sample successfully.



Spring MVC

Welcome to The Blade Spring MVC Sample Service Builder Portlet

ID	field1	field2	field3	field4	field5
31304	**Test**	true	2	40 Minutes Ago	This is an Entry

Figure 137.8: Click *Add* and fill out the sample fields to generate a custom entry in the portlet's table.

Unlike the `service-builder/basic-web` module, Spring MVC portlets must be delivered as portlet WAR projects. This project builds to a WAR file but leverages all of the Liferay Workspace tools and Gradle to build the WAR. You must build and deploy the `service-builder/basic-api` and `service-builder/basic-service` modules for this sample to work properly. For more information on using Spring MVC portlets in Liferay DXP, visit the Spring MVC tutorial.

What API(s) and/or code components does this sample highlight?

This sample demonstrates a Liferay DXP portlet built using the Spring Web MVC framework.

How does this sample leverage the API(s) and/or code component?

You can easily modify this sample by customizing its `SpringMVCPortletViewController` Java class or any of its JSPs stored in the `src/main/webapp/WEB-INF/jsp` folder. For more information on customizing this sample, see the Javadoc listed in this sample's `SpringMVCPortletViewController` Java class.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

Chapter 138

Extensions

This section focuses on Liferay sample extensions. You can view these sample extensions by visiting the `extensions` folder corresponding to your preferred build tool:

- Gradle sample extensions
- Liferay Workspace sample extensions
- Maven sample extensions

The following samples are documented:

- Control Menu Entry
- Document Action
- Gogo Shell Command
- Indexer Post Processor
- Model Listener
- Screen Name Validator

Visit a particular sample page to learn more!

138.1 Control Menu Entry

The Control Menu Entry sample provides a customizable button that is added to Liferay Portal's default Control Menu. When deploying this sample with no customizations, an additional button is added to the User (right side) portion of the Control Menu.

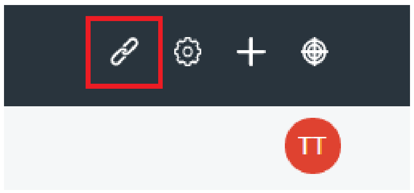


Figure 138.1: The User area of the Control Menu is provided an additional link button when the Control Menu Entry sample is deployed to Liferay DXP.

The button navigates the user to Liferay's website: https://www.liferay.com.

What API(s) and/or code components does this sample highlight?

This sample leverages the ProductNavigationControlMenuEntry API.

How does this sample leverage the API(s) and/or code component?

This sample first leverages the `ProductNavigationControlMenuEntry` interface as an OSGi service via the `@Component` annotation:

```
@Component(
    immediate = true,
    property = {
        "product.navigation.control.menu.category.key=" + ProductNavigationControlMenuCategoryKeys.USER,
        "product.navigation.control.menu.entry.order:Integer=1"
    },
    service = ProductNavigationControlMenuEntry.class
)
```

There are also two properties provided via the `@Component` annotation:

- `product.navigation.control.menu.category.key`: the category in which your entry should reside. The default Control Menu provides three categories: *SITES* (left portion), *TOOLS* (middle portion), and *USER* (right portion).
- `product.navigation.control.menu.entry.order:Integer`: the order in which your entry will be displayed in the category. Entries are ordered from left to right. For example, an entry with order 1 will be listed to the left of an entry with order 2. If the order is not specified, it's chosen at random based on which service was registered first in the OSGi container.

This sample also implements the `ProductNavigationControlMenuEntry` interface. The following methods are implemented:

- `getIcon(HttpServletRequest)`
- `getLabel(Locale)`
- `getURL(HttpServletRequest)`
- `isShow(HttpServletRequest)`

Refer to this sample's `BladeProductNavigationControlMenuEntry` class for Javadocs describing these methods. For more information on how to customize Liferay Portal's Control Menu, visit the Customizing the Control Menu tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.2 Document Action

The Document Action sample shows how to add a context menu option to an entry in the Documents and Media portlet. When deploying this sample with no customizations, an additional menu option is available in the Documents and Media Admin portlet and the Documents and Media portlet. This sample creates a *Blade Basic Info* option that displays basic information about the entry (e.g., file name, type, version, etc.). For example, the Admin portlet provides the new option as illustrated in the images below:

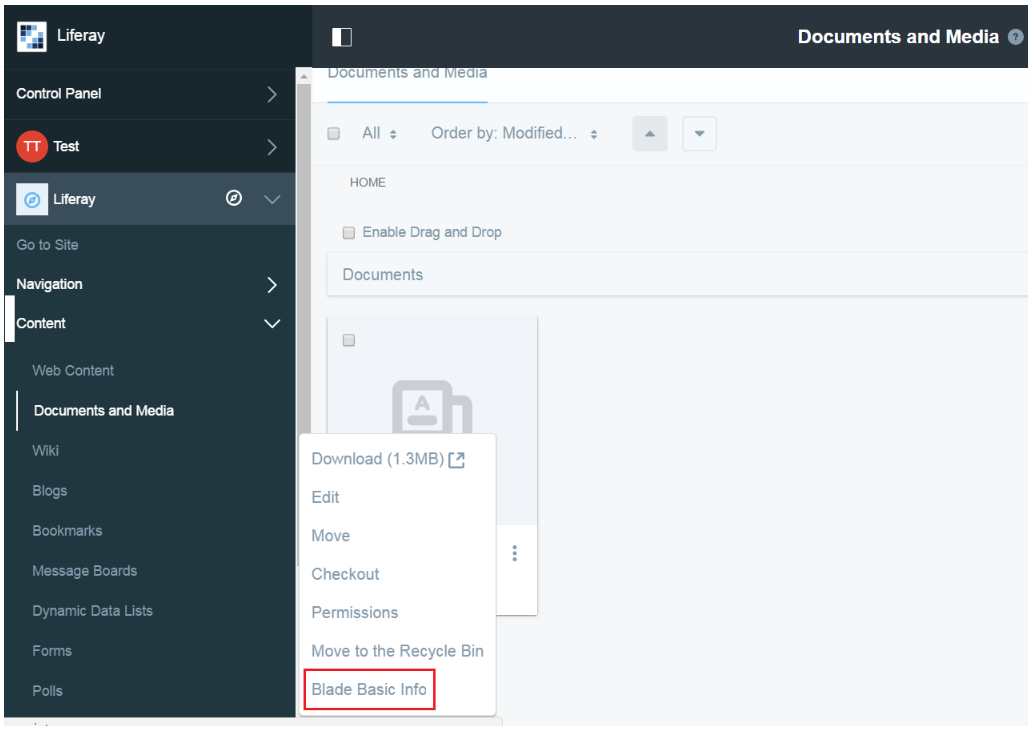

Figure 138.2: The new *Blade Basic Info* option is available from the entry's Options menu.

Likewise, the Documents and Media portlet provides the same option after selecting *Show Actions* from the portlet's Configuration menu.

What API(s) and/or code components does this sample highlight?

This sample leverages the PortletConfigurationIcon API.

How does this sample leverage the API(s) and/or code component?

There are four Java classes used in this sample:

- `BladeActionConfigurationIcon`: Adds the new context menu option to the Document Detail screen options (⋮) (top right corner) of the Documents and Media Admin portlet. See the Configuring Your Admin App's Actions Menu tutorial for more details.
- `BladeActionDisplayContext`: Adds the Display Context for the document action. More about Display Contexts are described later.
- `BladeActionDisplayContextFactory`: Adds the Display Context factory for the document action.

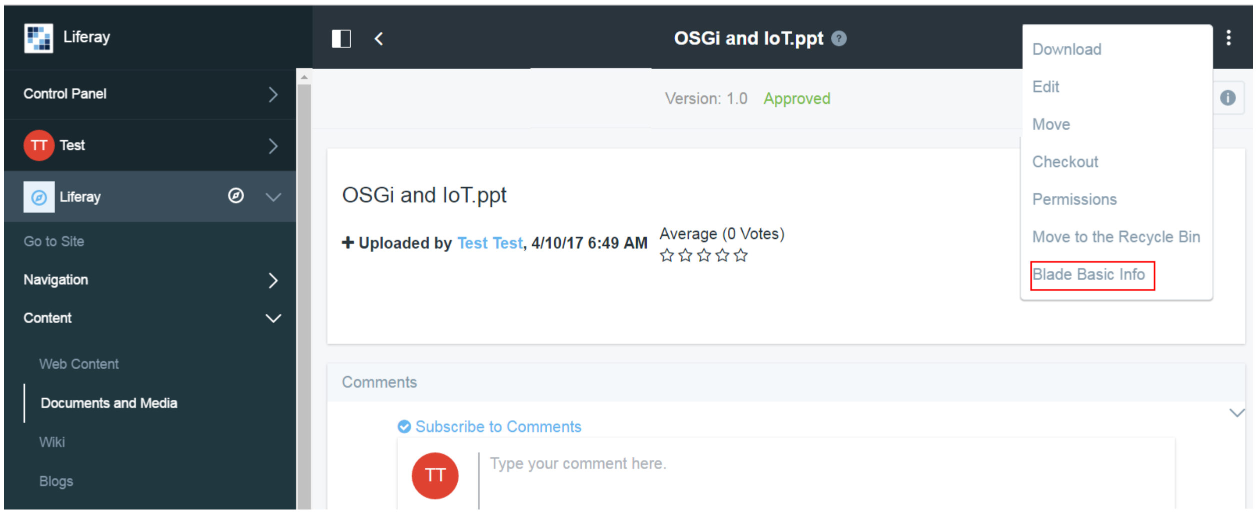

Figure 138.3: The new option is also available from the portlet's Document Details.

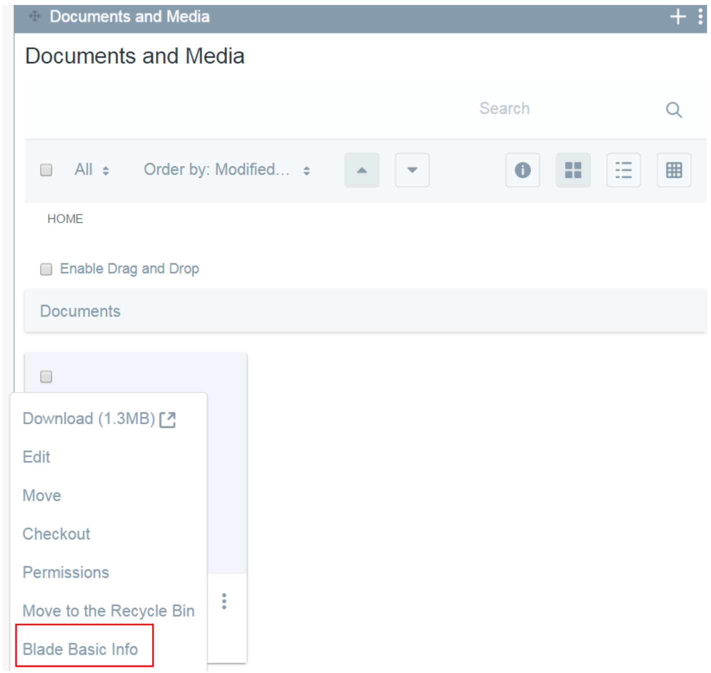

Figure 138.4: You can access the new *Blade Basic Info* option from the Documents and Media portlet added to a page.

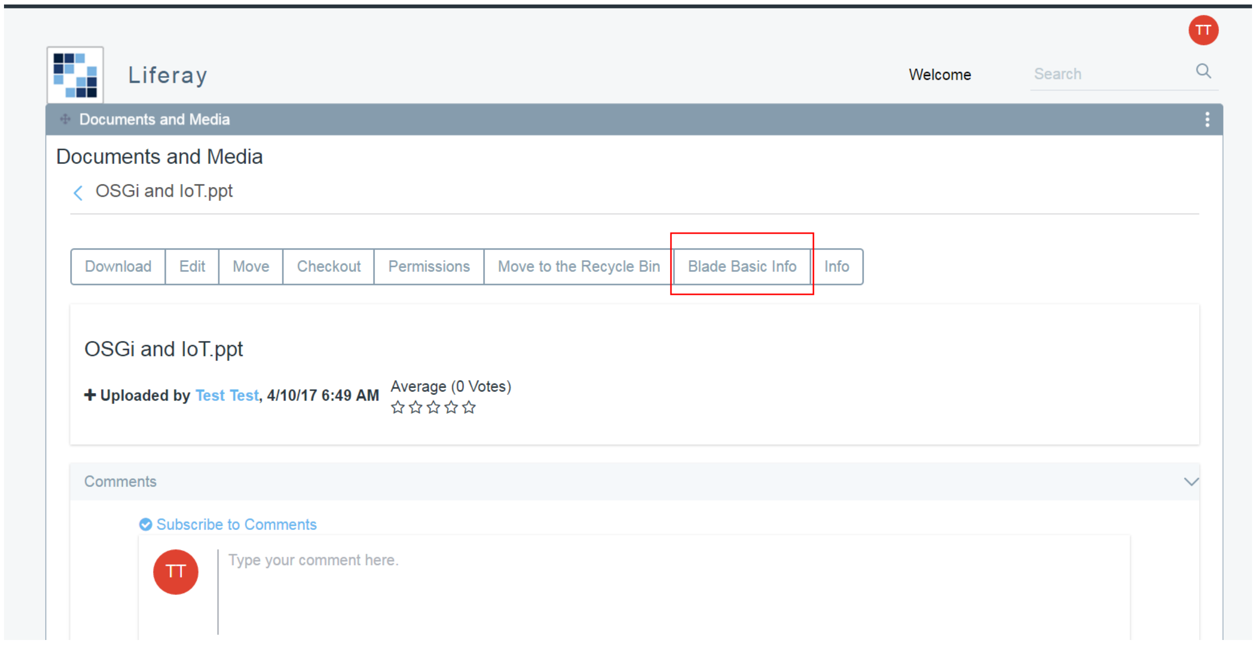

Figure 138.5: The Documents And Media portlet provides the option from its Document Detail too.

- `BladeDocumentActionPortlet`: Provides the portlet class, which extends the GenericPortlet. This class generates what is shown when the context menu option is selected.

A Display Context is a Java class that controls access to a portlet screen's UI elements. For example, the Document Library would use Display Contexts to provide its screens all their UI elements. It would use one Display Context for its document edit screen, another for its document view screen, etc. A portlet ideally uses a different Display Context for each of its screens.

A screen's JSP calls on the Display Context (DC) to get elements to render and to decide whether to render certain types of elements. Some of the DC methods return a collection of UI elements (e.g., a menu object of menu items), while other DC methods return booleans that determine whether to show particular element types. The DC decides which objects to display, while the JSP organizes the rendered objects and implements the screen's look and feel. You don't have to decide which elements to display in your JSP; simply call the DC methods to populate UI components with objects to render.

To customize or extend a portlet screen that uses a DC, you can extend the DC and override the methods that control access to the elements that interest you. For example, you can turn off displaying certain types of elements (e.g., actions) by overriding the DC method that makes that decision. You can add new custom elements (e.g., new actions) or remove existing elements (e.g., a delete action) from a collection of elements a DC method returns. The beauty of customizing via a DC is that you don't have to modify the JSP. You only modify the particular methods that are related to the UI customization goals. And JSP updates won't break the DC customizations. Replacing a JSP, on the other hand, can lead to missing an important JSP modification that a new Liferay version introduces.

As you create custom portlets, you may want to implement DCs. You can benefit from the separation of concerns that DCs provide and customers can extend your portlet DCs to specify which UI elements to display. And they don't need to worry about missing out on the updates you make to the JSPs.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.3 Gogo Shell Command

The Gogo Shell Command sample demonstrates adding a custom command to Liferay DXP's Gogo shell environment. All Liferay DXP installations have a Gogo shell environment, which lets system administrators interact with Liferay DXP's module framework on a local server machine.

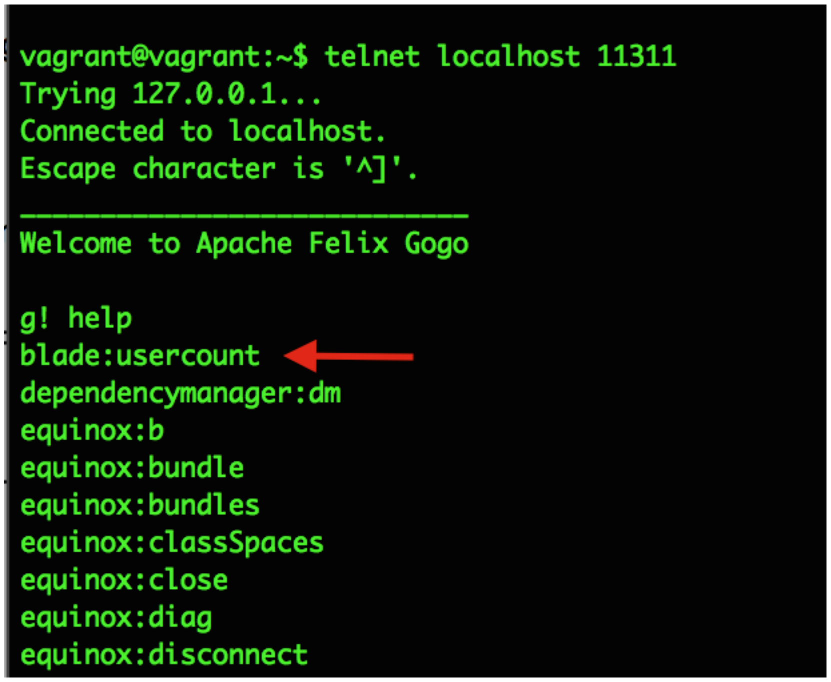
This example adds a new custom Gogo shell command called `usercount` under the `blade` scope. It prints out the number of registered users on your Liferay DXP installation.

To test this sample, follow the instructions below:

1. Start a Liferay DXP installation.

2. Using a command line tool, connect to your local Gogo shell. For example, you can do this by executing `telnet localhost 11311`.

3. Run `help` to view all the available commands. The sample Gogo shell command is listed.

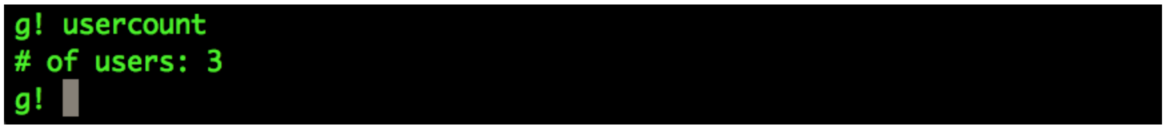


```
vagrant@vagrant:~$ telnet localhost 11311
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
____________________________
Welcome to Apache Felix Gogo

g! help
blade:usercount
dependencymanager:dm
equinox:b
equinox:bundle
equinox:bundles
equinox:classSpaces
equinox:close
equinox:diag
equinox:disconnect
```

Figure 138.6: The sample Gogo shell command is listed with all the available commands.

4. Execute `usercount` to execute the new custom command. The number of users on your running Liferay Portal installation is printed.



```
g! usercount
# of users: 3
g!
```

Figure 138.7: The outcome of executing the usercount command.

What API(s) and/or code components does this sample highlight?

This sample demonstrates creating a new Gogo shell command by leveraging `osgi.command.*` properties in a Java class.

How does this sample leverage the API(s) and/or code component?

To add this new Gogo shell command, you must implement the logic in a Java class with the following two properties:

- `osgi.command.function`: the command's name, which must match the method name in the registered service implementation.
- `osgi.command.scope`: the general scope or namespace for the command.

These properties are set in your class's `@Component` annotation like this:

```
@Component(
    property = {"osgi.command.function=usercount", "osgi.command.scope=blade"},
    service = Object.class
)
```

The logic for the usercount command is specified in the method with the same name:

```
public void usercount() {
    System.out.println(
        "# of users: " + getUserLocalService().getUsersCount());
}
```

This method uses *Declarative Services* to get a reference for the `UserLocalService` to invoke the `getUsersCount` method. This lets you find the number of users currently in the system.

For more information on using the Gogo shell, see the Using the Felix Gogo Shell tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.4 Indexer Post Processor

The Indexer Post Processor sample demonstrates using the `IndexerPostProcessor` interface, which is provided to customize search queries and documents before they're sent to the search engine, and/or customize result summaries when they're returned to end users. This basic demonstration prints a message in the log when one of the `*IndexerPostProcessor` methods is called.

To see this sample's messages in Liferay DXP's log, you must add a logging category to the portal. Navigate to *Control Panel* → *Configuration* → *Server Administration* and click on *Log Levels* → *Add Category*. Then fill out the form:

- *Logger Name*: `com.liferay.blade.samples.indexerpostprocessor`
- *Log Level*: `INFO`

Once you save the new logging category, you can witness the sample indexer post processor in action. For example, you can test the sample's `BlogsIndexerPostProcessor` implementation by creating a blog entry. When you publish the blog, the following message is logged in the console:

```
18:27:30,737 INFO  [http-nio-8080-exec-8][BlogsIndexerPostProcessor:76] postProcessDocument
```

What API(s) and/or code components does this sample highlight?

This sample leverages the IndexerPostProcessor API.

How does this sample leverage the API(s) and/or code component?

This sample contains four implementations of the `IndexerPostProcessor` interface:

- `BlogsIndexerPostProcessor`
- `MultipleEntityIndexerPostProcessor`
- `MultipleIndexerPostProcessor`
- `UserEntityIndexerPostProcessor`

All these classes leverage the interface as an OSGi service via the `@Component` annotation. For example, the `@Component` annotation of the `UserEntityIndexerPostProcessor` looks like this:

```
@Component(
    immediate = true,
    property = {
        "indexer.class.name=com.liferay.portal.kernel.model.User",
        "indexer.class.name=com.liferay.portal.kernel.model.UserGroup"
    },
    service = IndexerPostProcessor.class
)
```

There's one property type provided via the `@Component` annotation:

- `indexer.class.name`: the fully qualified class name of the indexed entity or an `Indexer` class itself.

This sample's implementations of the `IndexerPostProcessor` interface override the following methods:

- `postProcessContextBooleanFilter`
- `postProcessContextQuery`
- `postProcessDocument`

- `postProcessFullQuery`
- `postProcessSearchQuery(BooleanQuery, BooleanFilter)`
- `postProcessSearchQuery(BooleanQuery, SearchContext)`
- `postProcessSummary`

For more information on Liferay's Search API, refer to the Introduction to Liferay Search tutorial.

Where Is This Sample?

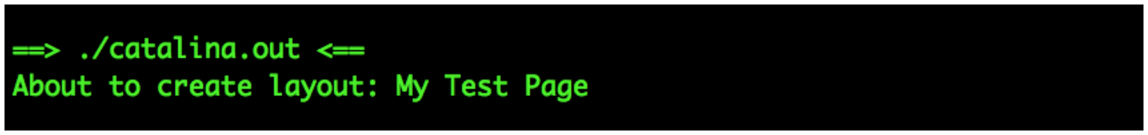
There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.5 Model Listener

The Model Listener sample demonstrates adding a custom model listener to a Liferay Portal out-of-the-box entity. When deploying this sample with no customizations, a custom model listener is added to the portal's layouts, listening for `onBeforeCreate` events. This means that any page creation will trigger this listener, which will execute before the new page is created.

For example, if a new page is added with the name *My Test Page*, the following message is printed to the console:



```
==> ./catalina.out <==
About to create layout: My Test Page
```

Figure 138.8: The sample model listener's message in the console.

You can also verify that the model listener sample was executed by navigating to the new page's *Configure Page* → *SEO* option. The HTML Title field looks like this:

What API(s) and/or code components does this sample highlight?

This sample leverages the ModelListener API.

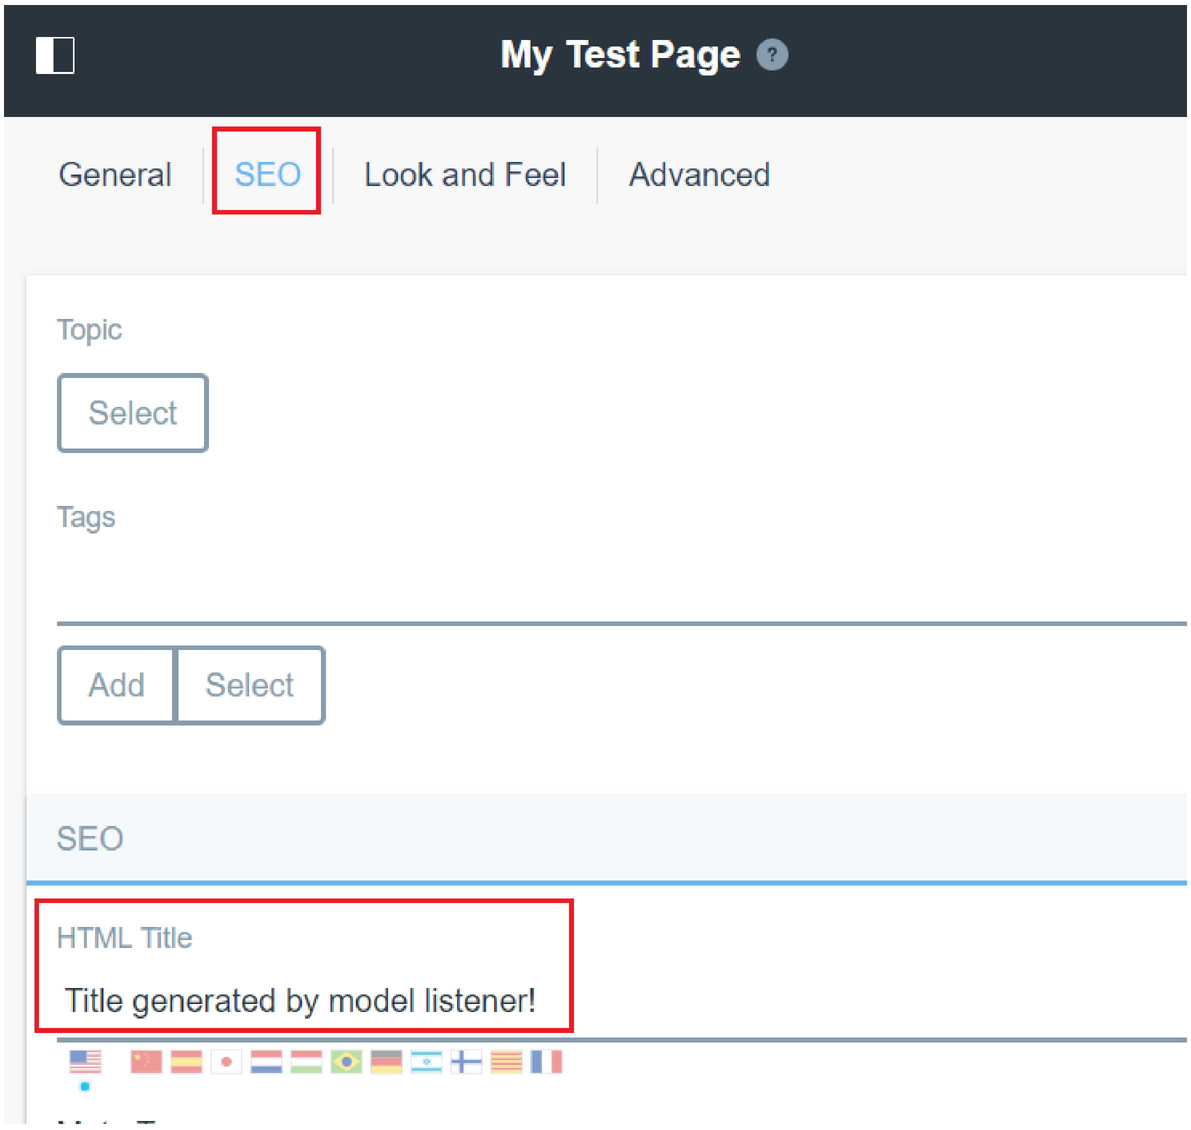
How does this sample leverage the API(s) and/or code component?

Model Listeners are used to listen for persistence events on models and take actions as a result of those events. Actions can be executed on an entity's database table before or after a `create`, `remove`, `update`, `addAssociation`, or `removeAssociation` event. It's possible to have more than one model listener on a single model too; the execution order is not guaranteed.

There are two steps to create a new model listener:

- Implement a Model Listener class
- Register the new service in Liferay's OSGi runtime

This sample adds the model listener logic in a new Java class named `CustomLayoutListener` that extends BaseModelListener.



HTML Title

Title generated by model listener!

Figure 138.9: The page's HTML title updated by the model listener sample.

```
public class CustomLayoutListener extends BaseModelListener<Layout> {

    @Override
    public void onBeforeCreate(Layout model) throws ModelListenerException {
        System.out.println(
            "About to create layout: " + model.getNameCurrentValue());

        model.setTitle("Title generated by model listener!");
    }

}
```

Important things to note in this code snippet are

- The entity to be targeted by this model listener is specified as the parameterized type (e.g., Layout).
- The overridden methods dictate the type of event(s) that are listened for (e.g., `onBeforeCreate`); they also trigger the logic execution.

The final step is registering the service in Liferay's OSGi runtime, which is accomplished by the following annotation (if using Declarative Services):

```
@Component(immediate = true, service = ModelListener.class)
```

For more information on model listeners, see the Creating Model Listeners tutorial.

Where Is This Sample?

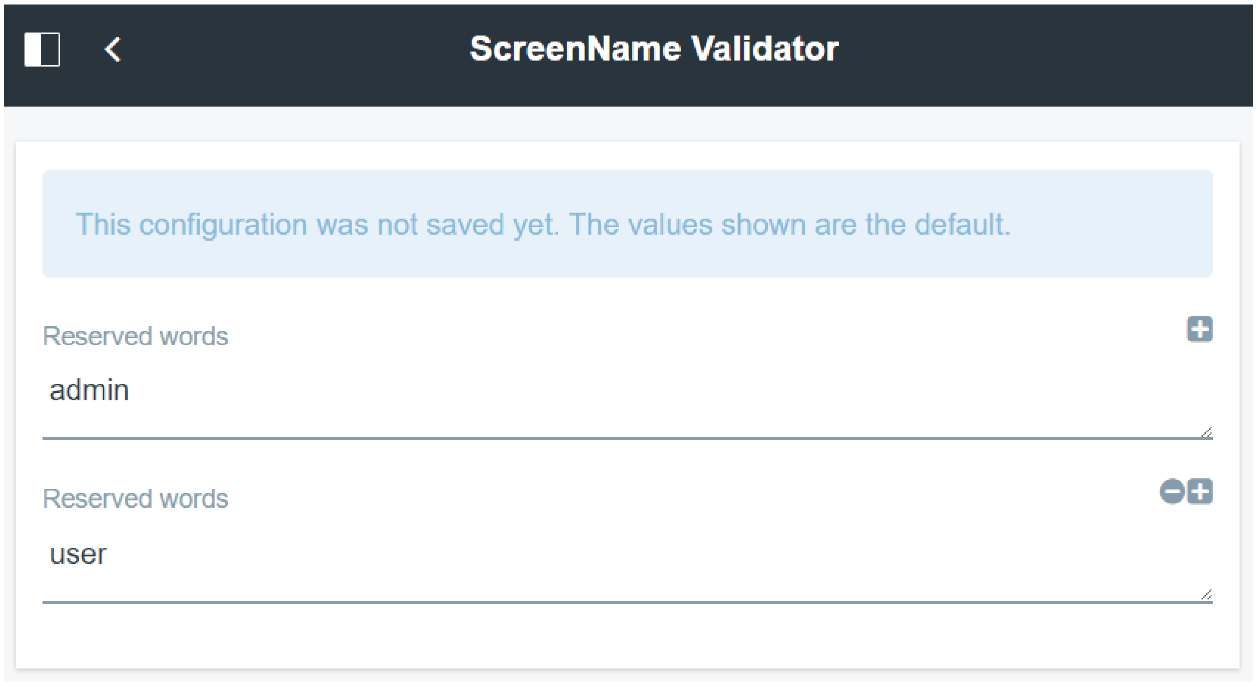
There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.6 Screen Name Validator

The Screen Name Validator sample provides a way to validate a user's inputted screen name. During validation, the screen name is tested client-side and server-side.

This sample checks if a user's screen name contains reserved words that are configured in the *Control Panel → Configuration → System Settings → Foundation → ScreenName Validator* menu. The default values for the screen name validator's reserved words are *admin* and *user*.



ScreenName Validator

This configuration was not saved yet. The values shown are the default.

Reserved words: admin

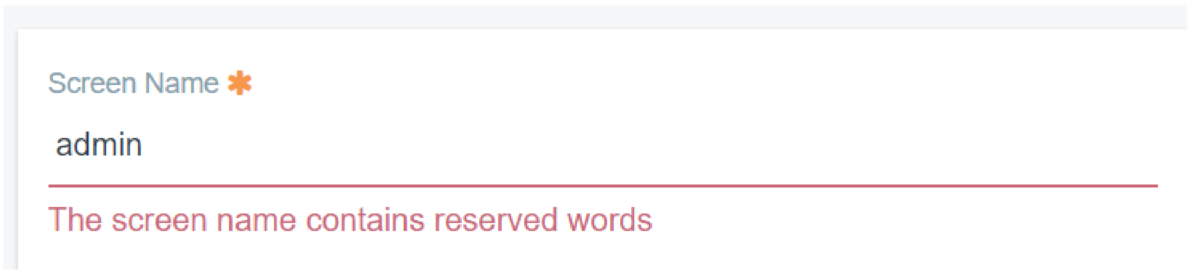
Reserved words: user

Figure 138.10: Enter reserved words for the screen name validator.

You can test this sample by following the following steps:

1. Deploy the Screen Name Validator to your portal installation.
2. Navigate to the *Control Panel → Users → Users and Organizations* menu.

3. Create a new user by selecting the *Add User* (+) button.
4. Adding a screen name that contains the word *admin* or *user*.



admin

The screen name contains reserved words

Figure 138.11: The error message displays when inputting a reserved word for the screen name.

What API(s) and/or code components does this sample highlight?

This sample leverages the ScreenNameValidator API.

How does this sample leverage the API(s) and/or code component?

To customize this sample, modify its `com.liferay.blade.samples.screenname.validator.internal.CustomScreenNameValidator` class.

You can also customize this sample's configuration by adding more properties in its `com.liferay.blade.samples.screenname` class.

For more information on customizing the Validation sample to fit your needs, see the Javadoc provided in this sample's Java classes.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

138.7 Servlet

The Servlet sample provides an OSGi Whiteboard Servlet in Liferay DXP. When deploying this sample and configuring the servlet, a *Hello World* message is displayed when accessing the servlet page URL. Log info is also outputted to your console.

To configure the servlet in Liferay DXP, complete the following steps:

1. Navigate to the *Control Panel* → *Configuration* → *Server Administration* → *Log Levels*.

2. Select *Add Category*.

3. Insert *com.liferay.blade.samples.servlet.BladeServlet* for the Logger Name and *INFO* for the Log Level.

4. Navigate to the http://localhost:8080/o/blade/servlet URL.

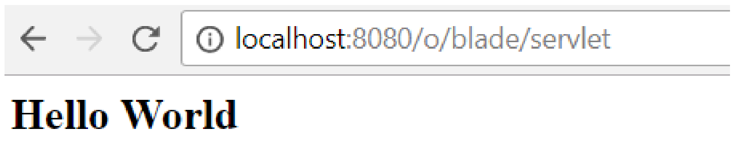


Figure 138.12: The servlet displays *Hello World* from the configured servlet page URL.

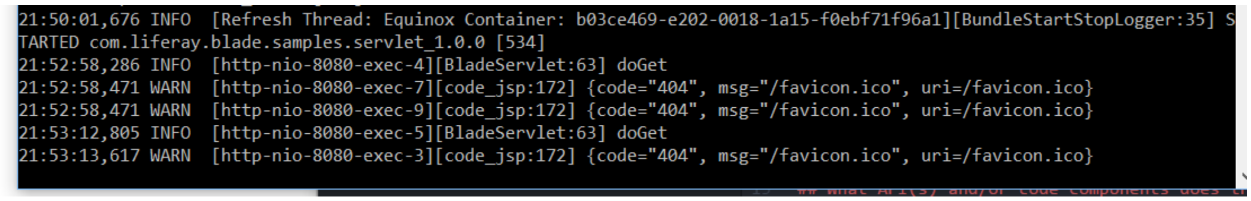


```
21:50:01,676 INFO  [Refresh Thread: Equinox Container: b03ce469-e202-0018-1a15-f0ebf71f96a1][BundleStartStopLogger:35] S
TARTED com.liferay.blade.samples.servlet_1.0.0 [534]
21:52:58,286 INFO  [http-nio-8080-exec-4][BladeServlet:63] doGet
21:52:58,471 WARN  [http-nio-8080-exec-7][code_jsp:172] {code="404", msg="/favicon.ico", uri=/favicon.ico}
21:52:58,471 WARN  [http-nio-8080-exec-9][code_jsp:172] {code="404", msg="/favicon.ico", uri=/favicon.ico}
21:53:12,805 INFO  [http-nio-8080-exec-5][BladeServlet:63] doGet
21:53:13,617 WARN  [http-nio-8080-exec-3][code_jsp:172] {code="404", msg="/favicon.ico", uri=/favicon.ico}
```

Figure 138.13: The servlet also logs info in the console.

What API(s) and/or code components does this sample highlight?

This sample leverages the HttpServlet API.

How does this sample leverage the API(s) and/or code component?

To customize this sample, modify its `com.liferay.blade.samples.servlet.BladeServlet` class. This class extends the `HttpServlet` class. Creating your own servlet for Liferay DXP is useful when you need to implement servlet actions. For example, if you wanted to implement the CMIS server by yourself with Apache Chemistry, you would need to implement your own servlet, managing requests at a low level.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

CHAPTER 139

OVERRIDES

This section focuses on Liferay sample overrides. You can view these sample overrides by visiting the `overrides` folder corresponding to your preferred build tool:

- Gradle sample overrides
- Liferay Workspace sample overrides
- Maven sample overrides

The following samples are documented:

- Core JSP Override
- Module JSP Override
- Resource Bundle Override

Visit a particular sample page to learn more!

139.1 Core JSP Override

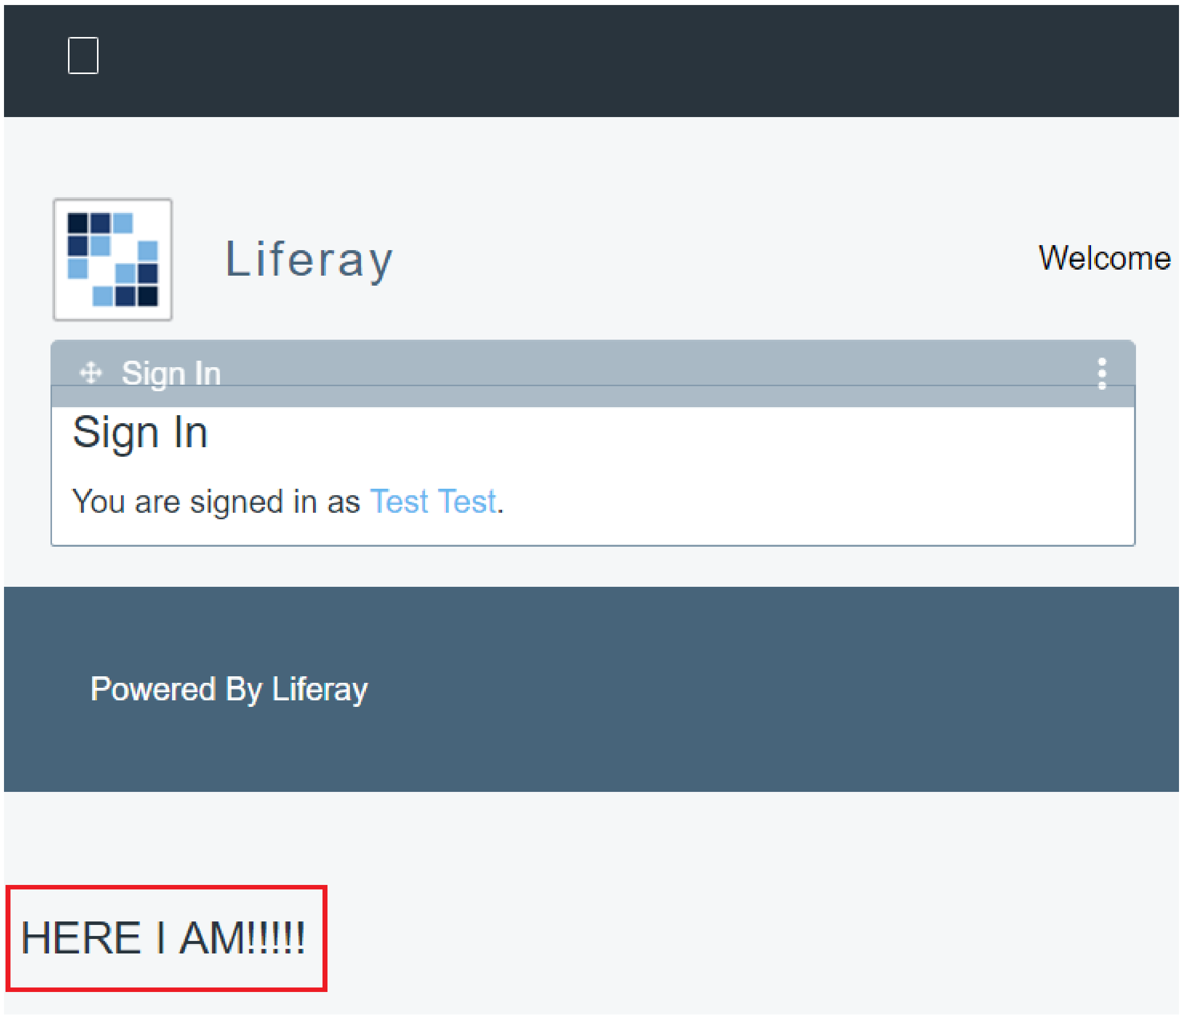
The Core JSP Override sample lets you override core/kernel JSPs by adding them to the module's `META-INF/jsps` folder. This module overrides the Liferay DXP's `bottom.jsp` file by inserting the `bottom-ext.jsp` file in the `META-INF/jsps/html/common/themes` folder. When deploying this sample with no customizations, sample text is added to the bottom of Liferay's default theme.

For more information on how to customize Liferay's Core using JSP overrides, visit the Overriding Core JSPs tutorial.

What API(s) and/or code components does this sample highlight?

This sample leverages the CustomJspBag API.

Important: Using core JSP overrides should be a last resort option only when there is no other way to customize functionality in your Liferay installation. It's up to the maintainer of this JSP override to properly maintain and adapt to changes in the underlying JSP implementation.



Sign In

You are signed in as Test Test.

HERE I AM!!!!!

Figure 139.1: Deploying a core JSP override overrides core functionality, like Liferay DXP's default theme.

How does this sample leverage the API(s) and/or code component?

You can easily modify this sample by customizing its `com.liferay.blade.samples.corejsphook.BladeCustomJspBag` Java class or adding additional JSPs in the configured JSP folder. You can modify the custom JSP folder's path by editing the `BladeCustomJspBag.getCustomJspDir()` method to return a different folder path.

For more information on customizing the Core JSP Override sample to fit your needs, see the Javadoc listed in this sample's `BladeCustomJspBag` class.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

139.2 Module JSP Override

The Module JSP Override sample conveys Liferay's recommended approach to override an application's JSP by leveraging OSGi fragment modules. This example overrides the default `login.jsp` file in the `com.liferay.login.web` bundle by adding the red text *changed* to the Sign In form.

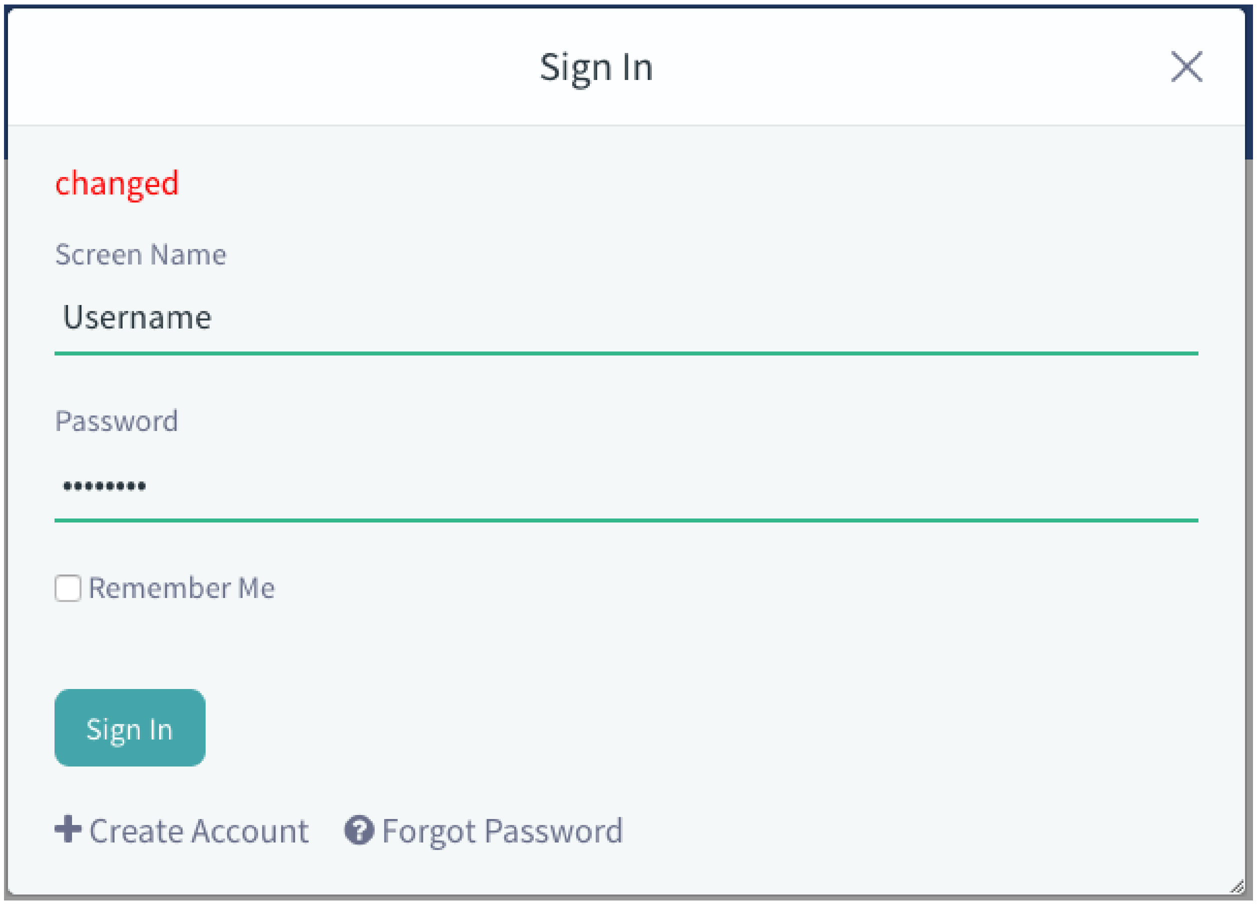


Figure 139.2: The customized Sign In form with the new *changed* text.

What API(s) and/or code components does this sample highlight?

This sample demonstrates how to create a fragment host module and configure it to override an existing module's JSP.

How does this sample leverage the API(s) and/or code component?

You can create your own JSP override by

- Declaring the fragment host.
- Providing the JSP that will override the original one.

To properly declare the fragment host in the `bnd.bnd` file, you must specify the host module's (where the original JSP is located) Bundle Symbolic Name and the host module's exact version to which the fragment belongs. In this example, this is configured like this:

```
Fragment-Host: com.liferay.login.web;bundle-version="1.0.0"
```

Then you must provide the new JSP intended to override the original one. Be sure to mimic the host module's folder structure when overriding its JAR. For this example, since the original JSP is in the folder `/META-INF/resources/login.jsp`, the new JSP file resides in the folder `src/main/resources/META-INF/resources/login.jsp`.

If needed, you can also target the original JSP following one of the two possible naming conventions: `original` or `portal`. This pattern looks like

```
<liferay-util:include
    page="/login.original.jsp"
    servletContext="<%= application %>"
/>
```

or

```
<liferay-util:include
    page="/login.portal.jsp"
    servletContext="<%= application %>"
/>
```

This approach can be used to override any application JSP (i.e., JSPs residing in a module). You can also add new JSPs to an existing module with this technique. If you need to override a core JSP, see the `core-jsp-override` sample.

For more information on using fragment bundles to override application JSPs, see the Overriding App JSPs tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

139.3 Resource Bundle Override

This example overrides the default `add-blog-entry` language key (English and Spanish) for Liferay DXP's default Blogs application. After deploying this sample hook to Liferay DXP, the Blogs application's *Add Blog Entry* button is modified to display *Overriden Add Blog Entry*. If you change Liferay DXP's default language to Spanish, the modified language key is translated to display in that language. For example, the text changes to *Añadir entrada sobreescrita*.

For reference, the Blogs application's language keys are stored in the liferay-portal Github repo's `modules/apps/collaboration/blogs/blogs-web/src/main/resources/content` folder.

What API(s) and/or code components does this sample highlight?

This sample leverages the ResourceBundleLoader API.

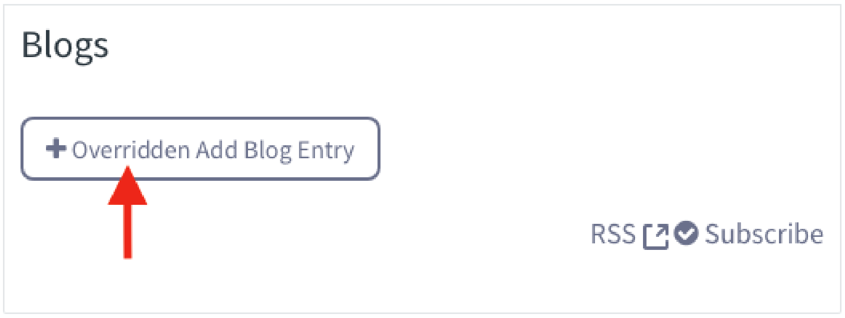

Figure 139.3: The customized Blogs application displays the new `add-blog-entry` language key in English.

How does this sample leverage the API(s) and/or code component?

This sample conveys the recommended approach to override an application's language keys file for any module that is deployed to Liferay DXP's OSGi runtime (not applicable to Liferay DXP's core language keys).

The steps to override applications' language keys are

- Implement a resource bundle loader.
- Register the service.
- Provide the new language keys that will override the original ones.

The resource bundle loader is a class that should implement the interface `com.liferay.portal.kernel.util.ResourceBundle`
Specifically, you must implement the `loadResourceBundle` method, which returns the loaded resource bundle:

```
@Override
public ResourceBundle loadResourceBundle(String languageId) {
    return _resourceBundleLoader.loadResourceBundle(languageId);
}
```

Then you must set the resource bundle loader to load the resource bundles as an `AggregateResourceBundleLoader`.

```
@Reference(target = "(&(bundle.symbolic.name=com.liferay.blogs.web)(!(component.name=com.liferay.blade.samples.hook.resourcebundle.ResourceBundleLoaderCompo
public void setResourceBundleLoader(
    ResourceBundleLoader resourceBundleLoader) {

    _resourceBundleLoader = new AggregateResourceBundleLoader(
        new CacheResourceBundleLoader(
            new ClassResourceBundleLoader(
                "content.Language",
                ResourceBundleLoaderComponent.class.getClassLoader())),
    resourceBundleLoader);
}
```

The `@Reference` annotation targets the original Blogs module by specifying its symbolic name `com.liferay.blogs.web`. This sample's own component name (i.e., `com.liferay.blade.samples.hook.resourcebundle.ResourceB`
is not targeted to use this resource bundle.

Also note the required parameters to set the resource bundle loader:

- The base language file name (e.g., `content.Language`).
- The classloader for your resource bundle loader.
- The resource bundle loader from the method's parameter.

The class should also register the resource bundle loader in the OSGi runtime. This is done by setting the following three properties:

- `bundle.symbolic.name`: The symbolic name of the target module (i.e., the module's keys you're overriding).
- `resource.bundle.base.name`: The resource bundle base name that points to your language files.
- `servlet.context.name`: The servlet context name of the target module.

These properties are set in your class's `@Component` annotation like this:

```
@Component(
    immediate = true,
    property = {
        "bundle.symbolic.name=com.liferay.blogs.web",
        "resource.bundle.base.name=content.Language",
        "servlet.context.name=blogs-web"
    }
)
```

Lastly, the new `language.properties` files should be added to the folder `src/content` for each locale's keys you want to override. Since this example's goal is to only override the English and Spanish keys, the `Language_en.properties` and `Language_es.properties` are added.

This approach can be used to override any application's language keys (i.e., `language.properties` files that are inside a module deployed to Liferay DXP's OSGi runtime). If you need to override Liferay DXP's core language keys, see the Modifying Global Language Keys tutorial.

For more information on using a resource bundle to override an application's language keys, see the Overriding a Module's Language Keys tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

Chapter 140

Themes

This section focuses on Liferay sample themes. You can view these sample themes by visiting the `themes` folder corresponding to your preferred build tool:

- Gradle sample themes
- Liferay Workspace sample themes
- Maven sample themes

The following samples are documented:

- Simple Theme
- Template Context Contributor
- Theme Contributor

Visit a particular sample page to learn more!

140.1 Simple Theme

The Simple Theme sample provides the base files for a theme, using the Theme Builder Gradle plugin. When deploying this sample with no customizations, a theme based off of the `_styled` base theme is created.

For more information on themes, visit the Introduction to Themes tutorial.

What API(s) and/or code components does this sample highlight?

This sample demonstrates a way to create a simple theme in Liferay DXP.

How does this sample leverage the API(s) and/or code component?

To modify this sample, add the `images`, `js`, or `templates` folder, along with your modified files, to the `src/main/webapp` folder. The sample already provides the `src/main/resources/resources-importer`, `src/main/webapp/WEB-INF`, and `src/main/webapp/css` folders for you. Add your style modifications to the provided `css/_custom.scss` file. For a complete explanation of a theme's files, see the Theme Reference Guide.

Welcome
Breadcrumb
Welcome
Hello World
Welcome to Liferay Community Edition Portal 7.0.2 GA3 (Wilberforce / Build 7002 / August 5, 2016).
Powered By Liferay

Figure 140.1: A theme based off of the Styled base theme is created when the Theme Blade sample is deployed to Liferay Portal.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

140.2 Template Context Contributor

The Template Context Contributor sample injects a new variable into Liferay DXP's theme context. When deploying this sample with no customizations, you can use the `${sample_text}` variable from any theme.

What API(s) and/or code components does this sample highlight?

Many developers prefer using templating frameworks like FreeMarker and Velocity, but don't have access to the common objects offered to those working with JSPs. Context contributors allow non-JSP developers an easy way to inject variables into their Liferay templates.

This sample leverages the TemplateContextContributor API.

How does this sample leverage the API(s) and/or code component?

You can easily modify this sample by customizing its `BladeTemplateContextContributor.java` Java class. For example, the default context contributor sample provides the `${sample_text}` variable by injecting it into Liferay's `contextObjects`, which is a map provided by default to offer common variables to non-JSP template developers. You can easily inject your own variables into the `contextObjects` map usable by any theme deployed to Liferay DXP.

Are you working with templates that aren't themes (e.g., ADTs, DDM templates, etc.)? You can change the context in which your variables are injected by modifying the `property` attribute in the `@Component` annotation. If you want your variable available for all templates, change it to

```
property = {"type=" + TemplateContextContributor.TYPE_GLOBAL}
```

For more information on customizing the Template Context Contributor sample to fit your needs, see the Javadoc listed in this sample's `com.liferay.blade.samples.theme.contributorBladeTemplateContextContributor` class. For more information on context contributors and how to create them in Liferay DXP, visit the Context Contributors tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

140.3 Theme Contributor

The Theme Contributor sample contributes updates to the UI of the theme body, Control Menu, Product Menu, and Simulation Panel. When deploying this sample with no customizations, the colors of the theme and aforementioned menus are updated.

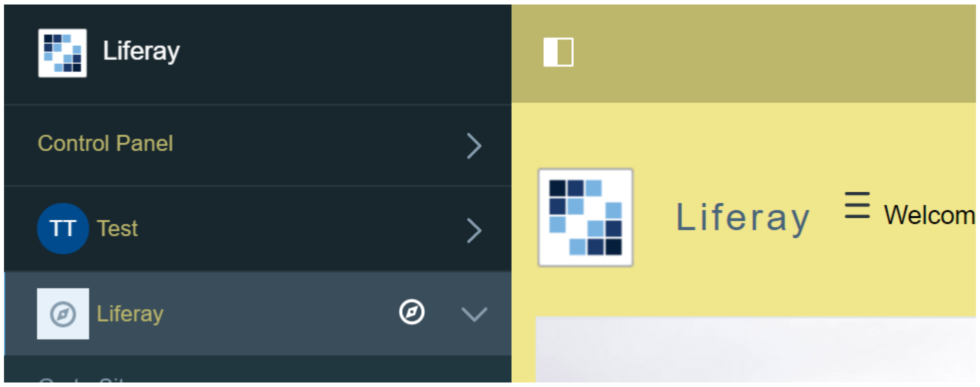

Figure 140.2: Your Liferay DXP pages and menu fonts now have a yellow tint.

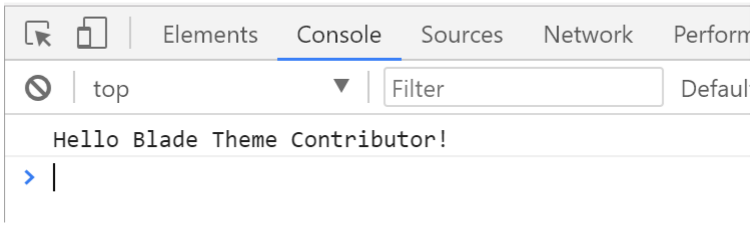
Also, there's a simple JavaScript update that is provided, which logs a message to the browser's console window that states *Hello Blade Theme Contributor!*.



```
Hello Blade Theme Contributor!
```

Figure 140.3: The message is printed to your browser's console window using JavaScript.

What API(s) and/or code components does this sample highlight?

This sample demonstrates a way to contribute updates to a Liferay DXP theme. Theme Contributors let you package UI resources (e.g., CSS and JS) independent of a theme to include on a Liferay DXP page.

How does this sample leverage the API(s) and/or code component?

To modify this sample, replace the corresponding JS or SCSS file with the JavaScript or styles that you want, or add your own JS or SCSS files. For example, this sample provides an update to the Control Menu's `background-color` in its `src/main/resources/META-INF/resources/css/blade.theme.contributor/_control_menu.scss` file:

```
body {
	.control-menu {
		background-color: darkkhaki;
	}
}
```

All of the SCSS files used in this sample are imported into the main `blade.theme.contributor.scss` file:

```
@import "bourbon";
@import "mixins";

@import "blade.theme.contributor/body";
@import "blade.theme.contributor/control_menu";
@import "blade.theme.contributor/product_menu";
@import "blade.theme.contributor/simulation_panel";
```

If you add your own SCSS files, you must add them to the list of imports in the `blade.theme.contributor.scss` file.

Likewise, the sample `blade.theme.contributor.js` logs a message to your browser's console window using the following JS logic:

```
console.log('Hello Blade Theme Contributor!');
```

For more information on Theme Contributors, visit the Theme Contributors tutorial.

Where Is This Sample?

There are three different versions of this sample, each built with a different build tool:

- Gradle
- Liferay Workspace
- Maven

140.4 Third Party Packages Portal Exports

The `com.liferay.portal.bootstrap` module exports many third party Java packages that can cause problems if used improperly. If your WAR's Gradle file, for example, uses the `compile` scope for a dependency that Liferay's OSGi runtime already provides, the dependency JAR is included in the WAR's `WEB-INF/lib` and deployed in the resulting WAB, and two versions of dependency classes wind up on the classpath. This can cause weird errors that are hard to debug.

To find a list of the packages exported by `com.liferay.portal.bootstrap`, go to the source file `modules/core/portal-bootstrap/system.packages.extra.bnd`. If you don't have access to the source code, the same list (in a less user-friendly format) is in the `META-INF/system.packages.extra.mf` file in `[LIFERAY_HOME]/osgi/core/com.liferay.portal.bootstrap.jar`. These packages are installed and available in Liferay's OSGi runtime. If your module or WAR uses one of them, specify the corresponding dependency as being "provided" (provided by Liferay DXP). Here's how to specify a provided dependency:

Maven: `<scope>provided</scope>`

Gradle: `providedCompile`

Now you can safely leverage third party packages Liferay DXP provides!

Configuring Dependencies

140.5 Resolving Common Output Errors Reported by the resolve Task

Liferay Workspace provides the `resolve` Gradle task to validate modules. This is very useful for finding issues and reporting them as output before deployment. For more information on running this task from Liferay Workspace, see the Validating Modules Against the Target Platform tutorial section. For general help with OSGi related issues, visit the Troubleshooting FAQ tutorial section.

For help interpreting the `resolve` task's output, see the list below for common output errors, what they mean, and how to fix them.

Missing Import Error

When your module refers to an unavailable import, the container throws this error. For example, suppose you have a module `test-service` that depends on the `com.google.common.base` package. If the container can't find that package, it throws this error:

```
Resolution exception in project 'modules:test-service': Unresolved requirements in root project 'modules:test-service':
    Mandatory:
        [osgi.wiring.package ] com.google.common.base; version=[23.0.0,24.0.0)
        [osgi.identity       ] test.service
```

This kind of error can also occur when separate modules require different versions of another module. If you have *module A* requiring *module Test version 1* and *module B* requiring *module Test version 4*, without running the resolver, both modules A and B would compile successfully. When they were deployed, however, one would fail in the OSGi runtime because both dependencies cannot be satisfied. These types of scenarios are difficult to diagnose, but with the `resolve` task, can be found with ease.

To fix missing import errors, you may need to adjust the export and/or import configuration of your modules. Also, see the Resolving Third Party Library Package Dependencies tutorial for more information on resolving import errors. Sometimes, this kind of error can be solved by editing the `resolve` task's list of capabilities. See the Depending on Third Party Libraries Not Included in Liferay DXP section to learn how to do this.

Missing Service Reference

If your module references a non-existent service, an error is thrown. This is helpful because service reference issues are hard to diagnose during deployment without using the Gogo Shell.

For example, if your module `test-portlet` references a service (e.g., `test.api.TestApi`) it does not have access to, the following error is thrown:

```
Resolution exception in project 'modules:test-portlet': Unresolved requirements in project 'modules:test-portlet':
    Mandatory:
        [osgi.identity ] test.portlet
        [osgi.service  ] objectClass=test.api.TestApi
```

To fix this, you must make the service available to your module. If you're expecting the service to be provided by your target platform, check to make sure it's being provided. If it's a service provided by a custom module, check that service provider module and ensure it's correctly providing that service to your module. To check the target platform for available services, follow the steps below:

1. Start your target platform instance.

2. Start the Gogo shell from a local telnet session (e.g., `telnet localhost 11311`).

3. List all services containing a keyword by running `services | grep "SERVICE_NAME"`. It's easiest to do this rather than listing all services since there are usually too many to sift through.

4. You can also list services provided by a component. Run `lb -s` to list all provided bundles by their bundle symbolic name (BSN). Find the BSN for the desired component and then run `scr:info <BSN>`.

If you're unable to track down your missing service, it may be provided by a customized Liferay DXP core feature or an external Liferay DXP feature. If this is the case, it isn't included in the target platform's default capabilities. You can make the custom service capability available to reference by generating a new custom distro JAR.

Missing Fragment Host

Referring to a non-existent fragment host throws an error. For example, if your `test.login` fragment is configured to modify a fragment host named `com.liferay.login.web` that cannot be referenced, the following error is thrown:

```
Resolution exception in project 'modules:test.login': Unresolved requirements in project 'modules:test-login':
    Mandatory:
        [osgi.identity    ] test.login
        [osgi.wiring.host ] com.liferay.login.web; version=1.0.10
```

Configuring a fragment host in your module is typically done with the `Fragment-Host` header in the `bnd.bnd` file:

```
Fragment-Host: com.liferay.login.web;bundle-version="[1.0.0,1.0.1)"
```

To fix this, inspect your target platform to ensure it includes the JAR you're attempting to add a fragment for. Your fragment host header may be referencing an incorrect bundle symbolic name (BSN) or version. The easiest way to check this is by using the Gogo Shell. Follow the steps below to find the bundle symbolic name:

1. Start your target platform instance.

2. Start the Gogo shell from a local telnet session (e.g., `telnet localhost 11311`).

3. List all installed bundles by BSN with the command `lb -s`. You can search through the output to find the BSN. If you already know the BSN and want to check the version, run `lb -s | grep "<BSN>"`.

Once you know the correct BSN/version to reference, update your `Fragment-Host` header to resolve the error.

For more information on fragments, see the JSP Overrides Using OSGi Fragments tutorial.

140.6 CKEditor Plugin Reference Guide

This reference guide provides a list of the default CKEditor plugins bundled with Liferay DXP's AlloyEditor. Each plugin below links to its `plugin.js` file for reference:

- about
- allyhelp
- allyhelpbtn
- ajaxsave
- autocomplete
- basicstyles
- bbcode
- bidi
- blockquote
- clipboard
- colorbutton
- colordialog
- contextmenu
- creole
- dialogadvtab
- div
- elementspath
- enterkey
- entities
- filebrowse
- find
- flash
- floatingspace
- font
- format
- forms
- horizontalrule
- htmlwriter
- image
- iframe
- indent
- itemselector
- justify
- link
- list
- liststyle
- lfrpopup
- magicline
- media
- newpage
- pagebreak
- pastefromword
- pastetext

- preview
- removeformat
- resize
- restore
- selectall
- showblocks
- showborders
- smiley
- sourcearea
- specialchar
- stylescombo
- tab
- table
- tabletools
- templates
- toolbar
- undo
- wikilink
- wysiwygarea

Note: The following CKEditor plugins are not available for inline mode in AlloyEditor at this time; however, you can still use them in the classic CKEditor:

- maximize
- print
- save

To use the Classic CKEditor instead of AlloyEditor, there are a few properties you can use, depending on the portlet. Add the properties that you need to your `portal-ext.properties` file:

```
editor.wysiwyg.default=ckeditor
editor.wysiwyg.portal-impl.portlet.ddm.text_html.ftl=ckeditor
editor.wysiwyg.portal-web.docroot.html.portlet.announcements.edit_entry.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.portlet.blogs.edit_entry.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.portlet.mail.edit.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.portlet.mail.edit_message.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.portlet.message_boards.edit_message.html.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.taglib.ui.discussion.jsp=ckeditor
editor.wysiwyg.portal-web.docroot.html.taglib.ui.email_notification_settings.jsp=ckeditor
```

140.7 Item Selector Criterion and Return Types

Liferay DXP bundles have apps and app suites containing `ItemSelectorCriterion` classes and `ItemSelectorReturnType` classes developers can use.

Item Selector Criterion Classes

Collaboration App Suite Modules:

- `com.liferay.item.selector.criteria.api`:

    - ImageItemSelectorCriterion: Image file entity type.
    - AudioItemSelectorCriterion: Audio file entity type.
    - FileItemSelectorCriterion: Document Library file entity type.
    - UploadItemSelectorCriterion: Uploadable file entity type.
    - URLItemSelectorCriterion: URL entity type.
    - VideoItemSelectorCriterion: Video file entity type.

- `com.liferay.wiki.api` has wiki criterion.

Web Experience App Suite Modules:

- `com.liferay.site.item.selector.api` has site criterion.
- `com.liferay.layout.item.selector.api` has layout criterion.
- `com.liferay.journal.item.selector.api` has web content criterion.

If there's no criterion class for your entity, you can create your own `ItemSelectorCriterion` class (tutorial coming soon).

Item Selector Return Type Classes

The Liferay Collaboration app suite's `com.liferay.item.selector.criteria.api` module includes the following return types:

- Base64ItemSelectorReturnType: Base64 encoding of the entity as a `String`.
- FileEntryItemSelectorReturnType: File entry information as a JSON object.
- URLItemSelectorReturnType: URL of the entity as a `String`.
- UUIDItemSelectorReturnType: Universally Unique Identifier (UUID) of the entity as a `String`.

If there's no return type class that meets your needs, you can implement your own `ItemSelectorReturnType` class (tutorial coming soon).

140.8 Breaking Changes

This document presents a chronological list of changes that break existing functionality, APIs, or contracts with third party Liferay developers or users. We try our best to minimize these disruptions, but sometimes they are unavoidable.

The breaking changes covered in this article apply to both the commercial and open source versions of Liferay.

Here are some of the types of changes documented in this file:

- Functionality that is removed or replaced
- API incompatibilities: Changes to public Java or JavaScript APIs

- Changes to context variables available to templates
- Changes in CSS classes available to Liferay themes and portlets
- Configuration changes: Changes in configuration files, like `portal.properties`, `system.properties`, etc.
- Execution requirements: Java version, J2EE Version, browser versions, etc.
- Deprecations or end of support: For example, warning that a certain feature or API will be dropped in an upcoming version.
- Recommendations: For example, recommending using a newly introduced API that replaces an old API, in spite of the old API being kept in Liferay Portal for backwards compatibility.

Breaking Changes List

The liferay-ui:logo-selector Tag Requires Parameter Changes

- **Date:** 2013-Dec-05
- **JIRA Ticket:** LPS-42645

What changed? The Logo Selector tag now supports uploading an image, storing it as a temporary file, cropping it, and canceling edits. The tag no longer requires creating a UI to include the image. Consequently, the `editLogoURL` parameter is no longer needed and has been removed. The tag now uses the following parameters to support the new features:

- `currentLogoURL`: the URL to display the image being stored
- `maxFileSize`: the size limit for the logo to be uploaded
- `tempImageFileName`: the unique identifier to store the temporary image on upload

Who is affected? Plugins or templates that are using the `liferay-ui:logo-selector` tag need to update their usage of the tag.

How should I update my code? You should remove the parameter `editLogoURL` and include (if neccessary) the parameters `currentLogoURL`, `maxFileSize`, and/or `tempImageFileName`.

Example

Old way:

```
<portlet:renderURL var="editUserPortraitURL" windowState="<%= LiferayWindowState.POP_UP.toString() %>">
    <portlet:param name="struts_action" value="/users_admin/edit_user_portrait" />
    <portlet:param name="redirect" value="<%= currentURL %>" />
    <portlet:param name="p_u_i_d" value="<%= String.valueOf(selUser.getUserId()) %>" />
    <portlet:param name="portrait_id" value="<%= String.valueOf(selUser.getPortraitId()) %>" />
</portlet:renderURL>

<liferay-ui:logo-selector
    defaultLogoURL="<%= UserConstants.getPortraitURL(themeDisplay.getPathImage(), selUser.isMale(), 0) %>"
    editLogoURL="<%= editUserPortraitURL %>"
    imageId="<%= selUser.getPortraitId() %>"
    logoDisplaySelector=".user-logo"
/>
```

New way:

```
<liferay-ui:logo-selector
    currentLogoURL="<%= selUser.getPortraitURL(themeDisplay) %>"
    defaultLogoURL="<%= UserConstants.getPortraitURL(themeDisplay.getPathImage(), selUser.isMale(), 0) %>"
    imageId="<%= selUser.getPortraitId() %>"
    logoDisplaySelector=".user-logo"
    maxFileSize="<%= PrefsPropsUtil.getLong(PropsKeys.USERS_IMAGE_MAX_SIZE) / 1024 %>"
    tempImageFileName="<%= String.valueOf(selUser.getUserId()) %>"
/>
```

Why was this change made? This change helps keep a unified UI and consistent experience for uploading logos in the portal. The logos can be customized from a single location and used throughout the portal. In addition, the change adds new features such as image cropping and support for canceling image upload.

Merged Configured Email Signature Field into the Body of Email Messages from Message Boards and Wiki

- **Date:** 2014-Feb-28
- **JIRA Ticket:** LPS-44599

What changed? The configuration for email signatures of notifications from Message Boards and Wiki has been removed. An automatic update process is available that appends existing signatures into respective email message bodies for Message Boards and Wiki notifications. The upgrade process only applies to configured signatures in the database. In case you declared signatures in portal properties (e.g., `portal-ext.properties`), you must make the manual changes explained below.

Who is affected? Users and system administrators who have configured email signatures for Message Boards or Wiki notifications are affected. System administrators who have configured portal properties (e.g., `portal-ext.properties`) must make the manual changes described below.

How should I update my code? You should modify your `portal-ext.properties` file to remove the properties `message.boards.email.message.added.signature`, `message.boards.email.message.updated.signature`, `wiki.email.page.added.signature`, and `wiki.email.page.updated.signature`. Then, you should append the contents of the signatures to the bodies you had previously configured in your `portal-ext.properties` file.

Example

Old way:

```
wiki.email.page.updated.body=A wiki page was updated.
wiki.email.page.updated.signature=For any doubts email the system administrator
```

New way:

```
wiki.email.page.updated.body=A wiki page was updated.\n--\nFor any doubts email the system administrator
```

Why was this change made? This change helps simplify the user interface. The signatures can still be set inside the message body. There was no real benefit in keeping the signature and body fields separate.

Removed get and format Methods that Used PortletConfig Parameters

- **Date:** 2014-Mar-07
- **JIRA Ticket:** LPS-44342

What changed? All the methods `get()` and `format()` which had the PortletConfig as a parameter have been removed.

Who is affected? Any invocations from Java classes or JSPs to these methods in `LanguageUtil` and `UnicodeLanguageUtil` are affected.

How should I update my code? Replace invocations to these methods with invocations to methods of the same name that take a `ResourceBundle` parameter, instead of taking a `PortletConfig` parameter.

Example

Old call:

```
LanguageUtil.get(portletConfig, locale, key);
```

New call:

```
LanguageUtil.get(portletConfig.getResourceBundle(locale), key);
```

Why was this change made? The removed methods didn't work properly and would never work properly, since they didn't have all the information they required. Since we expected the methods were rarely used, we thought it better to remove them without deprecation than to leave them as buggy methods in the API.

Web Content Articles Now Require a Structure and Template

- **Date:** 2014-Mar-18
- **JIRA Ticket:** LPS-45107

What changed? Web content is now required to use a structure and template. A default structure and template named *Basic Web Content* was added to the global scope, and can be modified or deleted.

Who is affected? Applications that use the Journal API to create web content without a structure or template are affected.

How should I update my code? You should always use a structure and template when creating web content. You can still use the *Basic Web Content* from the global scope (using the structure key `basic-web-content`), but you should keep in mind that users can modify or delete it.

Why was this change made? This change gives users the flexibility to modify the default structure and template.

Changed the AssetRenderer and Indexer APIs to Include the PortletRequest and PortletResponse Parameters

- **Date:** 2014-May-07
- **JIRA Ticket:** LPS-44639 and LPS-44894

What changed? The `getSummary()` method in the AssetRenderer API and the `doGetSummary()` method in the Indexer API have changed and must include a `PortletRequest` and `PortletResponse` parameter as part of their signatures.

Who is affected? These methods must be updated in all AssetRenderer and Indexer implementations.

How should I update my code? Add a `PortletRequest` and `PortletResponse` parameter to the signatures of these methods.

Example 1

Old signature:

```
protected Summary doGetSummary(Document document, Locale locale, String snippet, PortletURL portletURL)
```

New signature:

```
protected Summary doGetSummary(Document document, Locale locale, String snippet, PortletRequest portletRequest, PortletResponse portletResponse)
```

Example 2

Old signature:

```
public String getSummary(Locale locale)
```

New signature:

```
public String getSummary(PortletRequest portletRequest, PortletResponse portletResponse)
```

Why was this change made? Some content (such as web content) needs the `PortletRequest` and `PortletResponse` parameters in order to be rendered.

Only One Portlet Instance's Settings is Used Per Portlet

- **Date:** 2014-Jun-06
- **JIRA Ticket:** LPS-43134

What changed? Previously, some portlets allowed separate setups per portlet instance, regardless of whether the instances were in the same page or in different pages. For some of the portlet setup fields, however, it didn't make sense to allow different values in different instances. The flexibility of these fields was unnecessary and confused users. As part of this change, these fields have been moved from portlet instance setup to Site Administration.

The upgrade process takes care of making the necessary database changes. In the case of several portlet instances having different configurations, however, only one configuration is preserved.

For example, if you configured three Bookmarks portlets where the mail configuration was the same, upgrade will be the same and you won't have any problem. But if you configured the three portlet instances differently, only one configuration will be chosen. To find out which configuration is chosen, you can check the log generated in the console by the upgrade process.

Since configuring instances of the same portlet type differently is highly discouraged and notoriously problematic, we expect this change will inconvenience only a very low minority of portal users.

Who is affected? Affected users are those who have specified varying configurations for multiple portlet instances of a portlet type, that stores configurations at the layout level.

How should I update my code? The upgrade process chooses one portlet instance's configurations and stores it at the service level. After the upgrade, you should review the portlet's configuration and make any necessary modifications.

Why was this change made? Unifying portlet and service configuration facilitates managing them.

DDM Structure Local Service API No Longer Has the updateXSDFieldMetadata operation

- **Date:** 2014-Jun-11
- **JIRA Ticket:** LPS-47559

What changed? The `updateXSDFieldMetadata()` operation was removed from the DDM Structure Local Service API.

DDM Structure Local API users should reference a structure's internal representation; any call to modify a DDM structure's content should be done through the DDMForm model.

Who is affected? Applications that use the DDM Structure Local Service API might be affected.

How should I update my code? You should always use DDMForm to update the DDM Structure content. You can retrieve it by calling `ddmStructure.getDDMForm()`. Perform any changes to it and then call `DDMStructureLocalServiceUtil.updateDDMStructure(ddmStructure)`.

Why was this change made? This change gives users the flexibility to modify the structure content without concerning themselves with the DDM Structure's internal content representation of data.

The aui:input Tag for Type checkbox No Longer Creates a Hidden Input

- **Date:** 2014-Jun-16
- **JIRA Ticket:** LPS-44228

What changed? Whenever the aui:input tag is used to generate an input of type checkbox, only an input tag will be generated, instead of the checkbox and hidden field it was generating before.

Who is affected? Anyone trying to grab the previously generated fields is affected. The change mostly affects JavaScript code trying to add some additional actions when clicking on the checkboxes.

How should I update my code? In your front-end JavaScript code, follow these steps:

- Remove the `Checkbox` suffix when querying for the node in any of its forms, like `A.one(...)`, `$(...)`, etc.
- Remove any action that tries to set the value of the checkbox on the previously generated hidden field.

Why was this change made? This change makes generated forms more standard and interoperable since it falls back to the checkboxes default behavior. It allows the form to be submitted properly even when JavaScript is disabled.

Using util-taglib No Longer Binds You to Using portal-kernel's javax.servlet.jsp Implementation

- **Date:** 2014-Jun-19
- **JIRA Ticket:** LPS-47682

What changed? Several APIs in `portal-kernel.jar` contained references to the `javax.servlet.jsp` package. This forced `util-taglib`, which depended on many of the package's features, to be bound to the same JSP implementation.

Due to this, the following APIs had breaking changes:

- `LanguageUtil`
- `UnicodeLanguageUtil`
- `VelocityTaglibImpl`
- `ThemeUtil`
- `RuntimePageUtil`
- `PortletDisplayTemplateUtil`
- `DDMXSDUtil`
- `PortletResourceBundles`
- `ResourceActionsUtil`
- `PortalUtil`

Who is affected? This affects anyone calling the classes listed above.

How should I update my code? Code invoking the APIs listed above should be updated to use an `HttpServletRequest` parameter instead of the formerly used `PageContext` parameter.

Why was this change made? As stated previously, the use of the `javax.servlet.jsp` API in `portal-kernel` prevented the use of any other JSP impl within plugins (OSGi or otherwise). This limited what Liferay could change with respect to providing its own JSP implementation within OSGi.

Changes in Exceptions Thrown by User Services

- **Date:** 2014-Jul-03
- **JIRA Ticket:** LPS-47130

What changed? In order to provide more information about the root cause of an exception, several exceptions have been extended with static inner classes, one for each cause. As a result of this effort, some exceptions have been identified that really belong as static inner subclasses of existing exceptions.

Who is affected? Client code which is handling any of the following exceptions:

- `DuplicateUserScreenNameException`
- `DuplicateUserEmailAddressException`

How should I update my code? Replace the old exception with the equivalent inner class exception as follows:

- `DuplicateUserScreenNameException` → `UserScreenNameException.MustNotBeDuplicate`
- `DuplicateUserEmailAddressException` → `UserEmailAddressException.MustNotBeDuplicate`

Why was this change made? This change provides more information to clients of the services API about the root cause of an error. It provides a more helpful error message to the end-user and it allows for easier recovery, when possible.

Removed Trash Logic from DLAppHelperLocalService Methods

- **Date:** 2014-Jul-22
- **JIRA Ticket:** LPS-47508

What changed? The `deleteFileEntry()` and `deleteFolder()` methods in `DLAppHelperLocalService` deleted the corresponding trash entry in the database. This logic has been removed from these methods.

Who is affected? Every caller of the `deleteFileEntry()` and `deleteFolder()` methods is affected.

How should I update my code? There is no direct replacement. Trash operations are now accessible through the `TrashCapability` implementations for each repository. The following code demonstrates using a `TrashCapability` instance to delete a `FileEntry`:

```
Repository repository = getRepository();

TrashCapability trashCapability = repository.getCapability(
    TrashCapability.class);

FileEntry fileEntry = repository.getFileEntry(fileEntryId);

trashCapability.deleteFileEntry(fileEntry);
```

Note that the `deleteFileEntry()` and `deleteFolder()` methods in `TrashCapability` not only remove the trash entry, but also remove the folder or file entry itself, and any associated data, such as assets, previews, etc.

Why was this change made? This change was made to allow different kinds of repositories to support trash operations in a uniform way.

Removed Sync Logic from DLAppHelperLocalService Methods

- **Date:** 2014-Sep-05
- **JIRA Ticket:** LPS-48895

What changed? The `moveFileEntry()` and `moveFolder()` methods in `DLAppHelperLocalService` fired Liferay Sync events. These methods have been removed.

Who is affected? Every caller of the `moveFileEntry()` and `moveFolder()` methods is affected.

How should I update my code? There is no direct replacement. Sync operations are now accessible through the `SyncCapability` implementations for each repository. The following code demonstrates using a `SyncCapability` instance to move a `FileEntry`:

```
Repository repository = getRepository();

SyncCapability syncCapability = repository.getCapability(
    SyncCapability.class);

FileEntry fileEntry = repository.getFileEntry(fileEntryId);

syncCapability.moveFileEntry(fileEntry);
```

Why was this change made? There are repositories that don't support Liferay Sync operations.

Removed the .aui Namespace from Bootstrap

- **Date:** 2014-Sep-26
- **JIRA Ticket:** LPS-50348

What changed? The `.aui` namespace was removed from prefixing all of Bootstrap's CSS.

Who is affected? Theme and plugin developers that targeted their CSS to rely on the namespace are affected.

How should I update my code? Theme developers can still manually add an `aui.css` file in their `_diffs` directory, and add it back in. The `aui` CSS class can also be added to the `$root_css_class` variable.

Why was this change made? Due to changes in the Sass parser, the nesting of third-party libraries was causing some syntax errors which broke other functionality (e.g., RTL conversion). There was also a lot of additional complexity for a relatively minor benefit.

Moved MVCPortlet, ActionCommand and ActionCommandCache from util-bridges.jar to portal-kernel.jar

- **Date:** 2014-Sep-26
- **JIRA Ticket:** LPS-50156

What changed? The classes from package `com.liferay.util.bridges.mvc` in `util-bridges.jar` were moved to a new package `com.liferay.portal.kernel.portlet.bridges.mvc` in `portal-kernel.jar`.

Old classes:

```
com.liferay.util.bridges.mvc.ActionCommand
com.liferay.util.bridges.mvc.BaseActionCommand
```

New classes:

```
com.liferay.portal.kernel.portlet.bridges.mvc.BaseMVCActionCommand
com.liferay.portal.kernel.portlet.bridges.mvc.MVCActionCommand
```

In addition, `com.liferay.util.bridges.mvc.MVCPortlet` is deprecated, but was made to extend `com.liferay.portal.kernel.portlet.bridges.mvc.MVCPortlet`.

The classes in the `com.liferay.portal.kernel.portlet.bridges.mvc` package have been renamed to add the `MVC` prefix. These modifications were made after this breaking change, and can be referenced in LPS-56372.

Who is affected? This will affect any implementations of `ActionCommand`.

How should I update my code? Replace imports of `com.liferay.util.bridges.mvc.ActionCommand` with `com.liferay.portal.kernel.portlet.bridges.mvc.MVCActionCommand` and imports of `com.liferay.util.bridges.mvc.BaseActio` with `com.liferay.portal.kernel.portlet.bridges.mvc.BaseMVCActionCommand`.

Why was this change made? This change was made to avoid duplication of an implementable interface in the system. Duplication can cause `ClassCastExceptions`.

Convert Process Classes Are No Longer Specified via the convert.processes Portal Property, but Are Contributed as OSGi Modules

- **Date:** 2014-Oct-09
- **JIRA Ticket:** LPS-50604

What changed? The implementation class `com.liferay.portal.convert.ConvertProcess` was renamed `com.liferay.portal.convert.BaseConvertProcess`. An interface named `com.liferay.portal.convert.ConvertProcess` was created for it.

The `convert.processes` key was removed from `portal.properties`. Consequentially, `ConvertProcess` implementations must register as OSGi components.

Who is affected? This affects any implementations of the former `ConvertProcess` class, including `ConvertProcess` class implementations in EXT plugins. Until version 6.2, this type of service could only be implemented with an EXT plugin, given that the `ConvertProcess` class resided in `portal-impl`.

How should I update my code? You should replace `extends com.liferay.portal.convert.ConvertProcess` with `extends com.liferay.portal.convert.BaseConvertProcess` and annotate the class with `@Component(service=ConvertProces`

Then turn your EXT plugin into an OSGi bundle and deploy it to the portal. You should see your convert process in the configuration UI.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Migration of the Field Type from the Journal Article API into a Vocabulary

- **Date:** 2014-Oct-13
- **JIRA Ticket:** LPS-50764

What changed? The field *type* from the Journal Article entity has been removed. The Journal API no longer supports this parameter. A new vocabulary called *Web Content Types* is created when migrating from previous versions of Liferay, and the types from the existing articles are kept as categories of this vocabulary.

Who is affected? This affects any caller of the removed methods `JournalArticle.getType()` and `JournalFeed.getType()`, and callers of `ArticleTypeException`'s methods, that attempt to use the former `type` parameter of the `JournalArticle` or `JournalFeed` service.

How should I update my code? If your logic was not affected by the type, you can simply remove the `type` parameter from the Journal API call. If your logic was affected by the type, you should now use the `AssetCategoryService` to obtain the category of the journal articles.

Why was this change made? Web Content Types had to be updated in a properties file and could not be translated easily. Categories provide a much more flexible behavior and a better UI. In addition, all the features, such as filters, developed for categories can be used now in asset publishers and faceted search.

Removed the getClassNamePortletId(String) Method from PortalUtil Class

- **Date:** 2014-Nov-11
- **JIRA Ticket:** LPS-50604

What changed? The `getClassNamePortletId(String)` method from the `PortalUtil` class has been removed.

Who is affected? This affects any plugin using the method.

How should I update my code? If you are using the method, you should implement it yourself in a private utility class.

Why was this change made? This change was needed in order to modularize the portal. Also, the method is no longer being used inside Liferay Portal.

Removed the Header Web Content and Footer Web Content Preferences from the RSS Portlet

- **Date:** 2014-Nov-12
- **JIRA Ticket:** LPS-46984

What changed? The *Header Web Content* and *Footer Web Content* preferences from the RSS portlet have been removed. The portlet now supports Application Display Templates (ADT), which provide templating capabilities that can apply web content to the portlet's header and footer.

Who is affected? This affects RSS portlets that are displayed on pages and that use these preferences. These preferences are no longer used in the RSS portlet.

How should I update my code? Even though these preferences have been removed, an ADT can be created to produce the same result. Liferay will publish this ADT so that it can be used in the RSS portlet.

Why was this change made? The support for ADTs in the RSS portlet not only covers this use case, but also covers many other use cases, providing a much simpler way to create custom preferences.

Removed the createFlyouts Method from liferay/util.js and Related Resources

- **Date:** 2014-Dec-18
- **JIRA Ticket:** LPS-52275

What changed? The `Liferay.Util.createFlyouts` method has been completely removed from core files.

Who is affected? This only affects third party developers who are explicitly calling `Liferay.Util.createFlyouts` for the creation of flyout menus. It will not affect any menus in core files.

How should I update my code? If you are using the method, you can achieve the same behavior with CSS.

Why was this change made? This method was removed due to there being no working use cases in Portal, and its overall lack of functionality.

Removed Support for Flat Thread View in Discussion Comments

- **Date:** 2014-Dec-30
- **JIRA Ticket:** LPS-51876

What changed? Discussion comments are now displayed using the *Combination* thread view, and the number of levels displayed in the tree is limited.

Who is affected? This affects installations that specify portal property setting `discussion.thread.view=flat`, which was the default setting.

How should I update my code? There is no need to update anything since the portal property has been removed and the `combination` thread view is now hard-coded.

Why was this change made? Flat view comments were originally implemented as an option to tree view comments, which were having performance issues with comment pagination.

Portal now uses a new pagination implementation that performs well. It allows comments to display in a hierarchical view, making it easier to see reply history. Therefore, the `flat` thread view is no longer needed.

Removed Asset Tag Properties

- **Date:** 2015-Jan-13
- **JIRA Ticket:** LPS-52588

What changed? The *Asset Tag Properties* have been removed. The service no longer exists and the Asset Tag Service API no longer has this parameter. The behavior associated with tag properties in the Asset Publisher and XSL portlets has also been removed.

Who is affected? This affects any plugin that uses the Asset Tag Properties service.

How should I update my code? If you are using this functionality, you can achieve the same behavior with *Asset Category Properties*. If you are using the Asset Tag Service, remove the `String[]` tag properties parameter from your calls to the service's methods.

Why was this change made? The Asset Tag Properties were deprecated for the 6.2 version of Liferay Portal.

Removed the asset.publisher.asset.entry.query.processors Property

- **Date:** 2015-Jan-22
- **JIRA Ticket:** LPS-52966

What changed? The `asset.publisher.asset.entry.query.processors` property has been removed from `portal.properties`.

Who is affected? This affects any hook that uses the `asset.publisher.asset.entry.query.processors` property.

How should I update my code? If you are using this property to register Asset Entry Query Processors, your Asset Entry Query Processor must implement the `com.liferay.portlet.assetpublisher.util.AssetEntryQueryProcessor` interface and must specify the `@Component(service=AssetEntryQueryProcessor.class)` annotation.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal.

Replaced the ReservedUserScreenNameException with UserScreenNameException.MustNotBeReserved in UserLocalService

- **Date:** 2015-Jan-29
- **JIRA Ticket:** LPS-53113

What changed? Previous to Liferay 7, several methods of `UserLocalService` could throw a `ReservedUserScreenNameException` when a user set a screen name that was not allowed. That exception has been deprecated and replaced with `UserScreenNameException.MustNotBeReserved`.

Who is affected? This affects developers who have written code that catches the `ReservedUserScreenNameException` while calling the affected methods.

How should I update my code? You should replace catching exception `ReservedUserScreenNameException` with catching exception `UserScreenNameException.MustNotBeReserved`.

Why was this change made? A new pattern has been defined for exceptions that provides higher expressivity in their names and also more information regarding why the exception was thrown.

The new exception `UserScreenNameException.MustNotBeReserved` has all the necessary information about why the exception was thrown and its context. In particular, it contains the user ID, the problematic screen name, and the list of reserved screen names.

Replaced the ReservedUserEmailAddressException with UserEmailAddressException Inner Classes in User Services

- **Date:** 2015-Feb-03
- **JIRA Ticket:** LPS-53279

What changed? Previous to Liferay 7, several methods of `UserLocalService` and `UserService` could throw a `ReservedUserEmailAddressException` when a user set an email address that was not allowed. That exception has been deprecated and replaced with `UserEmailAddressException.MustNotUseCompanyMx`, `UserEmailAddressException.MustNotBePOP3User`, and `UserEmailAddressException.MustNotBeReserved`.

Who is affected? This affects developers who have written code that catches the `ReservedUserEmailAddressException` while calling the affected methods.

How should I update my code? Depending on the method you're calling and the context in which you're calling it, you should replace catching exception `ReservedUserEmailAddressException` with catching exception `UserEmailAddressException.MustNotUseCompanyMx`, `UserEmailAddressException.MustNotBePOP3User`, or `UserEmailAddressException.MustNotBeReserved`.

Why was this change made? A new pattern has been defined for exceptions. This pattern requires using higher expressivity in exception names and requires that each exception provide more information regarding why it was thrown.

Each new exception provides its context and has all the necessary information about why the exception was thrown. For example, the `UserEmailAddressException.MustNotBeReserved` exception contains the problematic email address and the list of reserved email addresses.

Replaced ReservedUserIdException with UserIdException Inner Classes

- **Date:** 2015-Feb-10
- **JIRA Ticket:** LPS-53487

What changed? The `ReservedUserIdException` has been deprecated and replaced with `UserIdException.MustNotBeReserved`.

Who is affected? This affects developers who have written code that catches the `ReservedUserIdException` while calling the affected methods.

How should I update my code? You should replace catching exception `ReservedUserIdException` with catching exception `UserIdException.MustNotBeReserved`.

Why was this change made? A new pattern has been defined for exceptions that provides higher expressivity in their names and also more information regarding why the exception was thrown.

The new exception `UserIdException.MustNotBeReserved` provides its context and has all the necessary information about why the exception was thrown. In particular, it contains the problematic user ID and the list of reserved user IDs.

Moved the AssetPublisherUtil Class and Removed It from the Public API

- **Date:** 2015-Feb-11
- **JIRA Ticket:** LPS-52744

What changed? The class `AssetPublisherUtil` from the `portal-kernel` module has been moved to the module `AssetPublisher` and it is no longer a part of the public API.

Who is affected? This affects developers who have written code that uses the `AssetPublisherUtil` class.

How should I update my code? This `AssetPublisherUtil` class should no longer be used from other modules since it contains utility methods for the Asset Publisher portlet. If needed, you can define a dependency with the Asset Publisher module and use the new class.

Why was this change made? This change has been made as part of the modularization efforts to decouple the different parts of the portal.

Removed Operations That Used the Fields Class from the StorageAdapter Interface

- **Date:** 2015-Feb-11
- **JIRA Ticket:** LPS-53021

What changed? All operations that used the `Fields` class have been removed from the `StorageAdapter` interface.

Who is affected? This affects developers who have written code that directly calls these operations.

How should I update my code? You should update your code to use the `DDMFormValues` class instead of the `Fields` class.

Why was this change made? This change has been made due to the deprecation of the `Fields` class.

Created a New getType Method That is Implemented in DLProcessor

- **Date:** 2015-Feb-17
- **JIRA Ticket:** LPS-53574

What changed? The `DLProcessor` interface has a new method `getType()`.

Who is affected? This affects developers who have created a `DLProcessor`.

How should I update my code? You should implement the new method and return the type of processor. You can check the class `DLProcessorConstants` to see processor types.

Why was this change made? Previous to Liferay 7, developers were forced to extend one of the existing `DLProcessor` classes and developers using the extended class had to check the instance of that class to determine its processor type.

With this change, developers no longer need to extend any particular class to create their own `DLProcessor` and their processor's type can be clearly specified by a constant from the class `DLProcessorConstants`.

Changed the Usage of the liferay-ui:restore-entry Tag

- **Date:** 2015-Mar-01
- **JIRA Ticket:** LPS-54106

What changed? The usage of the taglib tag `liferay-ui:restore-entry` serves a different purpose now. It renders the UI to restore elements from the Recycle Bin.

Who is affected? This affects developers using the tag `liferay-ui:restore-entry`.

How should I update my code? You should replace your calls to the tag with code like the listing below:

```
<aui:script use="liferay-restore-entry">
    new Liferay.RestoreEntry(
    {
            checkEntryURL: '<%= checkEntryURL.toString() %>',
            duplicateEntryURL: '<%= duplicateEntryURL.toString() %>',
            namespace: '<portlet:namespace />'
        }
    );
</aui:script>
```

In the above code, the `checkEntryURL` should be an `ActionURL` of your portlet, which checks whether the current entry can be restored from the Recycle Bin. The `duplicateEntryURL` should be a `RenderURL` of your portlet, that renders the UI to restore the entry, resolving any existing conflicts. In order to generate that URL, you can use the tag `liferay-ui:restore-entry`, which has been refactored for this usage.

Why was this change made? This change allows the Trash portlet to be an independent module. Its actions and views are no longer used by the tag; they are now the responsability of each plugin.

Added Required Parameter resourceClassNameId for DDM Template Search Operations

- **Date:** 2015-Mar-03
- **JIRA Ticket:** LPS-52990

What changed? The DDM template `search` and `searchCount` operations have a new parameter called `resourceClassNameId`.

Who is affected? This affects developers who have direct calls to the `DDMTemplateService` or `DDMTemplateLocalService`.

How should I update my code? You should add the `resourceClassNameId` parameter to your calls. This parameter represents the resource that owns the permission for the DDM template. For example, if the template is a WCM template, the `resourceClassNameId` points to the `JournalArticle`'s `classNameId`. If the template is a DDL template, the `resourceClassNameId` points to the `DDLRecordSet`'s `classNameId`. If the template is an ADT template, the `resourceClassNameId` points to the `PortletDisplayTemplate`'s `classNameId`.

Why was this change made? This change was made in order to implement model resource permissions for DDM templates, such as `VIEW`, `DELETE`, `PERMISSIONS`, and `UPDATE`.

Replaced the Breadcrumb Portlet's Display Styles with ADTs

- **Date:** 2015-Mar-12
- **JIRA Ticket:** LPS-53577

What changed? The custom display styles of the breadcrumb tag added using JSPs no longer work. They have been replaced by Application Display Templates (ADT).

Who is affected? This affects developers that use the following properties:

```
breadcrumb.display.style.default=horizontal

breadcrumb.display.style.options=horizontal,vertical
```

How should I update my code? To style the Breadcrumb portlet, you should use ADTs instead of using custom styles in your JSPs. ADTs can be created from the UI of the portal by navigating to *Site Settings → Application Display Templates*. ADTs can also be created programatically.

Why was this change made? ADTs allow you to change an application's look and feel without changing its JSP code.

Changed Usage of the liferay-ui:ddm-template-selector Tag

- **Date:** 2015-Mar-16
- **JIRA Ticket:** LPS-53790

What changed? The attribute `classNameId` of the `liferay-ui:ddm-template-selector` taglib tag has been renamed `className`.

Who is affected? This affects developers using the `liferay-ui:ddm-template-selector` tag.

How should I update my code? In your `liferay-ui:ddm-template-selector` tags, rename the `classNameId` attribute to `className`.

Why was this change made? Application Display Templates were being referenced by their UUID, which was usually not known by the developer. Referencing all DDM templates by their class name simplifies using this tag.

Changed the Usage of Asset Preview

- **Date:** 2015-Mar-16
- **JIRA Ticket:** LPS-53972

What changed? Instead of directly including the JSP referenced by the `AssetRenderer`'s `getPreviewPath` method to preview an asset, you now use a taglib tag.

Who is affected? This affects developers who have written code that directly calls an `AssetRenderer`'s `getPreviewPath` method to preview an asset.

How should I update my code? JSP code that previews an asset by calling an `AssetRenderer`'s `getPreviewPath` method, such as in the example code below, must be replaced:

```
<liferay-util:include
    page="<%= assetRenderer.getPreviewPath(liferayPortletRequest, liferayPortletResponse) %>"
    portletId="<%= assetRendererFactory.getPortletId() %>"
    servletContext="<%= application %>"
/>
```

To preview an asset, you should instead use the `liferay-ui:asset-display` tag, passing it an instance of the asset entry and an asset renderer preview template. Here's an example of using the tag:

```
<liferay-ui:asset-display
    assetEntry="<%= assetEntry %>"
    template="<%= AssetRenderer.TEMPLATE_PREVIEW %>"
/>
```

Why was this change made? This change simplifies using asset previews.

Added New Methods in the ScreenNameValidator Interface

- **Date:** 2015-Mar-17
- **JIRA Ticket:** LPS-53409

What changed? The `ScreenNameValidator` interface has new methods `getDescription(Locale)` and `getJSValidation()`.

Who is affected? This affects developers who have implemented a custom screen name validator with the `ScreenNameValidator` interface.

How should I update my code? You should implement the new methods introduced in the interface.

- `getDescription(Locale)`: returns a description of what the screen name validator validates.
- `getJSValidation()`: returns the JavaScript input validator on the client side.

Why was this change made? Previous to Liferay 7, validation for user screen name characters was hard-coded in `UserLocalService`. A new portal property named `users.screen.name.special.characters` has been added to provide configurability of special characters allowed in screen names.

In addition, developers can now specify a custom input validator for the screen name on the client side by providing a JavaScript validator in `getJSValidation()`.

Replaced the Language Portlet's Display Styles with ADTs

- **Date:** 2015-Mar-30
- **JIRA Ticket:** LPS-54419

What changed? The custom display styles of the language tag added using JSPs no longer work. They have been replaced by Application Display Templates (ADT).

Who is affected? This affects developers that use the following properties:

```
language.display.style.default=icon

language.display.style.options=icon,long-text
```

How should I update my code? To style the Language portlet, you should use ADTs instead of using custom styles in your JSPs. ADTs can be created from the UI of the portal by navigating to *Site Settings → Application Display Templates*. ADTs can also be created programatically.

Why was this change made? ADTs allow you to change an application's look and feel without changing its JSP code.

Added Required Parameter groupId for Adding Tags, Categories, and Vocabularies

- **Date:** 2015-Mar-31
- **JIRA Ticket:** LPS-54570

What changed? The API for adding tags, categories, and vocabularies now requires passing the `groupId` parameter. Previously, it had to be included in the `ServiceContext` parameter passed to the method.

Who is affected? This affects developers who have direct calls to the following methods:

- `addTag` in `AssetTagService` or `AssetTagLocalService`
- `addCategory` in `AssetCategoryService` or `AssetCategoryLocalService`
- `addVocabulary` in `AssetVocabularyService` or `AssetVocabularyLocalService`
- `updateFolder` in `JournalFolderService` or `JournalFolderLocalService`

How should I update my code? You should add the `groupId` parameter to your calls. This parameter represents the site in which you are creating the tag, category, or vocabulary. It can be obtained from the `themeDisplay` or `serviceContext` using `themeDisplay.getScopeGroupId()` or `serviceContext.getScopeGroupId()`, respectively.

Why was this change made? This change was made in order improve the API. The `groupId` parameter was always required, but it was hidden by the `ServiceContext` object.

Removed the Tags that Start with portlet:icon-

- **Date:** 2015-Mar-31
- **JIRA Ticket:** LPS-54620

What changed? The following tags have been removed:

- `liferay-portlet:icon-close`
- `liferay-portlet:icon-configuration`
- `liferay-portlet:icon-edit`
- `liferay-portlet:icon-edit-defaults`
- `liferay-portlet:icon-edit-guest`
- `liferay-portlet:icon-export-import`
- `liferay-portlet:icon-help`
- `liferay-portlet:icon-maximize`
- `liferay-portlet:icon-minimize`
- `liferay-portlet:icon-portlet-css`
- `liferay-portlet:icon-print`
- `liferay-portlet:icon-refresh`
- `liferay-portlet:icon-staging`

Who is affected? This affects developers who have written code that uses these tags.

How should I update my code? The tag `liferay-ui:icon` can replace the call to the previous tags. All the previous tags have been converted into Java classes that implement the methods that the `icon` tag requires.

See the modules `portlet-configuration-icon-*` in the `modules/apps/web-experience/portlet-configuration` folder.

Why was this change made? These tags were used to generate the configuration icon of portlets. This functionality will now be managed from OSGi modules instead of tags since OSGi modules provide more flexibility and can be included in any app.

Changed the Default Value of the copy-request-parameters Init Parameter for MVC Portlets

- **Date:** 2015-Apr-15
- **JIRA Ticket:** LPS-54798

What changed? The `copy-request-parameters` init parameter's default value is now set to `true` in all portlets that extend `MVCPortlet`.

Who is affected? This affects developers that have created portlets that extend `MVCPortlet`.

How should I update my code? To continue using the property the same way you did before this change was implemented, you'll need to change the default property. To change the property, set the init parameter to `false` in your class extending `MVCPortlet`:

```
javax.portlet.init-param.copy-request-parameters=false
```

Why was this change made? This change was made to allow for backwards compatibility.

Removed Portal Properties Used to Display Sections in Form Navigators

- **Date:** 2015-Apr-16
- **JIRA Ticket:** LPS-54903

What changed? The following portal properties (and the equivalent `PropsKeys` and `PropsValues`) that were used to decide what sections would be displayed in the `form-navigator` have been removed:

- `company.settings.form.configuration`
- `company.settings.form.identification`
- `company.settings.form.miscellaneous`
- `company.settings.form.social`
- `journal.article.form.add`
- `journal.article.form.update`
- `journal.article.form.default.values`
- `layout.form.add`
- `layout.form.update`
- `layout.set.form.update`
- `organizations.form.add.identification`
- `organizations.form.add.main`
- `organizations.form.add.miscellaneous`
- `organizations.form.update.identification`
- `organizations.form.update.main`
- `organizations.form.update.miscellaneous`
- `sites.form.add.advanced`
- `sites.form.add.main`
- `sites.form.add.miscellaneous`
- `sites.form.add.seo`
- `sites.form.update.advanced`
- `sites.form.update.main`
- `sites.form.update.miscellaneous`

- `sites.form.update.seo`
- `users.form.add.identification`
- `users.form.add.main`
- `users.form.add.miscellaneous`
- `users.form.my.account.identification`
- `users.form.my.account.main`
- `users.form.my.account.miscellaneous`
- `users.form.update.identification`
- `users.form.update.main`
- `users.form.update.miscellaneous`

The sections and categories of form navigators are now OSGi components.

Who is affected? This affects administrators who may have added, removed, or reordered sections using those portal properties. Developers using the constants defined in `PropsKeys` or `PropsValues` for those portal properties will also be affected.

How should I update my code? Since those properties no longer exist, you cannot rely on them. References to the constants of `PropsKeys` and `PropsValues` will need to be updated. You can use `FormNavigatorCategoryUtil` and `FormNavigatorEntryUtil` to obtain a list of the available sections and categories for a form navigator instance.

Changes to remove or reorder specific sections will need to be done through the OSGi console to update the service ranking or stop the components.

Adding new sections with Liferay Hooks will still work as a legacy feature, but the recommended way is using OSGi components to add new sections.

Why was this change made? The old mechanism to add new sections to `form-navigator` tags was very limited because it could only depend on portal for services and utils due to the new section that was rendered from the portal classloader.

There was a need to add new sections and categories to `form-navigator` tags via OSGi plugins in a more extensible way, allowing the developer to include new sections to access to their own utils and services.

Removed the Type Setting breadcrumbShowParentGroups from Groups

- **Date:** 2015-Apr-21
- **JIRA Ticket:** LPS-54791

What changed? The type setting `breadcrumbShowParentGroups` was removed from groups and is no longer available in the site configuration. Now, it is only available in the breadcrumb configuration.

Who is affected? This affects all site administrators that have set the `showParentGroups` preference in Site Administration.

How should I update my code? There are no code updates required. This should only be updated at the portlet instance level.

Why was this change made? This change was introduced to support the new Settings API.

Changed Return Value of the Method getText of the Editor's Window API

- **Date:** 2015-Apr-28
- **JIRA Ticket:** LPS-52698

What changed? The method `getText` now returns the editor's content, without any HTML markup.

Who is affected? This affects developers that are using the `getText` method of the editor's window API.

How should I update my code? To continue using the editor the same way you did before this change was implemented, you should change calls to the `getText` method to instead call the `getHTML` method.

Why was this change made? This change was made in the editor's window API to provide a proper `getText` method that returns just the editor's content, without any HTML markup. This change is used for the blog abstract field.

Moved the Contact Name Exception Classes to Inner Classes of ContactNameException

- **Date:** 2015-May-05
- **JIRA Ticket:** LPS-55364

What changed? The use of classes `ContactFirstNameException`, `ContactFullNameException`, and `ContactLastNameException` has been moved to inner classes in a new class called `ContactNameException`.

Who is affected? This affects developers who may have included one of the three classes above in their code.

How should I update my code? While the old classes remain for backwards-compatibility, they are being deprecated. You're encouraged to use the new pattern of inner classes for exceptions wherever possible. For example, instead of using `ContactFirstNameExeception`, use `ContactNameException.MustHaveFirstName`.

Why was this change made? This change was made in accordance with the new exceptions pattern being applied throughout Portal. It also allows the new localized user name configuration feature to be thoroughly covered by exceptions for different configurations.

Removed USERS_LAST_NAME_REQUIRED from portal.properties in Favor of language.properties Configurations

- **Date:** 2015-May-07
- **JIRA Ticket:** LPS-54956

What changed? The `USERS_LAST_NAME_REQUIRED` property has been removed from `portal.properties` and the corresponding UI. Required names are now handled on a per-language basis via the `language.properties` files. It has also been removed as an option from the Portal Settings section of the Control Panel.

Who is affected? This affects anyone who uses the `USERS_LAST_NAME_REQUIRED` portal property.

How should I update my code? If you need to require the user's last name, list it on the `lang.user.name.required.field.names` line of the appropriate `language.properties` files:

```
lang.user.name.required.field.names=last-name
```

Why was this change made? Portal property `USERS_LAST_NAME_REQUIRED` didn't support the multicultural user name configurations introduced in LPS-48406. Language property files (e.g., `language.properties`) now support these configurations. Control of all user name configuration, except with regards to first name, is relegated to language property files. First name is required and always present.

Removed Methods getGroupLocalRepositoryImpl and getLocalRepositoryImpl from RepositoryLocalService and RepositoryService

- **Date:** 2015-May-14
- **JIRA Ticket:** LPS-55566

What changed? The methods `getGroupLocalRepositoryImpl(...)` and `getLocalRepositoryImpl(...)` have been removed from `RepositoryLocalService` and `RepositoryService`. Although the methods are related to the service, they belong in a different level of abstraction.

Who is affected? This affects anyone who uses those methods.

How should I update my code? The removed methods were generic and had long signatures with optional parameters. They now have one specialized version per parameter and are in the `RepositoryProvider` service.

Example

Old call:

```
RepositoryLocalServiceUtil.getRepositoryImpl(0, fileEntryId, 0)
```

New call:

```
RepositoryProviderUtil.getLocalRepositoryByFileEntryId(fileEntryId)
```

Why was this change made? This change was made to enhance the Repository API and facilitate decoupling the API from the Document Library, as a part of the portal modularization effort.

Removed addFileEntry Method from DLAppHelperLocalService

- **Date:** 2015-May-20
- **JIRA Ticket:** LPS-47645

What changed? The `addFileEntry` method has been removed from `DLAppHelperLocalService`.

Who is affected? This affects anyone who calls the `addFileEntry` method.

How should I update my code? If you need to invoke the `addFileEntry` method as part of a custom repository implementation, use the provided repository capabilities instead. See `LiferayRepositoryDefiner` for examples on their use.

For other use cases, you may need to explicitly invoke each of the service methods used by `addFileEntry`.

Why was this change made? The logic inside the `addFileEntry` method was moved, out from `DLAppHelperLocalService` and into repository capabilities, to further decouple core repository implementations from additional (optional) functionality.

Indexers Called from Document Library Now Receive FileEntry Instead of DLFileEntry

- **Date:** 2015-May-20
- **JIRA Ticket:** LPS-55613

What changed? Indexers that previously received a `DLFileEntry` object (e.g., in the `addRelatedEntryFields` method) no longer receive a `DLFileEntry`, but a `FileEntry`.

Who is affected? This affects anyone who implements an Indexer handling `DLFileEntry` objects.

How should I update my code? You should try to use methods in `FileEntry` or exported repository capabilities to obtain the value you were using. If no capability exists for your use case, you can resort to calling `fileEntry.getModel()` and casting the result to a `DLFileEntry`. However, this breaks all encapsulation and may result in future failures or compatibility problems.

Old code:

```
@Override
public void addRelatedEntryFields(Document document, Object obj)
    throws Exception {

    DLFileEntry dlFileEntry = (DLFileEntry)obj;

    long fileEntryId = dlFileEntry.getFileEntryId();
```

New Code:

```
@Override
public void addRelatedEntryFields(Document document, Object obj)
    throws Exception {

    FileEntry fileEntry = (FileEntry)obj;

    long fileEntryId = fileEntry.getFileEntryId();
```

Why was this change made? This change was made to enhance the Repository API and make decoupling from Document Library easier when modularizing the portal.

Removed permissionClassName, permissionClassPK, and permissionOwner Parameters from MBMessage API

- **Date:** 2015-May-27
- **JIRA Ticket:** LPS-55877

What changed? The parameters `permissionClassName`, `permissionClassPK`, and `permissionOwner` have been removed from the Message Boards API and Discussion tag.

Who is affected? This affects anyone who invokes the affected methods (locally or remotely) and any view that uses the Discussion tag.

How should I update my code? It suffices to remove the parameters from the method calls (for consumers of the API) or the attributes in tag invocations.

Why was this change made? Those API methods were exposed in the remote services, allowing any consumer to bypass the permission system by providing customized `className`, `classPK`, or `ownerId` parameters.

Moved Indexer.addRelatedEntryFields and Indexer.reindexDDMStructures, and Removed Indexer.getQueryString

- **Date:** 2015-May-27
- **JIRA Ticket:** LPS-55928

What changed? Method `Indexer.addRelatedEntryFields(Document, Object)` has been moved into `RelatedEntryIndexer`.

`Indexer.reindexDDMStructures(List<Long>)` has been moved into `DDMStructureIndexer`.

`Indexer.getQueryString(SearchContext, Query)` has been removed, in favor of calling `SearchEngineUtil.getQueryString(S`
`Query)`

Who is affected? This affects any code that invokes the affected methods, as well as any code that implements the interface methods.

How should I update my code? Any code implementing `Indexer.addRelatedEntryFields(...)` should implement the `RelatedEntryIndexer` interface.

Any code calling `Indexer.addRelatedEntryFields(...)` should determine first if the `Indexer` is an instance of `RelatedEntryIndexer`.

Old code:

```
mbMessageIndexer.addRelatedEntryFields(...);
```

New code:

```
if (mbMessageIndexer instanceof RelatedEntryIndexer) {
    RelatedEntryIndexer relatedEntryIndexer =
        (RelatedEntryIndexer)mbMessageIndexer;

    relatedEntryIndexer.addRelatedEntryFields(...);
}
```

Any code implementing `Indexer.reindexDDMStructures(...)` should implement the `DDMStructureIndexer` interface.

Any code calling `Indexer.reindexDDMStructures(...)` should determine first if the `Indexer` is an instance of `DDMStructureIndexer`.

Old code:

```
mbMessageIndexer.reindexDDMStructures(...);
```

New code:

```
if (journalIndexer instanceof DDMStructureIndexer) {
    DDMStructureIndexer ddmStructureIndexer =
        (DDMStructureIndexer)journalIndexer;

    ddmStructureIndexer.reindexDDMStructures(...);
}
```

Any code calling `Indexer.getQueryString(...)` should call `SearchEngineUtil.getQueryString(...)`.

Old code:

```
mbMessageIndexer.getQueryString(...);
```

New code:

```
SearchEngineUtil.getQueryString(...);
```

Why was this change made? The `addRelatedEntryFields` and `reindexDDMStructures` methods were not related to core indexing functions. They were functions of specialized indexers.

The `getQueryString` method was an unnecessary convenience method.

Removed mbMessages and fileEntryTuples Attributes from app-view-search-entry Tag

- **Date:** 2015-May-27
- **JIRA Ticket:** LPS-55886

What changed? The `mbMessages` and `fileEntryTuples` attributes from the `app-view-search-entry` tag have been removed. Related methods `getMbMessages`, `getFileEntryTuples`, and `addMbMessage` have also been removed from the `SearchResult` class.

Who is affected? This affects developers that use the `app-view-search-entry` tag in their views, have developed hooks to customize the tag JSP, or have developed a portlet that uses that tag. Also, any custom code that uses the `SearchResult` class may be affected.

How should I update my code? The new attributes `commentRelatedSearchResults` and `fileEntryRelatedSearchResults` should be used instead. The expected value is the one returned by the `getCommentRelatedSearchResults` and `getFileEntryRelatedSearchResults` methods in `SearchResult`.

When adding comments to the `SearchResult`, the new `addComment` method should be used instead of the `addMbMessage` method.

Why was this change made? As part of the modularization efforts, references to `MBMessage` needed to be removed for the Message Boards portlet to be placed into its own OSGi bundle.

Replaced Method getPermissionQuery with getPermissionFilter in SearchPermissionChecker, and getFacetQuery with getFacetBooleanFilter in Indexer

- **Date:** 2015-Jun-02
- **JIRA Ticket:** LPS-56064

What changed? Method `SearchPermissionChecker.getPermissionQuery( long, long[], long, String, Query, SearchContext)` has been replaced by `SearchPermissionChecker.getPermissionBooleanFilter( long, long[], long, String, BooleanFilter, SearchContext)`.

Method `Indexer.getFacetQuery(String, SearchContext)` has been replaced by `Indexer.getFacetBooleanFilter(String, SearchContext)`.

Who is affected? This affects any code that invokes the affected methods, as well as any code that implements the interface methods.

How should I update my code? Any code calling/implementing `SearchPermissionChecker.getPermissionQuery(...)` should instead call/implement `SearchPermissionChecker.getPermissionBooleanFilter(...)`.

Any code calling/implementing `Indexer.getFacetQuery(...)` should instead call/implement `Indexer.getFacetBooleanFilter(...)`.

Why was this change made? Permission constraints placed on search should not affect the score for returned search results. Thus, these constraints should be applied as search filters. `SearchPermissionChecker` is also a very deep internal interface within the permission system. Thus, to limit confusion in the logic for maintainability, the `SearchPermissionChecker.getPermissionQuery(...)` method was removed as opposed to deprecated.

Similarly, constraints applied to facets should not affect the scoring or facet counts. Since `Indexer.getFacetQuery(...)` was only utilized by the `AssetEntriesFacet`, and used to reduce the impact of changes for `SearchPermissionChecker.getPermissionBooleanFilter(...)`, the method was removed as opposed to deprecated.

Added userId Parameter to Update Operations of DDMStructureLocalService and DDMTemplateLocalService

- **Date:** 2015-Jun-05
- **JIRA Ticket:** LPS-50939

What changed? A new parameter `userId` has been added to the `updateStructure` and `updateTemplate` methods of the `DDMStructureLocalService` and `DDMTemplateLocalService` classes, respectively.

Who is affected? This affects any code that invokes the affected methods, as well as any code that implements the interface methods.

How should I update my code? Any code calling/implementing `DDMStructureLocalServiceUtil.updateStructure(...)` or `DDMTemplateLocalServiceUtil.updateTemplate(...)` should pass the new `userId` parameter.

Why was this change made? For the service to keep track of which user is modifying the structure or template, the `userId` parameter was required. In order to add support to structure and template versions, audit columns were also added to such models.

Removed Method getEntries from DL, DLImpl, and DLUtil Classes

- **Date:** 2015-Jun-10
- **JIRA Ticket:** LPS-56247

What changed? The method `getEntries` has been removed from the `DL`, `DLImpl`, and `DLUtil` classes.

Who is affected? This affects any caller of the `getEntries` method.

How should I update my code? You may use the `SearchResultUtil` class to process the search results. Note that this class is not completely equivalent; if you need exactly the same behavior as the removed method, you will need to add custom code.

Why was this change made? The `getEntries` method was no longer used, and contained hardcoded references to classes that will be moved into OSGi bundles.

Removed WikiUtil.getEntries Method

- **Date:** 2015-Jun-10
- **JIRA Ticket:** LPS-56242

What changed? The method `getEntries()` has been removed from class `WikiUtil`.

Who is affected? Any JSP hook or ext plugin that uses this method is affected. As the class was located in portal-impl, regular portlets and other safe extension points won't be affected.

How should I update my code? You should review the JSP or ext plugin, updating it to remove any reference to the new class and mimicking the original JSP code. In case you need equivalent functionality to the one provided by `WikiUtil.getEntries()` you may use the `SearchResultUtil` class. While not totally equivalent, it offers similar functionality.

Why was this change made? The `WikiUtil.getEntries()` method was no longer used, and it contained hardcoded references to classes that will be moved into OSGi modules.

Removed render Method from ConfigurationAction API

- **Date:** 2015-Jun-14
- **JIRA Ticket:** LPS-56300

What changed? The method `render` has been removed from the interface `ConfigurationAction`.

Who is affected? This affects any Java code calling the method `render` on a `ConfigurationAction` class, or Java classes overriding the `render` method of a `ConfigurationAction` class.

How should I update my code? The method `render` was used to return the path of a JSP, including the configuration of a portlet. That method is now available for configurations extending the `BaseJSPSettingsConfigurationAction` class, and is called `getJspPath`.

If any logic was added to override the `render` method, it can now be added in the `include` method.

Why was this change made? This change was part of needed modifications to support adding configuration for portlets based on other technology different than JSP (e.g., FreeMarker). The method `include` can now be used to create configuration UIs written in FreeMarker or any other framework.

Removed ckconfig Files Used for CKEditor Configuration

- **Date:** 2015-Jun-16
- **JIRA Ticket:** LPS-55518

What changed? The files `ckconfig.jsp`, `ckconfig-ext.jsp`, `ckconfig_bbcode.jsp`, `ckconfig_bbcode-ext.jsp`, `ckconfig_creole.jsp`, and `ckconfig_creole-ext.jsp` have been removed and are no longer used to configure the CKEditor instances created using the `liferay-ui:input-editor` tag.

Who is affected? This affects any hook or plugin-ext overriding these files to modify the editor configuration.

How should I update my code? Depending on the changes, different extension methods are available:

- For CKEditor configuration options, an implementation of `EditorConfigContributor` can be created to pass or modify the expected parameters.
- For CKEditor instance manipulation (setting attributes, adding listeners, etc.), the `DynamicInclude` extension point `#ckeditor[_creole|_bbcode]#onEditorCreated` has been added to provide the possibility of injecting JavaScript, when needed.

Why was this change made? This change is part of a greater effort to provide mechanisms to extend and configure any editor in Liferay Portal in a coherent and extensible way.

Renamed ActionCommand Classes Used in the MVCPortlet Framework

- **Date:** 2015-Jun-16
- **JIRA Ticket:** LPS-56372

What changed? The classes located in the `com.liferay.portal.kernel.portlet.bridges.mvc` package have been renamed to include the *MVC* prefix.

Old Classes:

- `BaseActionCommand`
- `BaseTransactionalActionCommand`
- `ActionCommand`
- `ActionCommandCache`

New Classes:

- `BaseMVCActionCommand`
- `BaseMVCTransactionalActionCommand`
- `MVCActionCommand`
- `MVCActionCommandCache`

Also, the property `action.command.name` has been renamed to `mvc.command.name`. The code snippet below shows the new property in its context.

```
@Component(
    immediate = true,
    property = {
            "javax.portlet.name=" + InvitationPortletKeys.INVITATION,
            "mvc.command.name=view"
    },
    service = MVCActionCommand.class
)
```

Who is affected? This affects any Java code calling the `ActionCommand` classes used in the `MVCPortlet` framework.

How should I update my code? You should update the old `ActionCommand` class names with the new *MVC* prefix.

Why was this change made? This change adds consistency to the MVC framework, and makes it self-explanatory what classes should be used for the MVC portlet.

Extended MVC Framework to Use Same Key for Registering ActionURL and ResourceURL

- **Date:** 2015-Jun-16
- **JIRA Ticket:** LPS-56372

What changed? Previously, a single `ActionCommand` was valid for both `ActionURL` and `ResourceURL`. Now you must distinguish both an `ActionURL` and `ResourceURL` as different actions, which means you can register both with the same key.

Who is affected? This affects developers that were using the `ActionCommand` for `actionURLs` and `resourceURLs`.

How should I update my code? You should replace the `ActionCommands` used for `actionURLs` and `resourceURLs` to use `MVCActionCommand` and `MVCResourceCommand`, respectively. For example, for the new `MVCResourceCommand`, you'll need to use the `resourceID` of the `resourceURL` instead of using `ActionRequest.ACTION_NAME`.

Old Code:

```
<liferay-portlet:resourceURL copyCurrentRenderParameters="<%= false %>" var="exportRecordSetURL">
    <portlet:param name="<%= ActionRequest.ACTION_NAME %>" value="exportRecordSet" />
    <portlet:param name="recordSetId" value="<%= String.valueOf(recordSet.getRecordSetId()) %>" />
</liferay-portlet:resourceURL>
```

New Code:

```
<liferay-portlet:resourceURL copyCurrentRenderParameters="<%= false %>" id="exportRecordSet" var="exportRecordSetURL">
    <portlet:param name="recordSetId" value="<%= String.valueOf(recordSet.getRecordSetId()) %>" />
</liferay-portlet:resourceURL>
```

Why was this change made? This change was made to extend the MVC framework to have better support for `actionURLs` and `resourceURLs`.

Changed Java Package Names for Portlets Extracted as Modules

- **Date:** 2015-Jun-29
- **JIRA Ticket:** LPS-56383 and others

What changed? The Java package names changed for portlets that were extracted as OSGi modules in 7.0. Here is the complete list:

- `com.liferay.portlet.bookmarks` → `com.liferay.bookmarks`
- `com.liferay.portlet.dynamicdatalists` → `com.liferay.dynamicdatalists`
- `com.liferay.portlet.journal` → `com.liferay.journal`
- `com.liferay.portlet.polls` → `com.liferay.polls`
- `com.liferay.portlet.wiki` → `com.liferay.wiki`

Who is affected? This affects developers using the portlets API from their own plugins.

How should I update my code? Update the package imports to use the new package names. Any literal usage of the portlet `className` should also be updated.

Why was this change made? Package names have been adapted to the new condition of Liferay portlets as OSGi services.

Removed the DLFileEntryTypes_DDMStructures Mapping Table

- **Date:** 2015-Jul-01
- **JIRA Ticket:** LPS-56660

What changed? The `DLFileEntryTypes_DDMStructures` mapping table is no longer available.

Who is affected? This affects developers using the Document Library File Entry Type Local Service API.

How should I update my code? Update the calls to `addDDMStructureLinks`, `deleteDDMStructureLinks`, and `updateDDMStructureLinks` if you want to add, delete, or update references between `DLFileEntryType` and `DDMStructures`.

Why was this change made? This change was made to reduce the coupling between the two applications.

Removed render Method from AssetRenderer API and WorkflowHandler API

- **Date:** 2015-Jul-03
- **JIRA Ticket:** LPS-56705

What changed? The method `render` has been removed from the interfaces `AssetRenderer` and `WorkflowHandler`.

Who is affected? This affects any Java code calling the method `render` on an `AssetRenderer` or `WorkflowHandler` class, or Java classes overriding the `render` method of these classes.

How should I update my code? The method `render` was used to return the path of a JSP, including the configuration of a portlet. That method is now available for the same AssetRender API extending the `BaseJSPAssetRenderer` class, and is called `getJspPath`.

If any logic was added to override the `render` method, it can now be added in the `include` method.

Why was this change made? This change was part of needed modifications to support adding asset renderers and workflow handlers for portlets based on other technology different than JSP (e.g., FreeMarker). The method `include` can now be used to create asset renderers or workflow handlers with UIs written in FreeMarker or any other framework.

Renamed ADMIN_INSTANCE to PORTAL_INSTANCES in PortletKeys

- **Date:** 2015-Jul-08
- **JIRA Ticket:** LPS-56867

What changed? The constant `PortletKeys.ADMIN_INSTANCE` has been renamed as `PortletKeys.PORTAL_INSTANCES`.

Who is affected? This affects developers using the old constant in their code; for example, creating a direct link to it. This is not common and usually not a good practice, so this should not affect many people.

How should I update my code? You should rename the constant `ADMIN_INSTANCE` to `PORTAL_INSTANCES` everywhere it is used.

Why was this change made? This change was part of needed modifications to extract the Portal Instances portlet from the Admin portlet. The constant's old name was not accurate, since it originated from the old Admin portlet. Since the Portal Instances portlet is now extracted to its own module, the old name no longer resembles its usage.

Removed Support for filterFindBy Generation or InlinePermissionUtil Usage for Tables When the Primary Key Type Is Not long

- **Date:** 2015-Jul-21
- **JIRA Ticket:** LPS-54590

What changed? ServiceBuilder and inline permission filter support has been removed for non-`long` primary key types.

Who is affected? This affects code that is using `int`, `float`, `double`, `boolean`, or `short` type primary keys in the `service.xml` with inline permissions.

How should I update my code? You should change the primary key type to `long`.

Why was this change made? Inline permissioning was using the `join` method between two different data types and that caused significant performance degradation with `filterFindBy` queries.

Removed Vaadin 6 from Liferay Core

- **Date:** 2015-Jul-31
- **JIRA Ticket:** LPS-57525

What changed? The bundled Vaadin 6.x JAR file has been removed from portal core.

Who is affected? This affects developers who are creating Vaadin portlet applications in Liferay Portal.

How should I update my code? You should upgrade to Vaadin 7, bundle your `vaadin.jar` with your plugin, or deploy Vaadin libraries to Liferay's OSGi container.

Why was this change made? Vaadin 6.x is outdated and there are no plans for any new projects to be created with it. Therefore, developers should begin using Vaadin 7.x.

Replaced the Navigation Menu Portlet's Display Styles with ADTs

- **Date:** 2015-Jul-31
- **JIRA Ticket:** LPS-27113

What changed? The custom display styles of the navigation tag added using JSPs no longer work. They have been replaced by Application Display Templates (ADT).

Who is affected? This affects developers that use portlet properties with the following prefix:

```
navigation.display.style
```

This also affects developers that use the following attribute in the navigation tag:

```
displayStyleDefinition
```

How should I update my code? To style the Navigation portlet, you should use ADTs instead of using custom styles in your JSPs. ADTs can be created from the UI of the portal by navigating to *Site Settings → Application Display Templates*. ADTs can also be created programatically.

Developers should use the `ddmTemplateGroupId` and `ddmTemplateKey` attributes of the navigation tag to set the ADT that defines the style of the navigation.

Why was this change made? ADTs allow you to change an application's look and feel without changing its JSP code.

Renamed URI Attribute Used to Generate AUI Tag Library

- **Date:** 2015-Aug-12
- **JIRA Ticket:** LPS-57809

What changed? The URI attribute used to identify the AUI taglib has been renamed.

Who is affected? This affects developers that use the URI `http://alloy.liferay.com/tld/aui` in their JSPs, XMLs, etc.

How should I update my code? You should use the new AUI URI declaration:

Old:

```
http://alloy.liferay.com/tld/aui
```

New:

```
http://liferay.com/tld/aui
```

Why was this change made? To stay consistent with other taglibs provided by Liferay, the AUI `.tld` file was modified to start with the prefix `liferay-`. Due to this change, the XML files used to automatically generate the AUI taglib were modified, changing the AUI URI declaration.

Removed Support for runtime-portlet Tag in Body of Web Content Articles

- **Date:** 2015-Sep-17
- **JIRA Ticket:** LPS-58736

What changed? The tag `runtime-portlet` is no longer replaced by a portlet if it is found in the body of a web content article.

Who is affected? This affects any web content in the database (`JournalArticle` table) that uses this tag.

How should I update my code? Embedding another portlet is only supported from a template. You should embed the portlet by passing its name in a call to `theme.runtime` or using the right tag in FreeMarker.

Example

In Velocity:

```
$theme.runtime("145")
```

In FreeMarker:

```
<#assign liferay_portlet = PortalJspTagLibs["/WEB-INF/tld/liferay-portlet-ext.tld"] />

<@liferay_portlet["runtime"] portletName="145" />
```

Why was this change made? This change improves the performance of web content articles while enforcing a single way to embed portlets into the page for better testing.

Removed the liferay-ui:control-panel-site-selector Tag

- **Date:** 2015-Sep-23
- **JIRA Ticket:** LPS-58210

What changed? The tag `liferay-ui:control-panel-site-selector` has been deleted.

Who is affected? This affects developers who use this tag in their code.

How should I update my code? You should consider using the tag `liferay-ui:my-sites`, or create your own markup using the `GroupService` API.

Why was this change made? This tag is no longer used and will no longer be maintained properly.

Removed Methods Related to Control Panel in PortalUtil

- **Date:** 2015-Sep-23
- **JIRA Ticket:** LPS-58210

What changed? The following methods have been deleted:

- `getControlPanelCategoriesMap`
- `getControlPanelCategory`
- `getControlPanelPortlets`
- `getFirstMyAccountPortlet`
- `getFirstSiteAdministrationPortlet`
- `getSiteAdministrationCategoriesMap`
- `getSiteAdministrationURL`
- `isCompanyControlPanelVisible`

Who is affected? This affects developers that use any of the methods listed above.

How should I update my code? In order to work with applications displayed in the Product Menu, developers should call the `PanelCategoryRegistry` and `PanelAppRegistry` classes located in the `application-list-api` module. These classes allow developers to interact with categories and applications in the Control Panel.

Why was this change made? These methods are no longer used and they will not work properly since they cannot call the `application-list-api` from the portal context.

Removed ThemeDisplay Methods Related to Control Panel and Site Administration

- **Date:** 2015-Sep-23
- **JIRA Ticket:** LPS-58210

What changed? The following methods have been deleted:

- `getControlPanelCategory`
- `getURLSiteAdministration`

Who is affected? This affects developers that use either of the methods listed above.

How should I update my code? Site Administration is not a site per se; some applications are displayed in that context. To create a link to an application that is displayed in Site Administration, developers should use the method `PortalUtil.getControlPanelURL`. In order to obtain the first application displayed in a section of the Product Menu, developers should use the `application-list-api` module to call the `PanelCategoryRegistry` and `PanelAppRegistry` classes.

Why was this change made? These methods are no longer used and they will not work properly since they cannot call the `application-list-api` from the portal context.

Removed Control Panel from List of Sites Returned by Methods Group.getUserSitesGroups and User.getMySiteGroups

- **Date:** 2015-Sep-23
- **JIRA Ticket:** LPS-58862

What changed? The following methods had a boolean parameter to determine whether to include the Control Panel group:

- `Group.getUserSitesGroups`
- `User.getMySiteGroups`

This boolean parameter should no longer be used.

Who is affected? This affects developers that use either of the methods listed above passing the `includeControlPanel` parameter as `true`.

How should I update my code? If you don't need the Control Panel, remove the `false` parameter. If you still want to obtain a link to the Control Panel, you should do it in a different way.

The Control Panel is not a site per se; some applications are displayed in that context. To create a link to an application that is displayed in the Control Panel, developers should use the method `PortalUtil.getControlPanelURL`. In order to obtain the first application displayed in a section of the Product Menu, developers should use the `application-list-api` module to call the `PanelCategoryRegistry` and `PanelAppRegistry` classes.

Why was this change made? The Control Panel is no longer a site per se, but just a context in which some applications are displayed. This concept conflicts with the idea of returning a site called Control Panel in the Sites API.

Changed Exception Thrown by Documents and Media Services When Duplicate Files are Found

- **Date:** 2015-Sep-24
- **JIRA Ticket:** LPS-53819

What changed? When a duplicate file entry is found by Documents and Media (D&M) services, a `DuplicateFileEntryException` will be thrown. Previously, the exception `DuplicateFileException` was used.

The `DuplicateFileException` is now raised only by `Store` implementations.

Who is affected? Any caller of the `addFileEntry` methods in `DLApp` and `DLFileEntry` local and remote services is affected.

How should I update my code? Change the exception type from `DuplicateFileException` to `DuplicateFileEntryException` in `try-catch` blocks surrounding calls to D&M services.

Why was this change made? The `DuplicateFileException` exception was used in two different contexts:

- When creating a new file through D&M and a row in the database already existed for a file entry with the same title.
- When the stores tried to save a file and the underlying storage unit (a file in the case of `FileSystemStore`) already existed.

This made it impossible to detect and recover from store corruption issues, as they were undifferentiable from other errors.

Removed All References to Windows Live Messenger

- **Date:** 2015-Oct-15
- **JIRA Ticket:** LPS-30883

What changed? All references to the `msnSn` column in the Contacts table have been removed from portal. All references to Windows Live Messenger have been removed from properties, tests, classes, and the frontend. Also, the `getMsnSn` and `setMsnSn` methods have been removed from the `Contact` and `LDAPUser` models.

The following classes have been removed:

- `MSNConnector`

- `MSNMessageAdapter`

The following constants have been removed:

- `CalEventConstants.REMIND_BY_MSN`
- `ContactConverterKeys.MSN_SN`
- `PropsKeys.MSN_LOGIN`
- `PropsKeys.MSN_PASSWORD`

The following methods have been removed:

- `Contact.getMsnSn`
- `Contact.setMsnSn`
- `LDAPUser.getMsnSn`
- `LDAPUser.setMsnSn`

The following methods have been changed:

- `AdminUtil.updateUser`
- `ContactLocalServiceUtil.addContact`
- `ContactLocalServiceUtil.updateContact`
- `UserLocalServiceUtil.addContact`
- `UserLocalServiceUtil.updateContact`
- `UserLocalServiceUtil.updateUser`
- `UserServiceUtil.updateUser`

Who is affected? This affects developers who use any of the classes, constants, or methods listed above.

How should I update my code? When updating or adding a user or contact using one of the changed methods above, remove the `msnSn` argument from the method call. If you are using one of the removed items above, you should remove all references to them from your code and look for alternatives, if necessary. Lastly, remove any references to the `msnSN` column in the Contacts table from your SQL queries.

Why was this change made? Since Microsoft dropped support for Windows Live Messenger, Liferay will no longer continue to support it.

Removed Support for AIM, ICQ, MySpace, and Yahoo Messenger

- **Date:** 2015-Oct-22
- **JIRA Ticket:** LPS-59716

What changed? Liferay no longer supports integration with MySpace and AIM, ICQ, and Yahoo Messenger instant messaging services. The corresponding `aimSn`, `icqSn`, `mySpaceSn`, and `ymSn` columns have been removed from the `Contacts` table.

The following classes have been removed:

- `AIMConnector`
- `ICQConnector`
- `YMConnector`

The following constants have been removed:

- `CalEventConstants.REMIND_BY_AIM`
- `CalEventConstants.REMIND_BY_ICQ`
- `CalEventConstants.REMIND_BY_YM`
- `ContactConverterKeys.AIM_SN`
- `ContactConverterKeys.ICQ_SN`
- `ContactConverterKeys.MYSPACE_SN`
- `ContactConverterKeys.YM_SN`
- `PropsKeys.AIM_LOGIN`
- `PropsKeys.AIM_PASSWORD`
- `PropsKeys.ICQ_JAR`
- `PropsKeys.ICQ_LOGIN`
- `PropsKeys.ICQ_PASSWORD`
- `PropsKeys.YM_LOGIN`
- `PropsKeys.YM_PASSWORD`

The following methods have been removed:

- `getAimSn`
- `getIcqSn`
- `getMySpaceSn`
- `getYmSn`
- `setAimSn`
- `setIcqSn`
- `setMySpaceSn`
- `setYmSn`

The following methods have been changed:

- `updateUser`
- `addContact`

The following portal properties have been removed:

- `aim.login`
- `aim.password`
- `icq.jar`
- `icq.login`
- `icq.password`
- `ym.login`
- `ym.password`

Who is affected? This affects developers who use any of the classes, constants, methods, or properties listed above.

How should I update my code? When updating or adding a user or contact using one of the changed methods above, remove the `aimSn`, `icqSn`, `mySpaceSn`, and `ymSn` arguments from the method call. If you are using one of the removed items above, you should remove all references to them from your code and look for alternatives, if necessary. Lastly, remove from your SQL queries any references to former `Contacts` table columns `aimSn`, `icqSn`, `mySpaceSn`, and `ymSn`.

Also, a reference to any one of the removed portal properties above no longer returns a value.

Why was this change made? The services removed in this change are no longer popular enough to merit continued support.

Removed All Methods from SchedulerEngineHelper that Explicitly Schedule Jobs Using SchedulerEntry or Specify MessageListener Class Names

- **Date:** 2015-Oct-29
- **JIRA Ticket:** LPS-59681

What changed? The following methods were removed from `SchedulerEngine`:

- `SchedulerEngineHelper.addJob(Trigger, StorageType, String, String, Message, String, String, int)`
- `SchedulerEngineHelper.addJob(Trigger, StorageType, String, String, Object, String, String, int)`
- `SchedulerEngineHelper.schedule(SchedulerEntry, StorageType, String, int)`

Who is affected? This affects developers that use the above methods to schedule jobs into the `SchedulerEngine`.

How should I update my code? You should update your code to call one of these methods:

- `SchedulerEngineHelper.schedule(Trigger, StorageType, String, String, Message, int)`
- `SchedulerEngineHelper.schedule(Trigger, StorageType, String, String, Object, int)`

Instead of simply providing the class name of your scheduled job listener, you should follow these steps:

1. Instantiate your MessageListener.
2. Call `SchedulerEngineHelper.register(MessageListener, SchedulerEntry)` to register your `SchedulerEventMessageListen`

Why was this change made? The deleted methods provided facilities that aren't compatible with using declarative services in an OSGi container. The new approach allows for proper injection of dependencies into scheduled event message listeners.

Removed the asset.publisher.query.form.configuration Property

- **Date:** 2015-Nov-03
- **JIRA Ticket:** LPS-60119

What changed? The `asset.publisher.query.form.configuration` property has been removed from `portal.properties`.

Who is affected? This affects any hook that uses the `asset.publisher.query.form.configuration` property.

How should I update my code? If you are using this property to generate the UI for an Asset Entry Query Processor, your Asset Entry Query Processor must now implement the `include` method to generate the UI.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal.

Removed Hover and Alternate Style Features of Search Container Tag

- **Date:** 2015-Nov-03
- **JIRA Ticket:** LPS-58854

What changed? The following attributes and methods have been removed:

- The attribute `hover` of the `liferay-ui:search-container` tag.
- The method `isHover()` of the `SearchContainerTag` class.
- The attributes `classNameHover`, `hover`, `rowClassNameAlternate`, `rowClassNameAlternateHover`, `rowClassNameBody`, `rowClassNameBodyHover` of the `liferay-search-container` JavaScript module.

Who is affected? This affects developers that use the `hover` attribute of the `liferay-ui:search-container` tag.

How should I update my code? You should update your code changing the CSS selector that defines how rows look on hover to use the `:hover` and `:nth-of-type` CSS pseudo selectors instead.

Why was this change made? Browsers support better ways to style content on hover in a way that doesn't penalize performance. Therefore, this change was made to increase the performance of hovering over content in Liferay.

Removed AppViewMove and AppViewSelect JavaScript Modules

- **Date:** 2015-Nov-03
- **JIRA Ticket:** LPS-58854

What changed? The JavaScript modules `AppViewMove` and `AppViewSelect` have been removed.

Who is affected? This affects developers that use these modules to configure *select* and *move* actions inside their applications.

How should I update my code? If you are using any of these modules, you can make use of the following `SearchContainer` APIs:

- Listen to the `rowToggled` event of the search container to be notified about changes to the search container state.
- Configure your search container *move* options creating a `RowMover` and define the allowed *move* targets and associated actions.
- Use the `registerAction` method of the search container to execute your *move* logic when the user completes a *move* action.

Why was this change made? The removed JavaScript modules contained too much logic and were difficult to decipher. It was also difficult to add this to an existing app. With this change, every app using a search container can use this functionality much easier.

Removed the mergeLayoutTags Preference from Asset Publisher

- **Date:** 2015-Nov-20
- **JIRA Ticket:** LPS-60677

What changed? The `mergeLayoutTags` preference has been removed from the Asset Publisher.

Who is affected? This affects any Asset Publisher portlet that uses this preference.

How should I update my code? There is nothing to update since this functionality is no longer used.

Why was this change made? In previous versions of Liferay, some applications such as Blogs and Wiki shared the tags of their entries within the page. The Asset Publisher was able to use them to show other assets with the same tags. This functionality has changed, so the preference is no longer used.

Removed the liferay-ui:navigation Tag and Replaced with liferay-site-navigation:navigation Tag

- **Date:** 2015-Nov-20
- **JIRA Ticket:** LPS-60328

What changed? The `liferay-ui:navigation` tag has been removed and replaced with the `liferay-site-navigation:navigation` tag.

Who is affected? Plugins or templates that are using the `liferay-ui:navigation` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-site-navigation` tag library (if necessary) and update the tag namespace from `liferay-ui:navigation` to `liferay-site-navigation:navigation`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Removed Software Catalog Portlet and Services

- **Date:** 2015-Nov-21
- **JIRA Ticket:** LPS-60705

What changed? The Software Catalog portlet and its associated services are no longer part of Liferay's source code or binaries.

Who is affected? This affects portals which were making use of the Software Catalog portlet to manage a catalog of their software. Developers who were making use of the software catalog services from their custom code are also affected.

How should I update my code? There is no direct replacement for invocations to the Software Catalog services. In cases where it is really needed, it is possible to obtain the code from a previous release and include it in the custom product (subject to licensing).

Why was this change made? The Software Catalog was developed to implement the very first versions of what later become Liferay's Marketplace. It was later replaced and has not been used by Liferay since then. It has also been used minimally outside of Liferay. The decision was made to remove it so Liferay could be more lightweight and free time to focus on other areas of the product that add more value.

Removed the liferay-ui:asset-categories-navigation Tag and Replaced with liferay-asset:asset-categories-navigation

- **Date:** 2015-Nov-25
- **JIRA Ticket:** LPS-60753

What changed? The `liferay-ui:asset-categories-navigation` tag has been removed and replaced with the `liferay-asset:asset-categories-navigation` tag.

Who is affected? Plugins or templates that are using the `liferay-ui:asset-categories-navigation` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-asset` tag library (if necessary) and update the tag namespace from `liferay-ui:asset-categories-navigation` to `liferay-asset:asset-categories-navigation`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Removed the liferay-ui:trash-empty Tag and Replaced with liferay-trash:empty

- **Date:** 2015-Nov-30
- **JIRA Ticket:** LPS-60779

What changed? The `liferay-ui:trash-empty` tag has been removed and replaced with the `liferay-trash:empty` tag.

Who is affected? Plugins and templates that are using the `liferay-ui:trash-empty` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-trash` tag library (if necessary) and update the tag namespace from `liferay-ui:trash-empty` to `liferay-trash:empty`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Removed the liferay-ui:trash-undo Tag and Replaced with liferay-trash:undo

- **Date:** 2015-Nov-30
- **JIRA Ticket:** LPS-60779

What changed? The `liferay-ui:trash-undo` taglib has been removed and replaced with the `liferay-trash:undo` tag.

Who is affected? Plugins and templates that are using the `liferay-ui:trash-undo` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-trash` tag library (if necessary) and update the tag namespace from `liferay-ui:trash-undo` to `liferay-trash:undo`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Removed the getPageOrderByComparator Method from WikiUtil

- **Date:** 2015-Dec-01
- **JIRA Ticket:** LPS-60843

What changed? The `getPageOrderByComparator` method has been removed from `WikiUtil`.

Who is affected? This affects developers that use this method in their code.

How should I update my code? You should update your code to invoke `WikiPortletUtil.getPageOrderByComparator(String, String)`.

Why was this change made? As part of the modularization efforts it has been considered that that this logic belongs to wiki-web module.

Custom AUI Validators Are No Longer Implicitly Required

- **Date:** 2015-Dec-02
- **JIRA Ticket:** LPS-60995

What changed? The AUI Validator tag no longer forces custom validators (e.g., `name="custom"`) to be required, and are now optional by default.

Who is affected? This affects developers using custom validators, especially ones who relied on the field being implicitly required via the custom validator.

How should I update my code? There are several cases where you should update your code to compensate for this change. First, blank value checking is no longer necessary, so places where blank values are checked should be updated.

Old Code:

```
<aui:input name="privateVirtualHost">
    <aui:validator errorMessage="please-enter-a-unique-virtual-host" name="custom">
        function(val, fieldNode, ruleValue) {
            return !val || val != A.one('#<portlet:namespace />publicVirtualHost').val();
        }
    </aui:validator>
</aui:input>
```

New Code:

```
<aui:input name="privateVirtualHost">
    <aui:validator errorMessage="please-enter-a-unique-virtual-host" name="custom">
        function(val, fieldNode, ruleValue) {
            return val != A.one('#<portlet:namespace />publicVirtualHost').val();
        }
    </aui:validator>
</aui:input>
```

Also, instead of using custom validators to determine if a field is required, you should now use a conditional `required` validator.

Old Code:

```
<aui:input name="file" type="file" />

<aui:input name="title">
    <aui:validator errorMessage="you-must-specify-a-file-or-a-title" name="custom">
        function(val, fieldNode, ruleValue) {
            return !!val || !!A.one('#<portlet:namespace />file').val();
        }
    </aui:validator>
</aui:input>
```

New Code:

```
<aui:input name="file" type="file" />

<aui:input name="title">
    <aui:validator errorMessage="you-must-specify-a-file-or-a-title" name="required">
        function(fieldNode) {
            return !A.one('#<portlet:namespace />file').val();
        }
    </aui:validator>
</aui:input>
```

Lastly, custom validators that assumed validation would always run must now explicitly pass the `required` validator. This is done by passing in the `<aui:validator name="required" />` element. The `<aui:input>` tag listed below is an example of how to explicity pass the `required` validator:

```
<aui:input name="vowelsOnly">
    <aui:validator errorMessage="must-contain-only-the-following-characters" name="custom">
        function(val, fieldNode, ruleValue) {
            var allowedCharacters = 'aeiouy';
            var regex = new RegExp('[^' + allowedCharacters + ']');

            return !regex.test(val);
        }
    </aui:validator>
    <aui:validator name="required" />
</aui:input>
```

Why was this change made? A custom validator caused the field to be implicitly required. This meant that all validators for the field would be evaluated. This created a condition where you could not combine custom validators with another validator for an optional field.

For example, imagine an optional field which has an email validator, plus a custom validator which checks for email addresses within a specific domain (e.g., `example.com`). There was no way for this optional field to pass validation. Even if you handled blank values in your custom validator, that blank value would fail the email validator.

This change requires most custom validators to be refactored, but allows greater flexibility for all developers.

Moved Recycle Bin Logic Into a New DLTrashService Interface

- **Date:** 2015-Dec-02
- **JIRA Ticket:** LPS-60810

What changed? All Recycle Bin logic in Documents and Media services was moved from `DLAppService` into the new `DLTrashService` service interface. All moved methods have the same name and signatures.

Who is affected? This affects any local or remote caller of `DLAppService`.

How should I update my code? As all methods have been simply moved into the new service, calling the equivalent method on `DLTrashService` suffices.

Why was this change made? Documents and Media services have complex interdependencies that result in circular dependencies. Until now, `DLAppService` was responsible for exposing the Recycle Bin logic, delegating it to other components. The problem was, the components depended on `DLAppService` to implement their logic. Extracting the services from `DLAppService` was the only sensible solution to this circularity.

Deprecated the liferay-ui:flags Tag and Replaced with liferay-flags:flags

- **Date:** 2015-Dec-02
- **JIRA Ticket:** LPS-60967

What changed? The `liferay-ui:flags` tag has been deprecated and replaced with the `liferay-flags:flags` tag.

Who is affected? Plugins or templates that are using the `liferay-ui:flags` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-flags` tag library (if necessary) and update the tag namespace from `liferay-ui:flags` to `liferay-flags:flags`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Removed the liferay-ui:diff Tag and Replaced with liferay-frontend:diff

- **Date:** 2015-Dec-14
- **JIRA Ticket:** LPS-61326

What changed? The `liferay-ui:diff` tag has been removed and replaced with the `liferay-frontend:diff` tag.

Who is affected? Plugins and templates that are using the `liferay-ui:diff` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-frontend` tag library (if necessary) and update the tag namespace from `liferay-ui:diff` to `liferay-frontend:diff`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Taglibs Are No Longer Accessible via the theme Variable in FreeMarker

- **Date:** 2016-Jan-06
- **JIRA Ticket:** LPS-61683

What changed? The `${theme}` variable previously injected in the FreeMarker context providing access to various tags and utilities is no longer available.

Who is affected? This affects FreeMarker templates that are using the `${theme}` variable.

How should I update my code? All the tags and utility methods formerly accessed via the `${theme}` variable should now be accessed directly via tags.

Example 1

```
${theme.runtime("com.liferay.portal.kernel.servlet.taglib.ui.BreadcrumbEntry", portletProviderAction.VIEW, "", default_preferences)}
```

can be replaced by:

```
<@liferay_portlet["runtime"]
    defaultPreferences=default_preferences
    portletProviderAction=portletProviderAction.VIEW
    portletProviderClassName="com.liferay.portal.kernel.servlet.taglib.ui.BreadcrumbEntry"
/>
```

Example 2

```
${theme.include(content_include)}
```

can be replaced by:

```
<@liferay_util["include"] page=content_include />
```

Example 3

```
${theme.wrapPortlet("portlet.ftl", content_include)}
```

can be replaced by:

```
<@liferay_theme["wrap-portlet"] page="portlet.ftl">
    <@liferay_util["include"] page=content_include />
</@>
```

Example 4

```
${theme.iconHelp(portlet_description)}
```

can be replaced by:

```
<@liferay_ui["icon-help"] message=portlet_description />
```

Example 5

```
${nav_item.icon()}
```

can be replaced by:

```
<@liferay_theme["layout-icon"] layout=${nav_item.getLayout()} />
```

Why was this change made? Previously, the `{$theme}` variable was being injected with the `VelocityTaglibImpl` class. This created coupling between template engines and coupling between specific tags and template engines at the same time.

FreeMarker already offers native support for tags which cover all the functionality originally provided by the `{$theme}` variable. Removing this coupling helps future development while still keeping all the existing functionality.

Portlet Configuration Options May Not Always Be Displayed

- **Date:** 2016-Jan-07
- **JIRA Ticket:** LPS-54620 and LPS-61820

What changed? The portlet configuration options (e.g., configuration, export/import, look and feel, etc.) were always displayed in every view of the portlet and couldn't be customized.

With Lexicon, the configuration options displayed are based on the portlet's context, so not all options will always be displayed.

Who is affected? This affects portlets that should always display all configuration options no matter which view of the portlet is rendered.

How should I update my code? If you don't apply any change to your source code, you will experience the following behaviors based on the portlet type:

- **Struts Portlet:** If you've defined a `view-action` init parameter, the configuration options are only displayed for that particular view when invoking a URL with a parameter `struts_action` with the value indicated in the `view-action` init parameter and also in the default view of the portlet (when there is no `struts_action` parameter in the request).

- **Liferay MVC Portlet:** If you've defined a `view-template` init parameter, the configuration options are only displayed when that template is rendered by invoking a URL with a parameter `mvcPath` with the value indicated in the `view-template` init parameter. and also in the default view of the portlet (when there is no `mvcPath` parameter in the request).
- If it's a portlet using any other framework, the configuration options are always displayed.

In order to keep the old behavior of adding the configuration options in every view, you need to add the init parameter `always-display-default-configuration-icons` with the value `true`.

Why was this change made? Lexicon patterns require the ability to specify different configuration options depending on the view of the portlet by adding or removing options. This can be easily achieved by using the `PortletConfigurationIcon` classes.

The getURLView Method of AssetRenderer Returns String Instead of PortletURL

- **Date:** 2016-Jan-08
- **JIRA Ticket:** LPS-61853

What changed? The `AssetRenderer` interface's `getURLView` method has changed and now returns `String` instead of `PortletURL`.

Who is affected? This affects all custom assets that implement the `AssetRenderer` interface.

How should I update my code? You should update the method signature to reflect that it returns a `String` and you should adapt your implementation accordingly.
In general, it should be as easy as returning `portletURL.toString()`.

Why was this change made? The API was forcing implementations to return a `PortletURL`, making it difficult to return another type of link. For example, in the case of Bookmarks, developers wanted to automatically redirect to other potential URLs.

Removed the icon Method from NavItem

- **Date:** 2016-Jan-11
- **JIRA Ticket:** LPS-61900

What changed? The `NavItem` interface has changed and the method `icon` that would render the nav item icon has been removed.

Who is affected? This affects all themes using the `nav_item.icon()` method.

How should I update my code? You should update your code to call the method `nav_item.iconURL` to return the image's URL and then use it as you prefer.
Example:

```
<img alt="Page Icon" class="layout-logo" src="<%= nav_item.iconURL()" />
```

To keep the previous behavior in Velocity:

```
$theme.layoutIcon($nav_item.getLayout())
```

To keep the previous behavior in FreeMarker:

```
<@liferay_theme["layout-icon"] layout=nav_item_layout />
```

Why was this change made? The API was forcing developers to have a dependency on a taglib, which didn't allow for much flexibility.

Renamed Packages to Fix the Split Packages Problem

- **Date:** 2016-Jan-19
- **JIRA Ticket:** LPS-61952

What changed? Split packages are caused when two or more bundles export the same package name and version. When the classloader loads a package, exactly one exporter of that package is chosen; so if a package is split across multiple bundles, then an importer only sees a subset of the package.

Who is affected? The `portal-kernel` and `portal-impl` folders have many packages with the same name. Therefore, all of these packages are affected by the split package problem.

How should I update my code? You should rename duplicated package names if they currently exist somewhere else.

Example

- `com.liferay.counter` → `com.liferay.counter.kernel`
- `com.liferay.mail.model` → `com.liferay.mail.kernel.model`
- `com.liferay.mail.service` → `com.liferay.mail.kernel.service`
- `com.liferay.mail.util` → `com.liferay.mail.kernel.util`
- `com.liferay.portal.exception` → `com.liferay.portal.kernel.exception`
- `com.liferay.portal.jdbc.pool.metrics` → `com.liferay.portal.kernel.jdbc.pool.metrics`
- `com.liferay.portal.kernel.mail` → `com.liferay.mail.kernel.model`
- `com.liferay.portal.layoutconfiguration.util` → `com.liferay.portal.kernel.layoutconfiguration.util`
- `com.liferay.portal.layoutconfiguration.util.xml` → `com.liferay.portal.kernel.layoutconfiguration.util.xml`
- `com.liferay.portal.mail` → `com.liferay.portal.kernel.mail`
- `com.liferay.portal.model` → `com.liferay.portal.kernel.model`
- `com.liferay.portal.model.adapter` → `com.liferay.portal.kernel.model.adapter`
- `com.liferay.portal.model.impl` → `com.liferay.portal.kernel.model.impl`
- `com.liferay.portal.portletfilerepository` → `com.liferay.portal.kernel.portletfilerepository`

- com.liferay.portal.repository.proxy → com.liferay.portal.kernel.repository.proxy
- com.liferay.portal.security.auth → com.liferay.portal.kernel.security.auth
- com.liferay.portal.security.exportimport → com.liferay.portal.kernel.security.exportimport
- com.liferay.portal.security.ldap → com.liferay.portal.kernel.security.ldap
- com.liferay.portal.security.membershippolicy → com.liferay.portal.kernel.security.membershippolicy
- com.liferay.portal.security.permission → com.liferay.portal.kernel.security.permission
- com.liferay.portal.security.permission.comparator → com.liferay.portal.kernel.security.permission.comparator
- com.liferay.portal.security.pwd → com.liferay.portal.kernel.security.pwd
- com.liferay.portal.security.xml → com.liferay.portal.kernel.security.xml
- com.liferay.portal.service.configuration → com.liferay.portal.kernel.service.configuration
- com.liferay.portal.service.http → com.liferay.portal.kernel.service.http
- com.liferay.portal.service.permission → com.liferay.portal.kernel.service.permission
- com.liferay.portal.service.persistence.impl → com.liferay.portal.kernel.service.persistence.impl
- com.liferay.portal.theme → com.liferay.portal.kernel.theme
- com.liferay.portal.util → com.liferay.portal.kernel.util
- com.liferay.portal.util.comparator → com.liferay.portal.kernel.util.comparator
- com.liferay.portal.verify.model → com.liferay.portal.kernel.verify.model
- com.liferay.portal.webserver → com.liferay.portal.kernel.webserver
- com.liferay.portlet → com.liferay.portal.kernel.portlet
- com.liferay.portlet.admin.util → com.liferay.admin.kernel.util
- com.liferay.portlet.announcements → com.liferay.announcements.kernel
- com.liferay.portlet.asset → com.liferay.asset.kernel
- com.liferay.portlet.backgroundtask.util.comparator → com.liferay.background.task.kernel.util.comparator
- com.liferay.portlet.blogs → com.liferay.blogs.kernel
- com.liferay.portlet.blogs.exception → com.liferay.blogs.kernel.exception
- com.liferay.portlet.blogs.model → com.liferay.blogs.kernel.model
- com.liferay.portlet.blogs.service → com.liferay.blogs.kernel.service
- com.liferay.portlet.blogs.service.persistence → com.liferay.blogs.service.persistence
- com.liferay.portlet.blogs.util.comparator → com.liferay.blogs.kernel.util.comparator

- `com.liferay.portlet.documentlibrary` → `com.liferay.document.library.kernel`
- `com.liferay.portlet.dynamicdatamapping` → `com.liferay.dynamic.data.mapping.kernel`
- `com.liferay.portlet.expando` → `com.liferay.expando.kernel`
- `com.liferay.portlet.exportimport` → `com.liferay.exportimport.kernel`
- `com.liferay.portlet.imagegallerydisplay.display.context` → `com.liferay.image.gallery.display.kernel.display.co`
- `com.liferay.portlet.journal.util` → `com.liferay.journal.kernel.util`
- `com.liferay.portlet.layoutsadmin.util` → `com.liferay.layouts.admin.kernel.util`
- `com.liferay.portlet.messageboards` → `com.liferay.message.boards.kernel`
- `com.liferay.portlet.messageboards.constants` → `com.liferay.message.boards.kernel.constants`
- `com.liferay.portlet.messageboards.exception` → `com.liferay.message.boards.kernel.exception`
- `com.liferay.portlet.messageboards.model` → `com.liferay.message.boards.kernel.model`
- `com.liferay.portlet.messageboards.service` → `com.liferay.message.boards.kernel.service`
- `com.liferay.portlet.messageboards.service.persistence` → `com.liferay.message.boards.kernel.service.persistence`
- `com.liferay.portlet.messageboards.util` → `com.liferay.message.boards.kernel.util`
- `com.liferay.portlet.messageboards.util.comparator` → `com.liferay.message.boards.kernel.util.comparator`
- `com.liferay.portlet.mobiledevicerules` → `com.liferay.mobile.device.rules`
- `com.liferay.portlet.portletconfiguration.util` → `com.liferay.portlet.configuration.kernel.util`
- `com.liferay.portlet.rolesadmin.util` → `com.liferay.roles.admin.kernel.util`
- `com.liferay.portlet.sites.util` → `com.liferay.sites.kernel.util`
- `com.liferay.portlet.social` → `com.liferay.social.kernel`
- `com.liferay.portlet.trash` → `com.liferay.trash.kernel`
- `com.liferay.portlet.useradmin.util` → `com.liferay.users.admin.kernel.util`
- `com.liferay.portlet.ratings` → `com.liferay.ratings.kernel`
- `com.liferay.portlet.ratings.definition` → `com.liferay.ratings.kernel.definition`
- `com.liferay.portlet.ratings.display.context` → `com.liferay.ratings.kernel.display.context`
- `com.liferay.portlet.ratings.exception` → `com.liferay.ratings.kernel.exception`
- `com.liferay.portlet.ratings.model` → `com.liferay.ratings.kernel.model`
- `com.liferay.portlet.ratings.service` → `com.liferay.ratings.kernel.service`
- `com.liferay.portlet.ratings.service.persistence` → `com.liferay.ratings.kernel.service.persistence`
- `com.liferay.portlet.ratings.transformer` → `com.liferay.ratings.kernel.transformer`

Why was this change made? This change was necessary to solve the current split package problems and prevent future ones.

Removed the aui:column Tag and Replaced with aui:col

- **Date:** 2016-Jan-19
- **JIRA Ticket:** LPS-62208

What changed? The `aui:column` tag has been removed and replaced with the `aui:col` tag.

Who is affected? Plugins or templates that are using the `aui:column` tag must update their usage of the tag.

How should I update my code? You should import the `aui` tag library (if necessary) and update the tag namespace from `aui:column` to `aui:col`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

The title Field of FileEntry Models is Now Mandatory

- **Date:** 2016-Jan-25
- **JIRA Ticket:** LPS-62251

What changed? The `title` field of file entries was optional as long as a source file name was provided. To avoid confusion, the title is now required by the API and is filled automatically by the UI when a source file name is present.

Who is affected? This affects any user of the local or remote API. Users of the Web UI are unaffected.

How should I update my code? You should pass a non-null, non-empty string for the `title` parameter of the `addFileEntry` and `updateFileEntry` methods.

Why was this change made? The `title` field was marked as mandatory, but it was possible to create a document without filling it, as the backend would infer a value from the source file name automatically. This was considered confusing from a UX perspective.

DLUtil.getImagePreviewURL and DLUtil.getThumbnailSrc Can Return Empty Strings

- **Date:** 2016-Jan-28
- **JIRA Ticket:** LPS-62643

What changed? The `DLUtil.getImagePreviewURL` and `DLUtil.getThumbnailSrc` methods return an empty string if there are no previews or thumbnails for the specific image, video, or document.

Previously, if there were no previews or thumbnails, these methods would return a URL to an image based on the document.

Who is affected? This affects any developer invoking `DLUtil.getImagePreviewURL` or `DLUtil.getThumbnailSrc`.

How should I update my code? You should be aware that the method could return an empty string and act accordingly. For example, you could display the `documents-and-media` Lexicon icon instead.

Why was this change made? In order to display the `documents-and-media` Lexicon icon in Documents and Media, this change was necessary.

Removed the aui:button-item Tag and Replaced with aui:button

- **Date:** 2016-Feb-04
- **JIRA Ticket:** LPS-62922

What changed? The `aui:button-item` tag has been removed and replaced with the `aui:button` tag.

Who is affected? Plugins or templates that are using the `aui:button-item` tag must update their usage of the tag.

How should I update my code? You should import the `aui` tag library (if necessary) and update the tag namespace from `aui:button-item` to `aui:button`.

Why was this change made? This change was made as a part of the ongoing strategy to remove deprecated code.

Removed the WAP Functionality

- **Date:** 2016-Feb-05
- **JIRA Ticket:** LPS-62920

What changed? The WAP functionality has been removed.

Who is affected? This affects developers that use the WAP functionality.

How should I update my code? If you are using any of the following methods, you need to remove the parameters in those methods related to WAP.

- `LayoutLocalServiceUtil.updateLookAndFeel`
- `LayoutRevisionLocalServiceUtil.addLayoutRevision`
- `LayoutRevisionLocalServiceUtil.updateLayoutRevision`
- `LayoutRevisionServiceUtil.addLayoutRevision`
- `LayoutServiceUtil.updateLookAndFeel`
- `LayoutSetLocalServiceUtil.updateLookAndFeel`
- `LayoutSetServiceUtil.updateLookAndFeel`
- `ThemeLocalServiceUtil.getColorScheme`
- `ThemeLocalServiceUtil.getControlPanelThemes`
- `ThemeLocalServiceUtil.getPageThemes`
- `ThemeLocalServiceUtil.getTheme`

Why was this change made? This change was made because WAP is an obsolete functionality.

Removed the aui:layout Tag with No Direct Replacement

- **Date:** 2016-Feb-08
- **JIRA Ticket:** LPS-62935

What changed? The `aui:layout` tag has been removed with no direct replacement.

Who is affected? Plugins or templates that are using the `aui:layout` tag must remove their usage of the tag.

How should I update my code? There is no direct replacement. You should remove all usages of the `aui:layout` tag.

Why was this change made? This change was made as a part of the ongoing strategy to remove deprecated tags.

Deprecated the liferay-portlet:icon-back Tag with No Direct Replacement

- **Date:** 2016-Feb-10
- **JIRA Ticket:** LPS-63101

What changed? The `liferay-portlet:icon-back` tag has been deprecated with no direct replacement.

Who is affected? Plugins or templates that are using the `liferay-portlet:icon-back` tag must remove their usage of the tag.

How should I update my code? There is no direct replacement. You should remove all usages of the `liferay-portlet:icon-back` tag.

Why was this change made? This change was made as a part of the ongoing strategy to deprecate unused tags.

Deprecated the liferay-security:encrypt Tag with No Direct Replacement

- **Date:** 2016-Feb-10
- **JIRA Ticket:** LPS-63106

What changed? The `liferay-security:encrypt` tag has been deprecated with no direct replacement.

Who is affected? Plugins or templates that are using the `liferay-security:encrypt` tag must remove their usage of the tag.

How should I update my code? There is no direct replacement. You should remove all usages of the `liferay-security:encrypt` tag.

Why was this change made? This change was made as a part of the ongoing strategy to deprecate unused tags.

Removed the Ability to Specify Class Loaders in Scripting

- **Date:** 2016-Feb-17
- **JIRA Ticket:** LPS-63180

What changed?

- `com.liferay.portal.kernel.scripting.ScriptingExecutor` no longer uses the provided class loaders in the eval methods.
- `com.liferay.portal.kernel.scripting.Scripting` no longer uses the provided class loaders and servlet context names in eval and exec methods.

Who is affected?

- All implementations of `com.liferay.portal.kernel.scripting.ScriptingExecutor` are affected.
- All classes that call `com.liferay.portal.kernel.scripting.Scripting` are affected.

How should I update my code? You should remove class loader and servlect context parameters from calls to the modified methods.

Why was this change made? This change was made since custom class loader management is no longer necessary in the OSGi container.

User Operation and Importer/Exporter Classes and Utilities Have Been Moved or Removed From portal-kernel

- **Date:** 2016-Feb-17
- **JIRA Ticket:** LPS-63205

What changed?

- `com.liferay.portal.kernel.security.exportimport.UserImporter`, `com.liferay.portal.kernel.security.exportimport` and `com.liferay.portal.kernel.security.exportimport.UserOperation` have been moved from portal-kernel to the portal-security-export-import-api module.

- `com.liferay.portal.kernel.security.exportimport.UserImporterUtil` and `com.liferay.portal.kernel.security.expor` have been removed with no replacement.

Who is affected?

- All implementations of `com.liferay.portal.kernel.security.exportimport.UserImporter` or `com.liferay.portal.kernel.security.exportimport.UserExporter` are affected.

- All code that uses `com.liferay.portal.kernel.security.exportimport.UserImporterUtil`, `com.liferay.portal.kernel.se` `com.liferay.portal.kernel.security.exportimport.UserImporter`, or `com.liferay.portal.kernel.security.exportimpo` is affected.

How should I update my code? If you are in an OSGi module, you can simply inject the UserImporter or UserExporter references

```
@Reference
private UserExporter_userExporter;

@Reference
private UserImporter _userImporter;
```

If you are in a legacy WAR or WAB, you will need a snippet like:

```
Bundle bundle = FrameworkUtil.getBundle(getClass());

BundleContext bundleContext = bundle.getBundleContext();

ServiceReference<UserImporter> serviceReference =
    bundleContext.getServiceReference(UserImporter.class);

UserImporter userImporter = bundleContext.getService(serviceReference);
```

Why was this change made? The change was made to improve modularity of the user import/export subsystem in the product.

Deprecated Category Entry for Users

- **Date:** 2016-Feb-22
- **JIRA Ticket:** LPS-63466

What changed? The category entry for Site Administration → Users has been deprecated in favor of Site Administration → Members.

Who is affected? All developers who specified a `control-panel-entry-category` to be visible in Site Administration → Users are affected.

How should I update my code? You should change the entry from `site_administration.users` to `site_administration.members` to make it visible in the category.

Why was this change made? This change standardizes naming conventions and separates concepts between Users in the Control Panel and Site Members.

Deprecated Category Entry for Pages

- **Date:** 2016-Feb-25
- **JIRA Ticket:** LPS-63667

What changed? The category entry for Site Administration → Pages has been deprecated in favor of Site Administration → Navigation.

Who is affected? All developers who specified a `control-panel-entry-category` to be visible in Site Administration → Pages are affected.

How should I update my code? You should change the entry from `site_administration.pages` to `site_administration.navigation` to make it visible in the category.

Why was this change made? This change standardizes naming conventions and separates concepts in Product Menu

Removed the com.liferay.dynamic.data.mapping.util.DDMXMLUtil Class

- **Date:** 2016-Mar-03
- **JIRA Ticket:** LPS-63928

What changed? The class `com.liferay.dynamic.data.mapping.util.DDMXMLUtil` has been removed with no replacement.

Who is affected? All code that uses `com.liferay.dynamic.data.mapping.util.DDMXMLUtil` is affected.

How should I update my code? In an OSGi module, simply inject the DDMXML reference:

```
@Reference
private DDMXML _ddmXML;
```

In a legacy WAR or WAB, you need to get a DDMXML service reference from the bundle context:

```
Bundle bundle = FrameworkUtil.getBundle(getClass());

BundleContext bundleContext = bundle.getBundleContext();

ServiceReference<UserImporter> serviceReference =
    bundleContext.getServiceReference(DDMXML.class);

DDMXML ddmXML = bundleContext.getService(serviceReference);
```

Why was this change made? This change was made to improve modularity of the dynamic data mapping subsystem.

FlagsEntryService.addEntry Method Throws PortalException

- **Date:** 2016-Mar-04
- **JIRA Ticket:** LPS-63109

What changed? The method `FlagsEntryService.addEntry` now throws a `PortalException` if the `reporterEmailAddress` is not a valid email address.

Who is affected? Any caller of the method `FlagsEntryService.addEntry` is affected.

How should I update my code? You should consider checking for the `PortalException` in try-catch blocks and adapt your code accordingly.

Why was this change made? This change prevents providing an incorrect email address when adding flag entries.

Removed PHP Portlet Support

- **Date:** 2016-Mar-10
- **JIRA Ticket:** LPS-64052

What changed? PHP portlets are no longer supported.

Who is affected? This affects any portlet using the class `com.liferay.util.bridges.php.PHPPortlet`.

How should I update my code? You should port your PHP portlet to a different technology.

Why was this change made? This change simplifies future maintenance of the portal. This support could be added back in the future as an independent module.

Removed Liferay Frontend Editor BBCode Web, Previously Known as Liferay BBCode Editor

- **Date:** 2016-Mar-16
- **JIRA Ticket:** LPS-48334

What changed? The following things have been changed:

- Removed the `com.liferay.frontend.editor.bbcode.web` OSGi bundle
- Removed all hardcoded references/logic for the editor
- Added a log warning and logic to upgrade the editor property to `ckeditor_bbcode` if the old `bbcode` is being used. This log warning and logic will be removed in the future, along with LPS-64099.

Who is affected? This affects anyone who has the property `editor.wysiwyg.portal-web.docroot.html.portlet.message_board` set to `bbcode` in portal properties (e.g., `portal-ext.properties`).

How should I update my code? You should modify your `portal-ext.properties` file to remove the property `editor.wysiwyg.portal-web.docroot.html.portlet.message_boards.edit_message.bb_code.jsp`.

Why was this change made? Since Liferay Frontend Editor BBCode Web has been deprecated since 6.1, it was time to remove it completely. This frees up development and support resources to focus on supported features.

Removed the asset.entry.validator Property

- **Date:** 2016-Mar-17
- **JIRA Ticket:** LPS-64370

What changed? The property `asset.entry.validator` has been removed from `portal.properties`.

Who is affected? This affects any installation with a customized asset validator.

How should I update my code? You should create a new OSGi component that implements `AssetEntryValidator` and define for which models it will be applicable by using the `model.class.name` OSGi property, or an asterisk if it applies to any model.

If you were using the `MinimalAssetEntryValidator`, this functionality can still be added by deploying the module `asset-tags-validator`.

Why was this change made? This change has been made as part of the modularization efforts to decouple different parts of the portal.

Removed the swfupload and video_player Utilities

- **Date:** 2016-May-13
- **JIRA Ticket:** LPS-54111

What changed? The utilities `swfupload` and `video_player` have been removed.

Who is affected? This affects anyone who is using the `swfupload` AlloyUI module or any of the associated `swfupload_f*.swf` and `mpw_player.swf` flash movies.

How should I update my code? There are better, more standard ways to achieve upload currently. For instance, you can use A.Uploader to manage your uploads consistently across browsers.

For audio/video reproduction, you should update your code to use A.Audio and A.Video.

Why was this change made? This change removes outdated code no longer being used in the platform. In addition, this change avoids future security issues from outdated flash movies.

Moved Journal Portlet Properties to OSGi Configuration

- **Date:** 2016-Jul-29
- **JIRA Ticket:** LPS-58672

What changed? All Journal portlet properties have been moved to an OSGi configuration.

Who is affected? This affects anyone who is overriding the Journal portlet's `portlet.properties` file.

How should I update my code? Instead of overriding the Journal portlet's `portlet.properties` file, you can manage the properties from Portal's configuration administrator. This can be accessed by navigating to Liferay's Control Panel → *System Settings* → *Web Experience* and selecting the appropriate Web Content category.

Why was this change made? This change was made as part of modularization efforts to ease portlet configuration changes.

Moved the liferay-ui:journal-article Tag to Journal

- **Date:** 2016-Nov-24
- **JIRA Ticket:** LPS-69321

What changed? The `liferay-ui:journal-article` tag has been moved to the Journal (Web Content) application.

Who is affected? This affects developers using the `liferay-ui:journal-article` tag.

How should I update my code? You should use the `liferay-journal:journal-article` tag instead.

Example

Old code:

```
<liferay-ui:journal-article
    articleId="<%= article.getArticleId() %>"
/>
```

New code:

```
<liferay-journal:journal-article
    articleId="<%= article.getArticleId() %>"
    groupId="<%= article.getGroupId() %>"
/>
```

If you still want to use the `liferay-ui:journal-article` tag, you must deploy the `journal-taglib` module to your Liferay installation.

Why was this change made? This change was made as part of the modularization efforts for the Web Content application.

Deprecated the liferay-ui:captcha Tag and Replaced with liferay-captcha:captcha

- **Date:** 2016-Nov-29
- **JIRA Ticket:** LPS-69383

What changed? The `liferay-ui:captcha` tag has been deprecated and replaced with the `liferay-captcha:captcha` tag.

Who is affected? Plugins or templates that are using the `liferay-ui:captcha` tag need to update their usage of the tag.

How should I update my code? You should import the `liferay-captcha` tag library (if necessary) and update the tag namespace from `liferay-ui:captcha` to `liferay-captcha:captcha`.

Why was this change made? This change was made as a part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Moved Shopping File Uploads Portlet Properties to OSGi Configuration

- **Date:** 2016-Dec-08
- **JIRA Ticket:** LPS-69210

What changed? The Shopping file uploads portlet properties have been moved from Server Administration to an OSGi configuration named `ShoppingFileUploadsConfiguration.java` in the `shopping-api` module.

Who is affected? This affects anyone who is using the following portlet properties:

- `shopping.image.extensions`
- `shopping.image.large.max.size`
- `shopping.image.medium.max.size`
- `shopping.image.small.max.size`

How should I update my code? Instead of overriding the `portal.properties` file, you can manage the properties from Portal's configuration administrator. This can be accessed by navigating to Liferay's *Control Panel → Configuration → System Settings → Shopping Cart Images* and editing the settings there.

If you would like to include the new configuration in your application, follow the instructions for making your applications configurable in Liferay 7.0.

Why was this change made? This change was made as part of the modularization efforts to ease portal configuration changes.

Moved the Expando Custom Field Tags to liferay-expando Taglib

- **Date:** 2016-Dec-12
- **JIRA Ticket:** LPS-69400

What changed? The following tags have been deprecated and replaced:

- `liferay-ui:custom-attribute`
- `liferay-ui:custom-attribute-list`
- `liferay-ui:custom-attributes-available`

Who is affected? Plugins and templates that are using the aforementioned tags must update their usage of the tag.

How should I update my code? You should import the `liferay-expando` tag library (if necessary) and update the tag namespace from `liferay-ui` to `liferay-expando`:

- `liferay-ui:custom-attribute` → `liferay-expando:custom-attribute`
- `liferay-ui:custom-attribute-list` → `liferay-expando:custom-attribute-list`
- `liferay-ui:custom-attributes-available` → `liferay-expando:custom-attributes-available`

Why was this change made? This change was made as part of the ongoing strategy to modularize Liferay Portal by means of an OSGi container.

Moved Journal File Uploads Portlet Properties to OSGi Configuration

- **Date:** 2017-Jan-04
- **JIRA Ticket:** LPS-69209

What changed? The Journal File Uploads portlet properties have been moved from Server Administration to an OSGi configuration named `JournalFileUploadsConfiguration.java` in the `journal-service` module.

Who is affected? This affects anyone who is using the following portlet properties:

- `journal.image.extensions`
- `journal.image.small.max.size`

How should I update my code? Instead of overriding the `portal.properties` file, you can manage the properties from Portal's configuration administrator. This can be accessed by navigating to Liferay's *Control Panel → Configuration → System Settings → Web Content File Uploads* and editing the settings there.

If you would like to include the new configuration in your application, follow the instructions for making your applications configurable in Liferay 7.0.

Why was this change made? This change was made as part of the modularization efforts to ease portal configuration changes.

Deprecated the aui:tool Tag with No Direct Replacement

- **Date:** 2017-Feb-02
- **JIRA Ticket:** LPS-70422

What changed? The `aui:tool` tag has been deprecated with no direct replacement.

Who is affected? Plugins or templates that are using the `aui:tool` tag must remove their usage of the tag.

How should I update my code? There is no direct replacement. You should remove all usages of the `aui:tool` tag.

Why was this change made? This change was made as a part of the ongoing strategy to deprecate unused tags.

Build Auto Upgrade

- **Date:** 2017-Aug-17
- **JIRA Ticket:** LPS-73967

What changed? The `build.auto.upgrade` property in `service.properties` for Liferay Portal 6.x Service Builder portlets applies Liferay Service schema changes on rebuilding the services and redeploying the portlets.

Since 7.0, the per portlet property `build.auto.upgrade` is deprecated.

This change reintroduces Build Auto Upgrade in a new global property `schema.module.build.auto.upgrade` in the `[Liferay_Home]/portal-developer.properties` file.

Setting global property `schema.module.build.auto.upgrade` to `true` applies module schema changes for redeployed modules whose service build numbers have incremented. The `build.number` property in the module's `service.properties` file indicates the service build number.

Who is affected? This feature is available for developers to use in development only.

WARNING: DO NOT USE the Build Auto Upgrade feature in production. Liferay DOES NOT support Build Auto Upgrade in production.

How should I update my code? To use this feature in development, set global property `schema.module.build.auto.upgrade` in `[Liferay_Home]/portal-developer.properties` to `true`, increment your module's `build.number` in the `service.properties` file, and deploy the module.

Why was this change made? This change was made so that 7.0 developers could test database schema changes on the fly, without having to write upgrade processes.

Removed Exports from Dynamic Data Lists Web

- **Date:** 2017-Nov-27
- **JIRA Ticket:** LPS-75778

What changed? The `Dynamic Data Lists Web` module no longer exports the `com.liferay.dynamic.data.lists.web.asset` package.

Who is affected? This change affects anyone who is using the `com.liferay.dynamic.data.lists.web.asset` package. This particularly affects anyone using `com.liferay.dynamic.data.lists.web.asset.DDLRecordAssetRendererFactory` and casting the return `AssetRenderer` to `com.liferay.dynamic.data.lists.web.asset.DDLRecordAssetRenderer`.

How should I update my code? There are no replacements for this package; you must remove all usages. `DDLRecordAssetRendererFactory` can still be used as an OSGi service; however, you can no longer cast the returned `AssetRenderer` to `DDLRecordAssetRenderer`.

Why was this change made? This change was made to clean up LPKG dependencies.

Deprecated the social.activity.sets.enabled Property with No Direct Replacement

- **Date:** 2018-Jan-24
- **JIRA Ticket:** LPS-63635

What changed? The `social.activity.sets.enabled` property is no longer recognized by the Social Activity portlet. From Liferay Portal 7.0 onwards, Social Activity Sets will always be used.

Who is affected? This change affects anyone who has set the `social.activity.sets.enabled` property to `false`.

How should I update my code? No changes are necessary.

Why was this change made? The Social Activity portlet had two different versions with slightly different behaviors; one used in Liferay Portal and the other one in Social Office. To sync both components, and simplify its internal logic, activity sets are always enabled by default, with no option to disable them.

Removed Description HTML Escaping in PortletDisplay

- **Date:** 2018-Jul-17
- **JIRA Ticket:** LPS-83185

What changed? The portlet description stored in `PortletDisplay.java` is no longer escaped automatically.

Who is affected? This affects anyone who used the portlet description's escaped value to generate HTML. A small UI change could occur, as some characters may be unescaped.

How should I update my code? If you were using the `portletDescription` value to generate HTML, you should escape it using the proper escape sequence: `HtmlUtil.escape`.

Why was this change made? This change corrects a best practice violation regarding content escaping.

Removed Cache Bootstrap Feature

- **Date:** 2020-Jan-8
- **JIRA Ticket:** LPS-96563

What changed? The cache bootstrap feature has been removed. These properties can no longer be used to enable/configure cache bootstrap:
`ehcache.bootstrap.cache.loader.enabled`, `ehcache.bootstrap.cache.loader.properties.default`, `ehcache.bootstrap.cache.loader.properties.${specific.cache.name}`.

Who is affected? This affects anyone using the properties listed above.

How should I update my code? There's no direct replacement for the removed feature. If you have code that depends on it, you must implement it yourself.

Why was this change made? This change was made to avoid security issues.

140.9 What Changed Between Liferay npm Bundler 1.x and 2.x

This reference doc outlines the key changes between liferay-npm-bundler version 1.x and 2.x.

Automatically Formatting Modules for AMD

In version series 1.x of the bundler it was the developer's responsibility to wrap project modules in an AMD `define()` call. However, since 2.x the bundler does it for you, so the only requisite is that the project's code is transpiled/written for CommonJS modules model (the standard model for module handling in Node.js, that uses `require()` calls to load modules).

Isolating Project Dependencies

Package names are prefixed with the bundle name since version 2.0.0 of the bundler, but were left intact in previous versions. This strategy is used to isolate packages from different bundles. You can still deploy bundler 1.x packages (without prefix), and they will still work as they did for previous versions of the bundler.

Improved Peer Dependency Support

In bundler 1.x, there was only one shared peer dependency package available between portlets. With isolated dependencies per portlet, it's easy to honor peer dependencies perfectly. Peer dependencies can be resolved exactly as stated in projects because their names are prefixed with the project's name. This is possible because of the new liferay-npm-bundler-plugin-inject-peer-dependencies plugin. It scans all JS modules for `require` calls. If the bundler finds a required package in the `main.js` file, but it is not declared in the `package.json`, it resolves it to the proper version that is found in the `node_modules` folder. The plugin then injects a new dependency in the output `package.json` for the required package.

Note that injected dependency version constraints are the specific version number required, without caret or any other semantic version operator. This is to honor the exact peer dependency found in the project. Injecting more relaxed semantic version expressions could lead to unstable results.

Manually De-duplicating Through Importing

Namespacing means that each portlet gets its own dependencies. Only using the bundler this way obtains the same functionality as standard bundlers like webpack or Browserify, so you wouldn't need a specific tool like liferay-npm-bundler. Since Liferay DXP is a portlet based architecture, sharing dependencies among different portlets would be very beneficial.

In bundler 1.x that deduplication was made automatically, but there was no control over it. However, with version 2.x, you may now import packages from an external OSGi bundle, instead of using your own. This lets you put shared dependencies in one project, and reference them from the rest. Though This new way of de-duplication is not automatic, it leads to full control (during build time) of how each package is resolved.
